Editorial

Welcome to your preview of SLEEP 2025, the 39th Annual Meeting of the Associated Professional Sleep Societies, which is scheduled to be held in Seattle, Washington on June 7-11, 2025.

This abstract supplement unites the journal *SLEEP*, and the science of SLEEP 2025. All abstracts presented at SLEEP 2025 are included in this supplement. This year more than 1600 abstracts will be presented at the meeting. 168 will be presented in an oral presentation format, and the remainder will be presented in a poster format. Many authors of oral presentations will also be presenting their science in the poster hall, providing additional time to network with the authors of these important studies. In addition, this abstract supplement contains case reports submitted by individuals in Sleep Medicine Fellowships and other training programs.

Abstracts in this supplement are divided between Basic and Translational Sleep Science, and Clinical Sleep Science and Practice and then assigned to one of 27 subcategories. Each abstract has a unique four-digit number to facilitate identification and location both within this issue and at SLEEP 2025. The four-digit number in the abstract supplement matches the four-digit code published in the SLEEP 2025 Mobile App.

The SLEEP meeting fosters an environment in which members and attendees learn about the latest basic, translational, and clinical science and technologies, promoting the continued growth of the field through the dissemination of new knowledge. We look forward to seeing everyone and sharing in the success of this pivotal event and hope you consider joining the American Academy of Sleep Medicine and Sleep Research Society in Seattle, Washington in June.

CIRCADIAN CHANGES IN GRAPH THEORY MEASURES OVER THE COURSE OF SLEEP DEPRIVATION

David Negelspach[1], Kathryn Kennedy[1], Jungwon Cha[1], Alisa Huskey[1], Yangyang Du[2], William Killgore[1]

[1] The University of Arizona, [2] University of Michigan

Introduction: Circadian rhythms are known to modulate brain activity and connectivity, influencing neural network integration and cognitive performance. Graph theory measures, such as global efficiency (GE), can tell us about how the brain transfers information and may be used to explore how circadian regulation impacts the efficiency of information transmission across neural networks. The dynamics of how GE of the brain changes within a 24-hour period, and which regions show the most significant circadian pattern were investigated in this study. Given that cognitive demands change dynamically across a 24-hour period, we hypothesized that circadian oscillations in functional connectivity (GE) would be non-uniform across cortical and sub-cortical regions.
Methods: Twenty healthy subjects (9 females) were recruited from Tucson, AZ. After online screening, participants underwent a baseline overnight sleep study followed by 39 hours of total sleep deprivation. Functional MRI scans were collected at six-hour intervals along with assessments of cognitive status. We applied a cosine regression using a Levenberg Marquardt algorithm to analyze oscillatory changes in resting state GE calculated with the CONN toolbox (22.v2407).
Results: The right inferior temporal gyrus (rITG) and left thalamus demonstrated a significant circadian change in GE. Cosine regression of rITG yielded an oscillatory period: τ = 22.28 hours, acrophase =.13 radians, and mesor =.4944 (F = 9.72, P =.047, R^2 =.91). The left thalamus also yielded a significant circadian change in GE: τ = 24.87 hours, acrophase = -4.45 radians, and mesor =.46 (F = 16.0233, P = 0.02374, R^2 = 0.9413).
Conclusion: We found a significant circadian change in GE within the rITG and left thalamus, regions involved in visual processing, sensory integration, attention, and cognition. This suggests that global network connectivity in both regions changes rhythmically throughout the day. The differences in waveform properties between these regions, supports our hypothesis that circadian modulation affects certain parts of the brain heterogeneously. As such, cognitive functions like visual processing and sensory integration may exhibit corresponding fluctuations in efficiency and optimization.

24-HOUR VARIATION IN METABOLIC RESPONSES TO A 6.5-HOUR MEAL WINDOW IN HUMANS

Leilah Grant[1], Kritika Vashishtha[1], Shauni Omond[2], Lauren McKenzie[1], Melissa St Hilaire[3], Steven Lockley[1], Shadab Rahman[4]

[1] Brigham and Women's Hospital, [2] Brigham and Women's Hospital / Harvard Medical School, [3] Merrimack College, [4] Harvard Medical School

Introduction: Meal timing influences human health. For example, compared to eating during the day, eating identical meals at night acutely elevates levels of glucose and triglycerides. While most studies have compared single meals given at two distinct (often opposite) times of day, the timecourse of the 24-hour variation in metabolic responses to meals is unknown. The aim of this study was to examine systematically how the timing of meals across the 24-hour circadian cycle influences daily exposure to triglycerides, triglyceride-rich lipoproteins [remnant cholesterol (remnant-C)] and glucose.
Methods: Ten healthy adults (6 female) aged 22-35 years were randomized to a 16-hour intervention 'day' in dim light (< 3 lux) between two 8-h sleep episodes in darkness, with a 6.5-hour meal window in the center of the day scheduled at one of 16 stimulus times distributed every 90-minutes (~22.5 degrees) across the 24-hour day between participants. A 26–48.5-h constant routine (CR) with hourly identical meals preceded the intervention day. Blood samples collected every 20-60 minutes throughout the CR and intervention day were assayed for triglyceride, remnant-C and glucose. The 24-h area under the curve (AUC) of the intervention day was calculated and expressed relative to the first 24-h AUC of the CR to control for interindividual differences in metabolic analyte levels. Mealtime response curves were generated by analyzing the relative AUC by the clock time of meal onset using a single-harmonic sinusoidal regression.
Results: Significant mealtime response curves were generated for triglycerides ($p < 0.05$), remnant-C ($p < 0.01$) and glucose ($p < 0.001$). The fitted curve for the 24-h AUC showed that daily levels were lowest when eating during daytime hours for triglyceride and remnant -C, which were lowest when eating at ~7pm, and glucose, which was lowest at ~9am.
Conclusion: The timing of meals across the 24-hour day alters daily exposure to triglycerides, triglyceride-rich lipoproteins, and glucose, with generally worse metabolic responses when the eating window started at night compared to the day. These mealtime response curves can inform practical advice on timing diet-based interventions to reduce cardiometabolic health risks, particularly in shift workers and others who eat at night.

COMMON AND RARE GENETIC VARIATIONS ASSOCIATION ANALYSIS WITH FIFTEEN 24-HOUR REST-ACTIVITY RHYTHM MEASURES

Tariq Faquih[1], Chris Ho Ching Yeung[2], Pavithra Nagarajan[1], Raymond Noordam[3], Martin K. Rutter[4], Susan Redline[5], Richa Saxena[6], Qian Xiao[2], Heming Wang[1]

[1] Brigham and Women's Hospital, [2] University of Texas Health Sciences Center, [3] LUMC, [4] Manchester University, [5] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [6] Massachusetts General Hospital

Introduction: Rest-activity rhythm, as an indicator of circadian rhythm, is associated with multiple health outcomes. It is influenced by biological, behavioral, and social-environmental factors, but there is a limited understanding of its genetic basis.
Methods: High-quality accelerometry data, collected between 2006 and 2010 using triaxial devices (Axivity AX3), were used to derive eight parametric and seven non-parametric RAR variables from 85,784 UK Biobank participants of European ancestry (mean (SD) age 62.4 (7.83) years. 56% female). We

conducted genome-wide common variant and aggregated exome sequencing analyses separately on fifteen RAR variables using linear-mixed models adjusted for age, sex, number of valid wear days, and 10 genetic principal components. Genetic correlations between the RAR variables and with 232 phenotypes were evaluated using Spearman correlation and Linkage disequilibrium score regression (within RAR only). In addition, we performed pathway and gene-set-enrichment analysis to identify over-represented pathways and performed protein-protein interaction network analysis.

Results: Common variant analysis identified 21 unique genome-wide significant loci (p< 5e-8) associated with 8 different RAR variables. Notable associations were rs113851554 (MEIS1) with L5, L5 start-time (mean (standard error (SE): -0.14 (0.01), and -0.12 (0.01) respectively), rs757082192 (ART4) (-0.56 (0.10)) and rs183157147 (CENPJ) (0.98 (0.17)) with Down-Mesor. Exome-wide association analysis identified 8 significant genes (p< 2.8e-6) associated with 7 RAR variables. Notably, MICU3 and RAET1L/ULBP6 were significantly associated with M10 start time with an overall predicted missense and loss of function effect. Overall, the largest number of significant hits were related L5 (4 with L5 and 6 for L5 start time) followed by M10 (4 with M10 and 3 M10 start time) and relative amplitude (4 loci with positive effect estimates). Post-GWAS analyses of both genome- and exome-wide analyses identified overexpression and protein-protein interactions for gene sets related to neurological signaling, restless leg syndrome, chronotype, and mitochondrial functions.

Conclusion: These analyses revealed strong genetic associations with metrics of activity, rest, and overall rhythm stability. Our findings provide novel insight into the molecular pathways of rest-activity rhythms and their links to health conditions.

MELATONIN–SLEEP PHASE ANGLE PREDICTS MORTALITY IN WOMEN WITH ADVANCED BREAST CANCER

Jamie Zeitzer[1], Bita Nouriani[1], Eric Neri[1], Jane Kim[1], David Spiegel[1]

[1] Stanford University

Introduction: Sleep disruptions are commonly observed in women with cancer. One of the hypothesized causes of such disruption is a diminished circadian clock amplitude. Imputation of circadian amplitude in women with cancer has been mainly through examination of diurnal salivary cortisol patterns. Flattened diurnal salivary cortisol slopes have also been associated with longevity in a variety of cancers. These slopes, however, are susceptible to masking effects, notably stress.

Methods: In both women with advanced breast cancer (n=56) and age-matched controls (n=16), we obtained 24-hour plasma melatonin profiles through the use of an indwelling forearm catheter. Lights were kept dim during waketime and off during sleep, which was scheduled for eight hours during the habitual sleep time determined during two weeks of at-home actigraphy. Plasma melatonin concentrations were determined through radioimmunoassay. Melatonin timing and duration, sleep timing, the time between sleep and melatonin phase markers (phase angle) and survival duration (n=50) were calculated.

Results: Clock time of both dim light melatonin onset (DLMO; p=0.40, t-test) and melatonin midpoint (p=0.73, t-test) were indistinguishable between the women with cancer and controls, as was the difference in the duration of melatonin (p=0.10, t-test). Phase angle between DLMO and habitual bedtime was also indistinguishable between the groups (p=0.10, t-test). The phase angle between melatonin and sleep midpoints was, however, different between the two groups (p< 0.05, t-test), being on average shorter in those with cancer. In those with cancer, this phase angle was related to survival (p< 0.05, HR=1.57; Cox Proportional Hazards Model), even after accounting for previous treatment (p< 0.05, HR=1.89) or previous treatment, age, and typical sleep duration (p< 0.01; HR=2.24). Survival curves separated within the first three years after study, with 96% women with short phase angles being still alive and only 64% of women with long phase angles being still alive. From three to 8 years after the study, there was a parallel change in mortality in the two groups.

Conclusion: A shorter phase angle between melatonin and sleep is associated with greater longevity in women with advanced breast cancer.

DURATION OF THE CIRCADIAN BIOLOGICAL NIGHT DIFFERS BETWEEN EIGHT AND NINE HOUR SLEEP OPPORTUNITIES

Maeve Sheehy[1], Rebecca Cox[2], Alivia Blumenstein[2], Tina Burke[2], Christopher M. Depner[3], Molly Guerin[2], Emily Hay-Arthur[2], Shannon Lanza[2], Rachel Markwald[2], Andrew McHill[4], Hannah Ritchie[5], Kate Sprecher[2], Ellen Stothard[5], Dana Withrow[2], Kenneth Wright[2]

[1] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder Colorado, USA, [2] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA, [3] University of Utah, [4] Oregon Institute of Occupational Health Sciences, Oregon Health & Science University, Portland, Oregon, USA, [5] University of Colorado Boulder

Introduction: The duration between dim-light melatonin onset and offset represents the biological night, which tracks environmental darkness (i.e., scotoperiod). In humans, melatonin duration is longer after one week of exposure to natural winter (~9.33h light:14.67h dark) versus natural summer (~14.67h light:9.33h dark) light-dark cycles. Melatonin duration is also longer after one month of exposure to 14h versus habitual ~8h sleep opportunities; as well as in people who habitually sleep longer than 9h versus shorter than 6h. Our current aim was to determine whether a shorter difference in scotoperiod, 8h versus 9h sleep opportunities, impacts the duration of the biological night.

Methods: Archival data from 76 healthy adult participants (aged 26.1±6.8[Mean±SD]; 44 females) from five research protocols were examined. Depending on the study protocol, participants maintained consistent 8h (n=40) or 9h (n=36) sleep schedules for one or two weeks at home, verified with wrist-actigraphy and bed/waketime call-ins. 24-hour plasma or salivary melatonin samples were then collected in the laboratory under

dim-light conditions during wakefulness (< 10 lux max; ~1.9 lux, ~0.6 Watts/m2 in the angle of gaze) and darkness (0 lux) during sleep. Melatonin duration was calculated as the time between dim light melatonin onset (DLMO25%) and dim light melatonin offset (DLMOff25%).
Results: Melatonin duration was significantly longer in the 9h (11.1h±2.3) versus 8h (10.2h±1.2) (Mean±SD) sleep opportunity condition ($p < 0.05$).
Conclusion: The current findings demonstrate that as little as one hour difference in scotoperiod is associated with an ~0.9h difference in the duration of the biological night, suggesting that melatonin duration tracks even relatively minor changes in environmental light-dark exposure. These findings have important implications for circadian and sleep research, including understanding how the environment contributes to differences in biological night. In future studies, it will be important to determine the impact of the duration of the biological night on human physiology and behavior.

CIRCADIAN REGULATION OF EPITHELIAL VIRAL LOAD IN HEALTH AND IN ASTHMA

Weston Powell[1], Maria Kang[2], Carolina Daluz[2], Madison Ohm[2], Maria White[1], Elizabeth Vanderwall[1], Camille Gates[1], Lucille Rich[1], Jason Debley[3]
[1] Center for Respiratory Biology and Therapeutics, Seattle Children's Research Institute, [2] University of Washington, [3] Center for Respiratory Biology and Therapeutics

Introduction: Molecular circadian rhythms regulate cellular processes underlying health including innate immune pathways. Prior studies have implicated circadian regulation of viral responses as contributing to airway inflammation in asthma, but investigation in human cell models of airway epithelium has been limited. Using primary human airway epithelial cells differentiated at an air-liquid interface as an ex vivo organotypic model from healthy donors and donors with asthma, we investigated circadian-time dependent regulation of viral replication of rhinovirus-16 (RV16) in airway epithelial cells.
Methods: Primary bronchial epithelial cells (BECs) from donors with pediatric asthma (n=5) or healthy donors (n=4) were differentiated at an air-liquid interface to an organotypic epithelium in temperature cycled incubators. Intrinsic circadian rhythmicity following temperature cycling was confirmed using BMAL1:Luciferase recordings and western blotting for BMAL1. At circadian time 0 hours and circadian time 12 hours, RV16 was applied to the apical surface at a multiplicity of infection of 0.5. BEC were harvested for RNA isolation at 12, 24, 48 and 96 hours after infection for genome copy number assessment with qPCR.
Results: Temperature cycles of 12 hours at 37C and 12 hours at 34C for 6 days reliably synchronized intrinsic circadian rhythms measured in luciferase assays in both healthy AECs and AECs from donors with pediatric asthma. Circadian amplitude and period was similar between healthy BECs and BECs from donors with asthma by gene expression and BMAL:Luciferase recording. Infection at time zero during the circadian cycle as compared to infection occurring 12 hours later was associated with lower viral replication at 24, 48, and 96 hours after infection in healthy BECs.
Conclusion: The core circadian clock genes maintain rhythmicity in healthy and asthma airway epithelia. Circadian time regulates epithelial viral replication in healthy BECs. Future work will measure viral replication in BECs with genetic ablation of core circadian genes and in correlation with in vivo circadian rhythm measurements.

COMPARING POST-PRANDIAL GLYCEMIA AFTER LATE EATING VS LATE SLEEP: PRELIMINARY RESULTS FROM A RANDOMIZED CROSSOVER STUDY

Daisy Duan[1], Athena Mavronis[1], Luu Pham[2], Jonathan Jun[3]
[1] Johns Hopkins University School of Medicine, [2] Division of Pulmonary and Critical Care, Johns Hopkins University School of Medicine, [3] Johns Hopkins University

Introduction: Our previous work showed that a late dinner (22:00) compared to routine dinner (18:00) in healthy volunteers increased postprandial glucose and reduced dietary fat oxidation. However, it remains unclear whether these adverse metabolic effects are due to eating late in relation to endogenous circadian rhythm, or due to eating too close to sleep.
Methods: Dinner Time 2 Study compared the metabolic effects of dinner timing relative to dim-light melatonin onset (DLMO) and sleep timing in healthy volunteers. Participants completed three conditions in random order with a 3-4 week washout period: (1) early dinner (DLMO -3) + routine sleep (DLMO +2 to +10) = "early dinner" (ED); (2) late dinner (DLMO +1) + routine sleep = "late dinner" (LD); and (3) late dinner (DLMO +1) + late sleep (DLMO +6 to +14) = "late dinner + late sleep" (LD/LS). The main outcomes are differences in 4-h post-dinner area-under-the-curve glucose and insulin levels among the 3 conditions. We used Friedmans tests to compare outcomes among the 3 conditions and Wilcoxon signed rank tests to compare between each 2 conditions.
Results: 13 participants (7 female, 6 male, mean age 25 years, BMI 22.1 kg/m²) completed the study. Post-dinner glucose and insulin levels were different amongst the 3 conditions ($p=0.03$ and $p=0.002$ respectively). Compared to ED, LD increased 4-h post-prandial glucose by median of 11% ($p=0.008$) without changes in insulin levels (median difference -1.7%, $p=0.68$), while LD/LS increased post-prandial glucose by median of 15% ($p=0.004$) without significant change in insulin levels (median difference 13%, $p=0.17$). Compared to LD, delaying sleep after dinner did not significantly change post-prandial glucose (median difference 2.5%, $p=0.43$) or insulin levels (median difference 20.3%, $p=0.21$).
Conclusion: Late dinner in relation to melatonin onset increased post-prandial glucose, which was not mitigated by delaying sleep after late dinner. Our findings suggest that adverse glucose/insulin dynamics induced by late eating is primarily driven by circadian misalignment.

DIURNAL VARIATIONS IN CEREBRAL BLOOD FLOW: EFFECTS OF TIME-OF-DAY ON TASK-RELATED BRAIN ACTIVITY

Bowen Guo[1], Kaikai Yan[1], Tianxin Mao[1], Hengyi Rao[1]
[1] Shanghai International Studies University

Introduction: Human behavior and brain activity are influenced by circadian rhythms and homeostatic sleep pressure, leading to variations throughout the day. However, it remains unclear how task-induced brain activity changes with time-of-day, and whether these changes primarily arise from the task-state or the resting-state.
Methods: We assessed diurnal variations in cerebral blood flow (CBF) during resting-state and a simple psychomotor vigilance test (PVT) using arterial spin labeling (ASL) perfusion magnetic resonance imaging (MRI) at six fixed times (8:00, 10:00, 13:00, 15:00, 18:00, and 20:00) in 40 healthy participants (24 females, mean age 21.68 years). Behavioral outcomes were evaluated based on mean reaction time (RT), median RT, and lapses. Paired-sample t-tests were performed on whole-brain CBF at the voxel level for resting and task-states across the six time points, with Gaussian Random Field (GRF) correction.
Results: Behavioral results showed no significant effects of time-of-day on mean RT, median RT, or lapses (all $p > 0.05$), indicating that alertness remained stable throughout the day. Paired-sample t-tests revealed a trend of decreasing activation between resting and task-states as the day progressed, with 29,290 voxels activated during the first scan and 9,977 voxels activated during the last scan. ANOVA results revealed a significant main effect of time-of-day on task-induced CBF changes in the fronto-parietal network, ventral attention network, and salience network (all $p < 0.05$). Moreover, the modulation of task-induced CBF changes by time-of-day primarily originates from task-states. Specifically, CBF in the default mode network increased throughout the day during task-states, whereas CBF in the salience and fronto-parietal networks decreased from morning to night during task-states.
Conclusion: This study found no significant changes in diurnal vigilance at the behavioral level. However, task-induced activation decreased throughout the day, with the most notable changes occurring in task-states. The study highlights that time-of-day may influence the reproducibility of task-related functional MRI, suggesting future studies should account for this factor.

CHARACTERIZING DAILY 24-HOUR RHYTHMICITY IN CIRCULATING LIPIDS IN A MIXED CLINICAL INPATIENT POPULATION

Kritika Vashishtha[1], Leilah Grant[1], Steven Lockley[1], Melissa St Hilaire[2], Shadab Rahman[3]
[1] Brigham and Women's Hospital, [2] Merrimack College, [3] Harvard Medical School

Introduction: Circulating lipids are under control of the ~24-hour circadian clock in healthy individuals. How these rhythms are expressed in clinical populations, and whether they are altered by lipid-lowering medications (i.e., statins), is unknown.
Methods: We assessed 24-hour rhythmicity in clinical lipid outcomes from ~187,000 samples collected as part of routine medical care of 27,706 hospitalized patients (45% female, mean [±SD] age 70.9 ± 15.1 years) with mixed medical diagnoses. Outcomes included total cholesterol, triglycerides, HDL-C and LDL-C. Blood samples were dichotomized as statin or no-statin use based on each patient's prescription data. Cosinor regression was applied to hourly binned group-average time series data. Group averages were calculated either using all samples or stratified based on statin use.
Results: Cholesterol, HDL-C, and LDL-C exhibited significant 24-hour rhythms with a single acrophase (i.e., time of fitted peak) in the late afternoon (~15:24–18:06 h). Triglycerides exhibited a principal acrophase in the early morning (~01:36 h) and a secondary peak in the afternoon (~13:36 h). The use of statins was associated with a significant reduction in amplitude for triglycerides (~300%), HDL-C (~40%) and LDL-C (~80%) but did not change cholesterol rhythm amplitude or the acrophase for any of the lipid rhythms. The timing of cholesterol, HDL-C and LDL-C rhythms in the clinical population were similar to the timing observed in young healthy individuals under controlled laboratory conditions, differing only by up to ~3 hours. Furthermore, the differing peaks observed in triglycerides under constant routine (morning peak) and ambulatory diurnal conditions (afternoon peak) were reflected in the dual peak observed in the clinical population, suggesting multiple mechanisms underlying clinical expression of triglyceride rhythms.
Conclusion: Circulating lipids in an inpatient clinical population exhibited robust 24-hour daily rhythms. Rhythm amplitude but not timing was altered by statin use. The clinical data may reflect endogenous circadian variation in lipid timing for some outcomes, but understanding the mechanisms underlying rhythmic expression is necessary to interpret the timing of clinical or real-world data.

THE DIURNAL RHYTHMICITY OF UNTARGETED METABOLOMIC PROFILES IN HUMANS

Pavithra Nagarajan[1], Tariq Faquih[1], Bing Yu[2], Hassan Dashti[3], Robert Kaplan[4], Qibin Qi[4], Carmen Isasi[4], Frank Scheer[1], Richa Saxena[5], Susan Redline[6], Tamar Sofer[7], Heming Wang[1]
[1] Brigham and Women's Hospital, [2] The University of Texas Health Science Center, [3] Massachusetts General Hospital and Harvard Medical School, [4] Albert Einstein College of Medicine, [5] Massachusetts General Hospital, [6] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [7] Cardiovascular Institute, Beth Israel Deaconess Medical Center, Harvard Medical School

Introduction: The circadian system plays a crucial role in metabolic processes including glucose tolerance, lipid control, and

hormone secretion. Despite its importance, understanding of the rhythmicity underlying metabolites remains incomplete, with only a few (e.g., cortisol and melatonin) having well-characterized patterns. Recent metabolome-wide association studies have begun to uncover metabolite associations with several sleep and circadian traits (e.g. duration, midpoint time). However, associations may be confounded by diurnal rhythms, as blood samples are often collected at varying times. Thus, to provide insights into the temporal oscillations of serum metabolites and underscore the critical importance of temporally-sensitive clinical assessments, we conducted metabolomics association analyses on assay timing collected during the day.

Methods: For 6180 individuals in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL), 853 metabolites were quantified (Metabolon, Inc) in two batches from overnight fasting serum samples. Multivariable linear regression was conducted for each metabolite, with time of blood draw (ranging from morning to afternoon) as the primary exposure, adjusting for age, sex, study center, Hispanic/Latino background, fasting duration, self-reported bed and wake times, and sampling design. Timing variables were circularly transformed. Analysis was performed separately for each batch, and results meta-analyzed. Additionally, unsupervised density-based clustering analysis was conducted to reveal temporal patterns across metabolites.

Results: Single metabolite association analyses identified 51 metabolites significantly associated with blood assay timing after multiple testing correction. These include 33 metabolites prior reported to exhibit diurnal rhythms in plasma, of which 10 are connected to melatonin and cortisol activity. Of note are circadian regulators DHA and palmitate, that influence BMAL1 gene expression and SIRT1 activity. Significant metabolites reflect connections to psychiatric and sleep disorders, omega oxidation, prostaglandin synthesis, dopamine levels, and GLP-1 agonist design. Unsupervised clustering analysis identified three distinct clusters. Strikingly 48 of the 51 significant metabolites group into the same cluster. This cluster exhibits a characteristic pattern of a morning dip (7 AM–8 AM) followed by an afternoon peak (12 PM–2 PM).

Conclusion: Our analysis reveals known and novel rhythmic serum metabolites. Results underscore the importance of accounting for time of assay, when investigating metabolite associations with health disorders.

IN VIVO CIRCADIAN GENE EXPRESSION IN PEDIATRIC ASTHMA

Weston Powell[1], Lindsay Clark[2], Jason Debley[3]

[1] Center for Respiratory Biology and Therapeutics, Seattle Children's Research Institute, [2] Seattle Children's Research Institute, [3] Center for Respiratory Biology and Therapeutics

Introduction: Altered circadian gene expression is hypothesized to underlie circadian dependent differences in airway resistance and risk for asthma exacerbation in pediatric asthma. Previously in ex vivo organotypic epithelial cell cultures we identified neutrophilic and IL-17 signaling genes as losing circadian rhythmicity in pediatric asthma. However, measuring circadian rhythms of gene expression in vivo is difficult due to the need for repeat sampling. Using bioinformatic approaches, circadian time can be inferred in single samples and rhythmic genes identified when sampling a larger number of individuals randomly over the course of the day. We analyzed circadian rhythmic gene expression using a publicly available data of gene expression in children with and without asthma at age 10 from the URECA study to identify genes with altered circadian rhythmicity in asthma.

Methods: Gene expression from nasal swabs obtained at age 10 in 352 children, 249 without asthma and 103 with asthma were analyzed using CYCLOPS to identify rhythmic genes. Circadian time was defined using a set of 100 rhythmic genes identified from ex vivo epithelial cell cultures. Differential rhythmicity was analyzed using CompareRhythms and phase set enrichment (PSEA) used to identify genes whose expression concentrated at specific circadian times.

Results: CYCLOPS analysis identified 3694 genes with rhythmic expression on nasal epithelial swabs. Genes for TGF-beta signaling, IL-6 signaling, and interferon-alpha responses had peak expression in the morning, whereas cell cycle and oxidative phosphorylation genes peaked in the evening. Differential rhythmicity identified 182 with altered rhythmicity in asthma, with genes for interferon and viral responses increasing rhythmicity in asthma and genes for granulocyte activation and neutrophil migration had reduced rhythmicity in asthma.

Conclusion: Circadian gene expression of neutrophil migration and granulocyte activation genes is decreased in pediatric asthma based on in vivo nasal swabs. Loss of circadian regulation may contribute to aberrant expression of airway inflammatory genes in pediatric asthma.

CIRCADIAN REST-ACTIVITY RHYTHMS AND EPIGENETIC AGE ACCELERATION IN OLDER ADULTS

Chunyu Liu[1], David Sosnowski[1], Casandra Nyhuis[2], Jill Rabinowitz[3], William Eaton[4], Nanping Weng[5], Adam Spira[4], Brion Maher[1]

[1] Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, [2] Department of Public Health Sciences, Penn State College of Medicine, [3] Department of Psychiatry, Robert Wood Johnson Medical School, Rutgers University, [4] Johns Hopkins Bloomberg School of Public Health, [5] Laboratory of Molecular Biology and Immunology, National Institute on Aging, National Institutes of Health

Introduction: Circadian alterations are implicated in poor aging-related health outcomes, such as neurodegenerative diseases, cardiovascular diseases and metabolic disorders; yet, links with biological aging remains underexplored. We examined the association of actigraphic circadian rest/activity rhythms (RARs) with epigenetic age acceleration (EAA) in older adults.

Methods: We studied 191 participants from the Baltimore Epidemiologic Catchment Area Study Follow-Up (mean age 68.6±7.7 years; 66% female, 59% white) who completed 7.1±1.2 nights of wrist actigraphy and had valid DNA methylation and covariate data. Actigraphic RAR metrics included cosinor (amplitude, mesor, acrophase) and non-parametric indices [relative amplitude (RA), interdaily stability (IS), intradaily variability (IV), lowest 5-hour activity level (L5), highest 10-hour activity level (M10), L5 start time, and M10 start time]. DNA

methylation data from the Illumina EPIC array were used to calculate several epigenetic clocks (GrimAge, PhenoAge, Horvath Clock and Hannum Clock). EAA was defined as the difference between epigenetic and chronological age, with the residual method for sensitivity analysis.
Results: In analyses adjusted for chronological age, sex, and race, lower amplitude, RA, IS, and M10, and higher IV were significantly associated (per 1-SD decrease) with accelerated GrimAge [amplitude β = 0.80 (0.22, 1.38); RA β = 0.69 (0.15, 1.24); IS β = 0.61 (0.03, 1.20); M10 β = 0.73 (0.15, 1.3); IV β = -0.90 (-1.45, -0.35); all p <.05] and PhenoAge [amplitude β = 1.07 (0.02, 2.13); IS β = 1.11 (0.05, 2.16); all p <.05]; with non-significant, but directionally consistent, associations with Horvath and Hannum clocks. Additionally, individuals with an L5 start time after 1:30 am, compared to those between 12:00 am and 1:30 am, were 1.17 (0.06, 2.27) years older per GrimAge.
Conclusion: Our findings suggest that, reduced strength, stability, regularity, and later activity timing of circadian rhythms, are associated with accelerated epigenetic age, notably GrimAge and PhenoAge. These results highlight the role of circadian regulation in aging and underscore the importance of maintaining strong, stable, and well-timed rhythms to mitigate age-related biological deterioration.

COMPARING SLEEP LOSS AND CIRCADIAN EFFECTS IN COGNITIVE PERFORMANCE

Leon Lack[1], Adithya Abeywickrama[2], Andrew Vakulin[3], Claire Dunbar[3], Alisha Guyett[1]
[1] Flinders University, [2] Flinders University, [3] Adelaide Institute for Sleep Health, Flinders University

Introduction: Extended wakefulness of up to 24 hours has been associated with severe impairments in performance and attention measures. The impairment may not be due solely to sleep loss since some recovery of function occurs the next day even with continued sleep loss. A circadian effect is likely to be a significant contributor to performance measures and has been apparent in many studies. Despite this recognition, few studies have directly compared the contributions of accumulated sleep loss and circadian rhythm on cognitive performance.
Methods: We analyzed the data from 38 healthy sleepers (Mean (SD) age = 32.6 (12.9) years) who performed the 10-minute Psycho-Vigilance Task (PVT) 10 times across a 29-hour period of total sleep deprivation in laboratory protocol. The number of lapses (Reaction Time>500msec) was analyzed from each testing time. Two curve-fitting approaches were applied: (1) a linear function using least squares method to model time awake effects, and (2) a 24-hour cosine curve to model the circadian component. For both group mean data and individual participant data, we compared the amplitudes and variance accounted for (R^2) between the circadian and linear components. Within-subject statistical comparisons were conducted using paired t-tests.
Results: The 24-hour amplitude of the mean lapses curve was 14.1 lapses in the circadian component and 12.5 in the linear component and the variances were 72.3% and 57% respectively. Individual participant analyses means were 15.0 lapses and 12.75 lapses and variances of 59.5% and 40.4% for the circadian and linear curve fits, respectively. Within subjects t-tests showed the circadian component has significantly larger amplitude (t(37) = 2.56, p< 0.02) and higher variance accounted for by the circadian curve fit (t(37) = 5.14, p< 0.001) than from the linear fit.
Conclusion: Across the 29-hour sleep deprivation protocol the circadian component contributes a greater amplitude and variance accounted for in lapses of attention than the linear time awake component. Campaigns to improve public safety should draw as much attention to the danger of the circadian time of operation as to the amount of prior wakefulness.

THE CIRCADIAN TIMING OF SLEEP AFFECTS THE RATE OF ACCUMULATION OF OBJECTIVE NEUROBEHAVIORAL IMPAIRMENT ACROSS DAYS OF SLEEP RESTRICTION

Siobhan Banks[1], Mark McCauley[2], Christopher Jones[3], Mathias Basner[3], Hans Van Dongen[2]
[1] University of South Australia, [2] Washington State University, [3] University of Pennsylvania Perelman School of Medicine

Introduction: Chronic nighttime sleep restriction leads to the build-up of neurobehavioral impairment across days. Although it is known that the circadian timing of sleep mediates the effects of sleep loss, it is not known how the timing of restricted sleep influences the accumulation of neurobehavioral impairment over days. Here we investigated lapses on the psychomotor vigilance test (PVT) across days with restricted sleep placed in the late morning or late afternoon.
Methods: N=72 healthy young adults (ages 21-45y, 39% female) completed a 14-day in-laboratory study. After an 8h nighttime adaptation sleep opportunity (23:30–07:30) there was a baseline day with an 8h shifted sleep opportunity ending in late A) morning (11:30) or B) afternoon (19:30). Subjects were then randomized to 9 consecutive days of sleep restricted to 4h, 6h, or 8h time-in-bed (TIB) for late A) morning (11:30; n=19, 8, 8, respectively), or B) afternoon (19:30; n=13, 17, 7, respectively). Subjects were tested on a 10-minute PVT every ~2h during scheduled wakefulness. Daily averages for PVT lapses (RTs>500ms) observed 2-14h after scheduled awakening, expressed relative to average PVT lapses on theshifted baseline day, were analyzed with nonlinear mixed-effects regression to investigate differences in the build-up of neurobehavioral impairment between shifted sleep restriction doses.
Results: In the afternoon sleep conditions, PVT lapses showed a significant sleep dose-response effect (F=6.22, p=0.003), with the fastest accrual of impairment across days in the 4h condition (t=5.12, p< 0.001) and near-negligible impairment build-up in the 8h condition (t=1.00, p=0.32). However, in the morning sleep conditions, PVT lapses showed no sleep dose-response effect (F=0.01, p=0.99) with modest impairment growth across days overall (t=2.06, p=0.043) at just 43.7% the average rate observed in the afternoon sleep conditions.
Conclusion: In this sample of young adults, placing 6h and 4h daily sleep opportunities in the late morning appeared to

provide resilience against the accumulation of neurobehavioral impairment from sustained sleep restriction. Our results suggest that afternoon circadian promotion of wakefulness can sustain objective neurobehavioral functioning for at least 14h of wakefulness daily across multiple days of sleep restriction.

QUANTIFYING CIRCADIAN RESCUE OF COGNITIVE PERFORMANCE FOLLOWING TOTAL SLEEP DEPRIVATION: EXPERIMENTAL AND META-ANALYSIS EVIDENCE

Kaikai Yan[1], Tianxin Mao[1], Bowen Guo[1], Hengyi Rao[1]

[1] Shanghai International Studies University

Introduction: With increasing work pressure and the accelerated pace of modern life, sleep deprivation has become a common phenomenon. While existing research has predominantly focused on the cognitive impairments caused by total sleep deprivation (TSD), its dynamic changes over time have received limited attention. Notably, cognitive performance often improves in the afternoon or evening following TSD, a phenomenon termed "circadian rescue." However, its magnitude and task-specific variability remain underexplored. To address this gap, our study combines strictly controlled constant routine (CR) experiments with meta-analytic approaches, providing the first systematic quantification of the circadian rescue effect and offering novel empirical evidence to reveal its task-specific characteristics and underlying mechanisms.

Methods: In Study 1, 54 healthy participants (mean age 33.35 ± 8.73 years, 32 males) underwent 35 hours of sustained wakefulness while performing the Psychomotor Vigilance Task (PVT), Digit Symbol Substitution Test (DSST), and Karolinska Sleepiness Scale (KSS). Circadian rescue effects were quantified using behavioral performance and the two-process model. Study 2 extends this by conducting a meta-analysis to examine the circadian rescue effect across multiple cognitive tasks.

Results: Study1 results indicated that the rescue rate for PVT ranged from 33.01% to 52.11%, 45.73% for DSST, and a comparatively low 23.45% for KSS. Further analysis showed that process S had a significantly greater effect on KSS than on PVT and DSST (all $p < 0.001$), with a higher process S coefficient for PVT compared to DSST ($p < 0.01$). No significant differences in process C were observed across tasks (all $p > 0.05$), indicating a consistent circadian influence. The meta-analysis results further confirmed that the rescue rate for KSS was significantly lower than for PVT and DSST.

Conclusion: This study indicated that the circadian rescue effect plays a critical role in mitigating the negative impacts of TSD, particularly during circadian peak periods, which can partially counteract the negative effects of sleep loss on cognitive performance. These findings advance understanding of circadian regulation in cognitive performance, with implications for fatigue management strategies.

THE CIRCADIAN TIMING OF SLEEP AFFECTS THE DYNAMICS OF SUBJECTIVE SLEEPINESS ACROSS DAYS OF SLEEP RESTRICTION

Mark McCauley[1], Christopher Jones[2], Mathias Basner[2], Siobhan Banks[3], Hans Van Dongen[1]

[1] Washington State University, [2] University of Pennsylvania Perelman School of Medicine, [3] University of South Australia

Introduction: Chronically restricted nighttime sleep propagates an accumulation of objective performance deficits over days, but subjective sleepiness does not equivalently reflect this build-up of impairment. Here we studied the dynamics of subjective sleepiness over days with restricted sleep placed in the late morning or afternoon.

Methods: N=72 healthy young adults (ages 21-45y, 39% female) completed a 14-day in-laboratory study. After an 8h nighttime adaptation sleep opportunity (23:30–07:30) there was a baseline day with an 8h shifted sleep opportunity ending in late A) morning (11:30) or B) afternoon (19:30). Participants were then randomized to 9 consecutive days of restricted sleep with 4h, 6h, or 8h TIB ending in late A) morning (11:30; n=19, 8, 8, respectively), or B) afternoon (19:30 n=13, 17, 7, respectively). Participants rated their sleepiness on the Karolinska Sleepiness Scale (KSS) at ~2h intervals during scheduled wakefulness. Daily averages for sleepiness rated 2-14h after scheduled awakening, expressed relative to the shifted baseline, were analyzed with nonlinear mixed-effects regression to investigate the temporal dynamics of subjective sleepiness.

Results: In the late afternoon conditions, KSS sleepiness displayed a significant sleep dose-dependence ($F=3.44$, $p=0.038$). There was no significant change over the 9 days of sleep restriction for either the 4h or 6h sleep doses, but the 8h dose showed a modest decrease in KSS sleepiness over days ($t=-3.11$, $p=0.003$). In the late morning conditions, KSS sleepiness exhibited no sleep dose-dependence ($F=0.62$, $p=0.54$), and there were no significant changes over the 9 days of sleep restriction ($t=1.42$, $p=0.16$).

Conclusion: The dynamics of participants' subjective sleepiness across days of late afternoon sleep restriction were incongruent with their sleep dose-response accumulation of objective performance impairment (see companion abstract by Banks et al.). Rather, it seemed that subjective sleepiness stabilized in participants randomized to 6h or 4h restricted sleep opportunities, with some apparent adaptation to the shifted sleep timing over days for those randomized to the 8h sleep opportunities. However, across days of late morning sleep restriction, the afternoon circadian promotion of wakefulness appeared to mitigate participants' subjective sleepiness for at least 14h of wakefulness daily, as was also observed for their objective performance impairment.

TRAINING SCHEDULES AS A SYNCHRONISER OF ZEITGEBERS FOR ATHLETE CIRCADIAN CLOCKS

Elise Facer-Childs[1], Luis Mascaro[1], Josh Leota[1], Elliot Rosenberg[1]

[1] Monash University

Introduction: Circadian rhythms and sleep are essential for athletes' performance, recovery, and health. Disruption to these processes can result from mismatch between clock-regulated physiology and external time-givers (zeitgebers) such as light/dark cycles or feeding patterns. However, there is limited understanding of circadian biology in this population. This study investigates the impact of training schedules, particularly early morning trainings, on sleep and circadian biology in elite athletes.
Methods: This longitudinal study involved 52 elite male Australian Rules footballers (M-age = 24.38). Data were collected during a 2-week pre-season condition, which involved early morning trainings, and a 2-week in-season condition which did not have early morning trainings. The study was conducted during 2021 and 2022, resulting in two timepoints per condition. Participants wore wrist actigraphy devices to monitor sleep and light exposure and completed at-home circadian phase assessments. Circadian phase was assessed via salivary melatonin, collected hourly in controlled lighting conditions (< 10 lux) from four hours prior to habitual bedtime until one hour post habitual bedtime, and analysed using radioimmunoassay. Diurnal preference was collected using the reduced morningness-eveningness questionnaire (rMEQ). All timings were converted to standard time for analysis, controlling for year and age.
Results: Compared to in-season, pre-season periods (early morning training condition), were significantly associated with earlier first bright light exposure (-139 mins, p <.001), advanced circadian phase (-110 mins, p <.001), earlier sleep-wake timings (sleep onset: -84 mins, mid-sleep: -93mins, sleep offset: -103mins, all p <.001), and shorter total sleep time (-17 mins, p <.001). Diurnal preference did not moderate these relationships. The timing of first bright light exposure partially mediated the effect of condition (pre-season vs in-season) on mid-sleep time and circadian phase.
Conclusion: Early morning trainings can significantly disrupt sleep and advance circadian phase in elite athletes. The findings introduce the idea that training schedules could be acting as a synchroniser of zeitgebers for athlete clocks, influencing the timing of light exposure and exercise. Disruption to sleep and changes in circadian phase may impair performance and recovery, highlighting the need to consider optimised training schedules that align with individual circadian biology.

TIME ZONE CIRCADIAN MISALIGNMENT AND DEFENSIVE PERFORMANCE IN PROFESSIONAL HOCKEY

Arianne Perreault[1], Vincent Bourgon[1], Félix-Gabriel Duval[1], Geneviève Forest[1]
[1] Université du Québec en Outaouais

Introduction: Research has highlighted the impact of circadian rhythm misalignment on athletic performance in sports involving travel across time zones. Teams traveling westward often face circadian disadvantages during evening competitions, as they play at a later circadian alignment than their opponent. While previous studies have primarily focused on outcomes such as wins and losses, few have explored the effects of circadian misalignment on specific game statistics. This study investigates the influence of teams adjustment to time zones travel on the number of shots allowed to opponents.
Methods: Data from NHL games played between 2009 and 2021 (n = 27,642), excluding the COVID-19 season, were collected from online sources (hockey-reference.com). Travel-adjusted time zone was computed for both teams as shown in Charest et al. (2022), from which a Direction of Misalignment (westward, none, eastward) between teams was computed for each game. A one-way ANOVA was used with the Direction of Misalignment on the number of shots allowed to opponents.
Results: A significant effect of Direction of Misalignment was observed, F(2, 27640) = 3.26, p =.04. Teams with a circadian misalignment later than their opponents (westward alignment) allowed significantly more shots (M = 30.71) compared to teams with an earlier one (eastward alignment) (M = 30.27, p =.05). No significant difference was found between teams with a later circadian alignment and those with no difference (M = 30.39, p =.06), nor between teams with no difference and those with an earlier alignment (p =.66).
Conclusion: These results suggest that teams playing at a later part of their circadian alignment than their opponents allow more shots to opposing teams. This could indicate a circadian-related disadvantage that impairs defensive effectiveness on ice. Future research should investigate mechanisms to mitigate the effects of circadian misalignment in professional sports, potentially informing scheduling strategies to optimize player performance.

CIRCADIAN EFFECT ON PENALTIES IN THE NHL

Joshua Fournier[1], Vincent Bourgon[2], Félix-Gabriel Duval[2], Geneviève Forest[2]
[1] UQO, [2] Université du Québec en outaouais

Introduction: There is a growing recognition of the significant impact of circadian rhythms on professional athletic performance, where teams crossing multiple time zones for a game play at a different circadian alignment that their opponents. In the NHL, teams frequently travel and often don't return home between games. Few studies have explored which aspects of athletic performance and behavior are affected by circadian misalignment. The objective of this study was to investigate whether NHL teams show a circadian penalty disadvantage, controlling for the direction of team travel from the previous game.
Methods: Data from NHL games played between 2009 and 2021 (n=27,642), excluding those played during the COVID season, were extracted from online sources (hockey-reference.com). As described by Charest et al. (2022), a travel-adjusted time zone was computed for both teams, from which a Direction of Misalignment (westward, none, eastward) between teams was computed. A one-way ANOVA was used with the Direction of Misalignment on the number and the minutes of penalties.
Results: When there is a travel-adjusted time zone difference between the two teams, there is a significant difference in the penalty minutes, F(2,27640)=4.77, p<.008 and number of penalties received by the team, F(2,27640)=10.88, p<.001. Tukey post-hoc t-tests reveal that teams whose circadian alignment is

westward to their opponent had more penalty minutes (p=.006) and receive significantly more penalties (p<.001), than those who experienced no time zone difference with their opponents. Teams whose circadian alignment is westward to their opponent also received more penalties than those whose alignment is eastward to their opponent (p<.001).
Conclusion: These results suggest that teams playing at a later part of their circadian time than their opponents receive more penalties. This study offers insight on the necessity for members of professional organizations to better understand the potential impact of sleep and travels on behavior and overall performance outcomes during matches. Future studies should focus on strategies for optimizing athletes' circadian alignment, such as personalized travel schedules and light exposure protocols.

SLEEP SURVEY IN UNIVERSITY STUDENTS
Kyuto Yamazaki[1], Syoya Takeda[2], Mana Furuta[2], Ikuha Fukamachi[1], Akiko Noda[2]
[1] Chubu University College of Life and Health Sciences, [2] Chubu University Graduate School of Life and Health Sciences

Introduction: Irregular sleep patterns, which are heavily influenced by the 24-hour demands of modern society, represent a prevalent issue among university students. This irregularity, particularly the marked discrepancy between weekday and weekend sleep-wake patterns, often referred to as social jet lag, has been shown to exert a negative impact on both mental health and academic performance. The objective of this study is to thoroughly investigate the sleep habits of university students and explore their complex relationships with excessive daytime sleepiness and depression symptoms.
Methods: A total of 182 university students (77 males, 105 females, age: 19.5 ± 1.0 years) at Chubu University were surveyed using a Google Forms questionnaire. Data collected included sleep and wake times, social jetlag, sleep duration on weekdays and weekends, and the Quick Inventory of Depressive Symptomatology (QIDS-J) score and daytime sleepiness using the Epworth Sleepiness Scale (ESS). After approval by the Chubu University Ethics Review Committee, consent was obtained from all participants.
Results: The weekends wake-up time was significantly later than weekday wake-up (9:32 ± 2:27 vs 6:55 ± 0:57, p < 0.001). The weekends bedtime was significantly later than weekday bedtime (0:56 ± 1:33 vs 0:22 ± 1:51, p < 0.001). The weekends sleep duration was significantly longer than weekday sleep duration (8.0 ± 1.4 vs 6.0 ± 1.0 hours, p < 0.001). Social jetlag in wake time was significantly correlated with QIDS-J score and ESS score (QIDS-J: r=0.27, p < 0.001, ESS score: r = 0.23, p=0.002). Sleep jetlag in sleep duration was also correlated with QIDS-J score and ESS score (QIDS-J: r=0.22, p=0.004, ESS score: r= 0.23, p=0.002) and ESS score was significantly correlated with QIDS-J score (r=0.48, p < 0.001).
Conclusion: Social jetlag was associated with daytime sleepiness and depression symptoms. Our findings suggest that regular sleep-wake patterns may be beneficial to help prevent daytime sleepiness and depression symptoms in university students.

ASSOCIATION OF PHASE PREFERENCE TO CIRCADIAN PHASE AND SLEEP ONSET IN PRETEENS AND TEENAGERS
Sidney Kirchhof[1], Chloe Lambert[2], Caroline Gredvig-Ardito[3], Stephanie Crowley[4], Christine Acebo[2], Mary Carskadon[5]
[1] E.P. Bradley Hospital Sleep and Chronobiology Research Laboratory, [2] E.P. Bradley Hospital Sleep Research Laboratory, [3] EP Bradley Hospital, [4] Rush University Medical Center, [5] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: Phase preference (PP) measures include several questionnaires, the utility of which may vary with age. Here, we undertake a secondary analysis (Crowley et al., 2014) of PP questionnaires in preteens and teenagers to evaluate associations with circadian phase and sleep patterns.
Methods: The preteens comprised 44 adolescents (ages 9&10, 19F); teenage cohort includes 74 adolescents (ages 15&16, 34F). PP measures included: Carskadon et al. (1993, Owl), Smith et al. (1989, Smith), and Horne Östberg (1976, HOQ). Preteens completed all three PP measures (Owl, n=43; Smith, n=41; HOQ, n=35); teenagers completed HOQ (n=48) and Smith (n=73). Self-selected sleep-wake schedules at home were monitored via actigraphy for all participants. Sleep onset (SO) was estimated with standard scoring procedures (Acebo et al. 1999). At week's end, dim light melatonin onset (DLMO) phase was measured from saliva samples. Thirty-eight preteens and 56 teenagers completed questionnaires, actigraphy, and DLMO.
Results: Correlations among PP scores were strong in preteens (Owl vs. Smith r=.690, p<.001; Smith vs. HOQ r=.660, p<.001; Owl vs. HOQ r=.418, p=.012) and teenagers (Smith vs. HOQ r=.784, p<.001). PP scores were not correlated with DLMO phase for preteens or teenagers, though HOQ showed a trend (r= -.25, p=.090) with the teenagers. In preteens, PP was not correlated with SO, whereas both Smith (r= -.34, p=.012) and HOQ (r= -.46, p<.001) were correlated with SO in teenagers.
Conclusion: PP measures completed by preteens did not correlate with DLMO phase or SO; however, in teenagers, HOQ achieved near significant correlation with DLMO phase, and both PP measures were correlated with SO in the teens. These findings indicate that PP scores in teenagers may be more highly reflective of sleep pattern than circadian phase. Further, we conclude that age-related differences in PP ratings reflect different biobehavioral signals in preteens compared to teenagers. Finally, because of the stronger association of Owl to Smith than to HOQ, we suggest the Smith PP scale may be preferred for use in preteens.

CIRCADIAN PREFERENCE, BUT NOT CIRCADIAN PHASE, ASSOCIATES WITH STATE AND TRAIT LEVELS OF IMPULSIVITY IN ADOLESCENTS
Riya Mirchandaney[1], Daniel Buysse[2], Duncan Clark[1], Greg Siegle[2], Kathryn Guo[2], Meredith Wallace[1], Nina Oryshkewych[1], Brant Hasler[1]

[1] University of Pittsburgh, [2] University of Pittsburgh School of Medicine

Introduction: Adolescents with evening preference are at risk for alcohol and substance use problems, which may be partially explained by a connection between later sleep/circadian timing and greater impulsivity (a well-established contributor to substance use). This connection has been demonstrated with self-report measures of circadian timing in adults, but not with biological measures of circadian timing or in adolescents. Here we tested in a sample of adolescents whether (1) biological circadian timing associates with trait-level multi-dimensional impulsivity and (2) sleep/circadian timing proximally associates with state-level impulsivity on a day-to-day basis.
Methods: 210 adolescents (60.5% female; M age = 17.4 years) across two studies completed self-report measures of trait impulsivity (UPPS-P) and circadian preference (Composite Scale of Morningness), as well as laboratory assessments of circadian phase (salivary dim light melatonin onset). During the week-long ambulatory protocol, participants wore wrist actigraphs (to determine sleep midpoint and duration) and completed bedtime diaries assessing state impulsivity (abbreviated UPPS-P). For between-person analyses, we ran linear regression models predicting trait and mean state impulsivity by circadian preference and phase. For within-person analyses, we ran mixed models to determine if prior night sleep midpoint (with and without circadian phase as a moderator) or duration predicted next-day impulsivity. We controlled for age, sex assigned at birth, racial identity, and socioeconomic status in all models.
Results: Evening preference was associated with greater negative urgency (β=-.035, p=.003) at trait level, as well as greater lack of perseverance at both trait (β=-.04, p=.003) and state (β=-.028, p=.02) levels. Circadian phase was not associated with trait or state impulsivity. Within-person results were insignificant, although there was a trend-level interaction between sleep midpoint and circadian phase on next-day negative urgency (β=.056, p=.07).
Conclusion: Extending prior findings in adults, adolescents with evening preference reported greater impulsivity across subdimensions—they were more likely to quit difficult tasks and act impulsively when experiencing negative emotions. Surprisingly, biological circadian phase did not associate with impulsivity, although there was suggestive evidence that sleep and circadian timing may interact to predict greater impulsivity. Circadian preference measures may inadvertently capture impulsivity-related constructs independent of biological circadian phase.

EXPLORING THE ROLE OF SOCIAL JETLAG AND PEERS IN ADOLESCENT AGGRESSION

Amanda Bates[1], Emily Feldman[1], Rebecca Essien[1], Danica Slavish[1]
[1] University of North Texas

Introduction: Social jetlag, a misalignment between one's biological sleep-wake rhythms and socially imposed schedules is prevalent, is common among adolescents. This disruption in circadian rhythms may negatively impact the social cognition brain network, which is responsible for motivation and compassion, potentially contributing to difficulty connecting with peers and increased aggression towards others. Adolescents with healthy peer networks exhibit more prosocial behaviors, which may protect them from the negative impact of poor sleep. This study aims to investigate how social jetlag, deviant peer influence, and healthy peer networks interact to influence peer aggression in adolescents.
Methods: Data was analyzed from 10,414 adolescents participating in the Adolescent Brain Cognitive Development (ABCD) Study (M age = 12.00; 47.65% girls) who completed self-report measures, including the Munich Chronotype Questionnaire (MCTQ-C), Peer Behavior Profile, and Peer Network Health: Protective Scale.
Results: Multiple regression analyses revealed that increased social jet lag ($\beta = 0.02$, $p < 0.02$), shorter weekday sleep duration ($\beta = -0.058$, $p < 0.001$), and shorter free day sleep duration ($\beta = -0.045$, $p < 0.001$) were significantly associated with greater aggression perpetration. Additionally, having more deviant peers ($\beta = 0.236$, $p < 0.001$), better peer network health ($\beta = 0.026$, $p = 0.010$), and fewer positive peers ($\beta = -0.062$, $p < 0.001$) were linked to higher rates of aggression. Significant interactions emerged, with simple slope analyses indicating that the effect of social jet lag on aggression strengthened as the number of deviant peers increased.
Conclusion: This study highlights the adverse impact of social jetlag on adolescents' relational aggression perpetration, particularly in the presence of deviant peers. Social jetlag and lower sleep duration increase vulnerability to aggressive relational behaviors. Interventions aimed at regulating sleep schedules and promoting healthy peer relationships may mitigate the effects of social jetlag and reduce aggressive behaviors among adolescents.

Introduction: Individuals with insomnia often perceive their sleep as poorer than objectively measured sleep (e.g., by actigraphy). This phenomenon is known as sleep-wake state discrepancy (SWSD). However, the factors associated with SWSD, particularly among the youth population, are not well understood. Youth represents a distinct developmental period characterized by increased evening preference, irregular sleep-wake pattern and social jetlag, which may potentially influence SWSD. This study aimed to explore the relationship between SWSD and insomnia in youths.
Methods: The study included 87 adolescents (mean age: 20.20±2.15, female: 64.1%) meeting the DSM-5 diagnostic

criteria for insomnia disorder. Participants completed a 7-day sleep diary and actigraphy assessment for the computation of SWSD indices in total sleep time (TST), sleep onset latency (SOL), and wake after sleep onset (WASO). SWSD indices were calculated by subtracting the data from actigraphy and sleep diary, with a positive value indicating a subjective underestimation. Participants also completed the Munich chronotype questionnaire (MCTQ) and the depression anxiety stress scale (DASS) to assess chronotype and social jetlag and mood symptoms, respectively. Sleep regularity, especially bedtime and rise time variability, was evaluated using 7-day actigraphy-derived intra-individual variability.

Results: SWSD-TST was negatively correlated with the MCTQ-derived midpoint of sleep on free-days (MSF) and social jetlag (both p<.01). SWSD-WASO was negatively associated with the MCTQ-derived MSF and midpoint of sleep on workdays (MSW) (p<.01). There was no other significant association among the variables. Controlling for age, sex, depressive and anxiety symptoms, SWSD-TST remained significantly associated with social jetlag (β=-0.39, p<.001) and SWSD-WASO was associated with MCTQ-derived MSW (β=0.34, p<.005).

Conclusion: The findings suggested that SWSD in youths with insomnia is linked to late chronotype and greater social jetlag, underscoring the influence of circadian rhythm and sleep regularity on subjective sleep perception. These results highlighted the importance of considering these factors when understanding sleep disturbances in youths with insomnia.

CIRCADIAN AND HOMEOSTATIC TRENDS IN MOOD AND ALERTNESS ACROSS A 36-HOUR ULTRADIAN PROTOCOL IN ADOLESCENTS

Israel Edery[1], Adriane Soehner[1], Daniel Buysse[2], Margaret Kuzemchak[1], Meredith Wallace[1], Ronette Blake[1], Brant Hasler[1], Jessica Levenson[1], Duncan Clark[1], Colleen McClung[1], Peter Franzen[1]

Introduction: Circadian modulation of mood has been documented across several age groups and contexts but are less well documented in early/middle adolescents. We present novel findings on the trajectory of mood and alertness among early adolescents during a controlled 36-hour ultradian protocol.

Methods: Adolescents (N=55, ages 13–15.9 yrs) participated in a 36-hour ultradian protocol consisting of 2-hour cycles of 80-minutes of wakefulness followed by a 40-minute sleep opportunity beginning at 9:00 AM. Mood and alertness were assessed during each cycle using 100-point visual analog scales (higher scores: more positive mood, higher alertness). Participants were time isolated and in dim light conditions (< 10 lux) for the first 27.5 hours. Circadian and homeostatic trends were analyzed via Cosinor mixed effect modeling.

Results: Mood fluctuated significantly in a circadian pattern (B_cos=-2.21, [95% CI=-2.85, -1.56]; B_sin=2.43 [1.77, 3.10]; p < 0.001), with an amplitude of 3 units (95% CI: 2.6–3.9). The mean mood level (mesor) was 74.44 (95% CI: 70.9–77.7), with peaks (acrophase) occurring 8.81 hours into the protocol (5:49 PM; nadir at 5:49 AM). Mood declined slightly over the course of the 36-hour protocol at an average rate of 0.11 points per hour. Alertness also showed significant fluctuations (B_cos=-7.23, [95% CI=-8.41, -6.06]; B_sin=8.05 [6.83, 9.27]; p < 0.001), with an amplitude of 10.83 units (95% CI: 9.7–12.0) and a mean level (mesor) of 56 (CI: 51.5–60.0). Peaks occurred 8.79 hours into the protocol (5:47 PM; nadir at 5:47 AM), and alertness declined steadily at an average of 0.27 points per hour.

Conclusion: During an ultradian protocol, self-reported mood and alertness indicated a clear circadian pattern that declines across the night and increases the following day, though with some evidence of accrual of a sleep debt across the 36-hour protocol. Our finding of a ~5:48 PM peak in mood and alertness aligns with previous naturalistic studies of daily rhythms in positive mood that have reported peaks around in mid-afternoon/early evening. Thus, daily rhythms in mood may have an endogenous origin rather than being driven solely by sociocultural factors, such as the end of the school/work day.

CIRCADIAN RHYTHMS IN MELATONIN, CORE BODY TEMPERATURE, AND PERFORMANCE IN EARLY/MIDDLE ADOLESCENTS UNDERGOING A 36-HOUR ULTRADIAN PROTOCOL

Peter Franzen[1], Daniel Buysse[2], Mrudul Nagapurkar[1], Margaret Kuzemchak[1], Meredith Wallace[1], Ronette Blake[1], Brant Hasler[1], Jessica Levenson[1], Duncan Clark[1], Colleen McClung[1], Adriane Soehner[1]

[1] University of Pittsburgh, [2] University of Pittsburgh School of Medicine

Introduction: Adolescence is thought to involve dramatic changes in circadian rhythms and homeostatic sleep drive, but data demonstrating such changes in carefully-controlled laboratory studies remain sparse. We used an ultradian sleep-wake protocol to examine circadian rhythmicity in melatonin, core body temperature (CBT), and task performance in relation to age among early/middle adolescents.

Methods: Participants (N=54, ages 13.0–15.9) completed 2 weeks of actigraphy followed by 60-hour lab visit including a baseline night of polysomnography (PSG), followed by a 36-hour ultradian protocol in dim light (2-hour cycles of 80 minutes awake and a 40-minute sleep opportunity with PSG), and a recovery PSG night. Core body temperature (CBT) was measured continuously and salivary melatonin was sampled every 30–60 minutes. During each ultradian cycle, participants completed the psychomotor vigilance task (PVT) to index sustained attention (outcome: lapses) and the reward anti-saccade (RAS) task to assess inhibition of a prepotent response (outcome: accuracy). Circadian trends in performance and total sleep time (TST) during 40-minute sleep opportunities were examined with mixed effects cosinor models. Peak melatonin time was estimated using spline models. Associations between age and acrophase across outcomes were examined with bivariate correlations; associations between sleep, physiologic, and performance rhythms were examined with age-adjusted partial correlations.

Results: Significant circadian trends (all p's< 0.001) were observed in TST and PVT/RAS performance. In bivariate correlations, age was significantly associated with habitual sleep duration (r=-0.24, p=0.05), DLMO (r=0.37, p=0.018), and peak melatonin time (r=0.33, p=0.05), but not with habitual midsleep timing, acrophase of performance rhythms, or TST acrophase. Age-adjusted partial correlations indicated that DLMO was associated with peak melatonin time (r=0.59, p< 0.001), and marginally associated with CBT nadir (r=0.36, p=0.065) and PVT acrophase (r=0.33, p=0.096). CBT nadir was associated with habitual midsleep (r=0.49, p=0.005), TST acrophase (r=0.73, p< 0.001), and peak melatonin time (r=0.38, p=0.045).
Conclusion: In this sample of adolescents, age was associated with some, but not all sleep and circadian rhythm measures. Although strong circadian rhythms were observed in physiological and performance measures, the timing of these rhythms were not consistently associated with each other. Changes in circadian rhythms during adolescence may vary among different domains.

SUCCESS OF AT-HOME DIM LIGHT MELATONIN ONSET ASSESSMENT IN EARLY ADOLESCENTS WITH ADHD SYMPTOMS

Aashritha Sadu[1], Sinead Moyles[1], Gina Mason[2], Claire Mayew Sherman[1], Victoria Dionisos[1], Taylor Christiansen[1], David Barker[2], Daniel Dickstein[3], Mary Carskadon[2], Jared Saletin[2]
[1] E.P. Bradley Hospital Sleep Research Laboratory, [2] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University, [3] Department of Psychiatry, Harvard Medical School

Introduction: Circadian rhythms may be translationally relevant to adolescents with attention-deficit/hyperactivity-disorder (ADHD). Laboratory assessment of dim-light-melatonin-onset (DLMO) can be burdensome and prohibitive in youth with more severe ADHD presentations. Conversely, at-home protocols, while beneficial, may be impacted by the heterogeneity of ADHD. Here we examined the success of an at-home DLMO protocol in adolescents with lesser and greater ADHD severity.
Methods: Sixty adolescents (28M; age: 11.76±1.24 years, age-range: 10-15 years) in R01HD103665 ranging in ADHD presentation completed at least five nights of a fixed sleep schedule (10hr fixed to family-optimal rise time) followed by an evening DLMO assessment. Each was provided a collection kit including instructions, salivettes (Sarstedt AG & Co. KG), a 0.1-gram scale, log, ice pack, and light-blocking glasses. On the evening of assessment, staff described procedures over a video call and youth provided 10 saliva samples over 4.5hrs extending 1-hour past scheduled bedtime. Saliva was collected using salivettes and weighed by participants (targeting 9g; a second sample requested if weight< 8.7g). Staff called participants every 30 minutes to prompt sampling, and to log start and end-times and sample weight. Samples were stored in an insulated bag with an ice-pack and retrieved the next morning. Melatonin was measured by radioimmunoassay. DLMO phase was computed by interpolation (absolute threshold of 4 pg/ml). Indeterminate DLMO phases were resolved via consensus. We examined success of DLMO determination and whether it varied by ADHD symptoms (participants grouped by Conners-3-Parent ADHD Index Probability score as high (ADHDy; ≥50%ile; n=28) or low (ADHDn; < 50%ile n=32)).
Results: DLMO determination was successful in 92% of youth (n=55); five participants' data required adjudication (e.g., interpolation between two threshold crossings). We failed to identify DLMO in 5 participants (8%) for persistent suprathreshold melatonin values (n=3) or measurement error (n=2). ADHD status did not moderate measurement success ($\chi 2$=0.69, p=.44, Cramer's V=0.16). DLMO was identified in 96% of the ADHDy group (n=27) and 87% of the ADHDn group (n=28).
Conclusion: This work indicates the success of capturing at-home melatonin onset phase in our young sample on a fixed sleep schedule. ADHD status did not moderate the success of measurement.

ARE ADHD SYMPTOMS ASSOCIATED WITH CIRCADIAN PHASE PREFERENCE OR MELATONIN ONSET PHASE IN YOUTH ON A FIXED SLEEP SCHEDULE?

Sinead Moyles[1], Claire Mayew Sherman[1], Gina Mason[2], Victoria Dionisos[1], Taylor Christiansen[1], David Barker[2], Daniel Dickstein[3], Mary Carskadon[2], Jared Saletin[2]
[1] E.P. Bradley Hospital Sleep Research Laboratory, [2] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University, [3] Department of Psychiatry, Harvard Medical School

Introduction: Research indicates that attention-deficit/hyperactivity disorder (ADHD) may be associated with later circadian rhythms, particularly an evening phase preference. It remains unclear whether biological circadian parameters index ADHD symptoms. Here we investigated preliminary associations of ADHD symptoms in early adolescents with circadian phase preference, dim-light-melatonin onset (DLMO) phase, and phase angle to sleep onset.
Methods: We analyzed data from 50 adolescents in R01HD103655 with complete data on all measures (28F; age: 12.3±1.2yrs, range: 10-15yrs). ADHD symptoms were assessed with the Conners-3 Parent and age/sex-adjusted t-scores revealed a range of inattention (59.29±14.75, range=40-90) and hyperactivity/impulsivity (61.83 ±16.82, range=41-90) symptoms. Participants were off psychostimulants or exogenous melatonin and completed at least five nights of sleep stabilization (10h time-in-bed aligned to family-optimal risetime) prior to at-home DLMO collection. Each wore light-blocking glasses and provided one sample every 30 minutes for 4.5 hours extending 1 hour past bedtime—10 samples in total. DLMO phase was determined by interpolation (4 pg/mL threshold), and phase angle to sleep onset was calculated as the average actigraphy-estimated sleep onset of the 5 nights before DLMO – DLMO phase. We measured child self-reported phase preference (eveningness[low]-morningness[high]; 29.16±5.08; range: 12-38) and puberty status (categories 1-5; mode=3, range=1-4) using measures previously established by our group.
Results: More mature pubertal category and older age were associated with greater self-reported eveningness (r(46)=-.38, p<.01; r(47)=-.41, p<.01). No associations were found between puberty category or age and DLMO phase (|r|'s≤.011, p's ≥.90,) or phase angle (|r|'s≤.02, p's>.88). Higher inattention t-scores were

marginally associated with eveningness (r(45)=-.27, p=.07) but did not index DLMO phase or phase angle (|r|'s≤.01, p's>.81). There were no associations of circadian variables and hyperactivity/impulsivity (|r|'s≤.06, p's≥.68).
Conclusion: Despite perceptions of later circadian rhythms in ADHD, we found weak evidence linking ADHD symptoms with delayed circadian rhythms. Higher inattention symptoms were associated with a trend towards self-reported eveningness, however, neither inattention nor hyperactivity/impulsivity, was linked to biological DLMO phase or the phase angle of melatonin to sleep onset. These results indicate that altered circadian timing may not be a stable phenotype of ADHD when youth are placed on a stabilized sleep schedule.

ASSOCIATIONS BETWEEN REAL-LIFE LIGHT EXPOSURE PATTERNS AND SLEEP BEHAVIOR IN ADOLESCENTS

Luisa Lopes[1], Fernando Louzada[2], Julia Vallim[1], Sergio Tufik[3], Vânia D'Almeida[1]
[1] UNIFESP - Universidade Federal de São Paulo, [2] Universidade Federal do Parana, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: One of the most striking changes in the regulation of sleep-wake behavior during adolescence is circadian phase delay. Light exposure synchronizes circadian rhythms, impacting sleep regulation, however, the influence of real-life light exposure on sleep variations remains less clear. We aimed to describe the sleep and light exposure patterns of high school students with comparable schedules and socio-economic backgrounds, and evaluate whether there was any association between them, considering chronotype.
Methods: We analyzed 5 school days and 2 free days of actigraphy records, from 35 adolescents (24 female, mean age: 16.23±0.60 years). The sample was described using the Sleep Regularity Index (SRI), chronotype (actigraphy MSFsc), and self-reported diurnal preference (Morning/Evening Scale). Regression models were constructed to: assess the impact of light exposure (daytime and nighttime) on subsequent sleep episodes; and confirm whether the associations could be an indirect consequence of chronotype.
Results: Despite following similar routines, the SRI varied considerably (48.25 to 88.28). There was compatibility between the actigraphy proxy for chronotype and the self-reported diurnal preference, extracted using the Circadian rhythm scale for adolescents. Less light exposure during the day was associated with later sleep onset and shorter sleep duration. An increase of 100 lux in average daytime light exposure advance of 8.08 minutes in sleep onset and 7.16 minutes in sleep offset. When the regressions were controlled for chronotype, these associations persisted.
Conclusion: These findings facilitate discussions regarding the behavioral aspect of real-life light exposure's impact on sleep and its potential as a target for interventions aiming to enhance adolescents' sleep quality.

SLEEP REGULARITY INDEX AND LIGHT REGULARITY INDEX IN SIX-MONTH-OLD INFANTS

Rebeca Buest de Mesquita Silva[1], Mario Andre Leocadio Miguel[2], Fernando Louzada[3]
[1] Federal University of Parana, [2] Northumbria University, [3] Universidade Federal do Parana

Introduction: There is a bidirectional relationship between sleep patterns and light exposure patterns; in other words, sleep patterns influence light exposure patterns, and vice versa. Sleep regularity can be quantified using the Sleep Regularity Index (SRI), while the Light Regularity Index (LRI) has been recently proposed to measure the regularity of light exposure patterns. A positive correlation between SRI and LRI has been reported in adolescents (Hand et al., 2023). In this study, we tested whether the same correlation exists in six-month-old infants.
Methods: Mothers were recruited from two public hospitals in Ribeirão Preto, São Paulo, Brazil, resulting in a sample of 122 infants (mean age= 6,1 months). The babies wore actigraphs (ActLumus, Condor Instruments) on their ankles for one week. These devices have sensors to detect light exposure. Data were analyzed using pyActigraphy, an open-source Python package for actigraphy, with light exposure specifically processed using the pyLight module. Statistical analysis was conducted in RStudio. For each infant, the mean of the SRI and LRI, as well as the correlation between these variables, were calculated.
Results: As anticipated, a positive correlation of 0.77 ($p < 0.001$) was observed between SRI and LRI, indicating that higher LRI values were associated with higher SRI values. The means of LRI and SRI were 57.10 and 48.27, respectively.
Conclusion: The correlation between SRI and LRI in infants was significantly stronger than the one reported in adolescents (Hand et al., 2023). We attribute this difference primarily to the autonomy adolescents have in managing their time and schedules, a factor absent in infants. Studying the SRI/LRI relationship across different age groups may provide valuable insights into the synchronization processes of human circadian rhythms.

DELAYED OR DISPLACED: THE ROLE OF CIRCADIAN TIMING IN BEDTIME PROCRASTINATION

Steven Carlson[1], Helen Burgess[2], Bradley Appelhans[3], Lauretta Quinn[4], Chelsea Allen[1], Kelly Baron[1]
[1] University of Utah, [2] University of Michigan, [3] Rush University, [4] University of Illinois Chicago

Introduction: Introduction. Bedtime procrastination refers to the tendency to delay bedtime in the absence of external obligations. Bedtime procrastination undermines sleep health across

multiple dimensions, most notably delaying sleep and shortening sleep duration. To date, most research on mechanisms underlying bedtime procrastination focuses on cognitive or behavioral factors. However, sleep delays in bedtime procrastination may reflect delays in circadian phase. Accordingly, the present study sought to examine the role of circadian phase in bedtime procrastination. Further, we examined whether the associations between bedtime procrastination and sleep outcomes persisted when statistically adjusting for circadian phase.
Methods: Method. 102 adult participants (Mage = 35.8, SD = 9.8) with BMI 25-35 kg/m2 completed the bedtime procrastination scale and 7 days of sleep actigraphy monitoring three times over one year (baseline, 6 months, 12 months). Participants also completed the morningness-eveningness questionnaire at baseline. Circadian phase was assessed twice via in-lab dim light melatonin onset (DLMO) between baseline and 6 month time points, as well as at the 12 month time point. Multilevel models regressed bedtime procrastination onto DLMO, and sleep outcomes onto bedtime procrastination and DLMO.
Results: Results. Later average DLMO time across the two assessments was associated with higher average bedtime procrastination (B = 2.49, p < 0.001). This association remained significant when adjusting for age, sex, race, and average bedtime, but not for morningness-eveningness. For sleep outcomes, higher individual average bedtime procrastination was associated with later average bedtimes (B = 0.06, p < 0.001), remaining significant after adjusting for age, sex, race, and DLMO, but not for morningness-eveningness. In contrast, individual average bedtime procrastination was associated with shorter sleep duration only when adjusting for morningness-eveningness (B = -0.03, p = 0.014) and DLMO (B = -0.02, p = 0.035).
Conclusion: Discussion. This study demonstrated an association between bedtime procrastination and circadian timing. However, this association may be partially attributable to the shared association with morningness-eveningness. Furthermore, we demonstrate that the associations between bedtime procrastination and sleep timing and duration is not attributable to circadian timing. Together, these results support bedtime procrastination as a unique contributor to insufficient sleep.

INCIDENCE OF SOCIAL JETLAG IN THE CITY OF SÃO PAULO: A LONGITUDINAL STUDY FROM THE EPISONO COHORT

Julia Vallim[1], Guilherme Fernandes[2], Sergio Tufik[3], Monica Andersen[3], Vânia D'Almeida[1]
[1] UNIFESP - Universidade Federal de São Paulo, [2] Universidade Federal de São Paulo, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Social jetlag (SJL) is a measure that quantifies the difference in mid-sleep between work (or school) and free days. This phenomenon is associated with adverse health outcomes such as metabolic dysfunction and the development of sleep and mood disorders. The aim of the present work was to describe the prevalence and incidence of social jetlag in a representative sample of the population of the city of São Paulo.
Methods: A retrospective analysis using data from the 3rd edition of the population-based São Paulo Epidemiologic Sleep Study (EPISONO) and its follow-up, conducted in 2007 (N=1,042) and 2015 (N=695), respectively. Information on participants' bedtimes and wake-up times on work/school and free days was extracted from the UNIFESP Sleep Questionnaire, and SJL was calculated as the absolute difference between the mean mid-sleep time on work/school days and the mean mid-sleep time on free days. High SJL was defined as 2 hours or more.
Results: In 2007, 77.9% of volunteers had some amount of the discrepancy, with a prevalence of high SJL of 13.5%. In 2015, 72.2% of volunteers had some degree of the condition with a prevalence of high SJL of 11.5%. Over the 8 years of the EPISONO 3rd edition, 45.1% of subjects had an increase in SJL, 41.7% had a decrease, and 13.2% had no change. A total of 57 new cases of high SJL were found between 2007 and 2015 (incidence rate=8.2%). Of the 89 individuals who had high SJL in 2007 and were present at follow-up, 23 maintained the condition in 2015 (maintenance rate=3.3%). Conversely, 66 individuals transitioned to low SJL (remission rate=9.5%).
Conclusion: To our knowledge, this is the first longitudinal study describing these measures of the epidemiologic evolution of SJL in a Brazilian population-based sample. Given that its observed prevalence, as well as its health consequences, we raise the question of whether SJL should deserve attention as a public health issue.

A LONGITUDINAL OBSERVATIONAL STUDY ON MEAN AND DAILY VARIABILITY IN SLEEP MIDPOINT AND MENTAL HEALTH

Ruth Brombach[1], John Sy[1], Jacqueline Leete[2], Daniel Taylor[2], Kelly Kim[2], Ethan Olson[2], Kiley Pauck[2], Sarah Emert[3], Kenneth Bottrill[2], Jessica Dietch[1]
[1] Oregon State University, [2] University of Arizona, [3] Idaho State University

Introduction: Sleep timing (e.g. sleep midpoint) plays a significant role in mental health. Whereas person-level mean sleep midpoint has been linked to depression, anxiety, and stress, the impact of daily variability in sleep midpoint is underexplored. This study investigated whether within- and between-person variability in sleep timing predicted mental health outcomes among young adult college students.
Methods: Participants (N = 261, age M = 19.92 [4.79]) completed daily diaries over two weeks, providing data on sleep parameters and mental health symptoms (i.e., depression, anxiety, stress). Sleep midpoint was calculated as total sleep time [TST] + (sleep onset latency [SOL] + wake after sleep onset [WASO])/2 which was converted to hours centered on midnight. SAS PROC MIXED was used to run multilevel analyses with maximum likelihood estimation and Kenward-Roger degrees of freedom to model the effect of previous day sleep midpoint (level 1) and mean sleep midpoint (level 2) on mental health symptoms.
Results: Later mean sleep midpoint had worse depressive symptoms (β = 0.18, p<.001), anxiety symptoms (β = 0.20, p <.001), and stress (β = 0.36, p = 0.005). Within person analyses revealed later daily sleep midpoint predicted less anxiety the next day (β = -0.04, p = 0.02) but was not associated with depression or stress.

Gender explained some effects, with women showing stronger associations between mean sleep midpoint, anxiety and stress.
Conclusion: Young adult college students with later average sleep timing had poorer mental health symptoms. Daily anxiety was reduced on days following later sleep timing relative to a person's baseline, potentially reflecting adaptive behaviors like socializing or study-related activities. This suggests complex relationships between sleep timing and mental health. Further research is needed to determine whether these associations are influenced by chronotype or external factors, such as academic demands or conscientiousness. Moreover, studies promoting earlier and more consistent sleep timing should assess their potential benefits for mental health, particularly among young adults.
Support (if any): This study was supported by a Pac-12 Student-Athlete Health and Well-Being Initiative Grant and an in-kind grant from Fitbit Inc. Dr. Dietch's effort on this project was supported by a National Heart, Lung and Blood Institute grant 1K23HL157698.

TIMING OF HABITUAL EXERCISE DIFFERENTIALLY IMPACTS 24H GLUCOSE VARIABILITY IN HEALTHY ADULTS

Grissy Sime-Mora[1], Josiane Broussard[1], Corey Rynders[1], Robbie Beyl[2], Seth Creasy[3]
[1] Colorado State University, [2] Pennington Biomedical Research Center, [3] University of Colorado Anschutz Medical Campus

Introduction: Glucose homeostasis fluctuates daily, driven by circadian rhythms and behaviors like sleep, eating, and physical activity. Exercise has also been recognized as a critical factor in the regulation of glucose homeostasis, and emerging evidence suggests that the circadian timing of exercise timing may play an important role in glucose regulation. Therefore, this study compared 24h glucose levels and variability among healthy, physically active adults who self-report as habitual morning versus evening exercisers.
Methods: Healthy, self-reported habitual morning and evening exercisers were recruited to participate in the study. Continuous glucose monitors (CGM) were utilized to measure 24h interstitial glucose for up to 14 days. Daily diaries verified the timing of exercise relative to sleep. 24h glucose area under the curve (AUC) and glucose variability, estimated by the mean amplitude of glucose excursions (MAGE), were compared between groups across the full CGM wear period using t-tests. Results are presented as mean±SD.
Results: Eligible participants reported ≥150 min/wk of moderate intensity exercise., with bouts performed during the morning (n=8; 6 females; Age: 28±2y, BMI: 24±1.25 kg/m²) or evening (n=6; 4 females Age: 29±3y, BMI: 23±0.63 kg/m²). Exercise occurred at 2:40±0:32 hours after waking in the morning group and 9:51±0:23 hours after waking in the evening group. The number of exercise days during the study was comparable between groups (morning: 6.5±2.1 days out of 9.6±0.5 days vs evening: 7.4±0.8 days out of 10.6±4.7 days). Self-reported sleep duration was between 7-9 hours/night. Mean glucose AUC over 24-hours was not significantly different between morning and evening exercisers (p=0.72). However, 24-hour MAGE was significantly lower in the morning group compared with the evening group (22.4±1.0 vs. 24.01±1.1 mg/dL, p< 0.001).
Conclusion: These findings suggest that the timing of habitual exercise influences daily glucose variability, with morning exercise associated with more stable glucose levels compared to evening exercise in healthy young adults. Future studies are needed to determine whether aligning exercise timing with circadian rhythms may offer a simple, behavior-based strategy to optimize glycemic control.

Introduction: Insufficient sleep and circadian misalignment dysregulate glucose homeostasis. Interventions are needed for when insufficient sleep and circadian misalignment cannot be avoided (e.g., military operations, emergency responders, shift work). Prebiotics, defined as a substrate that is selectively utilized by host microorganisms conferring a health benefit, have been shown to beneficially affect glucose metabolism in non-human preclinical models and in humans. Here, we examined in a pilot study the effects of a combined Polydextrose (PDX) and Galacto-oligosaccharide (GOS) prebiotic supplement on 24-hour glucose levels during combined sleep restriction and circadian misalignment.
Methods: 5 healthy adults (aged 25.4±3.5, 2 females) completed a 39-day randomized, double-blind, placebo-controlled, cross-over study comparing a prebiotic–7.5g/day each of GOS [Frieslad Campina] and PDX [Dupont Nutrition & Biosciences] or placebo (maltodextrin [Grain Processing Corporation]) sachets dissolved in water with breakfast. Participants consumed 14 days of prebiotic or placebo at home while maintaining regular mealtimes and ~8h habitual sleep each night. Participants then completed an ~4-day in-laboratory study of combined sleep restriction and circadian misalignment with 3h sleep opportunities; the first at night and the second and third during the daytime. Prebiotic and placebo conditions continued in-laboratory. Timing and composition of food intake was identical during the in-laboratory segment for each condition and designed to maintain energy balance. Glucose levels were monitored every 15 min for ~60h using a continuous glucose monitor (FreeStyle Libre Pro [Abbott]). Participants had a 3-day washout period prior to repeating the protocol with the second condition. Mixed model ANOVA with condition and time as fixed factors were performed.
Results: Mean 24-hour glucose level over the ~60h of recording was significantly lower during prebiotic versus placebo treatment (p< 0.00001; Small effect size, Hedges' g bias corrected).
Conclusion: Preliminary findings from this pilot study suggest that a combination of prebiotic fibers taken prior to and during insufficient sleep and circadian misalignment may have some benefits for glucose metabolism.

EFFECTS OF TIME-RESTRICTED FEEDING ON SLEEP: A SYSTEMATIC REVIEW AND META-ANALYSIS

Gabriela Lima[1], Julia Vallim[1], Camila Marques[1], Ronaldo Thomatieli-Santos[1], Deilys Vazquez[1], Sergio Tufik[2], Gabriel Pires[2], Vânia D'Almeida[1]

[1] UNIFESP - Universidade Federal de São Paulo, [2] Universidade de Federal de São Paulo

Introduction: Studies in the field of chrononutrition have increased in recent years due to the link between circadian system, food intake, and metabolic health, emerging as an important tool for dealing with metabolic disorders and circadian misalignment. To date, chrononutritional interventions, such as time-restricted feeding (TRF), have been extensively studied with an emphasis on metabolism. However, the evidence regarding the effects of TRF on sleep health remains fragmented and inconclusive. To add to the information in this area and given the potential connections between sleep and metabolic health and the diversity of TRF interventions, a meta-analysis of the effect of TRF on sleep, measured by subjective and objective methods, will help to increase the level of evidence available on this topic.
Methods: The search was conducted in the databases MEDLINE, Scopus, Web of Science, EMBASE, LILACS and Cochrane CENTRAL until March 2024. The article selection process was conducted in two stages: first, the titles and abstracts were screened, and then the full texts were analyzed. The outcomes evaluated were self-reported total sleep time (TST), global score of the Pittsburgh Sleep Quality Index (PSQI), and objective TST measured by polysomnography or actimetry. Effects size for each individual study was calculated using raw mean difference and meta-analyses were performed using a DerSimonian and Laird's random effects model.
Results: The final sample included 51 articles from 17 countries, published between 2001 and 2023. The results showed that TRF decreased self-reported TST and impaired subjective sleep quality, as evidenced by an increase in the global score of the PSQI. Sub-group analyses of the studies conducted during the Ramadan showed that fasting decreased TST, while in non-Ramadan studies showed an increase TST.
Conclusion: Our results suggest that TRF has an effect on self-reported sleep duration and quality, which depends on the timing, type and duration of intervention. Further studies in which the eating window is considered may provide new perspectives on chrononutrition and sleep, and may contribute to its appropriate use as a tool for weight control and metabolic disorders prevention

CONSISTENT PARENTING AND BEDTIME ROUTINES MODERATE THE LINK BETWEEN ENTRAINMENT SIGNAL REGULARITY INDEX AND BMI INCREASE IN ELEMENTARY CHILDREN

Nana Jiao[1], Jennette Moreno[1]

[1] Children's Nutrition Research Center, Baylor College of Medicine

Introduction: In summer, children gain weight more rapidly compared to the school year. Having a lower entrainment signal related to increased summer Body Mass Index (BMI). However, the potential moderators are understudied. This study examined factors that moderated the relationship between summer entrainment regularity and changes in summer BMI among elementary children.
Methods: This longitudinal observational study included 119 elementary children aged 5 to 8 years (57% female, 83% healthy weight). BMI was assessed at late school-year (spring) and beginning of the following school-year (fall) in Houston, Texas. During the summer, child activity and sleep patterns were assessed using wrist-actigraphy for 7 days and 8 nights, in which activity was used to compute the Entrainment Signal Regularity Index (ESRI, range:0-1) based on the Hannay Model, with higher scores indicating greater synchrony and regulation of entrainment signals that ensure stable entrainment of circadian phase. Parents reported Comprehensive General Parenting Questionnaire (CGPQ), including sub-construct Structure-Consistency (range:1-5) with higher scores indicating greater parental predictable behaviors by providing clear and consistent guidelines, and keeping their promises, Bedtime Routines Questionnaire (BRQ), including subscale Routine Consistency (range:10-50) with higher scores indicating greater bedtime routine consistency, Children's Behavior Questionnaire (CBQ), Parental Stress Scale (PSS), and Interpersonal Support Evaluation List (ISEL). Hierarchical regressions were conducted to examine the moderators interacting with ESRI in predicting summer BMI change.
Results: Summer BMI increased by 0.39±0.79. ESRI score was 0.63±0.11. Average CGPQ Structure – Consistency and BRQ Routine Consistency were 3.79±0.36 and 38.36±8.07, respectively. After controlling for child age, sex, baseline BMI (spring), sleep duration, sleep midpoint, and moderate to vigorous exercise intensity, findings indicated that lower ESRI predicted a greater summer BMI increase. Further, ESRI interacted with CGPQ Structure-Consistency (β=0.28, t=2.82, p=0.006) and BRQ Routine Consistency (β=0.21, t=2.19, p=0.031) in predicting summer BMI increase, explaining an additional 6.9% and 4.1% of the variance, respectively. Nonsignificant moderators included CBQ, PSS, and ISEL.
Conclusion: The relationship between less entrainment regularity and greater increases in BMI during the summer was especially evident for elementary children exposed to less consistent parenting behaviors and bedtime routines.

CONSISTENCY OF INTERINDIVIDUAL DIFFERENCES IN THE AMPLITUDE OF DAILY ENERGY EXPENDITURE AND RESPIRATORY QUOTIENT RHYTHMS IN HEALTHY ADULTS

Zoe Meredith[1], Hannah Ritchie[1], Tristan Dear[1], Victoria Catenacci[2], Karen Shea[2], Elizabeth Connick[2], Thomas Moehlman[1], Ellen Stothard[1], Janine Higgins[2], Edward Melanson[2], Kenneth Wright[3]

[1] University of Colorado Boulder, [2] University of Colorado Anschutz Medical Campus, [3] Sleep and Chronobiology Laboratory,

Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA

Introduction: We have previously reported stable, trait-like interindividual differences for average 24-hour energy expenditure (EE) and respiratory quotient (RQ), and their average levels during scheduled wakefulness and sleep. However, interindividual differences in the daily amplitude of the EE and RQ rhythms remain to be explored. The amplitude of daily rhythms is of growing interest given that reduced amplitude (e.g., body temperature, physical activity) is associated with aging and disease.
Methods: 15 healthy adults (age 23.3±3.4 mean±SD, 7 females) completed a 4-day in-laboratory protocol consisting of one habituation night and three days of living in a whole room indirect calorimeter. Participants maintained consistent 8-hour sleep schedules at their habitual times for one week and consumed an outpatient energy-balanced diet for three days before in-laboratory testing. During calorimeter days, participants remained in constant bedrest, consumed the energy-balanced diet with meals 0.5h, 4.5h, 10.5h, and 14.5h after scheduled awakening, and were provided 8h sleep opportunities. EE and RQ were measured every minute. Daily amplitude of the EE and RQ rhythms was determined using non-orthogonal spectral analysis. Mixed-model ANOVA with participant as a random factor and day as a fixed factor was performed. Intraclass correlation coefficients (ICC) were calculated to examine the stability of individual differences.
Results: A significant main effect of participant was observed for EE and RQ amplitude (both $P < 0.01$), whereas the main effect of day was not significant for either ($P > 0.75$). The stability of individual differences in EE daily amplitude was almost perfect (ICC=0.90), whereas daily amplitude was moderate (ICC=0.43).
Conclusion: These findings indicate stable, trait-like interindividual differences in EE daily amplitude and less robust interindividual differences in RQ daily amplitude. Additional research is needed to understand the mechanisms contributing to these individual differences and why EE is more consistent than RQ, test for the stability of interindividual differences in other populations (e.g., aging, people with obesity), and determine their impact on physiological function.

ASSOCIATIONS BETWEEN REST-ACTIVITY RHYTHMS AND DIET QUALITY IN THE HISPANIC COMMUNITY HEALTH STUDY/STUDY OF LATINOS (HCHS/SOL)

Kaitlin Potts[1], Sina Kianersi[1], Tariq Faquih[2], Qian Xiao[3], Yasmin Mossavar-Rahmani[4], Daniela Sotres-Alvarez[5], Sanjay Patel[6], Tianyi Huang[7], Susan Redline[8], Heming Wang[2]
[1] Brigham and Women's Hospital, [2] Brigham and Women's Hospital, [3] University of Texas Health Sciences Center, [4] Albert Einstein College of Medicine, [5] UNC Gillings School of Global Public Health, [6] University of Pittsburgh, [7] National Institute on Aging, [8] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Poor diet quality and circadian disruption contribute to increased cardiometabolic risk, but it is unknown if activity-based markers of circadian rhythms associate with diet quality in free-living samples. We evaluated these associations in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL).
Methods: This cross-sectional study used diet and actigraphy/sleep data collected approximately two years apart. Diet quality was measured with the Alternate Healthy Eating Index 2010 (AHEI; higher indicates healthier) from two 24-hour dietary recalls. A subset of participants completed 7-day actigraphy (Philips Spectrum) with validated scoring of sleep-wake epochs and main sleep periods. Markers of the strength, regularity, and timing of the 24-hour rest-activity rhythm (RAR) were estimated with nonparametric and parametric (extended-cosinor) metrics derived from epoch-level activity counts, sleep regularity metrics (SD sleep duration and SD sleep onset time) derived from the scored sleep data, and self-reported chronotype estimated from the reduced Morningness-Eveningness questionnaire. Linear regression models estimated associations between RAR measures with standardized AHEI z-scores adjusting for energy intake, age, sex, Hispanic background, study site, education, employment, smoking, and depressive symptoms, and sampling design using survey weights.
Results: Among 1635 participants (mean age 45±12; 64% female), stronger rhythms—characterized by high activity during active periods and low activity during rest—were associated with higher diet quality. Those in the highest quartile of nonparametric relative amplitude (RA) had AHEI-z score 0.16 higher (95% CI: 0.02, 0.31) than those in the lowest quartile and a similar pattern was seen with the parametric pseudo-F. Irregular sleep duration (SD sleep duration >60 minutes) and timing (SD sleep onset time >60 minutes) were associated with lower diet quality, with mean AHEI-z scores (compared to < 60 minutes SD sleep duration/timing) of -0.13 (95% CI: -0.22, -0.03) and -0.11 (95% CI: -0.21, -0.01), respectively. Late chronotype also related to lower diet quality. Definitely-evening types had AHEI-z scores -0.35 (95% CI: -0.60, -0.10) lower than definitely-morning types.
Conclusion: In this community-based Hispanic cohort, stronger RAR, more regular sleep, and earlier chronotype associated with higher diet quality, suggesting that disrupted RAR may co-occur with unhealthy dietary patterns, amplifying cardiometabolic risk.

ASSOCIATION BETWEEN REST-ACTIVITY CIRCADIAN RHYTHMS AND MEAL TIMING: NHANES 2013-2014

Velarie Ansu Baidoo[1], Kristen Knutson[2], Joon Chung[3], Debbie Chung[4], Roberto Refinetti[5], Michael Grandner[6], Azizi Seixas[1], Girardin Jean-Louis[1]
[1] University of Miami Miller School of Medicine, [2] Northwestern University Feinberg School of Medicine, [3] University of Miami, [4] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [5] University of New Orleans, [6] University of Arizona College of Medicine

Introduction: Time restricted eating (TRE) is a novel dietary pattern that limits food intake to a certain time of day (~8-10

hours) without necessarily restricting caloric intake. Meal timing aligned with the internal biological clock has beneficial effects on metabolic health. Rest-activity rhythm (RAR) is a marker of circadian rhythmicity, and the use of wearable devices, such as actigraphy, has made it possible to assess 24-hour RAR. This study examined the association between actigraphy-derived RAR in relation to meal timing. It also investigated whether race/ethnicity is an additional factor that could modify such associations.

Methods: We used data from the National Health and Nutrition Examination Survey 2012-2013 (n=2944). 24-hour rest-activity metrics (mean, amplitude, acrophase, robustness) were derived from actigraphy data applying cosinor analysis. Outcomes of interest were meal timing variables (first, last, and eating duration; derived from two 24-hour dietary recalls) and race/ethnicity. Multiple linear regression analyses examined the associations between RAR metrics and meal timing and race/ethnicity. Adjusted covariates included age, sex, education, body mass index, total energy intake, and poverty to income ratio.

Results: Higher mean activity levels were associated with earlier mealtimes (β= -0.17, p=0.001), but also later last mealtimes (β= 0.07, p=0.01) and longer eating duration (β= 0.10, p < 0.0001). Having an earlier acrophase was also associated with shorter eating duration (β=-0.09, p=0.009) and a later acrophase was associated with later first mealtimes. (β=0.27, p=0.0004). For all models accounting for meal timing variables, non-Hispanic Asians and Black adults had lower amplitude and robustness compared with White adults (all p< 0.05). Moreover, other Hispanic and Mexican Americans had higher mean activity levels compared with White adults for all models (all p< 0.05).

Conclusion: Our findings support possible associations between meal timing variables and disrupted or weakened RAR. Having a lower amplitude and less robust RAR among non-Hispanic Asian and Black adults have implications for metabolic health, particularly relevant to the incidence of diabetes. Future research should examine the combined impact of TRE on circadian rhythms and metabolic health.

GREATER DEPRESSION SEVERITY IS ASSOCIATED WITH LATER CIRCADIAN EATING TIME IN THOSE WITH SEASONAL DEPRESSION

Alison Klevens[1], Maddison Taylor[1], Kathryn Roecklein[2], Delainey Wescott[1],

[1] University of Pittsburgh - Pittsburgh campus, [2] University of Pittsburgh

Introduction: Circadian misalignment is a transdiagnostic feature of depression and metabolic dysfunction. Timing of food intake can alter peripheral clocks creating internal circadian misalignment. The atypical symptoms of depression seen in seasonal affective disorder (SAD), such as over eating, can exacerbate circadian misalignment by delaying or prolonging the eating window. Greater atypical depression severity may have increased risk for metabolic dysfunction, possibly through pronounced misalignment. The current study tested the effects of depression severity on circadian eating behaviors in SAD. We hypothesized that greater depression severity would predict later circadian eating time and longer eating windows.

Methods: Participants age 18-65 included SAD (n=33), subsyndromal SAD (S-SAD; n=16), and controls (n=41; total N=90). Depression severity and circadian phase (dim light melatonin onset; DLMO) were measured in winter. Electronic diaries collected the timing of first and last meal to determine the daily eating window. Circadian eating time was calculated as the difference between DLMO and the midpoint between the first eating observation and last eating observation. Multi-level modeling with a random intercept of participant was used to examine the impact of depression severity on daily measures of circadian eating time and eating window length. Covariates included age, gender, weekday/weeknight, and number of diary assessments.

Results: Participants reported mealtimes over 4 to 19 days (M=8.88, SD=3.62). On average, eating midpoint occurred 7.24 hours before DLMO (SD=1.90). Average eating window length was 9.01 hours (SD=3.41). Greater depression severity was associated with later circadian eating time (i.e., shorter interval between eating midpoint and DLMO; b=-0.03, SE=0.01, p=0.03). Depression severity was not associated with eating window length (b=-0.02, SE=0.02, p=0.36).

Conclusion: In a sample of individuals with SAD greater depression severity was associated with later circadian eating time, suggesting that people with greater depression are eating closer to their biological night. Longitudinal data are needed to determine if mealtimes, circadian phase, or depression initiate a maladaptive cycle. In contrast to our hypothesis, no relationship was found between depression severity and length of eating window. Length of eating window is independent of timing of eating window, suggesting that timing may be more important than total hours of food consumption in depression.

REST-ACTIVITY-PATTERNS AND DAYTIME NAPPING DIFFER ACROSS ALZHEIMER'S DISEASE PHENOTYPES

Esther Li[1], Christine Walsh[1], Leslie Yack[2], Neus Falgàs[2], Natalie Pandher[1], Harli Grant[1], Joel Kramer[1], Renaud La Joie[2], Gil Rabinovici[1], Bruce Miller[2], MariLu Gorno-Tempini[2], Kamalini Ranasinghe[2], Keith Vossel[2], Lea Grinberg[1], Thomas Neylan[1]

[1] University of California, San Francisco, [2] UCSF

Introduction: Sleep disruption in Alzheimer's disease (AD) is common, linked to cognitive decline, and a major cause of institutionalization. While AD is associated with increased daytime napping, nocturnal wakefulness, and disrupted rest-activity rhythms (RAR), differences between amnestic (amAD) and atypical (atypAD; non-amnestic presentation) phenotypes remain underexplored. Our goal is to assess daytime napping and RAR across AD phenotypes: amnestic AD (amAD) and atypical AD (atypAD; non-amnestic presentation). Since sleep disturbances in amAD involves increased nocturnal awakenings and a decrease in total sleep, we hypothesized that RAR disruption would be amAD>atypAD> cognitively healthy older adults (HC), and that amAD have more frequent naps than atypAD.

Methods: Philips Spectrum PRO actigraphy watch was used to assess RAR in 17 amAD (8 females, Age: 74.3±9.3), 10 atypAD (4 females, Age: 69.6±9.8) and 11 HC (9 females, Age: 80±7.9). Daytime naps were assessed using 8-hour daytime EEG recordings in an independent cohort of 8 atypAD (5 females, Age: 61.1±5.6)

and 9 amAD (5 females, Age: 64.4±10.7). Preliminary actigraphy daytime sleep bouts were assessed in n=21 amAD and n=7 atypAD.
Results: RAR interdaily stability (IS) was divided into tertiles. A higher proportion of the amAD group were in the lower IS group, while greater proportions of HC and atypAD were in the highest IS tertile. Similar findings were seen for relative amplitude and activity during consecutive 10-hr periods of maximum activity. Using daytime continuous EEG recordings, we determined that amAD had a greater number of 5-minute or longer daytime sleep bouts than atypAD (62.5% vs 22.2% individuals slept more than 5mins/hr, respectively). There were also more daytime sleep bouts (based on actigraphy) in amAD (25.11 ± 8.7 bouts) as compared to atypAD (18.1 ± 2.9 bouts, $p< 0.05$).
Conclusion: Overall, actigraphy data and independent daytime EEG data suggest a more destabilized RAR in amAD compared to atypAD, with more wake disruptions and daytime sleep intrusions. These findings highlight the importance of distinguishing variants of AD in characterizing sleep/wake phenotypes. Future work will examine if differing sleep/wake features across AD variants are driven by differences in underlying neuropathology.

SEX DIFFERENCES IN CIRCADIAN BEHAVIOR AND GFAP EXPRESSION IN COGNITIVELY UNIMPAIRED OLDER ADULTS

Natalie Pandher[1], Esther Li[1], Leslie Yack[1], Brianne Bettcher[2], Rowan Saloner[1], Kaitlin Casaletto[1], Lea Grinberg[1], Thomas Neylan[1], Joel Kramer[1], Christine Walsh[1]
[1] University of California, San Francisco, [2] University of Colorado

Introduction: Glial fibrillary acidic protein (GFAP, marker of astrocyte activation) expression is associated with disrupted circadian rhythms and increased risk of cognitive impairment. The risk of cognitive impairment also increases with diminished rest-activity-rhythm (RAR) amplitude and robustness, advanced acrophase (time of peak activity) in men, and delayed acrophase in women. It is unclear if GFAP relates to circadian behaviors in a sex-dependent manner. We hypothesize that GFAP is increased in men with advanced acrophase and in women with delayed acrophase. Additionally, we expect that GFAP is linked with subjective reports of circadian type using the Circadian Type Inventory (CTI) in cognitively unimpaired (CU) older adults to assess sleep schedule preference (flexible or rigid) and daytime energy (languid or vigorous).
Methods: 31 males (M=74.6, SD=5.4 yrs) and 42 females (M=74.7, SD=5.6 yrs) completed the CTI and up to 10 days of actigraphy (Philips Spectrum Plus; AMI Motionlogger). In a subcohort (n=15), plasma GFAP was assessed. Data were analyzed with Pearson correlations, partial correlations, and ANOVAs where appropriate using SPSS.
Results: Acrophase time and CTI scores were significantly related (R2=0.146, beta=0.314, p=.02) with earlier acrophase linked to greater daytime vigor and more rigid sleep schedules in CU older adults. Males had less stable (interdaily stability: t(36)=-2.256, p=.03) and more fragmented RAR (interdaily variability: t(36)=3.514, p=.001) than females. Self-reported "vigorous" men had lower GFAP levels than "languid" men (t(5)=3.122, p=.03), but there were no differences between "flexible" and "rigid" men, or in women. Notably, delayed acrophase was associated with higher GFAP in men (R2=0.999, beta=1.257, p=.048) but not in women.
Conclusion: We identified sex differences in circadian behavior with CU men exhibiting less stable and more fragmented RAR than women. "Languid" men also had increased GFAP than "vigorous" men. The altered circadian behavior seen in CU males, particularly delayed acrophase, is associated with increased GFAP expression and indicates a potential link between circadian disruption, astrocyte activation, and dementia risk. This suggests circadian behaviors may be more conserved in older women and highlights the need for further investigation into sex-differences in RAR and neurodegenerative disease biomarkers.

FROM NORMAL VARIATION IN SLEEP TO CLINICAL SLEEP DISORDERS: GENETIC INSIGHTS FROM OVER ONE MILLION INDIVIDUALS

Lovemore Kunorozva[1], Matthew Maher[2], Michael Weedon[3], Andrew Wood[4], Samuel Jones[5], Erik Abner[6], Richa Saxena[2], Hanna M Ollila[5], Jacqueline M Lane[7]
[1] Harvard Medical School and Mass General Brigham, [2] Massachusetts General Hospital, [3] University of Exeter Medical School, [4] The University of Edinburgh, [5] University of Helsinki, [6] University of Tartu, [7] Brigham and Women's Hospital

Introduction: Sleep disorders affect over 30% of the population in the United States, making them among the most common yet underdiagnosed conditions with significant disease comorbidity and increase in mortality. Moreover, as occasional sleep problems are normal, clinical sleep disorders (CSDs) are often misinterpreted as normal variation in habitual sleep prior to seeing a physician. Furthermore, it is unknown if the biological mechanisms across sleep disorders are extremes of those that contribute to normal variation in sleep.
Methods: Here, we investigated the molecular mechanisms behind sleep disorders, habitual variation and objectively measured sleep traits and specific sleep medications using genetic and epidemiological data from the UK Biobank, Mass General Brigham Biobank, All of Us, Million Veteran Program and FinnGen, and meta-analyzing results from 1,630,075 individuals with up to 312,402 cases with a sleep disorder.
Results: We identified 573 separate loci with 695 independent signals for sleep disorders, 175 loci for habitual or objectively measured sleep traits and 124 loci with sleep medication use. We then replicated associations with CSD in the Estonian Biobank. Furthermore, genetic correlation analysis indicated genetic correlation between self-reported sleep problems and respective clinical disease for insomnia and clinical insomnia ($rg = 0.622$, $P = 2.49x10-08$), snoring and sleep apnea ($rg =0.679$, $P < 0.001$) but also excessive daytime sleepiness and narcolepsy ($rg = 0.411$, $P = 0.011$). However, individual genetic variants largely differed between the self-reported and clinically defined traits or medications used to treat sleep disorders.
Conclusion: Our findings suggest that habitual sleep traits have genetic basis similar to clinically significant sleep disorders whereas some of the key genetic susceptibility loci and their downstream mechanisms are likely separate between the CSDs and normal variation in sleep. Overall, our findings provide

insight into normal variation in sleep and highlight the trajectory of genetic variants that associate with clinical and pathological sleep disorders. Ultimately, our findings may provide insight into developing novel pharmaceutical targets for sleep disorders.

A COMBINED FIELD/LABORATORY STUDY TO INVESTIGATE BIOMOLECULAR DISRUPTIONS IN ENDOGENOUS CIRCADIAN RHYTHMICITY AMONG REAL-WORLD NIGHT SHIFT WORKERS

Brieann Satterfield[1], Sofia Fluke[1], Kirsie Lundholm[1], Hans Van Dongen[1]
[1] Washington State University

Introduction: Recent studies employing a laboratory study design with randomization to simulated night shift (NS) or day shift (DS) followed by a constant routine protocol exposed widespread NS-induced disruptions in endogenous biomolecular circadian rhythms. To investigate whether this generalizes to long-term NS workers in real-world shift schedules, we modified the design to a field/laboratory study combining participants' own real-world work shifts with a schedule-adapted laboratory constant routine.
Methods: As part of an ongoing study, 15 long-term DS workers and 7 long-term NS workers (ages 27-55y; 12f) participated in the combined field/laboratory study. After completing ≥3 consecutive DS or NS shifts, participants slept at home and then reported to the laboratory at 08:00 (DS) or 20:00 (NS) as if beginning another shift. After 2h laboratory acclimation they underwent a strictly controlled 24h constant routine with continuous wakefulness, fixed posture, and hourly isocaloric snacks. They completed the psychomotor vigilance test (PVT) and Karolinska Sleepiness Scale (KSS) every 3h. The two-process model was fitted to PVT lapses (RTs>500ms) and KSS sleepiness to compare the homeostatic and circadian processes between DS and NS workers.
Results: PVT lapses and KSS sleepiness increased steadily across the 24h constant routine in the DS workers, while peaking after both 14h and 24h in the NS workers as predicted by the two-process model ($\chi2$=270.2, p< 0.001). There was no difference in initial sleep homeostatic state between DS and NS workers (F=0.28, p=0.60), but the circadian process was delayed by 0.9±0.3h (mean±SE) in the NS workers (F=13.74, p=0.001).
Conclusion: In this combined field/laboratory study, the homeostatic and circadian processes produced expected neurobehavioral dynamics, even though the 24h constant routine started 12h later in the NS workers in accordance with their shifted prior work schedules. DS and NS workers did not differ in initial sleep homeostatic state, but there was a small delay in the endogenous circadian phase of the NS workers, as commonly observed in real-world shift operations. While awaiting confirmation with circulating melatonin, our results support the viability of this novel study design and its use for investigating the impact of real-world NS on biomolecular circadian rhythms.

IMPACT OF CIRCADIAN ADAPTATION ON SLEEP ARCHITECTURE IN SIMULATED SHIFTWORK

Shauni Omond[1], Leilah Grant[2], Melissa St. Hilaire[3], Laura Barger[2], George Brainard[4], Elizabeth Klerman[5], Steven Lockley[2], Shadab Rahman[6]
[1] Brigham and Women's Hospital / Harvard Medical School, [2] Brigham and Women's Hospital, [3] Merrimack College, [4] Thomas Jefferson University, [5] Mass General Brigham, [6] Harvard Medical School

Introduction: Shift workers commonly experience circadian misalignment, which disrupts sleep. We examined the impact of a dynamic lighting schedule on circadian adaptation and sleep architecture in a simulated shiftwork paradigm.
Methods: Healthy adults (n= 19, 10F, mean age [±SD] 36.20 ± 9.20 years) completed an 8-day inpatient protocol that included 4 consecutive nightshifts during which the sleep-wake schedule was delayed by 8 hours relative to each participant's habitual schedule. Participants were randomized to one of three dynamic lighting interventions during the four nightshifts that differed in illuminance, spectrum, and timing through the waking day and were expected to induce a phase delay. Circadian adaptation was assessed by comparing the plasma dim light melatonin onset (DLMO) measured before and after the nightshifts. Sleep during an 8-hour sleep opportunity was measured polysomnographically before the first nightshift (baseline) and after the fourth nightshift.
Results: The mean (±SEM) circadian phase-delay shift was -5.15±0.37 hours (range: -8.16 to -1.88 hours) of the targeted 8-hours. Sleep architecture did not differ across the three conditions, so data were combined for analyses. Compared to baseline, sleep after the fourth nightshift was associated with significantly reduced total sleep time (TST, 415.40±20.24 vs. 377.2±15.02 minutes, p < 0.01), stage 2 sleep (N2, 187.3±13.16 vs. 151.7±9.47 minutes, p< 0.01), and sleep efficiency (SlpEff, 86.05±4.19 vs. 78.52±3.11 %, p< 0.01), and increased wake after sleep onset (WASO, 52.92±19.15 vs. 84.79±15.10 mins, p< 0.05). Sleep onset latency (SOL) did not differ (18.02±5.32 v 14.68±2.45 mins, p=0.76). Greater circadian phase shifts, corresponding to more adaptation to the shifted sleep-wake schedule were correlated with increased TST (r2 = 0.49, p< 0.001), SlpEff (r2 = 0.49, p< 0.001), REM (r2 = 0.38, p< 0.01), and decreased WASO (r2 = 0.53, p< 0.001), but not SOL (r2 = 0.10, p=0.19).
Conclusion: The results show that greater circadian adaptation is associated with better sleep architecture. Additional studies are needed to optimize details of dynamic lighting schedules and lighting characteristics for preserving sleep quality in various shiftwork schedules.

THE MODERATING EFFECT OF SHIFT WORK ON CIRCADIAN RHYTHM DISRUPTION AND HEART RATE VARIABILITY DURING SLEEP

Minah Kim[1], Sang Ho Choi[2], Ha Young Lee[1], Jeong Eun Jeon[1], Jin Hyuk Yoo[1], Seung Hyun Kim[3], Jiyoon Shin[4], Mincheol Seo[5], Kyung Hwa Lee[1], Seog Ju Kim[6], Yu Jin Lee[1]

[1] Seoul National University Hospital, [2] Kwangwoon University, [3] Seoul National University Hospital, [4] Uijeongbu Eulji Medical Center, [5] Veteran Health Service Medical Center, [6] Samsung Medical Center

Introduction: It has been suggested that circadian rhythm disruption is closely associated with alterations in the autonomic nervous system, posing risks to both physical and mental health. Shift workers are particularly susceptible to circadian rhythm disruption. This study aimed to investigate the moderating effects of shift work on the association between circadian rhythm disruption and cardiac autonomic regulation during sleep.
Methods: Nocturnal polysomnography (PSG) and actigraphy data of 41 shift workers(mean age 34.0±8.6 years, 35 females) and 39 controls(mean age 35.9±9.5 years, 34 females) were analyzed. Time-domain, frequency-domain, and nonlinear heart rate variability (HRV) parameters were derived from 5-minute electrocardiogram (ECG) segments during sleep, and their averages were calculated for each sleep stage (W, N1, N2, N3, R). Cosinor analyses of actigraphy data were conducted to compute both parametric (e.g., amplitude, acrophase, F-statistics) and non-parametric parameters (e.g.,Interdaily Stability(IS), Intradaily Variability(IV)). Independent t-tests were conducted to compare group differences in HRV and cosinor analyses parameters. Moderation analyses were conducted to test the moderating effects of shift work on the relationship between circadian rhythm and autonomic regulation.
Results: Shift workers had higher Midline Estimating Statistic of Rhythm (MESOR) and Least active 5-hour period (L5) and lower IS, IV, Most active 10-hour period (M10) and Relative Amplitude (RA) (all Ps< 0.05). However, shift workers did not show significant differences in HRV parameters during sleep compared to controls. Shift work moderated the association between the mean HR during the N1 stage and F-statistics (F-statistics x shift work: b=0.002, SE=0.001, P=0.032), and between the mean HR during the N3 stage and RA (RA x shift work: b=20.064, SE=9.939, P=0.048). These associations were stronger in shift workers than controls.
Conclusion: Current study showed that circadian rhythm disruption was more pronounced in shift workers than controls. Even though shift workers showed no significant differences in HRV parameters compared to controls, the moderation results suggest that the influence of circadian rhythm disruption on cardiac autonomic regulation may be an important issue for shift workers.

CIRCADIAN TIMING AND INTENTION TO LEAVE DURING THE TRANSITION TO A SHIFT-WORK SCHEDULE

Kathryn Mcauliffe[1], Brooke Shafer[1], Andrew McHill[2]
[1] Oregon Health & Science University, [2] Oregon Institute of Occupational Health Sciences, Oregon Health & Science University, Portland, Oregon, USA

Introduction: Working during nighttime hours (i.e., shiftwork) is associated with high rates of job turnover, yet it is unclear what mechanisms directly increase intention to leave in shift workers. We therefore utilized a natural experiment in which newly hired employees transitioned from a daywork schedule to an early-morning shiftwork schedule to uncover what behaviors (i.e., workload, supportive workplace) or physiology (i.e., circadian timing) may promote higher intention to leave.
Methods: Thirty volunteers (11 female; aged [average±SD] 36.3±9.1yr) participated in a seventeen-week study beginning with an ~8h evening in-laboratory stay in dim-lighting (< 5lux) to calculate circadian timing via salivary dim-light melatonin onset (DLMO) (3pg/ml threshold). Following the in-laboratory collection, weekly surveys on intention to leave were collected, asking "I am seriously thinking about quitting my job" with Likert-scale responses of 1-Strongly Disagree to 5-Strongly Agree, while the participants were transitioning into an early-morning shift-work schedule (start time before < 7am). Average daily work hours and the highest score of intention to leave were calculated for each participant. At the end of 17-weeks, participants rated their perceived support at work with the Likert-scale question: "I felt that there was help available to me (at work)". Multiple linear regression was used to determine associations between workload, supportive workplace, DLMO and the intention to leave.
Results: A positive correlation was found between DLMO timing and intention to leave, such that later DLMO timing was associated with higher intention to leave (r=0.37, p=0.04). A negative correlation was found between supportive workplace scores and intention to leave, such that higher perceived support was associated with lower intention to leave (r=-0.16, p=0.01). Lastly, there was no association between daily hours worked and intention to leave (r=0.0016, p=0.84).
Conclusion: While transitioning into an early-morning shiftwork schedule, having a later DLMO, and thereby potentially higher morning circadian misalignment, was associated with a higher intention to leave; conversely, having higher perceived support at work may be protective. Further understanding the connection between circadian timing and intention to leave could have implications for providing support to workers transitioning into early-morning shiftwork to lower risk of turnover.

SEX DIFFERENCES AND SHIFT WORK HISTORY INFLUENCE INTERACTIONS BETWEEN SLOW WAVE SLEEP AND BODY TEMPERATURE

Matthew Lehrer[1], Ankit Parekh[2], Mary Fletcher[1], Aryan Govil[3], Richard Thomson[4], Daniel Buysse[5], Rodrigo Del Rio[3], Esther Blessing[6]
[1] University of Pittsburgh, [2] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [3] New York University School of Medicine, [4] CSIRO Australia, [5] University of Pittsburgh School of Medicine, [6] Department of Psychiatry, New York University Grossman School of Medicine

Introduction: Pre- and post-menopausal females have greater slow wave sleep (SWS) and delta power compared with males. However, the mechanisms underlying this sex difference remain unknown. Sleep and temperature regulation are highly interdependent. We explored whether sex differences in thermoregulation

interact with sex differences in SWS as a potential mechanism. We also explored whether a prior history of shift work, known to disrupt circadian rhythms and sleep, moderated body temperature-SWS relationships.
Methods: We compared measures of SWS and core body temperature (Tc) simultaneously recorded during a 60h laboratory study in males (n=36, mean age 68.85 yr) and females (n=37, mean age 68.02 yr). The 3-night protocol included one night of nocturnal PSG; one night of total sleep deprivation under constant routine conditions (36–40h) and one recovery PSG sleep night. The sample included 40 retired day workers (RDW) and 33 retired shift workers (RSW). Tc analysis focused on the sleep-associated Tc decline (Tdrop), known to correlate with SWS, during the recovery night.
Results: Compared to males, females had substantially higher recovery %SWS (13.8±10.75 vs 4.9±5.29 %, p< 0.001), SWS min (57.12±45.53 vs 18.26±20.77 min p < 0.001), mean delta power (109.01±44.91 vs 66.97±27.75, p < 0.001) and greater Tdrop (0.96±0.20 vs 0.82±0.28 °C, p < 0.05). Tdrop weakly correlated with %SWS in females (r=0.34, p = 0.07), but not in males. Tdrop was not significantly associated with SWS min and delta power in either sex. However, RDW females (n=17) showed moderate–strong and significant correlations: greater Tdrop correlated with greater %SWS (r=0.67, p< 0.01), SWS min (r=0.59, p < 0.05), and delta power (r=0.54, p< 0.05). These correlations were not significant in female RSW (despite similar SWS and Tdrop), or in male RSW or RDW (p > 0.10) all comparisons.
Conclusion: The association between SWS and sleep-associated core body temperature decline varies by sex and a history of shift work. Further studies may determine whether sex differences in temperature and sleep regulation results from known sexual dimorphism in sleep-wake promoting and thermoregulatory nuclei, and how this pattern interacts with sex-differences in risk for sleep disorders or other health problems.

ACUTELY DELAYING SLEEP ONSET CAUSES DYNAMIC CHANGES IN SLEEP ARCHITECTURE: INSIGHTS FROM A RANDOMIZED CROSSOVER STUDY

Jonathan Jun[1], Daisy Duan[2], Frank Sgambati[1], Luu Pham[3]
[1] Johns Hopkins University, [2] Johns Hopkins University School of Medicine, [3] Division of Pulmonary and Critical Care, Johns Hopkins University School of Medicine

Introduction: The timing of meals may influence weight control and cardiovascular health. In a previous randomized crossover study ("Dinner Time"), we found that a late dinner (22:00) compared to a routine dinner (18:00) increased post prandial glucose and reduced dietary fat oxidation. However, it remains unclear whether late dinner metabolic dysfunction is driven by circadian misalignment or by eating close to sleep.
Methods: We conducted a follow-up study ("Dinner Time 2") to compare the effects of dinner timing relative to dim-light melatonin onset (DLMO) and sleep timing. Participants completed three conditions in random order with a 3-4 week washout period: (1) early dinner (DLMO -3) + routine sleep (DLMO +2 to +10) = "early dinner" (ED); (2) late dinner (DLMO +1) + routine sleep = "late dinner" (LD); and (3) late dinner (DLMO +1) + late sleep (DLMO +6 to +14) = "late dinner + late sleep" (LD/LS). The primary outcome of this study is glucose which is reported separately. Here, we focus on the secondary outcome of sleep architecture (total sleep time, sleep efficiency, and sleep stage percentages) under each of the 3 conditions. We compared whole night sleep stage distributions using Kruskal-Wallis tests. We also examined temporal changes in sleep architecture using stratification of each 8-hour sleep period into quartiles.
Results: Thirteen participants (7 female, 6 male, mean age 25 years, BMI 22.1 kg/m²) completed the study. Total sleep time, sleep efficiency, and proportions of NREM and REM sleep did not differ significantly between ED, LD, and LD/LS. However, the LD/LS condition showed dynamic changes in sleep architecture: an increased proportion of stage 3 sleep in the first half of the night, followed by higher wakefulness and reduced REM sleep in the latter quarter of the sleep period.
Conclusion: This study examines whether the metabolic effects of late dinner are related to circadian phase or sleep timing. Delaying sleep after late dinner did not alter overall sleep architecture but changed the temporal distribution of sleep stages. These findings illustrate effects of homeostatic sleep drive while controlling for circadian rhythm.

REDEFINING SLEEP DISRUPTION: IMPACT OF BRIEF AWAKENINGS ON SELF-REPORTED SLEEP QUALITY

Renske Lok[1], Dwijen Chawra[2], Jamie Zeitzer[1]
[1] Stanford University, [2] Purdue University

Introduction: Self-reported sleep quality is a key determinant of physical and mental health, yet the relationship between objective sleep parameters and self-reported assessments remains complex. Wake After Sleep Onset (WASO), particularly its duration and frequency, is thought to disrupt self-perceived sleep quality, with a National Sleep Foundation consensus panel proposing a minimum of 5 minutes of duration for a midsleep awakening to be clinically relevant. The empirical validity of this threshold has yet to be rigorously tested. This study evaluates the impact of thresholding WASO duration and frequency on self-reported measures of sleep depth and restfulness.
Methods: Using data from the Sleep Heart Health Study (n = 3165), durations of PSG-determined episodes of midsleep awakening were labeled based on thresholds ranging from 15 seconds to 10 minutes. Random Forest (RF) regression models were employed to predict self-reported sleep quality (self-reported sleep depth and restfulness, scored on 5-point Likert scales) based on multiple objective sleep metrics including stepwise thresholded WASO. Additional covariates included demographic, anthropometric, health, and pre-sleep behavior variables. Model performance was assessed using 5-fold cross-validation, and feature importance was extracted to quantify the contributions of WASO duration and frequency to self-reported sleep quality.
Results: RF models explained 26.0% to 30.6% of the variance in self-reported sleep restfulness and 26.4% to 30.4% in sleep depth, with the greatest explanatory power observed at lower WASO thresholds (15–45 seconds). The 5-minute threshold for

an individual episode of midsleep awakening to "count" did not yield improvements in model performance for sleep restfulness (28.6%) or depth (28.4%).

Conclusion: Contrary to the proposition from the expert panel, brief wake episodes shorter than five minutes appear to have a measurable impact on self-reported sleep quality. This implies that any duration of awakening of at least 15 seconds has the capacity to impact one's self-reported sleep quality. These findings challenge the reliance on a 5-minute WASO threshold and underscore the importance of including shorter wake episodes in assessments of sleep quality.

GENOME-WIDE PLEIOTROPY ANALYSIS OF CIRCADIAN PREFERENCE AND BMI REVEALS ADCY3'S RHYTHMICITY IN ADIPOSE TISSUE

Cynthia Tchio[1]

[1] Massachusetts General Hospital

Introduction: Chronotype is the behavioral manifestation of our internal circadian clock, influencing whether individuals are early birds (morning people) or night owls (evening people). Chronotype significantly impacts complex diseases such as obesity. This study dissects the relationship between circadian preference and body mass index (BMI) using a genome-wide pleiotropy approach.
Methods: We conducted a genome-wide pleiotropy analysis to explore the associations between morning circadian preference and BMI, focusing on the tissue-specific expression and rhythmicity of key genes.
Results: We identified a lead locus, rs11676272 in ADCY3, associated with increased morning preference and decreased BMI. The rs11676272 (S107P) is a missense variant that destabilizes the ADCY3 protein structure, highlighting the gene's role in both circadian behavior and metabolic processes. In mouse models, Adcy3 expression was rhythmic in white and brown adipose tissues during constant darkness, and it oscillated anti-phase to the canonical circadian genes Clock and Bmal1. The presence of the Bmal1-specific E-box motif CACGTG on the Adcy3 gene suggests Bmal1 regulation of this rhythmicity, indicating a novel mechanism of circadian control within these tissues.
Conclusion: Findings from our genome-wide pleiotropy approach underscore a novel role of ADCY3 at the intersection of circadian regulation and metabolic health. This study offers new insights into the genetic architecture of these complex traits, highlighting the significance of tissue-specific rhythmicity in adipose tissue.

MULTI-OMICS STUDIES OF UPPER AIRWAY MUSCLES ADVANCE OBSTRUCTIVE SLEEP APNEA PATHOGENESIS INSIGHTS

Xiaoru Sun[1]*, Haiyang Wang*[2]*, Shixi Liu*[2]*, Jian Zou*[2]

[1] Stanford University, West China Hospital, Sichuan University, [2] West China Hospital, Sichuan University

Introduction: Obstructive sleep apnea (OSA) is a common sleep disorder characterized by upper airway collapse during sleep, with unclear molecular mechanisms. This study represents the first multi-omics investigation of upper airway muscles (UAMs) from OSA patients, integrating transcriptomics, proteomics, phosphoproteomics, and N-glycoproteomics to uncover key pathways involved in OSA pathogenesis.
Methods: Palatopharyngeal (Pal) muscle tissues were collected from 56 treatment-naïve OSA patients and 4 controls, with clinical data including polysomnography and laboratory tests. Multi-omics analyses were performed, and missing values were imputed using a random forest approach. Data underwent rigorous quality control to ensure analytical robustness.
Results: Transcriptomic analysis revealed 561 genes positively and 200 negatively correlated with the apnea-hypopnea index (AHI), highlighting pathways such as N-glycosylation and muscle contraction regulation. Proteomics identified 63 proteins positively and 19 negatively correlated with AHI, including key regulators in NF-κB signaling. Phosphoproteomics analysis found 112 AHI-associated phosphosites enriched in pathways such as MAPK signaling and axon guidance. N-glycoproteomics identified 40 glycosylation sites correlated with AHI, linked to ECM proteoglycans and lipid metabolism. Integrative analysis across all omics levels highlighted lipid metabolism, inflammation, and synapse function as critical pathways in OSA pathogenesis.
Conclusion: As the first multi-omics study on UAMs in OSA patients, this research provides novel insights into dysregulated pathways underlying UAM dysfunction. These findings lay a foundation for understanding OSA pathogenesis and developing targeted therapies.

THE HUMAN PHENOTYPE PROJECT: METABOLOMIC SIGNATURES OF SLEEP CHARACTERISTICS REVEAL GENDER-SPECIFIC INSIGHTS

Sarah Kohn[1]*, Alon Diament*[2]*, Anastasia Godneva*[3]*, Raja Dhir*[4]*, Adina Weinberger*[3]*, Yotam Reisner*[2]*, Hagai Rossman*[2]*, Eran Segal*[1]

[1] Weizman Institute of Science, [2] Pheno.AI, [3] Weizmann Institute of Science, [4] Swiss Institute of Allergy and Asthma Research (SIAF), University of Zurich

Introduction: Obstructive sleep apnea (OSA) represents a significant global health challenge that can lead to substantial metabolic and cardiovascular complications. Despite extensive research, the underlying metabolic mechanisms and comprehensive biomarkers of sleep disorders remain incompletely understood. Metabolomic approaches offer unprecedented insights into the complex biochemical interactions associated with sleep pathophysiology, potentially bridging critical gaps in our understanding of OSA pathogenesis.
Methods: Utilizing the comprehensive Human Phenotype Project cohort, we conducted an extensive metabolomic analysis of sleep characteristics. The study encompassed 4,374 adults (2,122 males, 2,252 females) with 10,693 nights of WatchPAT-300 (ZOLL Itamar) wrist worn home sleep apnea test monitoring, in total 3,909,716 minutes of data collection and 457 sleep-related measurements. Employing nuclear magnetic resonance (NMR) spectroscopy, we identified levels of 171 metabolites in the participants' serum, and applied advanced machine-learning algorithms to explore bidirectional predictive relationships between sleep traits and metabolite profiles. Clinical OSA was defined based on peripheral Apnea-Hypopnea Index (pAHI) measurement and daytime sleepiness reporting.
Results: Key findings revealed 96 metabolites positively and 20 metabolites negatively correlated with pAHI, as adjusted for age, sex and body mass index with statistical significance maintained after false discovery rate correction ($P < 0.0001$). Sleep characteristics could contribute to the predictions of over 82% (141/171) of the serum metabolomics for males and 43% (75/171) for females, in a held-out set of individuals, outperforming age and BMI as predictors for these measurements. Notably, serum

metabolite analysis demonstrated gender-specific predictive power for clinical OSA symptoms in males but not in females. The metabolite profile surpassed traditional predictors like age and BMI in predicting daytime sleepiness and elevated pAHI ($P = 5\times10^{-9}$). Particularly, lower Albumin and higher Tyrosine levels emerged as significant predictors of clinical OSA symptoms in male participants.

Conclusion: Our study reveals significant gender-specific metabolic variations in obstructive sleep apnea, with sleep characteristics demonstrating strong predictive power for metabolite profiles, particularly in males. The demonstrated ability to predict OSA symptoms through metabolite analysis offers a novel perspective on personalized sleep disorder diagnostics and pathophysiological mechanism discoveries.

GENETIC VARIANTS ASSOCIATED WITH RESTLESS LEGS SYNDROME AND ITS COMORBIDITIES: AN ANALYSIS BY A PHENOME WIDE ASSOCIATION STUDY

Teresa Guthrie[1], Lisa Bastarache[1], Jing He[1], Brian Aloisi[1], Laurel Schaefer[1], Kanika Bagai[1], Pjotr Prins[2], Byron Jones[2], Arthur Walters[1]

[1] Vanderbilt University Medical Center, [2] University of Tennessee Health Science Center

Introduction: Restless Legs Syndrome (RLS) is associated with health issues such as iron deficiency, kidney disease, and cardiovascular disease. Our research aims to identify genetic risk factors for RLS and its comorbid conditions. Phenome Wide Associations studies (PheWAS) are reverse genetic studies where a known genetic variant is tested against a population to look for a phenotype. This is opposed to Genome Wide Association Studies (GWAS) where a known phenotype is tested against a population to look for a genotype. PheWAS studies can also reveal other clinical conditions that are frequently associated with a population of interest such as RLS.

Methods: We searched the NHGRI-EBI GWAS Catalog for genetic variants significantly associated with RLS. We conducted PheWAS on these genetic variants in Vanderbilt University Medical Center's biobank, BioVU. The cohort included 72,642 individuals of European ancestry. We assessed whether the known association with each variant and RLS was replicated, and we determined whether phenotypes other than RLS were associated with these same RLS associated allelic variants.

Results: We identified 365 variants associated with RLS in a recent version of the GWAS catalog and completed PheWAS on 359 of them. We replicated the RLS association in 84 variants. Additionally, 52 of the 365 variants were significantly associated with other traits in the GWAS and PheWAS replicated 9 of these associations. These nine confirmations included conditions commonly linked to RLS such as hypertension, chronic kidney disease, hypercholesterolemia and insomnia. Furthermore, PheWAS identified phenotypes associated with 22 RLS alleles that were not reported in the GWAS catalog as being associated with these alleles. Many of these conditions such as thyroid disease, digestive diseases, rheumatoid arthritis and diabetes, are also commonly associated with RLS as determined by clinical and epidemiology studies.

Conclusion: Our findings highlight the complex genetics of RLS and its comorbid conditions. By identifying and replicating genetic variants associated with RLS and other traits, we provide evidence of shared genetic factors between RLS and other medical conditions or traits that may explain their frequent co-occurrence.

PLEIOTROPIC EFFECTS OF GENETIC VARIANTS ON SUBSTANCE USE DISORDER AND SLEEP PATTERNS

Bruna Marquezini[1], Mariana Moyses-oliveira[2], Malú Zamariolli[2], Laís Berro[3], Vinícius Dokkedal-Silva[1], Dalva Poyares[1], Jose Carlos Galduroz[1], Monica Andersen[1], Sergio Tufik[1]

[1] Departamento de Psicobiologia, Universidade Federal de São Paulo, [2] Sleep Institute, Associação Fundo de Incentivo à Pesquisa, [3] Department of Psychiatry and Human Behavior, University of Mississippi Medical Center

Introduction: Substance use disorder (SUD) is associated with several negative health outcomes, including sleep disorders. Although this correlation is well established, little is known about the genetic mechanisms underlying the comorbidity between sleep problems and SUD

Methods: We have conducted a phenome-wide association study (PheWAS) in the São Paulo Epidemiologic Sleep Study (EPISONO). The single nucleotide variants (SNV) rs4238213 and rs4727799 were selected from previous genome-wide association studies for SUD. The association of genotypes with the 460 phenotypes filtered from the EPISONO database was conducted, and the covariates of the model included age, age-squared (age^2), sex and principal components (PCs 1 to 10). To correct for multiple testing, we applied Bonferroni tests, treating each trait as a test, independently for each SNV. Non-parametric tests were applied to validate nominally significant associations identified in the PheWAS ($p< 0.05$).

Results: We showed possible SNVs' associations with 36 phenotypes in the EPISONO database. We validated the implication of these variants with substance use as they showed nominal association with SUD in our admixed cohort. In addition to the validation of previously reported results, suggestive associations were observed for phenotypes related to sleep-disordered breathing, sleepiness, and sleep patterns. The minor allele of the SNV rs4238213 was nominally associated with lower odds of Tobacco use (OR=0.78; p-value=0.02) and higher odds of being in the group of people who reported having used medication to stay awake (OR=2.88; p-value=6.95x10-4). The risk allele may also be linked to increase in REM sleep latency (REM latency) (β=0.10; p-value=0.03), and increased odds of having nighttime nasal obstruction (OR=1.37, p-value=0.02). The SNV rs4727799's minor allele was nominally associated with higher odds of tobacco use (OR=1.61; p-value=0.04), decreased chance of dozing off while reading (OR=1.37, p-value=0.01), presence of clinically relevant respiratory arousal index (OR=1.35; p-value =0.02) and increased RERA index (β=0.14; p=0.01).

Conclusion: Our results suggest a pleiotropic effect of both SNVs on SUD and sleep-related traits, highlighting the possibility of

an overlap between the genetic factors involved in the risk for SUD and sleep phenotypes.

PLEIOTROPIC EFFECTS OF APOE VARIANTS ON A SLEEP-BASED ADULT EPIDEMIOLOGICAL COHORT

Mariana Moyses-Oliveira[1], Malú Zamariolli[2], Priscila F Tempaku[2], Amanda Mosini[2], Lais A. Souza-Cunha[3], Rafael Naime Ruggiero[3], Julia Ribeiro da Silva Valim[3], Dalva Poyares[3], Vânia D'Almeida[4], Monica Andersen[3], Sergio Tufik[3]

[1] Sleep Institute, [2] Sleep Institute, Associação Fundo de Incentivo à Pesquisa, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo, [4] UNIFESP - Universidade Federal de São Paulo

Introduction: APOE ε4 allele has been implicated in sleep or circadian disturbances in older adults and/or in the context of neurodegeneration. However, the effect of APOE variants on sleep patterns remain unexplored in general adult population. Phenome Wide Association study (PheWAS) approach was applied in a sleep-based adult epidemiological cohort to address pleiotropic effects of APOE variants.
Methods: PheWAS analysis was performed on the São Paulo Epidemiologic Sleep Study (EPISONO), an adult epidemiological sample (1,042 individuals, 20-80 years-old) submitted to objective and subjective sleep evaluations, laboratory tests, clinical scales, anthropomorphic measurements and sociodemographic inquiries (1,182 traits/individual). SNP-array and qPCR determined APOE alleles. PheWAS was performed with an additive genetic model for rs7412 variant, using age, sex, principal components, socioeconomic classification and body mass index as covariates. Validation analysis was performed for combinations of APOE full haplotypes (ε3ε3/ε2ε2/ε4ε4/ε2ε3/ε2ε4/ε3ε4). We then leveraged UKBiobank (UKBB, N=449,734) GWAS summary statistics from previous studies which addressed self-reported chronotype.
Results: Nominal associations (PheWAS p< 0.05) between the rs7412 genotype and 5 continuous traits were identified and confirmed by non-parametric tests: LDL and total cholesterol blood concentrations, Morningness-Eveningness Questionnaire (MEQ) score, power of gamma and beta electroencephalographic (EEG) frequency bands in N1 and N3, respectively. The association with LDL levels remained significant after Bonferroni correction. All these 5 traits were significantly associated with at least 1 APOE haplotype combination. Lower LDL and cholesterol levels were associated with ε2ε3, higher MEQ scores were observed in ε2ε2 individuals, higher power of gamma waves in N1 was associated with ε2ε2, ε2ε3 and ε4ε4 (with indication ε2 dosage effect), and higher power of beta waves in N3 was associated with the ε2ε3. In UKBB, nominal association between self-reported chronotype and rs7412 was observed.
Conclusion: Extensive APOE associations with lipid metabolism were replicated in an admixed cohort. Suggestive associations of APOE genotype with diurnal preference and variables derived from sleep EEG spectral analysis present preliminary evidence of the effect of these variants over sleep patterns and individual differences in circadian typology. The assessment of associations between APOE variants with MEQ scores polysomnography spectral analysis data in humans is unprecedent in literature.

SHARED GENETIC VARIANTS OF RESTLESS LEGS SYNDROME WITH ADHD, BLOOD PRESSURE, INSOMNIA AND CIRCADIAN RHYTHMICITY: A COMPARISON OF GWAS STUDIES

Teresa Guthrie[1], Sahar Salimi[2], Mostafa Rahnama[2], Kanika Bagai[1], Laurel Schaefer[1], Arthur Walters[1]

[1] Vanderbilt University Medical Center, [2] Tennessee Technological University

Introduction: Restless Legs Syndrome (RLS) disrupts sleep and in epidemiological and clinical studies is co-morbid with other conditions such as iron deficiency, kidney disease, and cardiovascular disease. Our research aims to identify genetic risk factors associated with RLS and its comorbid conditions.
Methods: We searched the NHGRI-EBI Genome Wide Association (GWAS) Catalog for genetic allelic variants significantly associated with RLS. We further searched the catalog and identified which RLS-associated variants were also associated with other traits or conditions. For these conditions, the allelic variants were found through studies that focused on the condition of interest, not RLS.
Results: Our analysis identified 365 allelic variants associated with RLS. Among these, 52 variants were associated with at least one other trait, many of which are known comorbidities of RLS. We found the most significant association between variants associated with both RLS and blood pressure measurements: 3 variants with diastolic and 4 variants with systolic blood pressure, supporting previous findings that connect RLS with cardiovascular disease (for systolic blood pressure alone, the corrected p-value = 8.30 x 10 - 53). This was followed closely by the association between variants of insomnia and RLS with 13 variants showing significant associations with both conditions (for insomnia alone, the corrected p-value =8.30 x 10-50). Additionally, several variants were associated with both RLS and attention deficit hyperactivity disorder (ADHD) (4 variants), as well as RLS and circadian rhythm disturbances (3 variants).
Conclusion: Our data suggest a strong genetic association between hypertension and RLS. Our data also suggest a significant association between RLS and insomnia, ADHD, and circadian rhythm disturbances. We cannot definitively say that conditions like ADHD and RLS are inherited together; rather, the same alleles could affect susceptibility to both disorders. It is also possible that the symptoms of conditions like ADHD and insomnia could be caused by the symptoms of RLS. Our approach, not previously applied to RLS, could identify new genetic allelic variants associated with traits not previously known to be associated with RLS.

FOXP1 GENE REGULATES THE CIRCADIAN CLOCK AND ITS LOSS OF FUNCTION IMPAIRS SLEEP PATTERNS

Bruna Marquezini[1], Mariana Moyses-oliveira[2], Lais A. Souza-Cunha[1], Malú Zamariolli[2], Manuella Almada[2], Monica Andersen[1], Sergio Tufik[1]

[1] Departamento de Psicobiologia, Universidade Federal de São Paulo, [2] Sleep Institute, Associação Fundo de Incentivo à Pesquisa

Introduction: The haploinsufficiency of the FOXP1 protein is associated with a rare genetic disorder of neurodevelopment. Sleep disturbances have already been reported in 45% of patients with pathogenic variants in FOXP1. However, the biological pathways linking sleep traits to the FOXP1-associated syndrome remain unclear.
Methods: Benefited from recent large-scale genome wide association studies, was manually curated a set of genes associated with sleep traits, including a broad list of sleep disorders and circadian phenotypes. Subsequently, we generated a list of genes directly regulated by FOXP1 by mapping previously described FOXP1 genomic binding sites (data available at the ENCODE database) to gene promoters using Bedtools. We contrasted these 2 gene sets to generate an intersection gene list. A pathway enrichment analysis was performed using this latter gene list of overlapping genes as input. The Benjamini–Hochberg test was used to identify enriched pathways with a significance threshold of adjusted p-value< 0.01. Gene Ontology and Kyoto Encyclopedia of Genes and Genomes terms were considered in the over-representation analysis. Intersect gene lists were used as input on a protein–protein interaction (PPI) analysis via String database, a minimal interaction score of 0.7 enabling physical interactors in the network.
Results: There were 510 overlapping genes between the gene lists associated with sleep traits (1,062 genes total) and FOXP1 regulatory targets (8,596 genes total). The shared gene set between those two gene lists is greater than expected by chance (p-value=2.6x10-7; OR=1.4), indicating significant genetic overlap. Significantly enriched pathways among these 510 intersect genes are related to neuronal function (Axon Guidance (adjusted p-value=2.29x10-05; OR=5.76)), Circadian Rhythm (adjusted p-value=7.82x10-07; OR=18.5), and Regulation of Insulin Secretion (adjusted p-value=8.66x10-03; OR=5.63). PPI analysis using the sleep versus FOXP1 regulatory targets set as input generated a network with 15 nodes. The network encompasses 3 proteins related to Diabetes Mellitus and 9 proteins related to neurological diseases.
Conclusion: The set of overlapping genes and biological pathways highlighted by this study may serve as a starting point for new functional investigations of shared molecular mechanisms between sleep disturbances and rare developmental syndromes related to FOXP1 and its regulatory targets.

EXPLORING THE BIDIRECTIONAL CAUSAL ASSOCIATIONS BETWEEN SLEEP TRAITS AND METABOLOMIC PROFILE IN HUMANS

Xiao Tan[1]
[1] Zhejiang University

Introduction: Unhealthy sleep patterns are common phenomena which may lead to a spectrum of adverse cardiometabolic outcomes. Metabolites play pivotal roles in the relevant underlying mechanisms, yet the causal associations between sleep and metabolome in humans remain unclear.
Methods: This study applied one-sample Mendelian randomization (MR) to explore the relationship between sleep traits (sleep duration per day, short sleep duration (≤6 h), long sleep duration (≥9 h), and insomnia) and 249 metabolites among 166,436 participants from the UK Biobank. Single nucleotide polymorphisms identified in genome-wide association studies were used as instrumental variables. Initially, the two-stage least squares (2SLS) approach was performed to explore causality. Subsequently, inverse-variance weighted (IVW) and complemented methods were used as sensitivity analysis to further test the robustness of the results. Reverse MRs from each metabolites to sleep variables were also conducted.
Results: Genetically predicted insomnia was causally associated with level of most lipids and led to increased levels of acetoacetate (β2SLS [SE] = 0.173 [0.064]; βsensitivity-IVW [SE] = 0.039 [0.018]), glycoprotein acetyls (β2SLS [SE] = 0.768 [0.063]; βsensitivity-IVW [SE] = 0.111 [0.022]), and decreased levels of citrate (β2SLS [SE] = -0.155 [0.062]; βsensitivity-IVW [SE] = -0.058 [0.019]). Genetically predicted sleep duration was causally associated with increased average diameter for low density lipoprotein particles (β2SLS [SE] = 0.120 [0.032], βsensitivity-IVW [SE] = 0.106 [0.045]). Short sleep duration caused an increased the level of triglycerides in very low density lipoprotein subclass, apolipoprotein B to apolipoprotein A1 ratio and a decreased level of high density lipoprotein. We found no causal evidence for the effects of metabolites on any sleep variable.
Conclusion: Our study found that insomnia may lead to a wide range of metabolic disturbances, particularly in lipid metabolism, with short sleep similarly impacting lipid metabolic processes. This suggests that sleep traits may cause adverse outcomes through certain metabolic pathways.

TRANSCRIPTIONAL DYNAMICS OF SLEEP DEPRIVATION AND SUBSEQUENT RECOVERY SLEEP IN THE MALE MOUSE CORTEX

Caitlin Ottaway[1], *Alexander Popescu*[2], *Kaitlyn Ford*[3], *Taylor Patterson*[4], *Ashley Ingiosi*[5], *Elizabeth Medina*[1], *Stephanie Hicks*[6], *Kristan Singletary*[1], *Lucia Peixoto*[7]
[1] Washington State University, [2] Yale University, [3] Seattle Children's, Center for Developmental Biology and Regenerative Medicine, [4] Seattle Children's, [5] Ohio State University, [6] Johns Hopkins, [7] Sleep and Performance Research Center, Washington State University

Introduction: Sleep is a critical physiological process governed by circadian and homeostatic mechanisms. The circadian clock controls sleep timing, while the sleep homeostat regulates sleep need (sleep pressure), which increases with wakefulness. Acute sleep deprivation (SD) raises sleep pressure, as measured by frontal cortex polysomnography. This pressure maximizes after 5-6 hours of SD and is largely alleviated with 2-3 hours of recovery sleep (RS). While sleep pressure dynamics are well understood, the molecular mechanisms underlying sleep homeostasis remain largely unexplored despite the established effects of SD on gene transcription.
Methods: Novel bulk RNA-sequencing data was combined with open-access cortex datasets (n = 3-5) of adult male C57BL/6J

mice. Mice underwent SD (3 or 5-6 hours) followed by RS (2 or 6 hours). The remove unwanted variance method was used to normalize the data and correct for lab biases. The edgeR package was used to determine differentially expressed genes (DEGs) with a false discovery rate < 0.05. Functional annotation analysis occurred using the Database for Annotation, Visualization, and Integrated Discovery to understand the DEGs' functional implications.

Results: We report that 5-6 hours of SD had the largest effect on gene expression, altering 7,493 genes. SD predominantly repressed gene expression. DEGs associated with circadian rhythm and DNA damage/repair uniquely showed changes at 3 and 5-6 hours of SD but returned to baseline by 2 hours of RS. DEGs that took longer to become uniquely expressed at 5-6 hours and normalized quickly within 2 hours of RS were associated with RNA-binding, chromatin regulation, oxidative phosphorylation, and glutathione metabolism.

Conclusion: Our findings reveal that gene expression patterns closely track sleep pressure dynamics, potentially illuminating the molecular underpinnings of sleep homeostasis. Most notably, we identified a substantial group of genes that mirror the build-up of sleep pressure during SD and rapidly normalize with RS. These genes regulate critical cellular processes, including DNA repair mechanisms, epigenetic modifications, and oxidative stress responses - pathways that may represent novel therapeutic targets for sleep disorders. Future investigations will focus on manipulating these pathways to understand better how they contribute to the cellular regulation of sleep.

Introduction: Neurodevelopmental disorders, which involve atypical brain development, often result in learning disabilities, developmental delays, intellectual disabilities, behavioral issues, epilepsy, and sleep disturbances. Among these, synaptopathies genetic neuropsychiatric conditions affecting synaptic function—lead to a wide range of neuropsychiatric symptoms. One such condition, SYNGAP1-associated syndrome, is primarily caused by loss-of-function mutations and is characterized by intellectual disability, global developmental delay, autism, and epilepsy.

Methods: This study focused on sleep behaviors in children with SYNGAP1-associated syndrome, using two standardized assessment tools: the Children's Sleep Habit Questionnaire and the Sleep Disturbance Scale for Children.

Results: The researchers compared the sleep patterns of 23 children with confirmed SYNGAP1 mutations to those of neurotypical children matched for age and sex. The results revealed that 78.3% of the children with SYNGAP1 mutations had epilepsy, often resistant to treatment. In terms of sleep, these children exhibited significantly higher levels of disturbance compared to their neurotypical peers. Key findings included increased bedtime resistance, longer sleep durations, more frequent night awakenings, and a greater reliance on parental presence to fall asleep. Additionally, children with SYNGAP1-associated syndrome had more difficulty sleeping away from home. Caregivers of these children reported poor sleep quality, reflecting the broader challenges associated with caregiving for children with neurodevelopmental disorders.

Conclusion: The findings highlight the critical link between neurodevelopmental conditions and sleep disturbances, underscoring the need for targeted interventions to improve sleep quality for both affected children and their caregivers. This study emphasizes the importance of addressing sleep issues in children with neurodevelopmental disorders as part of a comprehensive approach to their care and well-being.

SUBJECTIVE SLEEP ASSESSMENTS AND CLINICAL EVALUATIONS OF INDIVIDUALS HARBORING NOVEL PATHOGENIC DEAF1 VARIANTS

Pedro Guerreiro[1], Amanda Mosini[2], Mariana Moyses-Oliveira[3], Lais A. Souza-Cunha[1], Bianca Balbueno[2], Gustavo Moreira[2], Claudia Berlim de Mello[2], Sandra Doria Xavier[2], Malú Zamariolli[2], Vera Meloni[1], Monica Andersen[1], Sergio Tufik[1]

[1] Departamento de Psicobiologia, Universidade Federal de São Paulo, [2] Sleep Institute, Associação Fundo de Incentivo à Pesquisa, [3] Sleep Institute

Introduction: DEAF1-Associated Neurodevelopmental Disorders (DAND) are a spectrum of rare genetic conditions caused by pathogenic variants in the DEAF1 gene. Despite the high prevalence of sleep disturbances in those with DAND, the specific nature and mechanisms underlying these issues remain poorly understood. This study aims to assess patients' genetic and clinical data and evaluate the prevalence, severity, and types of sleep disturbances in DAND, as well as patient caregivers' sleep quality.

Methods: We recruited 12 Brazilian individuals with DAND and sex- and age- matched neurotypical controls for comparison. Patients' sleep patterns were assessed using the Sleep Disturbance Scale for Children and the Children's Sleep Habits Questionnaire, while Pittsburgh Sleep Quality Index was used to assess caregivers' sleep quality. Genetic data and clinical data were collected via patients' medical records and surveys applied

to caregivers. Statistical comparisons were made using the Mann-Whitney U-test.
Results: Genetic analyses revealed novel DEAF1 variants, including missense mutations located outside or flanking known protein domains, expanding the complexity of the DAND genotype. DAND patients exhibited significantly worse sleep patterns and habits than controls, particularly in subscales addressing parasomnias and insomnia. Caregivers' sleep quality was poor across both groups, however score differences did not reach statistical significance.
Conclusion: This study underscores the importance of addressing sleep disturbances in DAND, which may relieve comorbidities and improve caregiver sleep quality. Future studies with larger cohorts and objective sleep assessments are needed to confirm our findings and explore targeted therapeutic interventions.

ABERRANT BILIRUBIN LEVELS IN INSOMNIA PATIENTS AND UGT1A1 GENE VARIANTS

Haimeng Bai[1], Sandra Smieszek[1], Naoise Synnott[1], Changfu Xiao[1], Christos Polymeropoulos[1], Gunther Birznieks[1], Mihael Polymeropoulos[1],
[1] Vanda Pharmaceuticals Inc.

Introduction: Insomnia disorder is characterized by the difficulty in initiating or maintaining sleep and corresponding daytime dysfunction occurs in 10–20% of the population. Although the molecular underpinnings of sleep-onset insomnia remain unclear many large-scale genetic studies have been conducted pointing to UGT1A1 loci as some of the strongest risk variants. UGT1A1 codes for an enzyme that is responsible for glucuronidation of bilirubin and may a role in relationship between insomnia and bilirubin metabolism. In this study, we explored the association of bilirubin levels in insomnia patients as compared with controls and in association with UGT1A variants.
Methods: Blood samples were obtained from adults (ages 18-70) with a diagnosis of insomnia participating in a clinical trial of 322 patients with primary using polysomnography (PSG) measures of sleep. Bilirubin was measured at baseline in the serum of the patients.
Results: Insomnia patients (n=322) at baseline had significantly lower levels of serum bilirubin when compared to healthy sleeping cohort as controls (n=273, p-value=1.75e-14), with mean values 0.32 MG/DL in cases and 0.51 controls. This effect was consistent when using a different set of controls (n=2841, p-value=8.09e-17, mean=0.44) and upon correction for covariates. Furthermore, we have run a genome wide association analysis using linear model to study variants associated with bilirubin levels on variants with MAF ≥0.01. One of the top variants associated with bilirubin at baseline in the insomnia cases was rs4148325 with a MAF of 0.36, where minor allele was associated with higher bilirubin levels (rs4148325 (β = 0.2 mg/dl per T allele increase; p = 3.82e-11)). We expanded the analysis with single gene tests which showed that UGT1A1 gene is significant especially for MAF>0.05 variants (SKAT p=0.009). The variant with highest OR in terms of cases/controls was rs1042640 a UTR3 variant with a MAF of 0.20.
Conclusion: Hypobilirubinemia is most commonly seen in patients with metabolic dysfunction, which may lead to cardiovascular complications and possibly stroke. The circadian clock was shown to protect against the neurotoxic consequences of increased bilirubin by regulating bilirubin detoxification. Further studies are warranted in order the further understand the aberrant levels on bilirubin in insomnia patients, and fundamentally their cause of an effect aspects.

DIFFERENTIAL EPITHELIAL GENE EXPRESSION AFTER VIRAL INFECTION IN AIRWAY EPITHELIAL CELLS IN PEDIATRIC OSA

Maria Kang[1], Madison Ohm[1], Carolina Daluz[1], Lindsay Clark[2], Maria White[3], Elizabeth Vanderwall[3], Camille Gates[3], Jason Debley[4], Weston Powell[3]
[1] University of Washington, [2] Seattle Children's Research Institute, [3] Center for Respiratory Biology and Therapeutics, Seattle Children's Research Institute, [4] Center for Respiratory Biology and Therapeutics

Introduction: Obstructive sleep apnea (OSA) in children is linked to early life viral infections and increased severity of viral respiratory illnesses. As respiratory viral infections occur in airway epithelial cells, we investigated differences in epithelial viral responses using an organotypic epithelial cell model in children with OSA as compared to children without. We hypothesized that gene expression in response to rhinovirus (RV16) infection would differ between healthy children and children with OSA.
Methods: Primary airway epithelial cells (AECs), from both healthy pediatric donors (n=5) and children diagnosed with OSA by polysomnography (n=4), cultured at an air-liquid interface were infected with RV16 on the apical surface at a multiplicity of infection of 0.5. RNA-sequencing quantified gene expression at baseline and after RV16 infection, and Limma was used to identify genes with differential expression in response to infection in healthy AECs as compared to AECs from donors with OSA. Weighted gene co-expression network analysis (WGCNA) was able to organize the identified genes into groups of interest. Using Enrichr, the primary biological functions of the gene groupings were analyzed.
Results: Following infection, 4724 genes in healthy and 3876 genes in OSA were differentially expressed as compared to pre-infection; 122 genes were found to have differing gene expression responses to RV16 in OSA when compared to healthy cell lines. WGCNA identified two modules of gene expression with opposite expression patterns following infection in OSA compared to healthy. One module consists of 23 genes enriched for DNA repair and replication which are upregulated in healthy but downregulated in OSA after RV16 infection. A second module consists of 43 genes enriched for glycogen metabolism which are downregulated in healthy but upregulated in OSA following RV16 infection.
Conclusion: Epithelial cell gene expression differs in response to RV16 in healthy AECs as compared to AECs from children with OSA. Given the small sample size, further studies are needed to investigate the relationship of OSA severity and

clinical phenotypes of OSA with epithelial responses to viral infection. Future work will relate in vivo expression to ex vivo gene expression.

CENTRAL AND PERIPHERAL NLRP3 INFLAMMASOME ACTIVATION AND SLEEP ARE MODULATED BY VAGAL AFFERENT AND EFFERENT NERVES

Mark Zielinski[1], John Craig[2], Allison Gibbons[2]

[1] Boston VAMC and Harvard Medical School, [2] Boston VAMC

Introduction: The NOD-like receptor (NLR) family, pyrin domain–containing protein 3 (NLRP3) inflammasome is a protein complex found in most nucleated cells that activates caspase-1 to convert the pro-forms of the somnogenic molecules IL-1 beta (IL-1β) and IL-18 into their active forms. Inflammatory stimuli, such as lipopolysaccharide (LPS), applied to the peritoneum increases IL-1β in the nucleus tractus solitarius (NTS) and cortex, in part, by stimulating the vagal afferents. Vagal efferent stimulation can function to attenuate peripheral inflammation, although findings are often mixed due to stimulation of both vagal afferents and efferents. Our goal was to determine the effects of vagal nerve afferent and efferent specific stimulation on sleep, slow-wave-activity (SWA), and central and peripheral NLRP3 inflammasome activation.

Methods: Two-month-old NLRP3 knockout and wildtype mice underwent surgery for polysomnography and were implanted with an electrical stimulating nerve cuff around the vagus nerve that was bilaterally severed superiorly or inferiorly or not at all to only stimulate the vagal afferents or efferents. Mouse vagal nerves were stimulated after vehicle or LPS was applied to the peritoneum. Separate groups of mice underwent identical treatments and liver, NTS, and somatosensory cortical tissues were taken for gene expression analysis by real-time polymerase chain reaction. Significance was set at $p < 0.05$.

Results: LPS significantly enhanced non-rapid-eye movement sleep (NREMS) and SWA in wildtype mice that had intact vagal nerves, but these responses were significantly attenuated in mice with vagal nerves severed. Vagal afferent stimulation significantly enhanced NREMS and SWA, although vagal efferent stimulation did not significantly alter sleep or SWA. NLRP3 mice exhibited significant attenuations in NREMS and SWA responses to LPS and vagal afferent nerve stimulation. Vagal afferent stimulation significantly increased NLRP3 and IL-1β expression in the NTS and somatosensory cortices and vagal efferent stimulation significantly attenuated increased liver but not NTS or somatosensory cortex NLRP3 and IL-1β gene expression levels from LPS.

Conclusion: These data suggest that vagal nerve afferents stimulate NLRP3 inflammasome activation in the NTS and somatosensory cortices to induce NREMS and SWA, but vagal afferent stimulation can attenuate peripheral inflammation.

IMMUNITY TO INFLUENZA B AND CROSS-REACTIVITY TO PANDEMRIX/PH1N1 IN NARCOLEPSY

Guo Luo[1], Jing Zhang[1], Emmanuel Mignot[1]

[1] Stanford University

Introduction: Narcolepsy type 1 (NT1) is caused by 85-95% hypocretin (HCRT) neuron loss due to a combination of genetic and environmental risk factors and associated with DQA1*01:02/DQB1*06:02 (DQ0602, 98%) and T cell receptor (TCR)gene AJ24/AJ28/BV4-2. Pandemic influenza A H1N1 (pH1N1) and Pandemrix vaccination in 2009-2010 induced NT1onset. Antigen specific T cell immune response in NT1 supports adaptive (auto) immunity against HCRT and Pandemrix/pH1N1. Despite this progress, the mechanism behind HCRT neuron loss and how the flu triggers a response against HCRT are unclear.

Methods: Anti-hemagglutination (HA) antibody was first measured using HA inhibition assay. Binding affinity of B/Victoria candidate peptides to DQ0602 was next tested using a competition binding assay. Antigen-DQ0602 restricted/reactive T cells were further isolated using tetramer DQ0602 and single-cell RNA sequenced with 10X. Lastly, TCR clones were transfected into Jurkat 76 for TCR activation by a certain peptide presented by DQ0602.

Results: Two independent studies of our laboratory and a Chinese group have shown a higher HAI titer against B/Brisbane/60/2008 in NT1. We detected reactive CD4+ T cells to a B/Victoria PB1 epitope that is homologous to Pandemrix/pH1N1 PB1 segment. In addition, we built a TCR repertoire a) restricted by HCRT and Pandemrix/pH1N1at baseline peripheral blood mononuclear cells (PBMCs) (n>430) and b) from single-cell RNA sequencing cerebrospinal fluid(CSF) samples (n>2,000), and found the identical activated TCR clones in both baseline and cultured PBMCs.

Conclusion: Our research showed influenza B plays a role in NT1 pathogenesis and potential cross-reactivity to PB1 between B/Victoria and Pandemrix/pH1N1.

BACTERIAL PEPTIDOGLYCAN RECEPTOR PGLYRP1 IS INVOLVED IN SLEEP LOSS RECOVERY AND SLEEP LOSS-INDUCED CHANGES IN BRAIN GENE EXPRESSION

Erika English[1], Catherine M. Schwartzmann[1], Madison G. McDonald[1], James M. Krueger[1]

[1] Washington State University

Introduction: Microbes and their products have profound influences on host physiology and pathology. Bacterial cell wall components, peptidoglycan, muropeptides, and their receptors are sleep-promoting and mediators of immune and inflammatory activity. Peptidoglycans circulate, reaching many host organs including brain where they are important for brain development and behavior. Peptidoglycan receptor Pglyrp1 is expressed in brain, upregulates with sleep loss, and increases in brain

alongside gut microbial colonization during early development. Sleep regulatory roles for peptidoglycan and its receptors remain unclear. We proposed involvement of brain peptidoglycan in host sleep-wake cycles. Thus, we sought to describe peptidoglycan in brain in the context of sleep and following sleep disruption and to identify candidate molecules involved in brain detection and consequent signaling events.
Methods: Using a Pglyrp1-/- mouse model we characterized brain peptidoglycan levels and sleep with the PiezoSleep system (Signal Solutions, Lexington, KY). NanoString nCounter technology (Brucker Spatial Biology, Seattle, WA) was used to profile brain gene expression of neuroinflammatory and peptidoglycan-linked genes in undisturbed and sleep deprived (ZT0-6) conditions.
Results: Undisturbed sleep did not differ in WT and Pglyrp1-/- mice. After sleep disruption, sleep rebound was altered including increased sleep for 16h (compared to baseline) for WT mice vs. full recovery at 6h post-SD for Pglyrp1-/- mice. Further, while sleep loss amount during sleep deprivation was similar for WT and Pglyrp1-/- mice, 223 vs. 239 minutes, recovery sleep (gain from baseline) was 114 minutes for WT mice vs. only 64 minutes for Pglyrp1-/- mice, i.e., for WT and Pglyrp1-/- mice, recovery sleep was decreased from sleep loss amounts by 49% and 73%, respectively. Changes in brain peptidoglycan levels and gene expression following sleep loss were unique to WT and Pglyrp1-/- mice. Inflammatory gene expression profiles were altered in Pglyrp1-/- mice including differential expression of prostaglandin-, Il1-, and TNF-linked genes for Pglyrp1-/- mice as compared to WT mice.
Conclusion: Our work supports a role for peptidoglycan and Pglyrp1 in regulating the response to sleep loss. Collectively, findings present an underappreciated aspect of sleep regulation, suggesting sleep physiology is tied to microbe-host evolution and the holobiont condition.

PROFILING INFECTIOUS ANTIBODY AND AUTO-ANTIBODIES OF TYPE-1 NARCOLEPSY

Han Yan[1], Ling Lin[1], Jing Zhang[2], Emmanuel Mignot[2]
[1] Stanford Center for Sleep Sciences and Medicine, Stanford University, [2] Stanford University

Introduction: Genetic studies suggest autoimmunity as the cause of narcolepsy-cataplexy characterizing as orexin cell dysfunction, but as no autoantibodies have been conclusively identified, proof for autoimmunity is lacking. Autoreactive T cells directed against hypocretin have been found but differences between narcolepsy and controls are modest. Findings about increased anti-streptolysin O (ASO) antibody and TRIB2 autoantibodies in narcolepsy have been inconsistent. In this study, we extended our study of ASO and TRIB2 to more cases and tested for autoantibodies against 49 proteins enriched in hypocretin neurons.
Methods: Sera of 249 recent-onset (within 2.1years) type-1 narcolepsy patients and 449 controls recruited from 1999 to 2019 were tested for ASO using a latex slide agglutination assay. Autoantibodies of 49 enriched autoantigens of hypocretin neurons including TRIB2 were tested in sera of 223 patients and 314 controls using recombinant [35S]-labeled autoantigen radio-ligand assay. Association between narcolepsy and geometric mean of ASO titers and binary outcomes using ≥1:200 as a cutoff value were analyzed by multi-variable linear and logistic regression. Ranks were assigned to indexes calculated by counts of β particles divided by counts of background on the same assay. Ranks were compared between patients and controls by Kruskal-Wallis U test.
Results: Controls were matched with patients by sex, year and season of sample collection, but with older age [15.03±0.72 vs 19.86±0.52yrs]. 92.5% patients were HLA-DQB1*0602 positive whereas 50.6% in controls. ASO titers were positive in 121 of 249 (48.6%) patients compared to 168 of 449 (37.4%) controls. Increased ASO was thus associated with recent onset narcolepsy [OR=1.37(1.16, 1.63), p=0.01], and the significance [OR=1.40(1.09, 1.79), p=0.01; co-efficient=0.23(0.04,0.41), p=0.02] still presented after controlling for sex, age and season of collection. In contrast, no association were found between recent onset narcolepsy and any autoantibody tested. Percentage of subjects with positive TRIB2 antibody in patients was higher than controls only in 2004-2006 based on plot of percentage of positive between patients and control each year, explaining why initial results were positive.
Conclusion: ASO are increased in recent-onset narcolepsy cases across 20 years. Autoantibodies against 49 hypocretin-cell enriched proteins were not detected. TRIB2 autoantibodies were transiently associated with recent narcolepsy onset in 2004-2006.

TOTAL SLEEP DEPRIVATION INDUCED TNF-A RESPONSE IS EXACERBATED IN MILD TRAUMATIC BRAIN INJURY

Lillian Skeiky[1], Vera Matrosova[1], Michael Smith[1], Elizabeth Metzger[1], Kent Werner[2]
[1] The Geneva Foundation, Tacoma, Washington, [2] Department of Neurology, Uniformed Services University of the Health Sciences, Bethesda, Maryland

Introduction: Total sleep deprivation (TSD) has been shown to cause an increase in circulating proinflammatory cytokines. This well-characterized proinflammatory cytokine response is associated with distinct changes in sleep physiology, cognitive impairment, and in instances of chronic exposure to sleep loss, impaired immune function and vulnerability to stressors. There are potential individual differences in immune response resulting from sleep loss. Mild traumatic brain injury (mTBI) is often associated with an increase in proinflammatory cytokines, which may lead to a neuroinflammatory cascade in the brain and exacerbate post-injury cognitive impairment. This cytokine elevation usually peaks shortly following an injury, and typically returns to baseline levels within a few weeks. Given that mTBI is associated with increased proinflammatory cytokine activation on its own, we investigated whether individuals with a history of mTBI may be more susceptible to TSD-induced proinflammatory cytokine activation.
Methods: Twenty-five adults (9 females, 16 males; 9 with a history of mTBI) underwent 38-hours of at-home TSD, followed

by an in-laboratory polysomnographically recorded recovery sleep period. Blood was drawn at roughly 38-hours of TSD, and again in the morning following recovery sleep. Whole blood was spun down for plasma and a multi-array electrochemiluminescence proinflammatory panel was performed on plasma samples in duplicate.
Results: A one-way ANOVA controlling for sex, age, and Body Mass Index showed that TNF-α concentration following TSD was significantly higher in mTBI, as compared to healthy controls ($P < 0.05$), with levels decreased following recovery sleep ($P > 0.05$).
Conclusion: Our results may suggest that mTBI is associated with vulnerability to proinflammatory cytokine activation, specifically TNF-α, following TSD. While our participants were not in the acute stages of injury, TSD may have exposed underlying immune-related vulnerability in mTBI. Future work will investigate if TNF-α activation mediates variability in TSD-induced cognitive impairment and in sleep physiology following TSD in participants with mTBI.

DETERMINING THE IMPORTANCE OF GAP JUNCTION PROTEIN CONNEXIN36 IN SLEEP-WAKEFULNESS AND TASK-EVOKED EEG ACTIVITY

RADHIKA BASHEER[1], Sean Carey[2], Victoria Lombardi[3], DAVID uygun[4], James M McNally[5]
[1] Harvard Medical School-VA BHS- Boston VA Res Inst., [2] VA Boston Healthcare System, [3] VA Boston Healthcare System-Boston VA Res Inst., [4] VABHS Harvard Medical School Dept of Psychiatry, [5] VA Boston Healthcare System-Harvard Medical School

Introduction: Neuronal gap junctions, also termed electrical synapses consisting of connexin36 (Cx36) protein, are extensively expressed in the mammalian forebrain and are suggested to play a significant role in state regulation and thalamocortical network activity. Cx36 is predominantly expressed in GABAergic neurons in the adult brain and represents a common mechanism for electrical coupling between inhibitory neurons. Specifically, the intercellular communications between the GABAergic neurons in the thalamic reticular nucleus (TRN) occur predominantly via Cx36 containing electrical synapses. We have examined the effect of a Cx36 global gene knockout (KO) and TRN-specific localized CRISPR-Cas-mediated Cx36 gene knockdown (KD) on sleep/wake state and spontaneous and evoked EEG activity.
Methods: We examined the sleep/wake state, spontaneous and task-evoked EEG activity in auditory steady-state response (ASSR), mismatch negativity (MMN), and social interaction behavioral test in Cx36KO mice and in PV-Cre-Cas9 mice before and after localized Cx36 gene KD.
Results: While Cx36KO mice exhibited limited sleep/wake abnormalities, power spectral density analysis of spontaneous EEG activity revealed significant impairment in gamma and beta band activity. Interestingly, sigma band activity significantly decreased prior to NREM-REM transitions. While we observed no changes in sleep spindle density, the amplitude and duration of spindles showed statistically significant decreases in Cx36KO mice. Additionally, Cx36KO mice exhibited a blunted gamma band response to acute ketamine (15 mg/kg; IP), impaired 40 Hz ASSR, and an abnormal response in the mismatch negativity task (decreased ERP peak amplitude & evoked-power). Finally, Cx36KO mice exhibit significant impairment in social investigation-induced low-frequency gamma band activity. Preliminary observations in TRN-Cx36 KD mice showed similar impairment in ASSR and social investigation-induced gamma band activity.
Conclusion: Our data suggests that Cx36 is involved in regulating thalamocortical network activity. Further, impairments in Cx36KO mice are consistent with abnormalities observed in neuropsychiatric disorders, including schizophrenia, suggesting Cx36 containing gap junctions as a novel therapeutic target.

SICK AND TIRED OF COVID-19 - GENETIC RISK FACTORS, FATIGUE AND SLEEP DISTURBANCES IN LONG COVID

Vilma Lammi[1], Long COVID Host Genetics Initiative Consortium[1], Hanna M Ollila[1]
[1] University of Helsinki

Introduction: SARS-CoV-2 infection can lead to prolonged symptoms including fatigue, breathing difficulties, brain fog, and sleep disturbances. The global Long COVID Host Genetics Initiative aims to elucidate genetic factors and mechanisms undermining post-acute sequelae of COVID-19.
Methods: Long COVID was defined using questionnaire information on symptoms and recovery from COVID-19, or electronic health record data with post COVID-19 conditions diagnoses. Genome-wide association studies (GWAS) were used to identify genetic risk loci, and linkage disequilibrium score regression (LDSC) to study wider genetic correlations between traits.
Results: With mixed-ancestry meta-analysis of 24 GWAS comparing Long COVID cases (N=3,018) to population controls (N=1,093,995), we identified variants in chromosome 6 associated with Long COVID (chr6:41,515,652G>C, rs9367106; P=1.8E-10). The signal replicated in 9,500 independent Long COVID cases (vs 798,835 population controls; P< 0.05). Long COVID risk variants in this region have been shown to increase FOXP4 gene expression in the lung (P=5.3E-9, normalized effect size (NES) = 0.56) and in the hypothalamus (P=2.6E-6, NES=1.4) (expressed quantitative loci (eQTL) in GTEx data). Using GWAS summary statistics and LDSC, we found Long COVID after test-verified SARS-CoV-2 infection (vs those recovered from the infection within 3 months, N=46,208) genetically correlated with insomnia symptoms (P=0.002). Diagnoses for fatigue (OR=2.8, P=1E-174) and sleep disorders (ICD-10 F51; OR=2.2, P=1E-23) were enriched in electronic health records of Long COVID cases (N=3,684) compared to age- and sex-matched controls (N=64,783) in the FinnGen biobank dataset.
Conclusion: Long COVID and other post-viral conditions cause a burden for the health and economy of individuals, families, and societies. Debilitating fatigue, cognitive dysfunction, and

sleep disturbances contribute to the multifaceted pathology and should be carefully assessed and treated.

GLOBAL AND LOCAL CHEMOGENETIC DELETION OF THE NOP RECEPTOR DISRUPTS BOTH SPONTANEOUS AND NOP AGONIST-INDUCED SLEEP

Yu Sun[1], Ryan Tisdale[1], Stephanie Lee[2], Chen Yin[2], Charlene Sykes[2], Gavin Scheldrup[1], Akihiko Ozawa[3], Lawrence Toll[3], Michael Bruchas[4], Thomas Kilduff[2]

[1] SRI, [2] SRI International, [3] Florida Atlantic University, [4] University of Washington

Introduction: We have previously shown that NOPR agonism induced sleep and increased EEG delta power in rats, mice and non-human primates, suggesting that the N/OFQ-NOPR system may have an unrecognized role in sleep/wake regulation. In the present studies, we tested the hypothesis that the N/OFQ-NOPR system is a component of the endogenous sleep/wake regulatory system by deleting NOPRs globally. We then determined whether interruption of NOPR transmission specifically in the lateral hypothalamic area (LHA) contributed to the effects observed after global NOPR deletion.
Methods: Homozygous floxed NOPR mice were bred with B6.Cg-Ndor1Tg(UBCcre/ERT2)1Ejb/1J mice (JAX 070001) to produce a strain (iNOPR mice) in which deletion of NOPRs could be induced by tamoxifen (TMX). In the local deletion study, AAV2-CMV-Cre-eGFP or AAV10-CMV-hrGFP was injected into the LHA of floxed NOPR mice. EEG, EMG, activity and Tb were measured by telemetry.
Results: TMX administration to homozygous Cre+ iNOPR mice resulted in a massive knockdown of NOPR expression as determined by Western blotting. Whereas administration of the NOPR agonist Ro64-6198 (3 mg/kg, i.p.) suppressed activity, reduced Tb and increased NREM sleep in Cre+ iNOPR mice before TMX administration and in Cre- mice both before and after TMX administration, these effects were abolished following TMX treatment in the Cre+ iNOPR mice, providing pharmacological confirmation of NOPR deletion. Within-animal comparisons of pre vs. post TMX-treated Cre+ iNOPR mice revealed that NOPR deletion produced partial insomnia with 5.3±1.4% more Wake time over 24-h ($p = 0.028$) and 11.5±1.4% more Wake during the light phase ($p < 0.001$), the major sleep period in mice. Conversely, NREM sleep decreased by 4.7±1.4% ($p = 0.04$) over 24-h and 10.4±1.4% ($p < 0.001$) during the light phase. Following treatment with Ro64-6198 (3mg/kg, i.p.), activity and Tb increased in LHA NOPR deletion mice whereas both measures decreased in control mice. Local LHA NOPR deletion also eliminated the NREM-promoting effect of Ro64-6198, indicating LHA NOPR neurons mediating the NREM-promoting effect.
Conclusion: These results support the hypothesis that loss of endogenous NOPR tone increases wake and reduces sleep amounts. We identified the LHA as a region mediating Ro64-6198 induced promotion of NREM sleep.

THE RELATIONSHIP OF SLEEP DISORDER HISTORY WITH GRAY MATTER BOLD-CSF COUPLING AMONG PERSONS AT RISK FOR AND WITH ALZHEIMER'S DISEASE

Gawon Cho[1], Xiao Liu[2], Adam Mecca[1], Brienne Miner[1]

[1] Yale University, [2] The Pennsylvania State University

Introduction: The glymphatic system has been proposed to remove metabolic waste from the brain through CSF movement and its exchange with interstitial fluid. It has been hypothesized to mediate the impact of sleep deficiency on Alzheimer's disease [AD] pathogenesis. gBOLD-CSF is the coupling of slow (i.e., < 0.1 Hz) gray matter blood-oxygen-level-dependent-signals and slow cerebrospinal fluid flow, and a proposed proxy measure of glymphatic transport. However, its association with sleep disorder history in persons along the AD spectrum remains unknown.
Methods: This study included twenty-seven participants who completed medical interview and MRI at the Yale's Alzheimer's Disease Research Center (3 AD, 1 mild cognitive impairment, and 23 cognitively normal). Sleep disorder history was based on reporting active management for a diagnosis of insomnia or apnea. gBOLD-CSF coupling was quantified based on resting-state fMRI (repetition time=1000ms), using a previously published approach. Briefly, timeseries of gBOLD were extracted by aligning the fMRI and Harvard-Oxford atlas to each participant's native space. CSF-signal timeseries were extracted from the bottom slice with a manually drawn CSF mask. For each participant, cross-correlation function between gBOLD and CSF timeseries was calculated. The negative peak correlation coefficient occurring within a 2-6 second time lag was used to quantify maximum gBOLD-CSF coupling. T-tests were used to compare gBOLD-CSF coupling by sleep disorder history.
Results: Mean age was 65.4 (SD=8.6), 59.3% were women, 44% carried ≥1 ApoE4 allele (1 missing), and mean educational attainment was 17 (SD=2.6) years. Mean gBOLD-CSF coupling in individuals who had insomnia was -0.16, which was weaker than that of individuals without insomnia (absolute difference=0.12, [95%CI=-0.15,0.40];p=0.19). Mean gBOLD-CSF coupling in individuals with apnea was -0.16, which was weaker than that among people without apnea (0.13, [-0.07,0.33];p=0.09).
Conclusion: Among individuals at risk of/with AD, there was a trend for reduced gBOLD-CSF coupling associated with insomnia and apnea. These findings provide preliminary evidence that glymphatic-related fluid transport among persons with a sleep disorder may be disrupted. This finding supports the hypothesis that glymphatic transport is associated with sleep. Future work should validate these findings in larger samples.

CHEMOGENETIC ACTIVATION OF LATERAL HYPOTHALAMIC CAMKIIA NEURONS IN PARTIALLY AND FULLY HCRT NEURON-DEGENERATED MICE

Chen Yin[1], Yu Sun[2], Charlene Sykes[1], Thomas Kilduff[1]

[1] SRI International, [2] SRI

Introduction: Degeneration of the hypothalamic hypocretin/orexin (Hcrt) neurons underlies the sleep disorder Narcolepsy Type 1 (NT1), leading to excessive daytime sleepiness (EDS), cataplexy and other sleep disturbances. The lateral hypothalamus (LH) plays a critical role in sleep-wake regulation. We recently showed that LH CaMKIIα neurons are wake-active and that chemogenetic activation of these cells prolongs wakefulness for as long as 6 hours (Heiss et al., 2024, PNAS). We hypothesized that LH CaMKIIα neuron activation might compensate for the loss or dysfunction of Hcrt neurons and counteract EDS

in narcolepsy, thereby serving as a potential therapy for individuals suffering from hypoarousal disorders. We present here preliminary data on the efficacy of LH CaMKIIα neuron activation to promote wakefulness in both partially and fully Hcrt neuron-degenerated mice and to reduce cataplexy in fully Hcrt degenerated mice.
Methods: Orexin-tTA; TetO-DTA mice (n = 8) mice were bilaterally injected with AAV2-CaMKIIα-hM3D(Gq)-mCherry into the LH and implanted with telemetry transmitters for EEG/EMG recording. Hcrt neurons were ablated by substituting doxycycline-containing chow with normal rodent chow (Dox (-) condition) for 6 weeks. When the Hcrt neurons were either partially-degenerated (2 weeks Dox (-)) or fully degenerated (6 weeks Dox (-)), LH CaMKIIα neurons were chemogenetically activated by injection of deschloroclozapine (DCZ, 0.3 mg/kg, i.p.) at ZT18. As a control, each mouse also received a saline injection on a different day.
Results: Activation of LH CaMKIIα neurons profoundly increased Wakefulness and reduced NREM sleep in both partially and fully (Wakefulness: $p < 0.001$; NREM: $p < 0.001$) Hcrt neuron-degenerated mice. Furthermore, DCZ treatment significantly reduced both the number of cataplexy bouts ($p = 0.048$) and bout duration ($p = 0.035$) in fully Hcrt neuron-degenerated mice.
Conclusion: Activation of LH CaMKIIα neurons has profound wake-promoting effects even in the absence of Hcrt neurons, indicating that the wake-promoting effects of LH CaMKIIα neurons are independent of the Hcrt system. Consequently, LH CaMKIIα neuron activation may have therapeutic effects on the primary symptoms of narcolepsy: EDS and cataplexy.

CHRONIC ADRENERGIC BLOCKADE WITH PRAZOSIN ENHANCES GLYMPHATIC FUNCTION IN A MURINE MODEL

Joshua Cho[1], Mathew Sevao[2], Thomas Ehler[2], Murray Raskind[2], Jeffrey J. Iliff[2]
[1] University of Washington, [2] VISN [20] Mental Illness Research, Education, and Clinical Center

Introduction: The glymphatic system involves the AQP4-facilitated movement of cerebrospinal fluid (CSF) through perivascular channels into the brain parenchyma where it exchanges with interstitial fluid to facilitate clearance of solutes, such as amyloid beta and tau protein. The glymphatic system has been characterized as the brain's waste clearance system and its dysfunction has been implicated as a clinical, non-genetic factor in several neurodegenerative diseases such as Alzheimer's disease and Parkinson's disease. The glymphatic system is primarily active during sleep, thus, our group aimed to evaluate the influence of factors that affect sleep, and thereby, glymphatic function. Norepinephrine (NE) signaling from the locus coeruleus (LC) is involved in inducing and coordinating states of alertness. Wakefulness is driven and sustained by LC-NE signaling (and other monoamines), while sleep is achieved through the inhibition of this circuit. Thus, we hypothesized that inhibiting NE signaling could enhance sleep and thereby glymphatic function.
Methods: To evaluate the influence of NE on the glymphatic system, we treated C57BL/6 mice with a chronic, 7-day treatment of the alpha-1 adrenergic receptor antagonist, prazosin. Utilizing intracisternal injection of infrared and fluorescent tracers, we labeled, tracked, and quantified CSF tracer distribution in vivo with a newly validated dynamic, live imaging technique and ex vivo through whole-slice fluorescence imaging.
Results: Measurement of in vivo, dynamic CSF tracer movement revealed higher levels of mean fluorescence intensity over time (20-42 minutes post-intracisternal injection) in prazosin-treated mice when compared to control, vehicle-treated mice. In addition, ex vivo, slice-based histology showed higher levels of CSF tracer in the dorsal cortex of female, prazosin-treated mice vs. control.
Conclusion: Prazosin-treated mice exhibited significantly higher levels of mean glymphatic enhancement compared to controls, indicating that inhibition of NE signaling can improve glymphatic function. Given the contribution of dysfunctional NE signaling and impaired glymphatic clearance in a multitude of neurological diseases, our study is a promising example of the potential benefit of prazosin treatment. As a next step, we are currently exploring if chronic prazosin administration can improve disease outcomes in a mouse model of tau pathology, P301S/PS19 mice, where we will evaluate sleep, cognitive impairment, glymphatic function, and tau deposition/pathology.

SEX- AND SUBREGION-SPECIFIC VULNERABILITY OF HIPPOCAMPUS AND AMYGDALA TO INTERMITTENT HYPOXIA OF INFANT RATS

Yu Takenouchi[1], Jun Hosomichi[2], Kitanon Angkanawaraphan[2], Hideyuki Maeda[3], Haixin Hong[4], Chidsanu Changsiripun[5], Takashi Ono[1]
[1] Department of Orthodontic Science, Graduate School of Medical and Dental Sciences, Institute of Science Tokyo, [2] Department of Orthodontic Science, Graduate School of Medical and Dental Sciences, Institute of Science Tokyo, Tokyo, Japan, [3] Department of Forensic Medicine, Graduate School of Medicine, [4] Shenzhen People's Hospital, [5] Department of Orthodontics, Faculty of Dentistry, Chulalongkorn University

Introduction: Obstructive sleep apnea (OSA) in early childhood results in neurodevelopmental deficits due to nocturnal intermittent hypoxia (IH). Hypoxemia during infancy induces structural changes in the hippocampus and amygdala of children. However, the mechanism underlying this phenomenon remains unclear. This study aimed to elucidate the molecular pathogenesis of cognitive and emotional deficits induced by IH exposure during infancy, using a rat model of IH exposure that recapitulates sleep-disordered breathing.
Methods: One-week-old Sprague-Dawley rats underwent IH at 20 cycles/h (nadir, 4% O2; peak, 1% O2; 0% CO2) or normoxic air (N group) for 8 h/day on postnatal days 8–21. Learning/memory function, emotional behavior, and locomotor activity were examined. Immunohistochemistry for BDNF and BrdU was performed in the hippocampal cornu ammonis (CA) 1 and CA3 regions, dentate gyrus (DG), and amygdala. Ntrk2, Hif1a and Epas1 mRNA levels were determined for each region.
Results: IH exposure negatively regulated long-term spatial memory and anxiety in male and female rats, and short-term

spatial memory in male rats. The effects of IH on brain development were validated by the increased expression of Ntrk2 and Epas1 mRNA in the DG, Ntrk2 and Hif1a mRNA in the amygdala of male rats, and an increase in the immunohistochemically stained areas in the DG and amygdala in male rats.
Conclusion: These findings provide in vivo evidence for sex- and subregion-specific functional linkages between cognitive function, anxiety tendency, and IH during the early growth period.
Support (if any): This study was technically supported by the Animal Research Center, Tokyo Medical University and the Research Core Center, Institute of Science Tokyo.

THE SLEEP-DEPENDENT REGULATION OF THE E/I RATIO EMERGES DURING THE CRITICAL PERIOD OF THE PRIMARY VISUAL CORTEX

Benjamin Menarchek[1], Michelle Bridi[1]
[1] West Virginia University School of Medicine

Introduction: Maturation of the excitation/inhibition (E/I) ratio is necessary for the development of cortical circuits and optimal brain function. In young adult mice, excitatory and inhibitory synaptic transmission oscillates in a sleep-dependent manner, such that the E/I ratio is increased following the wake-rich periods and decreased following sleep-rich periods. However, exactly when the E/I ratio oscillation emerges in development is unknown. Given that sleep is developmentally regulated and important to synaptic plasticity, we hypothesize that the sleep-dependent E/I oscillation will emerge by the critical period (P24-35) of the primary visual cortex (V1) in wild-type mice, a window of heightened plasticity during postnatal development.
Methods: We used whole-cell patch clamp electrophysiology to isolate miniature inhibitory and excitatory postsynaptic currents (mI/EPSCs) to examine synaptic transmission at V1 L2/3 pyramidal neurons.
Results: We found that a daily alteration in the frequency, a marker for spontaneous presynaptic vesicle release, but not amplitude, a marker for postsynaptic receptor composition, emerges during the beginning of the critical period (P24-P28). The emergence of a daily E/I oscillation during the visual critical period advances the idea of sleep's essential role in brain development.
Conclusion: These results also give rise to further questions about how sleep may modulate the E/I ratio's contribution to synaptic plasticity. Future experiments will observe sleep properties under normal housing conditions in postnatal mice using a novel EEG/EMG implant, investigate if the trajectory of the E/I oscillation emergence is altered in neurodevelopmental conditions using an autism-related mouse model, and identify genes related to the E/I ratio oscillation that are differentially expressed by sleep and time of day using spatial transcriptomics. Collectively, these studies will expand our knowledge of how sleep-dependent regulation of the E/I ratio is crucial for neurotypical development and proper circuit function.

UP-REGULATION OF KLF2: A POTENTIAL THERAPEUTIC STRATEGY FOR NEUROINFLAMMATION INDUCED BY INTERMITTENT HYPOXIA

chong xu[1], jing zhang[1], yu shi[1]
[1] Tianjin Medical University General Hospital

Introduction: Intermittent hypoxia (IH) is a hallmark manifestation of obstructive sleep apnea (OSA), a prevalent breathing disorder. IH causes central nervous system (CNS) inflammation and ultimately leads to neuropathy, and it is regarded as a crucial contributor to cognitive impairment in OSA. However, the mechanisms by which IH-related neuroinflammation leads to cognitive impairment remain unclear and need further exploration.
Methods: C57BL/6J mice were exposed to experimental IH or normoxia for four weeks. Subsequently, the cerebral cortex and hippocampus were separately harvested for mRNA sequencing. Bioinformatics analysis was utilized to screen the differentially expressed genes. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses were conducted on the identified differentially expressed genes. The genes commonly altered in the cortex and hippocampus were screened out for experimental verification by Western Blotting (WB) and quantitative polymerase chain reaction (qPCR) in mouse brains and BV-2 microglial cells subjected to IH. To verify the influence of Krüppel-like factor 2(Klf2) on neuroinflammation, BV-2 microglial cells were transfected with plasmids for Klf2 overexpression. The expression levels of inflammatory factors, including TNF-α, IL-1β, and iNOS, were determined through various experimental approaches, namely qPCR, WB, and immunofluorescence. The knockdown of Klf2 in BV-2 microglial cells with siRNA was performed to confirm the abovementioned results.
Results: Compared with normoxia condition, 112 and 22 differentially expressed mRNAs were screened out in the cerebral cortex and hippocampus, respectively, following IH treatment. These genes may be differentially regulated during IH. The results showed that the mRNA and protein expressions of Klf2 declined at both the cellular and animal levels after exposure to IH. Hence, Klf2 was selected to explore its role in IH-induced neuroinflammation further. As revealed by the results, the overexpression of Klf2 in BV-2 microglial cells reduced the release of inflammatory factors like TNF-α and IL-1β induced by intermittent hypoxia. Moreover, the knockdown of Klf2 gene expression mediated by siRNA exacerbated the corresponding inflammatory response.
Conclusion: Microglial Klf2 is identified as a neuroinflammation mediator. Future research will be directed towards further exploring the specific molecular mechanisms of Klf2 in IH-induced neuroinflammation.

TACR1-CRE;SST-FLPO MICE AS A TOOL TO STUDY SLEEP-ACTIVE CORTICAL NEURONS

Stephanie Lee[1], Chen Yin[1], Charlene Sykes[1], Renata Batista-Brito[2], Thomas Kilduff[1]

[1] SRI International, [2] Albert Einstein College of Medicine

Introduction: While most cortical neurons exhibit reduced activity during slow wave sleep (SWS), we previously identified a population of cortical GABAergic neurons that are active during sleep in three different species. This subpopulation of GABAergic neurons co-expresses somatostatin (Sst), neuronal nitric oxide synthase (Nos1), the Neurokinin-1 receptor (Tacr1) and chondrolectin (Chodl), and corresponds to the Type 1 nNOS neurons that have long-range intracortical projections in mammals. These "SNTC" cells express c-Fos during SWS proportional to the homeostatic sleep drive that accumulates during the preceding wakefulness. However, the role of SNTC cells in sleep regulation, if any, is unknown. Here, we utilized Tacr1-T2A-Cre;Sst-IRES-FlpO mice, an intersectional cross that allowed us to target these cells, to investigate the role of cortical SNTC neurons in sleep/wake regulation.
Methods: Tacr1-T2A-Cre;Sst-IRES-FlpO mice were crossed with Ai65 mice for labeling of SNTC neurons. The sensitivity and specificity of these cells were determined by immunohistochemistry for nNOS. Responses to Substance P were measured with slice electrophysiology. For sleep deprivation studies, one group of mice underwent 6 hours of sleep deprivation (SD) and another received 2 hours of recovery sleep (RS) following SD. For chemogenetic activation of SNTC cells, AAV8.nEF.Con/Fon.DREADD(Gq)-mCherry.WPRE.hGH was injected at 16 sites across both hemispheres of the cerebral cortex in Tacr1-Cre;Sst-FlpO mice (n=7) and mice were implanted for EEG/EMG recording. Saline or deschloroclozapine (DCZ; 0.3mg/kg, i.p.) was administered at ZT18 on recording days.
Results: The sensitivity and specificity of Tacr1/Sst/Ai65 neurons for nNOS protein were determined to be 91.5±2.5% and 59.2±5.8%, respectively (n=5). Substance P activated the majority of cortical Tacr1/Sst/Ai65 neurons (78%, 14/18 cells). Consistent with our previous findings, 64.5±1.19 Tacr1/Sst/Ai65 neurons expressed c-Fos during RS compared to 4.75±0.25 cells during SD ($p < 0.0001$). As also shown by the Batista-Brito lab using Nos1-CreERT2;Sst-FlpO mice, chemogenetic activation of cortical Tacr1/Sst neurons increased NREM sleep ($p=0.0041$).
Conclusion: Our findings indicate that Tacr1/Sst/Ai65 cells are active during sleep and that activation of these cells can drive NREM sleep. These observations are consistent with our previous results and show that Tacr1-Cre;Sst-FlpO mice will be useful to further characterize the role of SNTC neurons in sleep/wake control.

RESTORATION OF NREM SLEEP IN AN ALZHEIMER'S DISEASE MOUSE MODEL THROUGH 40-HZ AUDITORY STIMULATION BY REDUCING TONIC GABA CURRENTS IN NNOS NEURONS

Mincheol Park[1], Chanyoung Cheong[1], Jinhong Kim[1], Tae Kim[1]
[1] Gwangju Institute of Science and Technology

Introduction: The sensory stimulation at 40 Hz showed therapeutic impacts on Alzheimer`s disease (AD). Previous studies reported that amyloid-beta (Aβ) accumulation and sleep disturbances in AD have a positive feedback loop and impaired Ca2+ influx and volume transient in astrocytes. However, the role of astrocytes in sleep disturbances remains unknown. We hypothesized that 40-Hz auditory stimulation could ameliorate sleep disturbances by enhancing the astrocytic Ca2+ influx.
Methods: We used 6-month-old 5xFAD as an Alzheimer`s disease model. Two-hour daily 40-Hz auditory stimulation was applied for two-weeks. We recorded the 24-hour electroencephalographic (EEG) for sleep-wake analysis in pre- and post-stimulation days. Reactive astrocytes and GABA were measured using immunohistochemistry. Patch clamping recordings measured the tonic GABA currents of nNOS neurons. Using GCaMP6f and intrinsic optical signals measured astrocytic Ca2+ and volume swelling. qRT-PCR quantified the transcriptional levels.
Results: Our study demonstrated that repeated auditory steady-state responses (rASSR) at 40 Hz mitigated Aβ pathology and sleep disturbances. We observed that astrocytic γ-aminobutyric acid (GABA) reduced inhibition on neuronal nitric oxide synthase (nNOS)-containing neurons, sleep-promoting cortical neurons, by rASSR. Additionally, rASSR enhanced neuronal activity-induced transient volume and Ca2+ influx in astrocytes, which subsequently decreased monoamine oxidase B (MAO-B) and increased nuclear factor erythroid 2-related factor 2 (Nrf2). Finally, optogenetic enhancement of astrocytic Ca2+ influx using monSTIM1 mimicked the therapeutic effects of the 40 Hz rASSR.
Conclusion: Our findings suggest that 40-Hz rASSR ameliorates Aβ pathology and sleep disturbances by neuron-astrocyte interaction.

THE STRUCTURAL INFLUENCE OF DISORDERED SLEEP ON THE WAKE INTRUSION INDEX

Matthew Gratton[1], Nancy Hamilton[2], Amber Watts[2], Emily Cramer[3], Bethany Gerardy[4], Younes Magdy[5], Garrett Baber[2], Diego Mazzotti[1]

Introduction: Individually, insomnia and obstructive sleep apnea (OSA) are significant public health concerns. Insomnia affects nearly a third of the population, while OSA affects 9% to 38% of adults. Their co-occurrence (COMISA) results in severe health outcomes, including cardiometabolic and neurocognitive morbidity, impaired sleep quality, and reduced quality of life. Although both disorders disrupt sleep, it is difficult to disentangle the effect of each disorder on conventional physiological surrogates of sleep quality. This study attempts to quantify the contributions of OSA and insomnia to the Wake Intrusion Index (WII), a measure of subthreshold intrusions of wakefulness on sleep. We hypothesized that WII is influenced by both respiratory and non-respiratory arousal mechanisms.
Methods: We leveraged polysomnography data and self-reported insomnia symptoms from individuals in the Sleep Heart Health Study. WII was calculated based on the odds-ratio product, a measure of sleep depth. We used structural equation modeling to examine the shared and unique contributions of both respiratory indices such as the Apnea Hypopnea Index and the Oxygen Desaturation Index and frequency of different insomnia symptoms on the WII.
Results: We found that our data had a two-factor structure representing respiratory related arousals, containing all the respiratory variables, and non-respiratory related arousal which contained the questions related to insomnia. Both respiratory

and non-respiratory latent variables influenced the WII, however the non-respiratory arousal (β=8.22) factor had a notably higher influence on the WII over the respiratory arousal factor (β=1.02).
Conclusion: Our study demonstrates that both respiratory and non-respiratory arousal mechanisms significantly influence the WII. These findings highlight the importance of addressing both components in treatment strategies to improve sleep quality and overall health outcomes in COMISA patients.

THE MULTIPLICITY OF DREAMS REPORTED FROM NIGHTLY AWAKENINGS

James Pagel[1], Geoff Carre[2]
[1] University of Colorado Health Science Center, [2] Cape Breton University

Introduction: Dream recall has high individual variability affected by a wide spectrum of methodological variables. The possibility that multiple dreams are typically experienced each night has received minimal study.
Methods: 51 subjects were recruited from college psychology classes (35 F/16 M, mean age 22.2). The intake questionnaire queried subject dream recall varying from no dream recall=1, to multiple dreams from each night of sleep=7. A smart phone app with a sixty-minute delay was then used at home to induce hourly awakenings utilizing a bed side check list to notate: no dreaming or defined forms of dreaming including dreams with content, white dreams (awareness of dreaming without content), and nightmares. 44 subjects (86%) competed the full protocol of 8 dream checkoff reports. Reasons for discontinuation: concern with sleep loss (1), technical issues with alarm (2), early rising for work (1), spousal complaint (1).
Results: The mean number of dreams reported on intake using Likert scale was 4.647 (1-3/week). Checkoff dream recall reports were obtained from 395 total awakenings: no dreaming (#150 - 38%); content dreams #98 (25%); white dreams #74 (19%); and nightmares # 14 (3.5%). Some form of dreaming was reported on 186 (47%) of awakenings. Mean number of dreams reported was 4.0/individual during the night of study. One individual reported no dream recall on any awakening and 2/51 reported dreams with content on every awakening. 6/51 (12%) reported some form of dreaming at every awakening. For individuals completing the full protocol, non-dreaming was reported significantly more often on the first two hourly awakenings compared to the last 2 awakenings ($X2=24.7$, $p< 0.001$). There was a statistically significant association between reported intake questionnaire dream recall and the number of dreams reported on checklist during the night of study (Pearson $r = 0.571$, $p < 0.001$).
Conclusion: This small pilot study utilizes a novel, low-tec, safe, and easily expandable protocol to study changes dream recall across the night. Individuals reporting a higher frequency of dream recall on intake had a significantly higher level of dreaming reported from serial awakenings. 12 % of subjects reported some form of dreaming on every awakening.

PREPROCESSING RESULTS FROM AN ALL-NIGHT FMRI SLEEP STUDY

Patrick Wang[1], Danielle Greene[1], Hadar Halivni[1], Niki Lam[1], Hendrik Mandelkow[1], Nils Yang[1], Zeynep Demir[1], Pinar Ozbay[1], Gail Tarlton[1], June Yi[1], Sara Inati[1], Jacco de Zwart[1], Peter van Gelderen[1], Jeff Duyn[1], Dante Picchioni[1]
[1] National Institutes of Health

Introduction: Functional magnetic resonance imaging (fMRI) is emerging as a useful technique for investigating brain activity during sleep, offering superior spatial resolution compared to electroencephalography (EEG). A prior pilot study conducted by our lab highlighted the potential of fMRI to elucidate the neural correlates of dreaming, arousal thresholds, and other sleep-related phenomena. To expand on these findings, we conducted an extensive all-night fMRI sleep study. Here, we describe quality control metrics obtained during data preprocessing.
Methods: Healthy participants (n=58) were enrolled in a two-night fMRI-EEG sleep study protocol. 43 participants successfully completed both nights, while 15 were withdrawn during the first or second night. At 6-8 random intervals throughout the night, participants were woken by auditory stimuli, which increased in intensity until wake onset. Once awake, participants completed a dream questionnaire. Preprocessing of fMRI data was performed using the Analysis of Functional Neuroimages (AFNI) toolbox, including nonlinear alignment to a Tailarach template, data censoring to eliminate outlier time points and artifacts from excessive head motion, and regression of systemic confounds from autonomic variability.
Results: A total of 877 runs of fMRI data were recorded with a mean length of 43.4 min (SD=34.5 min). Average temporal signal-to-noise ratio in brain voxels across all runs was 48.14 (SD=4.99). Post-regression, average global correlation across voxels was 0.013 (SD=0.005), indicating effective suppression of systemic confounds. Average maximum within-run motion displacement was a modest 2.78 mm (SD=2.23 mm), and average fraction of time points censored due to motion or outliers was 8.84% (SD=8.88%). Average spatial correlation between each subject's anatomical and functional scans was 0.837 (SD=0.021), attributable to differences in brain coverage and resolution. Average spatial correlation between each subject's anatomical scan and the Tailarach template was 0.981 (SD=0.005).
Conclusion: These preprocessing results indicate the successful collection and preprocessing of high-quality, low-noise data and validate the effectiveness of our all-night fMRI sleep study protocol. Our next step is to perform group analyses using the auditory arousal threshold and dream questionnaire data collected.

EXTENDED AMYGDALA NEURAL CIRCUITS LINKING HORMONAL INFLUENCES ON BODY TEMPERATURE TO SLEEP AND CIRCADIAN RHYTHMS

Brittany Bush[1], Haniyyah Sardar[2], Faith Aloboudi[1], Ivy Hoang[1], Ethan Rogers[3], Allison Morningstar[1], Yihe Ma[1], Louisa Dal Cengio[4], Rebecca Buchanan[1], Erin Gibson[2], William Giardino[1]

[1] Stanford University, [2] Stanford University School of Medicine, [3] Stanford, [4] Stanford School of Medicine

Introduction: Sleep is key for socioemotional function, and the neuronal mechanisms underlying sleep and emotional regulation remain understudied, especially in women. Body temperature fluctuations are a key feature of sleep/circadian rhythms and are modulated by gonadal steroid hormones. Several brain structures are implicated in interactions between emotional behaviors, hormonal status, and sleep/wake regulation, including the bed nucleus of the stria terminalis (BNST), a core component of the extended amygdala. The BNST regulates emotional responses to stress and consists of distinct cellular populations, including neurons expressing tachykinin2 (Tac2), the gene encoding Neurokinin B (NKB). Tac2/NKB signaling drives the hypothalamic-pituitary-gonadal reproductive axis and is implicated in social stress as well as hot flashes. Thus, we hypothesized that Tac2-BNST neurons regulate hormonal influences on body temperature, sleep, and corresponding emotional arousal states.
Methods: We used wireless telemetry systems for monitoring locomotor activity and core body temperature, and EEG/EMG monitoring for characterizing sleep/wake states in female mice across the estrous cycle, examining changes due to Tac2-BNST chemogenetic stimulation using the excitatory Gq-DREADD (hM3Dq-mCherry). Additional studies assessed sex differences in Tac2-BNST circuit organization using anterograde viral tracing of neuronal output pathways.
Results: We identified estrous cycle effects on core body temperature, which was increased during high estradiol states (estrus and proestrus). Intriguingly, this effect was reversed by Tac2-BNST Gq stimulation. Additionally, we identified a trend toward increased REM and NREM sleep following activation of Tac2-BNST neurons, relative to viral controls. Anterograde tracing revealed greater Tac2-BNST innervation of the lateral hypothalamus (LH) in male mice compared to females, providing a potential circuit basis for sex differences in emotional and thermoregulatory influences on sleep/wake.
Conclusion: Overall, these studies add to our understanding of sex differences in hormonal influences on sleep and will advance the development of therapeutic strategies for treating disorders of stress and sleep by manipulating the Tac2/NKB system.

THE SPACE-TIME ORGANIZATION OF SLEEP SLOW OSCILLATIONS AS POTENTIAL BIOMARKER FOR HYPERSOMNOLENCE

Mahmoud Alipour[1], Chelsea Cadle[2], Joseph Rausch[2], Sara Mednick[3], Jesse Cook[4], David Plante[5], Paola Malerba[2]

[1] University of Chicago, [2] Nationwide Children's Hospital, [3] University of California, Irvine, [4] University of Wisconsin-Madison, School of Medicine and Public Health, Department of Psychiatry, [5] University of Wisconsin–Madison

Introduction: Research suggests that spatial organization of slow wave activity (SWA) could be altered in hypersomnolence. Slow oscillations (SOs; 0.5-1.5 Hz), single waveform events contributing to SWA, can be labeled as Global, Frontal, or Local depending on their presentation on the scalp. We showed that SO types differentiate in amplitudes, coordination with sleep spindles, and propagation patterns. This study applies our data-driven analysis to the sleep of adults with and without hypersomnolence (HYP) and major depressive disorder (MDD), to explore the potential relevance of SO space-time patterns as HYP signatures in the sleep EEG.
Methods: We leverage an existing dataset of nocturnal polysomnography with high-density EEG in 83 adults, organized in four groups depending on presence/absence of HYP (coded as HYP+/-) and on presence/absence of major depressive disorder (coded as MDD+/-). We detect SOs separately in each of the 173 EEG channels overlaying the scalp and group co-detections at a fixed delay (±400 ms) with k-means clustering to label each SO as Global, Local or Frontal. We compute the percentage of each SO type for each participant as fraction of the total SO count for the night. We identify six scalp regions (frontal, central, parietal, occipital, left and right temporal) to average amplitude of SOs of each type. Group comparisons of SO percentages and SO amplitudes were conducted considering either two groups (presence/absence of HYP, combining two groups in each) or the four groups separately, using general linear models as analyses of variance.
Results: Our data shows more Frontal SOs and reduced Global SO amplitude at centro-parietal regions in HYP+MDD- compared with controls. As Global SOs are known to travel fronto-parietally, we interpret these results as related to loss of coordination of Global SO activity in hypersomnolence without depression, resulting in an overabundance of Frontal SOs.
Conclusion: This study suggests that Frontal and Global SOs may differentiate individuals with hypersomnolence and without depression, and that the space-time organization of SOs could be a mechanistically relevant indicator of changes in sleep brain dynamics related to hypersomnolence.

A FEATURE-DRIVEN CLASSIFICATION METHOD TO IDENTIFY SPACE-TIME PROFILES OF SLOW OSCILLATIONS IN LOW DENSITY EEG

Jeffrey Gaither[1], Paola Malerba[1]

[1] Nationwide Children's Hospital

Introduction: Sleep slow oscillations (SOs, 0.5-1.5Hz) in the EEG reflect highly synchronous cortical large travelling waves, tied to cortical neurodevelopment, and thought to reflect sleep homeostasis, as well as support memory stabilization, in particular through their coordination with other sleep rhythms. Objective, data-driven description of the spatio-temporal organization of SOs on the EEG manifold is relevant to investigations

on their functional role in cognition and health. Earlier work by our group has introduced a data-driven approach showing that SOs organize on the electrode manifold as Global, Frontal and Local SOs, based on their co-detection at multiple electrodes within a short delay. However, our current approach requires at least 24 head electrodes, preventing its applicability in standard diagnostic polysomnography and at-home studies. We here introduce a deterministic method that identifies space-time profiles of SO types in low density EEG.
Methods: We use >200 waveform features spanning amplitude, phase, and signal complexity. We use a training set (22 individuals, 64 EEG channels) and validation set (34 individuals, 32 EEG channels). Timing of SO events was used to extract activity at 8 EEG channels: F3/4, C3/4, P3/4, O1/2. Machine learning classifiers (xgboost in python) were trained on progressively fewer channels, in 4 conditions: FCPO, FCP, FC and F channels. A version of the model using restricted features was also tested. Model performance was quantified with accuracy and log-loss. Feature role in SO type prediction was studied with SHAP feature-importance.
Results: We introduce a portable SO classifier trained on data recorded from eight or less head EEG channels. Our model recovers an SO's class with accuracy around 75%, and log-loss below 0.6, with performance consistent across the three types. Loss of accuracy in validation was small for all cases except the F channels (only 2 electrodes). Feature importance showed that Global and Frontal SOs are characterized by central and frontal activity, respectively.
Conclusion: These portable simplified SO classification models expand the domain in which the space-time dynamics of sleep oscillations can be used to discover biomarkers and propose target for interventions in clinical populations.

GENOTYPE-PHENOTYPE CORRELATION FOR SLEEP PATTERNS IN THE CRI DU CHAT SYNDROME

Anna Kloster[1], Mariana Moyses-oliveira[2], Lais A. Souza-Cunha[3], Amanda Mosini[2], Bianca Balbueno[2], Manuella Almada[2], Sandra Doria Xavier[2], Monica Andersen[3], Sergio Tufik[3]
[1] Universidade Federal de São Paulo, [2] Sleep Institute, Associação Fundo de Incentivo à Pesquisa, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Cri du Chat Syndrome (CDCS) is a rare genetic disorder affecting 1 in 50,000 live births. It results from deletions in the short arm of chromosome 5 (5p), with most deletion sizes varying between 5 and 40Mb. CDCS is characterized by distinct physical features, neurodevelopmental disorders, including autism spectrum disorder, and behavioral and sleep disturbances. However, there has been limited research on the relationship between 5p deletions and sleep problems. This study aimed to detail sleep disturbances that are more frequent in CDCS patients than in neurotypical individuals and establish genotype-phenotype correlations.
Methods: Individuals with CDCS were molecularly genotyped with fine chromosomal breakpoint definition, allowing detailed genotype-phenotype analysis. In our study, 8 individuals with CDCS aged 1–31 years were compared with 8 neurotypical age- and sex-matched controls. Sleep problems were assessed using the Sleep Disturbance Scale for Children (SDSC), and correlations between deletion size and sleep disturbances were analyzed. Within the 5p segment commonly deleted in CDCS, 3 genes have been associated with sleep-related traits: SLC6A3, ADCY2 and TERT. We identified which of the patients had these genes deleted and correlated them with their sleep patterns.
Results: The results revealed that sleep problems, such as difficulty falling asleep, nighttime awakenings, and rhythmic movements, were more common in the CDCS group when compared to the neurotypical group. However, there was no significant correlation between the size of the deletion and the severity of sleep problems. In 4 patients, the 3 sleep-related genes (SLC6A3, ADCY2, and TERT) were deleted in 5p, and only 1 individual with CDCS had none of the genes in monosomy. Associations between the genome dosage of these 3 genes and sleep patterns in CDCS individuals were not observed.
Conclusion: These findings underscore the critical role of sleep in neurodevelopment and the impact of disrupted sleep on daily functioning. While CDCS patients exhibit higher rates of sleep disturbances than neurotypical individuals, these issues are not directly linked to deletion sizes. Further research is needed to understand the genetic and biological mechanisms underlying sleep problems in CDCS and improve care strategies for affected individuals.

PRE-SLEEP INORGANIC NITRATE USE AND SLEEP QUALITY: A PILOT STUDY

Joshua Bock[1], Vinyas Shraffi Venkatesh[1], Ian Greenlund[1], Chieko Allgauer[1], Gianna Migliaccio[1], Garret Rounds[1], Erik StLouis[1], Virend Somers[1]
[1] Mayo Clinic

Introduction: Poor sleep quality is bidirectionally associated with cardiovascular and neurocognitive disorders. Preclinical data implicate nitric oxide (NO) in the onset, and maintenance, of sleep. Acute inorganic nitrate supplementation increases NO bioavailability via serial reduction for >12hrs. We tested if objective (Aim 1) or subjective (Aim 2) sleep quality was better following acute, pre-sleep nitrate supplementation relative to a placebo.
Methods: Seven non-shift working adults (4F/3M, 40±8yrs, 25.8±1.6kg/m2) with no history of sleep, cardiovascular, or neurocognitive disorders completed three overnight polysomnography (PSG) visits with time in bed standardized to 2200-0600hrs. Visit 1 was for acclimation and screening for sleep-disordered breathing. On Visits 2 and 3, participants consumed beetroot juice containing (6.45mmol) or devoid of (0mmol) inorganic nitrate at 2200 using a randomized, cross-over study design. PSG-derived outcomes included slow-wave (SWS) and rapid eye-movement (REM) sleep, sleep efficiency, and wake after sleep onset (WASO). Subjective sleep quality assessments were administered in-laboratory including a 0-10 scale, the Stanford Sleepiness Scale (SSS), and performance with mental arithmetic shortly after awakening.
Results: No participant demonstrated evidence for sleep-disordered breathing (apnea-hypopnea index = 1.7±0.9events/hr). Total sleep time (TST, 434±17 vs. 412±19min), sleep efficiency (89±3 vs. 85±4%), as well as SWS duration (75±10 vs.

66±9min) and percent of TST (17±2 vs. 16±2%) were higher after nitrate relative to the placebo (p< 0.05 for all). WASO (47±16 vs. 62±19min, p< 0.05) was lower after nitrate versus placebo and no differences were seen in REM sleep duration (131±23 vs. 117±12min, p=0.45) nor percent of TST (30±5 vs. 29±3%, p=0.80). Neither the 0-10 scale (6.7±0.5 vs. 6.8±0.6units, p=0.84), SSS (2.6±0.4 vs. 2.5±0.3units, p=0.68), or arithmetic performance (82±3 vs. 81±5% correct, p=0.85) differed post-nitrate compared to post-placebo.
Conclusion: These data suggest that acutely increasing nocturnal NO levels via pre-sleep inorganic nitrate supplementation improves objective indices of sleep quality in healthy adults. However, greater amounts of nitrate or prolonged supplementation (weeks) may be needed to improve perceived sleep quality.

IMPACT OF CANNABIS FREQUENCY, POTENCY, AND STRAINS ON SLEEP IN THE HERBAL HEART STUDY: INVESTIGATING LINKS TO DIFFICULTY FALLING AND STAYING ASLEEP

Bria-Necole Diggs[1], Amrit Baral[1], Ranya Marrakchi El Fellah[2], Kylee Krivijanski[2], Girardin Jean-Louis[1], Denise Vidot[2]
[1] University of Miami Miller School of Medicine, [2] School of Nursing and Health Studies, University of Miami

Introduction: Evidence suggests that cannabis may impact sleep. The objective of this study is to examine the pattern of specific cannabis consumption characteristics, including frequency of usage, potency/grade and strain, by self-reported sleep difficulties in a cohort of young adult cannabis consumers (CB+).
Methods: The study draws on data from the ongoing Herbal Heart Study (N=200), which examines the impact of cannabis use on subclinical cardiovascular risk among 18-to-35-year-olds in South Florida. Cannabis potency/grade and strain were self-reported via the Cannabis Potency Questionnaire; cannabis use frequency was assessed using the Drug Use History Questionnaire. Difficulty falling asleep and difficulty staying asleep was self-reported via the Medical History Questionnaire. "Poor sleep", a composite, binary variable, was created for individuals who reported experiencing at least one sleep difficulty. Chi-Square/Fisher's Exact tests were conducted where appropriate.
Results: The analytic sample of CB+ (n=126) had an average age of 25.8 years (SD=4.8), 57.1% were female, and 60.3% Hispanic. Among CB+, 24.6% reported difficulty falling asleep and 20.6% reported difficulty staying asleep. Among those with difficulty falling asleep, the majority (77.4%) consumed cannabis more than 20 times a month while 16.1% consumed 10-20 days. Twenty-six percent of participants with a high frequency of cannabis use experienced difficulty staying asleep, compared to 0% of low frequency and 5.3% of moderate-frequency cannabis use (p=0.01). Almost half of the low-to-moderate-grade consumers reported poor sleep (47.4%), compared to 18.2% of high-grade consumers who reported experiencing poor sleep (p=0.04). A greater proportion of respondents consuming indica strain of cannabis (40.0%) reported experiencing overall poor sleep, compared to 28.1% of hybrid consumers and 27.3% of sativa consumers experiencing poor sleep.
Conclusion: Findings suggest a complex relationship between cannabis use patterns, strain types, and sleep difficulties, highlighting the potential for certain consumption behaviors to exacerbate or alleviate poor sleep outcomes. Understanding these associations is critical as cannabis use becomes increasingly normalized, and individuals seek tailored options for sleep support.

NORADRENERGIC MODULATION CONTROLS CEREBRAL HEMODYNAMICS DURING SLEEP

Michael Wenke[1], Md Shakhawat Hossain[1], Patrick Drew[1]
[1] The Pennsylvania State University

Introduction: Cortical arteries undergo coordinated dilations and constrictions during non-rapid eye movement (NREM) sleep that can drive the circulation of cerebrospinal fluid (CSF). CSF flow is thought to stimulate glymphatic clearance and remove metabolic waste, but the drivers of arterial dynamics during sleep remain poorly understood. We explored how norepinephrine (NE), a vasoconstrictor and arousal promoting neuromodulator, could control arterial dynamics during NREM sleep in mice.
Methods: We used two-photon microscopy and fiber photometry to simultaneously measure cortical NE levels and vascular dynamics in head-fixed mice during sleep. NE was measured using a virally expressed GPCR activation-based NE sensor (GRABNE-2m). Blood plasma was visualized with fluorescent albumin (Alb.mScarlet) and intravascular injections of tetramethylrhodamine-isothiocyanate (TRITC). Sleep state was monitored and classified using electrocorticography, electromyography, pupillometry, and behavioral tracking.
Results: We found norepinephrine (NE) levels in the somatosensory cortex were highest during wakefulness, decreased during NREM, and were lowest during rapid eye movement (REM) sleep. Arteriole diameter and blood volume increased during NREM with pulsations consistent with periarterial pumping and was highest during REM sleep. Immediately prior to arousal from sleep, local NE levels rapidly increased back to waking baseline levels, followed by vasoconstriction. To determine if NE release is sufficient to produce these hemodynamic changes at arousal events, we optogenetically stimulated the locus coeruleus (LC) of transgenic mice (TH-cre+ and DBH-cre+) expressing a cre-dependent channelrhodopsin (ChR2) in noradrenergic neurons. Fiber photometry recordings showed that optogenetic stimulation of the LC triggered NE increases and causes vasoconstrictions analogous to those in natural awakening events. Pharmacologic inhibition of NE receptors attenuated vasoconstriction seen during optogenetic stimulation.
Conclusion: Together these experiments suggest that NE signaling is a key driver of the hemodynamic changes seen throughout NREM sleep and at arousal events. Knowledge of the underlying mechanism governing CSF movement and glymphatic clearance during sleep can inform the development of NE-modulating therapies to improve waste clearance and slow neurodegeneration in patients with neurological disorders.

PHARMACOGENETIC EFFECTS OF MODAFINIL AND CAFFEINE DURING SLEEP DEPRIVATION: DIFFERENTIAL INFLUENCE OF DAT1 GENOTYPE

Rachael Muck[1], Kimberly Honn[1], Brieann Satterfield[1], Kirsie Lundholm[1], Jonathan Wisor[1], Hans Van Dongen[1]
[1] Washington State University

Introduction: Striatal dopaminergic and adenosinergic signaling mechanisms are believed to mediate neurobehavioral impairment during total sleep deprivation (TSD). A variable number tandem-repeat polymorphism in the dopamine transporter gene (DAT1) modulates striatal dopamine and trait vulnerability to TSD. However, trait vulnerability to TSD is task-dependent. We conducted a pharmacogenetic study to investigate the role of striatal dopaminergic circuits in mediating TSD-induced impairment on distinct neurobehavioral tasks.
Methods: N=73 healthy adults (ages 25.2±5.2y; 39 males) completed a double-blind, in-laboratory TSD study. After a 10h sleep opportunity, subjects underwent 38h TSD and were randomly assigned to a drug condition. At 4h intervals from 17h to 29h awake (01:00, 05:00, 09:00, and 13:00), they received caffeine (200mg/dose; n=26), modafinil (alternating 200mg and 0mg doses; n=25), or placebo (n=22). At ~2h intervals throughout TSD, a 10min Psychomotor Vigilance Test (PVT), 4min Digit Symbol Substitution Task (DSST), and Karolinska Sleepiness Scale (KSS) were administered to measure vigilant attention, associative learning, and subjective sleepiness, respectively. PVT log-transformed signal-to-noise ratio (LSNR), DSST number correct, and KSS ratings were expressed relative to well-rested baseline (11:30–20:00 average) and analyzed using mixed-effects regression.
Results: There were 44 DAT1 10-repeat (10R) allele homozygotes and 29 DAT1 9-repeat (9R) allele carriers, with 16/16/12 (10R/10R) and 10/9/10 (9R) subjects in the caffeine/modafinil/placebo conditions. DAT1 genotype modulated PVT performance in the placebo ($F[1,67]=5.92$, $p=0.018$) and caffeine ($F[1,67]=5.26$, $p=0.025$) conditions, whereas it modulated DSST performance in the modafinil ($F[1,67]=13.16$, $p< 0.001$) and placebo ($F[1,67]=5.71$, $p=0.020$) conditions, with the 10R homozygotes exhibiting less impairment. DAT1 genotype also modulated KSS ratings in the caffeine condition ($F[1,67]=5.53$, $p=0.024$), but the 10R homozygotes reported greater sleepiness.
Conclusion: DAT1 genotype modulated neurobehavioral impairment during TSD in a task-dependent and drug-dependent manner, indicating distinct underlying mechanisms. Our results corroborate earlier findings that TSD-induced deficits in vigilant attention are dissociable from those in associative learning, and both are dissociable from subjective sleepiness. The observed genotype by drug interaction corroborates modafinil's purported dopaminergic mechanism of action. Our findings are consistent with a role for integrated dopaminergic and adenosinergic signaling mechanisms of the striatal indirect pathway in modulating some, but not all, aspects of sleep-deprived neurobehavioral functioning.

NREM SLEEP OSCILLATIONS ARE ALTERED IN YOUNG ADULTS WITH HEIGHTENED TRAIT ANXIETY

Hazal Arpaci[1], Nandita Banik[1], Pinar Kurdoglu Ersoy[2], Ciara Harrington[1], Aycan kapucu[2], Bengi Baran[3]
[1] University of Iowa, [2] Ege University, [3] The University of Iowa

Introduction: NREM oscillations play a critical role in memory consolidation, yet their role in sleep-dependent processing of affect and anxiety symptoms remains poorly understood. The present study examines the links between NREM oscillations, emotional memory, anxiety symptoms, and negative affect and investigates whether NREM oscillations are altered in individuals with elevated trait anxiety.
Methods: Forty-two non-help-seeking young adults (M = 19.3, SD = 1.8 years; 77% female), with high (n = 26) vs moderate-to-low (n = 16) levels of trait anxiety symptoms were monitored during a 2 hr mid-day nap opportunity. Sleep-dependent consolidation of emotional memory was tested during this interval. Upon awakening, participants completed the State-Trait Anxiety Inventory (STAI) and Positive and Negative Affect Schedule (PANAS). Sleep spindles and slow oscillations (SO) during N2 and N3 sleep were characterized with automated detectors.
Results: In the entire sample, increased SO activity was associated with reduced negative affect (tsum=-17.41, pcorrected=.045, 7 electrodes) and state anxiety (tsum=-18.74, pcorrected=.046, 7 electrodes), while spindle activity correlated with higher levels of negative affect (tsum=31.57, pcorrected=.02, 13 electrodes) and state anxiety (tsum=31.23, pcorrected=.03, 13 electrodes). The High Anxiety group exhibited reduced SO activity (tsum=-30.29, pcorrected =.04, 6 electrodes) and delta power (tsum=-49.31, pcorrected=.04, 21 electrodes), with no differences in sleep architecture. No group differences were observed in sleep-dependent memory consolidation.
Conclusion: We demonstrated that SO activity is altered in young adults with heightened trait anxiety and is associated with reduced anxiety and negative affect in the entire sample, identifying a putative anxiolytic function. These findings suggest that NREM oscillations may be a novel target for interventions aimed at reducing anxiety.

IMPACT OF INSUFFICIENT SLEEP ON BIOMARKERS OF NEURODEGENERATION AND NEUROINFLAMMATION IN HEALTHY ADULTS

Erin Kishman[1], Brice McConnell[2], Corey Rynders[1], Lauren Smith[1], Christina Coughlan[2], Adriana Solano[2], Kenneth Wright[3], Josiane Broussard[1]
[1] Colorado State University, [2] University of Colorado Anschutz Medical Campus, [3] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA

Introduction: Sleep disturbances are common among individuals with neurodegenerative diseases including Alzheimer's Disease (AD). Furthermore, sleep disturbances are associated with accelerated cognitive decline and an increased risk of developing AD. Here we examined the impact of four nights of insufficient sleep on biomarkers of neurodegeneration in healthy adults. We hypothesized that insufficient sleep would increase circulating concentrations of markers of neurodegeneration and neuroinflammation including glial fibrillary acidic protein (GFAP), neurofilament light chain (NfL), tau protein, and ubiquitin carboxy-terminal hydrolase 1 (UCHL1).
Methods: Eighteen healthy adults (8 females/10 males) with a mean age of 25±3 years and a mean BMI of 22.7±1.8 kg/m2 participated in a 6-day inpatient study. The protocol consisted of one 9-hour sleep opportunity, followed by four consecutive nights of 5-hour sleep opportunities, and one night of recovery sleep. Fasting blood samples were drawn in the morning, one hour after waking following the initial 9-hour sleep opportunity (baseline), and after the fourth night of insufficient sleep. Samples were analyzed by the Quanterix single molecule array SR-X Analyzer. Single-tailed paired t-tests were performed for a priori hypotheses. Two-tailed t-tests explored potential sex differences. Results are reported as mean±SD.
Results: Participants averaged 7.9±0.8 hours of actigraphy recorded sleep at baseline and 4.5±0.3 hours during insufficient sleep. Baseline concentrations of each biomarker were as follows: GFAP 36.0±12.2, pg/mL; NfL, 4.4±2.0 pg/mL; tau protein, 1.7±0.6 pg/mL; and UCHL1, 17.2±12.5 pg/ml. Compared to baseline, four nights of insufficient sleep resulted in a 18±36% increase in GFAP (p=0.03) and a 13±23% increase in NfL (p=0.03), while tau protein and UCHL1 remained unchanged. No sex differences were detected in the biomarker responses to insufficient sleep.
Conclusion: Four nights of insufficient sleep led to increases in GFAP and NfL, which are markers of brain injury and inflammation and are elevated in AD. These findings highlight the importance of adequate sleep duration and provide a potential mechanistic link between sleep disruption and the development neurodegenerative conditions.

PAIN PHENOTYPING IN PATIENTS WITH CHRONIC INSOMNIA

Nasreen Akhtar[1], Ananya Dwivedi[1], Renu Bhatia[1]
[1] All India Institute of Medical Sciences, New Delhi

Introduction: Sleep plays a pivotal role in the central nervous system's ability to process and integrate sensory information. Disruptions in sleep architecture, such as those seen in insomnia, can impair nociceptive processing and alter sensory perception, thereby influencing pain modulation. Quantitative Sensory Testing (QST) provides a standardized methodology for assessing sensory processing and pain phenotyping by measuring thresholds for detecting and tolerating thermal stimuli, which are often dysregulated in insomnia.
Methods: This observational study includes 6 patients diagnosed with chronic insomnia and 6 age- and sex-matched healthy controls. The parameters evaluated using QST were: warm detection threshold, cold detection threshold, hot pain threshold, cold pain threshold, hot pain tolerance threshold, and cold pain tolerance threshold (°C).
Results: Patients with insomnia demonstrated significantly higher warm detection thresholds (p=0.0008) and cold detection thresholds (p=0.02) compared to controls. The mean hot pain threshold in insomnia patients was 43.73°C, significantly higher than 38.54°C in controls (p=0.0012). Similarly, cold pain thresholds were elevated in insomnia patients (p=0.002). Cold pain tolerance thresholds were markedly higher in the insomnia cohort (p=0.0001). However, no statistically significant difference was observed in hot pain tolerance thresholds between the two groups.
Conclusion: The findings indicate attenuated sensory responsiveness in individuals with insomnia. Chronic insomnia is associated with dysregulation of the central pain modulation systems, particularly within the descending inhibitory pathways originating in the brainstem and modulated by the periaqueductal gray (PAG) and rostroventromedial medulla (RVM). Insomnia may impair the release of endogenous opioids and neurotransmitters like serotonin and norepinephrine, reducing the efficiency of descending pain inhibition and altering thermal pain thresholds.

CHANGES IN NETWORK CRITICALITY AND DIRECTED FUNCTIONAL CONNECTIVITY AS SLEEP PROGRESSES: INSIGHTS INTO THE RESTORATIVE FUNCTIONS OF SLEEP

Maya de Sulzer Wart[1], Hanieh Bazregarzadeh[1], Antonio Martin[1], Hélène Blais[1], Charles Gervais[1], Rosalie Girard Pepin[1], Julie Carrier[1], Jean-Marc Lina[1], Nadia Gosselin[1], Catherine Duclos[1]
[1] Hôpital du Sacré-Coeur de Montréal

Introduction: Sleep plays a crucial role in restoring the brain's functions and preparing it for the cognitive demands of the next day. However, little is known about how the brain's functional dynamics support these functions. This study aims to investigate how network criticality and directed functional connectivity changes as sleep progresses across the night.
Methods: We recorded overnight polysomnography using 256-channel electroencephalography (EEG) in 16 adults (50.2±19.1 years, 6 females). We extracted the first and last episodes of each sleep stage (N=86), as well as wakefulness before and after the sleep episode (N=32), with a minimal duration of 3.5 minutes. To assess criticality, we calculated chaoticity, proximity to edge-of-chaos criticality (PECC), the pair correlation function (PCF), and Lempel-Ziv complexity (LZC). Additionally, the directed phase lag index (dPLI) was used to calculate the feedback dominance index (FDI) in the alpha frequency band (8-13 Hz). Two-way repeated measures ANOVAs, with post-hoc tests using Tukey's correction, were used to compare sleep-wake stages and timing (first vs. last episode).
Results: Across all sleep and wakefulness stages, PCF showed higher values in the later episodes than in the earlier ones (p<

0.001). LZC showed similar results, with later episodes having higher complexity than earlier ones across all states (p< 0.01). Finally, FDI was higher towards the end of the night compared to the beginning across all states (p< 0.05), but only for the left hemisphere. Chaoticity and PECC showed no significant changes between first and last episodes.
Conclusion: These findings suggest that sleep may lead to a gradual restoration of criticality, complexity and feedback-dominant connectivity as the night progresses. The increase of PCF suggests that the brain's activity moves closer to a critical point, and the higher LZC indicates more complexity in later episodes, both pointing to more optimal information processing, adaptability, and computational efficiency. Finally, the increase of FDI suggests that sleep restores anterior-to-posterior information flow as the night advances, potentially supporting the reintegration of distributed neural networks necessary for cognitive functioning and consciousness upon awakening.

RELATIONSHIP OF AUDITORY HYPEREXCITABILITY AND SLEEP EFFICIENCY IN CHILDREN WITH AUTISM SPECTRUM DISORDER

Maayan Yakir[1], Judy Mahmalji[2], Adriana Rios[2], Meagan Herrera[2], Michaela Cordova[2], Alexandra Boxberger[2], Sabrena Tuy[2], Rakesh Bhattacharjee[3], Inna Fishman[2], Annika Linke[2]
[1] University of California San Diego, [2] San Diego State University, [3] University of California, San Diego

Introduction: Sleep problems are common in Autism Spectrum Disorder (ASD), affecting up to 80% of this population. Previous studies have shown associations between sensory hypersensitivity and sleep disturbances in ASD but the potential mechanisms underlying this link are not well defined. Our study tests the hypothesis that altered auditory cortex excitation/inhibition (E/I) balance can explain sleep disturbances in children with ASD.
Methods: Typically developing (TD) children and those with ASD were enrolled in a multi-modal neuroimaging study assessing sleep and neurobehavior. The Hurst Exponent was derived from functional magnetic resonance imaging (fMRI; 12 minutes, TR=1125ms) as a proxy of E/I ratio for the bilateral primary auditory cortex. Sleep quality was assessed using actigraphy in the two weeks preceding the MRI scan. ANCOVA was used to analyze relationships between sleep measures and Hurst exponent, controlling for fMRI quality (in-scanner motion) and age. The results are preliminary as enrollment is ongoing.
Results: Data from 42 participants was included (TD n=25, ASD n=17; 6-11 years, mean=8, SD=1.7). The ASD and TD groups did not significantly differ on age, sex, actigraphy adherence (mean=11±2.8 days) or fMRI quality. Compared to TD participants, actigraphy in children with ASD showed increased sleep onset latency, decreased total sleep time and decreased sleep efficiency (all p< 0.05). The Hurst Exponent was lower in ASD participants, in comparison to TD children, in both left and right auditory cortices (p< 0.05), suggestive of increased excitability. Lower Hurst Exponent in right auditory cortex was associated with lower sleep efficiency (p< 0.05) and increased wake after sleep onset (WASO, p=0.051), in all children, independent of their diagnosis. A similar trend was observed in the left auditory cortex in association with sleep efficiency (p=0.054).
Conclusion: Using objective measures, our data shows correlation between altered excitability of auditory cortex with sleep efficiency and WASO. While this relationship appears to be independent of an ASD diagnosis, we note that children with ASD are disproportionately affected by hypersensitivity to sounds. Our results suggest that this may contribute to disrupted sleep in children with autism.

MULTIDIMENSIONAL SLEEP HEALTH AND ITS ASSOCIATIONS WITH HIPPOCAMPAL VOLUME IN MIDDLE-AGE AND OLDER ADULTS

Kristin Calfee[1], Soomi Lee[1]
[1] The Pennsylvania State University

Introduction: The hippocampus is a subcortical brain structure that is known to play a key role in sleep and the consolidation of memories during sleep. Evidence to support that chronic sleep disruptions may hinder neurogenesis and cell proliferation in the adult hippocampus have been found in both human and animal models. Although this suggests that the hippocampus may be structurally sensitive to poor sleep in adulthood, few studies use a multidimensional approach to sleep health incorporating objectively measured characteristics. This study examined the cross-sectional relationship between hippocampal volume and multidimensional sleep health.
Methods: The current study used a sample of 108 adults (Mage = 47) from the Refresher sample of the Midlife in the United States (MIDUS) study's Neuroscience and Biomarker subprojects to investigate the relationship between bilateral hippocampus volume and a composite measure of sleep health using the Ru-SATED (regularity, satisfaction, alertness, timing, efficiency, and duration) dimensions. We used two sleep health composite scores: one calculated based only on self-reported sleep measures and the other one calculated based on the combination of both actigraphy and self-reported sleep measures.
Results: Higher self-reported sleep health composite score (indicating better sleep) was associated with greater hippocampal volume even after adjusting for total intracranial volume, sociodemographic covariates, depression, and time between survey data and neuroimaging (B = -.18, SE =.08, p =.04). These results did not reach significance, however, when using the sleep health composite score comprised of a combination of self-reported and Actigraphy-recorded sleep dimensions (B = -.09, SE =.08, p =.26).
Conclusion: These findings suggest that although there may be a link between sleep health and hippocampal volume, further investigation is needed with larger samples and samples with more diverse sleep health phenotypes as the MIDUS sample had relatively good self-reported and actigraphy-measured sleep health on average. Longitudinal studies are also needed to determine possible causation and directionality of this relationship, which may provide a foundation for investigating possible mechanisms such as lifestyle factors and inflammation.

INFLAMMATORY BIOMARKERS AND SLEEP: INSIGHTS INTO NEURODEGENERATION AND ALZHEIMER'S DISEASE IN DIVERSE POPULATIONS

Carla Gibbs[1], Sadeaqua Scott[1], April Rogers[2], Tatjana Rundek[3], Girardin Jean-Louis[3]

[1] University of Miami, [2] St. John's University, [3] University of Miami Miller School of Medicine

Introduction: Sleep plays a vital role in maintaining brain health, supporting critical functions such as memory, toxin clearance, and neural repair. Sleep disruption increases the risk of Alzheimer's disease (AD) and aging-related dementias. Neuroinflammation, driven by dysregulated sleep and aging, has emerged as a key contributor to AD pathology. Understanding specific inflammatory biomarkers, such as FKBP5, NRSF, IL-6, and TNF-α, in diverse populations may aid early diagnosis and intervention. We hypothesize that changes in the expression of these biomarkers are associated with aging and AD progression, providing insights into neuroinflammation and cognitive decline, particularly with sleep disturbances.

Methods: This study analyzed gene expression in frontal cortical regions of brain samples from individuals aged < 40 to 106 years, using publicly available data (GSE53890). Groups included young (< 40 years), middle-aged (40–70 years), normal-aged (70–94 years), extremely aged (95–106 years), and AD patients. We applied the Hallmark Inflammatory Response and Peptidyl Proline Modification Gene Sets to identify 292 inflammatory gene markers relevant to neuroinflammation. Biomarkers of inflammation (FKBP5, NRSF, IL-6, and TNF-α) were evaluated for their association with aging and AD. Linear regression and Spearman correlation analyses were conducted using GraphPad Prism to examine biomarker expression patterns.

Results: We analyzed gene expression patterns and identified significant changes in FKBP5, NRSF, IL-6, and TNF-α with aging and AD progression. FKBP5 expression was elevated in non-AD aging individuals (R^2=0.5448), consistent with its role in inflammation regulation. NRSF expression remained stable with normal aging (R^2=0.2793). Cytokine markers IL-6 and TNF-α were linked to advanced disease stages, suggesting their utility in tracking AD progression.

Conclusion: These findings underscore the potential of inflammatory biomarkers such as FKBP5, NRSF, IL-6, and TNF-α to enhance our understanding of aging and Alzheimer's disease (AD) pathology. Our lab is actively conducting NIH-funded studies to further investigate these and other inflammatory markers within the context of sleep disturbances and AD risk. This research seeks to unravel the mechanisms underlying neuroinflammation and cognitive decline, with a particular focus on underrepresented Black and Latin-American populations, to promote health equity and inform the development of targeted interventions aimed at reducing AD risk.

REM ALPHA BURSTS PREDICT HIPPOCAMPAL-DEPENDENT FORGETTING

Alessandra Shuster[1], Elizabeth McDevitt[2], Sara Mednick[1]
[1] University of California, Irvine, [2] Princeton University

Introduction: Recent research has identified mechanisms in REM sleep involved in hippocampal-dependent memory consolidation, specifically with forgetting, and implicated REM alpha bursts in these processes. Additionally, REM sleep rescues non-hippocampal memories weakened by interference, although it is unclear if this also applies to hippocampal memories. We investigated whether REM alpha burst activity impacted forgetting differentially for weak vs. strong hippocampal memories, with the prediction that greater burst activity would predict more forgetting for strong memories.
Methods: We utilized a validated burst detection algorithm to identify alpha bursts (8-13 Hz) during overnight REM sleep in young adults (n = 24, 18 – 35 years). Before and after sleep, participants completed a Face-Name Association (FNA) task, with interference introduced via an AB-AC paradigm to a proportion of the face-name pairs prior to sleep. Accuracy was measured pre-sleep, post-sleep, and for the overnight difference (post-sleep - pre-sleep). We correlated REM alpha burst power and performance for weak (pairs with interference) and strong (pairs without interference) memories.
Results: Participants exhibited forgetting overnight for both weak and strong memories ($p < .05$), with no difference in the extent of forgetting between the two ($p > .05$). REM alpha burst power predicted forgetting for strong memories ($p < .05$), with areas of significance concentrated in the posterior right hemisphere, a hemisphere involved in whole face processing. In contrast, no significant association was found between REM alpha burst power and weak memories ($p > .05$), or with any task performance metric pre-sleep or post-sleep ($p < .05$).
Conclusion: We demonstrate that REM alpha bursts impact strong and weak hippocampal-dependent memories differently, with increased burst activity predicting more forgetting for strong memories, but not weak. These results suggest that alpha bursts are involved in peak normalization during REM sleep, a process where strong and weak memories are leveled such that they are more equally available at retrieval.

CLOUDED COGNITIVE AWARENESS: THE ROLE OF SUBJECTIVE AND OBJECTIVE SLEEP IN OLDER ADULTS' AWARENESS OF COGNITIVE FUNCTIONING

Amy Costa[1], Christina McCrae[1], Ashley Curtis[1]
[1] University of South Florida

Introduction: Cognitive complaints are common in aging, but associations between them and cognitive functioning are inconclusive. Given relationships between sleep and cognition in aging, this study tested whether sleep (subjective and objective) characteristics moderated associations between objective and subjective cognition in older adults.
Methods: Older adults (N=108, Mage=68.6±5.8, 66 women; NCT04282642, AASM:256-FP-21, PI:Curtis) completed cognitive tasks [NIH Toolbox Pattern Comparison (processing speed), Auditory Verbal Learning (episodic memory), List Sort (working memory), Dimensional Change Card Sort (cognitive flexibility)], Cognitive Failures Questionnaire (CFQ-memory, CFQ-distractibility, CFQ-blunders subscores), and 2-weeks of sleep diaries. A subgroup of participants (N=65) completed polysomnography (Sleep Profiler-PSG2TM). Multiple regressions examined whether sleep [subjective/objective sleep onset latency (SOL), total sleep time (TST), sleep efficiency (SE)] moderated associations between objective cognition and cognitive complaints.
Results: Sleep (subjective SOL, TST, SE, objective TST) moderated associations between cognitive domains and cognitive complaints (R2-change's=.02-.04, p's=.01-.04). In those with shortest subjective SOL, worse processing speed was associated with more blunder complaints (B=.-.24, p=.02). In those with longest subjective SOL, worse episodic memory was associated with more distractibility complaints (B=-.49, p=.04). In those with longest TST, worse working memory was associated with more blunder complaints (B=-.96, p=.04). In those with lowest subjective SE, worse episodic memory was associated with less blunder complaints (B=.45, p=.04) and worse cognitive flexibility was associated with less memory complaints (B=1.69, p=.01). In those with highest subjective SE, worse episodic memory was associated with more blunder complaints (B=-.47, p=.04) and worse cognitive flexibility was associated with more memory complaints (B=-1.64, p=.01). In those with shortest objective TST, worse working memory was associated with less blunder complaints (B=1.20, p=.01), and worse cognitive flexibility was associated with less memory complaints (B=2.47, p=.04). In those with longest objective TST, worse cognitive flexibility was associated with more memory complaints (B=-.19, p=.04).
Conclusion: Overall patterns suggest, in older adults, worse sleep may exacerbate the discrepancy between subjective/objective cognition, while better sleep may converge them. Sleep should be considered when interpreting subjective reports versus neuropsychological/objective cognition.
Support (if any): This research was made possible by awards (PI:Curtis) from the American Academy of Sleep Medicine Foundation, a foundation of the American Academy of Sleep Medicine.

HOW DOES THE MENSTRUAL CYCLE AFFECT OVERNIGHT EMOTIONAL MEMORY CONSOLIDATION?

Allison Morehouse[1], Alessandra Shuster[1], Andres Pena[1], Jing Zhang[2], Ali Ekhlasi[1], Negin Sattari[1], Marie Gombert[3], Elisabet Alzueta[3], Fiona Baker[3], Katharine Simon[1], Sara Mednick[1]
[1] University of California, Irvine, [2] Harvard Medical School/ Massachusetts General Hospital, [3] SRI International

Introduction: Hormonal fluctuations across the menstrual cycle modulate sleep architecture and NREM sleep spindles (sigma activity: 12-15 Hz), but their role in sleep-dependent memory consolidation is unclear. Studies report that emotional memory consolidation is modulated by sleep spindles and estrogen, independently. Yet, their combined effects on memory remains unknown. To address this gap, we investigated how hormonal fluctuations (estrogen and progesterone) across the menstrual cycle affect spindle density and emotional memory consolidation.

Methods: Using a within-subject repeated measures design, fifty-eight healthy women (18–35yr), who were contraceptive-free and with regular menstrual cycles, were assessed in a sleep lab at four timepoints of their menstrual cycle, in random order: low hormones (menses), high estrogen (pre-ovulation), high estrogen and progesterone (mid-luteal), and falling hormones (late-luteal). Participants were tested on an Emotional Pictures Task (neutral and negative) with emotional reactivity (subjective valence and arousal) measured pre and post each night of in-lab sleep, with difference scores calculated and sex hormones measured at each visit. Linear mixed effects models were utilized with the high-estrogen phase (pre-ovulation) as the reference category.
Results: Menstrual phase status impacted emotional memory and reactivity. Compared to the high-estrogen phase, 1) pre-sleep memory (d') for neutral pictures was higher at mid-luteal (b=.199, p=.014); 2) arousal for negative images was reduced at menses post-sleep (b=-.377, p=.026) and for difference score (b=-.436, p=.012); and 3) d' difference score for neutral images was significantly reduced at mid-luteal (b=-.249, p=.038). Additionally, during the high-estrogen phase, there was a significantly different relation to memory (but not arousal) compared to other phases, with spindle density associated with fewer false alarms and greater d' for both negative and neutral images (all p's<.05).
Conclusion: During the high-estrogen phase, women showed less arousal for negative images and better memory for neutral images. Similarly, negative and neutral memory was significantly enhanced by spindles during the high-estrogen phase. Estrogen-related changes in sleep spindles may shift the female brain to be more emotionally resilient during the pre-ovulation phase.

RECOVERY SLEEP RESPIRATION PREDICTS MEMORY FOLLOWING SLEEP DEPRIVATION

Alisa Huskey[1], Kymberly Henderson-Arredondo[2], Jason Katz[2], Sydney Carpenter[2], Shelby Cantrell[2], A'mour Canty[2], Allie Jepson[1], Catherine Seader[2], Elizabeth Le[2], David Negelspach[1], William Killgore[1]
[1] The University of Arizona, [2] University of Arizona

Introduction: Respiratory activity modulates memory formation and reactivation during wakefulness and sleep, particularly during inhalation. Schreiner and colleagues found that slow-oscillation-spindle coupling most commonly occurs around inhalation peaks and predicts memory reactivation following a nap. Sleep deprivation increases respiratory rate, and impacts cortical pre-inspiratory motor potential amplitude and diaphragm activity. We hypothesized that inspiratory respiration during recovery sleep would have a more pronounced impact on memory the following day compared to baseline sleep.
Methods: Participants were healthy adults (i.e., 9 women; mean age = 23.6, range = 18-36yo) recruited for a 36-hour sleep deprivation period. Baseline and recovery sleep were monitored with polysomnography. Respiratory metrics were derived from chest and abdomen breathing effort belts: respiration rate, time-domain frequency, and amplitude change from onset to peak of inspiration and expiration. Memory was assessed in the morning following baseline and recovery sleep one to three hours after waking from 0830 to 1000 hours. The verbal-auditory memory module of the Repeatable Battery Assessment of Neuropsychological Status assessed immediate memory and delayed memory, comprising total memory percentile, all of which were outcome variables in linear regression analyses conducted using the lmer and parameters packages in RStudio. Predictors were respiration metrics. All variables were compared between baseline and recovery sleep using paired-samples t-tests.
Results: Lower frequency of inspiratory breaths during sleep predicted greater memory percentile following recovery sleep compared to baseline sleep (B=-5.47[CI:-11.61, 0.68], p=0.079). Similarly, lower inspiratory amplitude predicted greater delayed memory performance during recovery sleep compared to baseline (B=-0.03[CI:-0.06, 0], p=0.076). Respiration rate increased from baseline to recovery sleep (p=0.005), whereas immediate memory performance decreased (p=0.022). There were no other significant differences between baseline and recovery.
Conclusion: In line with previous research, we found that the inspiratory phase during recovery sleep predicts memory. Mechanisms by which inspiration improves memory are still under investigation. The inspiratory breath drives CSF flow, which may facilitate more efficient glymphatic clearance during sleep, leading to improved memory. Furthermore, Zelano and colleagues found that respiratory rhythms entrain hippocampal oscillations.

SLEEP VARIABILITY RELATES TO NEURAL OSCILLATIONS AND PREDICTS ATTENTION IN ALZHEIMER'S DISEASE

Maggie Rempe[1], Grant Garrison[2], Seth Springer[1], Ryan Glesinger[2], Hannah Okelberry[2], Aubrie Petts[2], Christine Embury[2], Craig Johnson[1], Pamela May-Weeks[1], Rachel Spooner[2], Tony Wilson[2]
[1] University of Nebraska Medical Center, [2] Boys Town National Research Hospital

Introduction: The importance of intra-individual sleep variability on pathology and cognition in Alzheimer's disease (AD) is increasingly recognized, but the impact of such variability on the neurophysiology underlying cognition is poorly understood.
Methods: Thirty-two participants on the AD spectrum (ADS; amyloid-PET positive and diagnosed with mild cognitive impairment or AD) and 34 cognitively-normal older adults were included in this analysis. Participants completed a neuropsychological battery from which attention domain scores were calculated, wore an actigraph, and completed a visual attention task during magnetoencephalography (MEG). Actigraph data with sleep diaries were cleaned, reconciled, and analyzed using the Cole-Kripke algorithm. To assess variability, the standard deviation of wake time (wake SD) was used. MEG data were transformed into the time-frequency domain and significant task-related oscillatory responses were imaged. Age, education, and sex were included in all analyses as nuisance covariates.
Results: Significant group interactions with wake SD were observed in theta activity in bilateral superior frontal gyri (SFG; p<.005) and alpha oscillations in the left middle frontal gyrus (p<.005). In the ADS group, we tested whether theta oscillations mediated the relationship between wake SD and attention scores, as measured by neuropsychological assessment, and found that

greater wake SD (p=.005) and greater left SFG theta (p=.038) predicted worse attention. Additionally, greater wake SD was predictive of weaker left SFG theta oscillations (p=.031). There was an indirect effect strongly approaching significance (95% CI:[-0.00, 0.02]), and a significant total effect (95% CI:[-0.03, 0.00]), such that greater wake time variability, concomitant with stronger left SFG theta power, resulted in worse attention performance.

Conclusion: These findings support the importance of sleep hygiene for patients with AD and help solidify sleep as an influential factor in the observed cognitive and neurophysiological outcomes of AD. Sleep health is a key modifiable risk factor and understanding its complex interactions with AD pathology and symptomatology has the potential to vastly benefit prevention, early detection, and help guide future therapeutic interventions.

SEX DIFFERENCES IN THE ASSOCIATION OF 24H MELATONIN AREA UNDER THE CURVE WITH COGNITIVE FUNCTION IN OLDER ADULTS

Matthew Lehrer[1], Robert Krafty[2], Meryl Butters[1], Daniel Buysse[3]

[1] University of Pittsburgh, [2] Emory University, [3] University of Pittsburgh School of Medicine

Introduction: Melatonin exhibits neuroprotective benefits in animals, and more circulating melatonin may be associated with better cognitive function in humans. Melatonin is responsive to circulating estradiol and may therefore be more relevant to cognitive function in females compared to males, especially during aging. However, methodological considerations including lack of rigorous melatonin collection and brief, insensitive cognitive measures limit the conclusions from previous investigations. We examined associations of 24h melatonin secretion with cognitive function and explored sex differences in these associations.

Methods: Participants were 29 cognitively unimpaired retired adults (13 females, 16 males; mean age: 68.4 +/-5.6 years). All participants completed an in-lab 24h circadian unmasking protocol (dim light, bedrest, time isolation, constant wakefulness) and a comprehensive neurocognitive battery an average of 6 months after the lab study. Saliva was sampled hourly during the lab protocol and assayed for melatonin. Area under the curve (AUC) was calculated using a spline-based smoothing model. The neurocognitive battery assessed attention, executive function, immediate and delayed recall memory, language, and visuospatial function. Regression analyses examined associations between melatonin AUC and cognitive domains and were adjusted for age and educational attainment.

Results: In the full sample, greater 24h melatonin AUC was associated with better immediate recall memory (beta =.40, p =.033), delayed recall memory (beta =.42, p =.022), and visuospatial function (beta =.56, p =.002). In females, greater melatonin AUC was associated with better immediate recall memory (beta =.72, p =.003), delayed recall memory (beta =.71, p =.020), and visuospatial function (beta =.67, p =.009). Associations were not statistically significant in males (ps >.36).

Conclusion: Greater melatonin may serve as a protective factor for cognitive function in older adults, particularly among females. Any cognitive benefits conferred by greater melatonin production may reflect circadian (e.g., robustness of the circadian timing system) and/or non-circadian (i.e., neurobiological benefits of melatonin as a hormone) properties. Follow up in a larger sample is warranted to confirm sex differences.

DECODING SPATIOTEMPORAL DYNAMICS OF SLEEP SPINDLES AND THEIR AGE-RELATED EFFECTS ON EMOTIONAL MEMORY CONSOLIDATION

Thea Ng[1], Lindsey Mooney[2], Irina Orlovsky[2], Morgan Barnes[3], Cassandra Delvey[3], Lena Gaudette[2], Karolina Rusin[2], Katrina Rodheim[3], Bethany Jones[2], Rebecca Spencer[2]

[1] Mount Holyoke College, [2] University of Massachusetts, Amherst, [3] University of Massachusetts Amherst

Introduction: Sleep spindles (SPs) play a pivotal role in sleep-dependent memory consolidation, yet their role in coordinating long-range communication of memory and how this function is altered by aging remain unclear. Our study examined spatiotemporal gradients of SP metrics as they propagate across the cortex, and quantified their relevance to memory consolidation mechanisms in young and older adults using computational modeling.

Methods: Healthy young adults (N=15, YA) and older adults (N=15, OA) completed immediate and delayed recall tasks for emotional recognition memory on both nap and wake days. High-density polysomnography and fMRI data were collected. Unequal variance signal detection (UVSDT) and drift-diffusion models (DDM) modeled the mechanism underlying memory consolidation. Multi-Gaussian curve fitting improved individual and topographical measurements in SP and slow oscillation (SO) peak frequencies and powers following irregular resampling auto-spectral analysis (IRASA). Traveling waves modeled spatiotemporal gradients in SP metrics (frequency, power, density, SO coupling), with memory relevances tested using mixed-effect models corrected for multiple comparisons.

Results: YA exhibited significantly better retention in drift rate v (memory evidence accumulation speed, delayed/immediate, paired ps< 0.001) and da (bias-adjusted detection accuracy, paired ps< 0.05) post-nap compared to wake day for both negative and neutral memories. OA showed opposite but insignificant trends (ps>0.5). YA retained better negative memory than OA post-nap (p=0.02), but not neutral memory (p=0.41). Sleep/wake condition and its interaction with age were associated with v and da (ps< 0.05). OA showed a significantly larger SP frequency gap between frontotemporal and centroparietal clusters than YA (ps< 0.01), characterized by a quadratic cliff across electrodes with a trough at frontotemporal regions (p< 0.001). This discontinuity correlated with poorer retention in v (r=-0.570, p=0.002) and da (r=-0.621, p=0.001) on nap but not wake days (ps>0.05) in both age groups.

Conclusion: While sleep is known to improve retention accuracy, our findings redefine its mediating role in overall consolidation mechanisms from the computational perspective. We provide the first evidence that SP frequency changes continuously along cortical gradients rather than in discrete fast/slow subtypes. Their memory relevance offers important insights into SP involvement in long-distance memory transfer, with

age-related SP disruptions linked to impaired consolidation processes.

A DATA-DRIVEN MULTIDIMENSIONAL APPROACH EXAMINING THE RELATIONSHIP BETWEEN COGNITION AND SLEEP COMPOSITES IN THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS

Caitlin Ballard Paquet[1], Nataliia Kozhemiako[2], Cecilia Castro-Diehl[3], Timothy M. Hughes[4], Suzanne Bertisch[1], Shaun Purcell[1], Susan Redline[5]

[1] Brigham and Women's Hospital, Harvard Medical School, [2] Brigham & Women's Hospital, [3] Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Harvard Medical School, [4] Wake Forest School of Medicine, [5] Department of Medicine, Brigham and Women's Hospital, Harvard Medical Sch ool

Introduction: Sleep is critical for maintaining overall brain health and may influence the onset and perpetuation of cognitive impairment. Since sleep is a complex and multi-dimensional construct, we hypothesized that methods that incorporate multi-modal measurement of sleep across various domains (i.e. sleep continuity, macro-architecture, power spectral density) may identify groupings of correlated variables that serve as distinct phenotypes that predict cognitive performance outcomes.
Methods: Multimodal measurement of sleep (actigraphy, polysomnography, patient-reported outcomes) and cognitive testing were completed around the time of the 5th follow-up exam (2010 – 2013) from the Multi-Ethnic Study of Atherosclerosis (MESA), a large multiethnic cohort in the United States. A principal components analysis (PCA) with varimax rotation was utilized on 39 sleep variables from multiple domains of sleep health for 1,414 participants who had complete sleep data (overnight polysomnography, 7-day actigraphy, and questionnaires) and completed cognitive function testing. Cognition was measured by performance on the Digit Symbol Coding Task (DSCT), a subtest of the WAIS-III measuring processing speed, working memory, and visuospatial processing. Scores on the DSCT were modeled as the primary outcome and were regressed onto scores derived from principal components (PC, $p < .05$) while controlling for important covariates.
Results: The study sample had an average age of 68.9 years, was 54.3% female, and 38.7% White, 26.3% Black/African American, 24.3% Hispanic, and 10.7% Chinese. Thirteen novel sleep composites were extracted from the PCA that explained about 71% of variance within the sample. Scores from 4 PCs were significantly ($p < .05$) related to DSCT scores when controlling for demographic and lifestyle factors. The description of each of the 4 PCs were as follows: 1) generalized EEG power, 2) strength of rest-activity pattern, 3) spindle and slow oscillation coupling, 4) spindle density.
Conclusion: In this study, interpretable cognition-related sleep composites were identified and characterized by EEG features and actigraphy metrics that have been previously linked to cognition in prior research. Use of data-driven and multi-dimensional approaches may efficiently identify composite biomarkers of multi-dimensional sleep associated with cognitive impairment. Examining correlated dimensions of sleep may shed light on how sleep health and cognition are related.

COMORBID INSOMNIA AND SLEEP APNEA (COMISA) IS ASSOCIATED WITH WORSE VERBAL EPISODIC MEMORY IN OLDER WOMEN

Breanna Holloway[1], Christian Harding[1], Pamela DeYoung[2], Crystal Kwan[1], Lanna Avetisyan[1], Kitty Lui[1], Sonia Ancoli-Israel[3], Sarah Banks[1], Ina Djonlagic[4], Atul Malhotra[2]

[1] UC San Diego, [2] University of California, San Diego, [3] UCSD, [4] Beth Israel Deaconess Hospitals, Harvard Medical School

Introduction: Women show a higher prevalence of comorbid insomnia and sleep apnea (COMISA) and Alzheimer's disease (AD) than men. Episodic memory is sensitive to early AD-related changes and may be particularly vulnerable to sleep fragmentation in COMISA. While women often outperform men in verbal episodic memory, sleep disturbances may attenuate this. We hypothesized that those with COMISA would perform worse on verbal memory than those without COMISA, with the effects stronger in women than men.
Methods: Ninety-two older adults (ages 65-83yrs) with normal cognition underwent polysomnography, neuropsychological testing, and sleep questionnaires as part of a larger study. The sample was 55.4% women, 83.7%White, 90.2% Non-Hispanic, 20% APOE4 carriers, and 73.9% with Bachelor's degree or higher. COMISA, present in 37% of participants, was defined by an AHI≥5/h and an Insomnia Severity Index (ISI) score≥11. Cognition was assessed using the Alzheimer Disease Cooperative Study Preclinical Alzheimer Cognitive Composite (ADCS-PACC), comprising z-scored Mini-Mental State Exam, Logical Memory Delayed Recall, Digit Symbol Substitution Test, and Free and Cued Selective Reminding Test total score. We conducted moderated linear regression analyses to examine whether gender moderated the relationship between COMISA and cognition, adjusting for age, APOE4 status, body mass index, and education.
Results: Moderated regression showed COMISA and male gender were independently associated with worse ADCS-PACC and Logical Memory scores. A significant COMISA-by-gender interaction was only observed for the Logical Memory subtest, ($B=1.20$, $SE=0.40$, $p=.003$). The overall model accounted for 20% of the variance in scores, $F(7, 84)=3.08$, $p=.006$. COMISA was significantly associated with worse verbal memory ($B=-1.00$, $SE= 0.26$, $p<.001$), and female gender was associated with better verbal memory ($B=-0.75$, $SE=0.24$, $p=.002$). Conditional effects showed that the negative association between COMISA and verbal memory was significant only among the women($B=-1.00$, $SE=0.26$, $p<.001$), with women with COMISA performing significantly worse on verbal memory than those without COMISA.
Conclusion: These findings suggest that COMISA may have a gender-specific impact on verbal memory, with women being particularly affected. Future studies will examine underlying sleep-related mechanisms on AD biomarkers to better understand the unique vulnerabilities in women at risk for AD.

EXPLORING THE LINK BETWEEN TOTAL SLEEP DURATION ON COGNITIVE PERFORMANCE IN OLDER VETERANS: A PRELIMINARY REPORT

Laura Saturnino[1], Ifeoma Ezeilo[1], Carleara Weiss[2]

[1] Jacobs School of Medicine & Biomedical Sciences, [2] University at Buffalo School of Nursing

Introduction: Sleep is an influential factor in cognitive performance, with short sleep duration (6 hours or less) negatively impacting cognition. Prolonged, untreated sleep disturbances have been linked to dementia diagnosis and Alzheimer's disease.
Methods: Here, we conducted a secondary cross-sectional data analysis from a clinical trial (NCT05500170, PI: Weiss) investigating the effects of dietary supplementation with nicotinamide riboside on sleep and cognition in older Veterans (n=24, aged 65-85 years old). We focused on baseline findings related to sleep duration and cognitive function, employing descriptive analysis and Pearson correlation coefficients. Sleep duration was collected using the Fitbit Charge 5, a wrist-worn device capable of monitoring multiple sleep parameters, including total sleep time, time in bed, sleep efficiency, sleep latency, and wake after sleep onset. Cognitive function was evaluated using the Montreal Cognitive Assessment (MoCA), a screening tool for mild cognitive dysfunction. The MoCA analyzes various cognitive domains, including attention and concentration, orientation, language, and memory, with an additional point awarded for higher education attainment. MoCA total score ranges from 0 to 30, with scores above 26 indicating normal cognition, 18-25 reflecting mild cognitive impairment, 10-15 indicating moderate impairment, and severe impairment with a score below 10.
Results: Participants reported TST ranged from 1.84-6.70 hours, and MoCA scores ranged from 25-29 (SD value = 1.25). Preliminary findings showed a modest positive correlation between average baseline total sleep duration and cognitive function (r=0.362).
Conclusion: Future investigations will assess the longitudinal relationship between total sleep duration and cognition progression.

REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION ENHANCES SLOW-WAVE ACTIVITY AND RESPONSE SPEED IN OLDER ADULTS

Michelle Stepan[1], Ahmad Mayeli[1], Alexis Whitehead[1], Christine Peng[1], Rima Habte[1], Kamakashi Sharma[1], Sabine Janssen[1], Savannah Applegate[2], Meredith Wallace[1], Daniel Buysse[3], Fabio Ferrarelli[1], Kristine Wilckens[3]

[1] University of Pittsburgh, [2] Temple University, [3] University of Pittsburgh School of Medicine

Introduction: Sleep slow-wave activity (SWA) is associated with overnight memory retention and cognition in young adults, but the role of SWA in these processes among older adults at risk for cognitive decline is poorly understood. This study investigated how a single session of excitatory repetitive transcranial magnetic stimulation (rTMS) affected subsequent SWA, overnight memory retention, and cognition in older adults with cognitive complaints.
Methods: Twenty older adults (Mage=70 years, SD=5.2) participated in a 40-minute rTMS session of either high frequency (10Hz) active stimulation (n=11) or sham (n=9) applied over the left dorsolateral prefrontal cortex during wakefulness. SWA was assessed using 64-channel high-density EEG during a baseline and post-rTMS night. Overnight memory retention and executive function were assessed the morning following each overnight, with encoding for the memory tasks occurring the evening prior. Statistical Nonparametric Mapping (SnPM) identified topographic changes in SWA. Mixed linear models tested effects of rTMS on cognition. Bivariate correlations explored whether increases in SWA were associated with improvements in cognition across groups.
Results: In the active stimulation group, SWA increased across the whole night in a medial fronto-parietal cluster (pSnPM=.028) and within the first NREM period (NREM1) in a fronto-parietal (pSnPM=.003) and occipital cluster (pSnPM=.049). Stroop reaction time (RT) improved in the active stimulation group relative to sham, F=6.79, p=.011. Other cognitive outcomes were unaffected, ps>.13. The improvement in Stroop RT correlated with increased NREM1 SWA in the fronto-parietal cluster, r=-.54, p<.038. Exploratory analyses showed that increased SWA also correlated with Stroop RT improvements on congruent and neutral trials and accuracy improvements on neutral trials, rs>-.54, ps<.040, but not improvements in overnight memory retention.
Conclusion: These preliminary results suggest that rTMS produces robust increases in SWA and may improve reaction time in older adults with cognitive complaints. However, one night of increased SWA may be insufficient to modulate overnight memory retention in older adults at risk for cognitive decline. Future studies should test whether multi-session rTMS produces reliable cognitive improvements through SWA.

DEFINING "TOO LITTLE" AND "TOO MUCH" SLEEP: FINDINGS ON SLEEP DURATION AND COGNITIVE DECLINE IN MIDDLE-AGED AND OLDER GENERAL POPULATION

Hyun (Monica) Kim[1], Terry Goldberg[1], Soriul Kim[2], Seungku Lee[3], Seonjoo Lee[1], Chol Shin[3]

[1] Columbia University, [2] Seowon University, [3] Korea University

Introduction: Sleep is crucial for maintaining cognitive and brain health. While it is now well-established that there exists a U-shaped curve between sleep duration and neurocognitive outcomes, with extreme sleep durations having adverse effect on cognitive aging, there is a lack of consensus on what is considered "too little" or "too much" sleep. Thus, the current study was designed to examine the association between habitual sleep duration and cognitive performance changes in a community-based sample of middle-aged and older adults.
Methods: Baseline data of 2,696 cognitively normal participants (mean age 58.6 6.7 years, 49.9% females) from the Korean Genome and Epidemiology Study (KoGES) were in included in the analyses. These individuals were followed up after 4 years to determine changes in various domains of cognitive performance.

Habitual sleep duration was measured using self-reports and was used as a continuous variable in linear and quadratic terms in linear mixed models assessing the association between sleep and cognitive performance changes. Age, sex, education, cardiovascular disease, smoking, alcohol consumption, sleep medication, APOE genotype, depression, and sleep apnea were used as covariates in the analytic model.
Results: Linear or quadratic terms of sleep duration did not have significant main effects on cognitive outcomes. However, there was a significant interaction between quadratic sleep duration and time on the Trail Making Test-B (TMT-B), indicating that short and long ends of sleep durations were associated with slower performance on cognitive set-shifting. Furthermore, specific ranges of sleep duration ≤4.32 and ≥8.13 hours were determined to be significantly associated with poorer TMT-B performance.
Conclusion: Our findings reiterate the importance of maintaining healthy sleep duration and further suggest that obtaining 5-8 hours of sleep would be optimal to slow the decline of cognitive performance changes in middle-aged and older adults. We suggest that identification and interventions on aberrant sleep duration should become routine clinical practice in the aging populations.

IMPACT OF REM OSA AND HYPOXIC BURDEN ON SLEEP-DEPENDENT SPATIAL NAVIGATIONAL MEMORY AND WHITE MATTER INTEGRITY IN COGNITIVELY NORMAL ELDERLY WITH OSA

Anjona Datta[1], Luisa F. Figueredo[2], Daphne Valencia[1], Katarina Martillo[1], Jeongyeon Hwang[3], Sajila Wickramaratne[1], Anna Mullins[1], Korey Kam[4], Ankit Parekh[4], Indu Ayappa[5], David Rapoport[1], Ricardo Osorio[2], Andrew Varga[4]
[1] Icahn School of Medicine at Mount Sinai, [2] Department of Psychiatry, New York University Grossman School of Medicine, [3] Department of Neurology, Icahn School of Medicine at Mount Sinai, [4] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [5] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Overnight sleep enhances spatial navigational performance, but such benefits may be minimized by OSA. In this study, we aimed to explore whether REM-specific OSA (REM AHI4%) and Hypoxic Burden (HB) influence overnight task performance differentially compared to standardly-defined presence/absence of OSA, and investigate associations between these sleep apnea variables and diffusion tensor imaging (DTI) metrics of white matter integrity in brain regions critical for memory consolidation.
Methods: Using a virtual 3D Maze, 133 cognitively normal, community-dwelling older adults (age = 66.5 ± 6.4 years, 56% female) performed three timed trials of spatial navigation before (evening) and after (morning) polysomnographically-recorded sleep and analyzed for differences in overnight percent change in completion time (%ΔCT) and trial-by-trial performance. Participants were grouped by overall OSA presence/absence (AHI4% all sleep ≥ 5 events/h vs. < 5 events/h), severe vs. absent REM OSA (REM AHI4% ≥ 30 vs. < 5 events/h) and HB quartiles e.g., time spent under 90% blood SpO_2 (T90), area under the oxygen desaturation curve (HB-AUC). A subset of 57 subjects had brain structural MRI including DTI sequences. We assessed correlations between REM AHI4%, HB, and DTI metrics of white matter integrity (fractional anisotropy (FA)).
Results: Of the 133 participants, 71 had untreated OSA (AHI4% = 11.9 [15.1] events/h). At the group level, we did not observe significant differences in %ΔCT or trial-by-trial performance in those with vs without OSA, however, significant differences in %ΔCT ($p = 0.04$), pre-sleep trial interactions ($p = 0.02$), and post-sleep performance ($p = 0.05$) were observed in severe vs absent REM OSA. Similarly, highest T90 quartiles showed significant pre-sleep trial interactions ($p = 0.01$) and post-sleep group differences ($p = 0.01$) compared to lowest HB quartiles. We observed significant inverse associations between REM AHI4% and corpus callosum FA ($R = -0.31$, $p = 0.02$) and between HB-AUC and cingulum FA (-0.34, $p = 0.01$).
Conclusion: REM AHI4% and HB values seem to be stronger predictors of poor spatial navigational memory performance than standard AHI criteria. Moreover, their associations with white matter damage provide potential mechanistic insight into the cognitive deficits observed in older adults with OSA.

THE INFLUENCE OF INSOMNIA SEVERITY ON COGNITIVE FUNCTIONS IN OLDER SURGICAL PATIENTS

Mili Jimenez Gallardo[1], Andrea Castillo Suárez[1], Anaëlle Charles[1], Elizabeth Sugg[2], Peng Li[3], John Hwabejire[2], Harold Fogel[2], Stuart Hershman[2], John Siliski[2], Christopher Melnic[2], Kun Hu[3], Lei Gao[3]
[1] Massachusetts General Hospital/Harvard Medical School, [2] Massachusetts General Hospital, [3] Massachusetts General Hospital/Harvard Medical School

Introduction: Sleep disorders, including insomnia, affect up to one-third of older adults over the age of 65 undergoing surgery, yet they often remain untreated. Insomnia-related sleep disturbances have been linked to weakened immune function, delayed recovery, and impaired cognitive abilities (e.g., attention, memory, language), particularly in older adults. However, the influence of sleep-related disorders on cognitive functions in older surgical patients remains unclear. Given the increasing hospitalization rates in older adults, we hypothesized that greater insomnia severity would be associated with poorer cognitive performance.
Methods: A cohort of 17 older adults (≥70 years) scheduled for total knee, total hip, or spine surgery was recruited. One week before their scheduled surgery, participants were asked to complete the Insomnia Severity Index (ISI) questionnaire and the Montreal Cognitive Assessment (MOCA), which assessed primary cognitive functions, including abstraction, attention, language, orientation, and delayed recall.
Results: We computed a simple linear regression model analysis to investigate whether ISI scores predicted cognitive performances using the total MOCA scores as our key dependent variables. Additional model predictors were tested included surgery type, sex, and age. In alignment with our hypothesis, results suggested that for every 1 SD increase in ISI scores a 0.09 SD

decrease in MOCA scores was predicted (SE =.07, p = 0.26). Although not statistically significant, these preliminary findings are promising, as we are still collecting data and anticipate stronger trends as we reach sufficient statistical power.
Conclusion: Out preliminary results seemed to indicate that older adults with higher insomnia severity may exhibit larger cognitive impairments, potentially increasing their vulnerability during surgical recovery. Further investigation is warranted.

ROLE OF ENCODING OPPORTUNITY AND CHANGE IN SLOW WAVE ACTIVITY ACROSS K-COMPLEXES ON SLEEP-DEPENDENT SPATIAL NAVIGATIONAL MEMORY IN OLDER ADULTS

Masrai Williams[1], Anna Mullins[2], Korey Kam[3], Ankit Parekh[3], Omonigho Michael Bubu[4], Ricardo Osorio[4], David Rapoport[2], Indu Ayappa[5], Bresne Castillo[1], Zachary Roberts[1], Ahmad Fakhoury[1], Daphne Valencia[2], Reagan Schoenholz[1], Andrew Varga[3]
[1] Mount Sinai Hospital, [2] Icahn School of Medicine at Mount Sinai, [3] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [4] Department of Psychiatry, New York University Grossman School of Medicine, [5] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: While younger adults show significant overnight spatial navigational memory (SNM) performance gains, older adults exhibit attenuated improvements, possibly due to reduced slow wave activity (SWA) during non-REM sleep. Older adults may show equivalent offline gains to younger adults if provided an enhanced encoding opportunity. This study examined whether increased encoding opportunities enhance SNM consolidation in cognitively normal older adults. We additionally probed whether particular features of sleep microstructure correlated with overnight change in performance.
Methods: Thirty-nine cognitively normal older adults (mean age: 65 years, range: 55–76, 79% female) without sleep complaints completed a timed virtual maze task before and after polysomnography over two nights. Encoding opportunities increased from three pre-sleep trials on night 1 to six on night 2. We measured overnight percent change in completion time (CT) and a morning 20-minute psychomotor vigilance task (PVT). We used hierarchical linear regression to assess contributions of full-night SWA (0.5-4Hz) and the average change in SWA across K-complexes (Delta SWAK) toward overnight SNM performance changes.
Results: Increased encoding opportunities on night 2 did not significantly impact overnight SNM performance (p = 0.49) or PVT reaction times (p = 0.67). On night 1, age, sex, years education, and mean reaction time explained 2.0% of the variance in overnight CT change. Delta SWAK in central regions significantly explained an additional 30% of the variance in CT change ($\beta = 0.56$, p = 0.001, $\Delta R^2 = 0.30$), without a significant contribution of SWA. On night 2, age, sex, years education, and mean reaction time explained 12.4% of the variance in overnight CT change, with a particular contribution from sex. We did not observe sleep microstructure features that significantly explained additional variance beyond this baseline.
Conclusion: Increasing encoding opportunities did not enhance SNM consolidation in older adults. Central Delta SWAK significantly predicted overnight CT change on the first but not second night, which is possibly related to a differential contribution of sex between nights. Delta SWAK represents a potentially novel correlate of offline memory processing that could be explored further along with interactions with sex.

SLEEP-DEPENDENT WORKING MEMORY ACROSS THE MENSTRUAL CYCLE

Temilade Adekoya[1], Alessandra Shuster[1], Allison Morehouse[1], Peremoboere Uzoigwe[2], Yunke Chen[1], Ali Ekhlasi[1], Jing Zhang[3], Negin Sattari[1], Marie Gombert[4], Fiona Baker[4], Katharine Simon[1], Sara Mednick[1]
[1] University of California, Irvine, [2] University of California, Irvine, CA, [3] University of California- Irvine, [4] SRI International

Introduction: Alarmingly few studies track sleep and cognition across the phases of the menstrual cycle. Existing studies fail to encapsulate the complex interactions that arise by neglecting to study each of the four hormone phases within a cycle-haver, or limiting the number of variables(e.g. sleep/cognition or menstrual cycle/cognition). This creates a gap in knowledge about how the menstrual cycle affects sleep-dependent cognitive processes. We aim to fill this gap by specifically examining how the menstrual cycle modulates sleep-dependent working memory (WM).
Methods: Healthy young women (18-35yrs; n=65) completed four experimental visits at specific phases of their menstrual cycle: menses, pre-ovulation, mid-luteal, and late luteal. Each visit, women slept overnight with in-lab polysomnography and completed a WM operation span (OSPAN) task before and after sleep. We used linear-mixed-models (LMMs) to predict post-sleep WM performance, with menstrual phase, sleep variables (i.e. sleep architecture and spindle (12-15Hz) density), and pre-sleep WM as predictors. Pearson's correlations were performed to examine the relationship between sleep and post-sleep performance, with a median split to divide participants into high and low pre-sleep performance groups.
Results: We found a significant interaction between pre-sleep WM performance and phase ($p < 0.05$) where pre-sleep performance moderated menstrual phase effects on post-sleep WM, with greater improvements during pre-ovulation compared with mid-luteal. No sleep variables contributed to this interaction. Next, we examined the predictability of each sleep variable on WM performance irrespective of phase. We found an interaction between pre-sleep performance and minutes in REM ($p < 0.05$) and spindle density ($p < 0.05$). Correlations demonstrated that lower REM sleep and spindle density (both $p < 0.01$) predicted better post-sleep WM improvement only in low pre-sleep WM performers.
Conclusion: Our results show that sleep-dependent WM varies across the menstrual cycle, with greater WM during the high estrogen, pre-ovulation phase. While sleep variables did not impact the phase-WM interaction, we found that sleep independently contributed to working memory through our REM and spindle density results. Though we have yet to demonstrate a three-way link, our sleep variable results support previous work showing a negative correlation between NREM sigma and WM.

SEX DIFFERENCES IN SLEEP AND EPISODIC MEMORY AND EXECUTIVE FUNCTIONING

Fumiko Hamada[1], Soomi Lee[2]

[1] USF, [2] The Pennsylvania State University

Introduction: Sex differences in sleep quality and cognitive performance have been well studied. However, less is known about sex differences in the association between sleep quality and cognitive performance. This study investigates whether older men and women differ in the concurrent and prospective associations between sleep quality, episodic memory (EM), and executive functioning (EF).
Methods: Data came from 390 older adults who participated in the Midlife in the United States Study at two-time points (T1: 2005-2006, T2: 2013-2017, Mage at T2=62). Participants responded to the Pittsburgh Sleep Quality Index (PSQI) and completed the EM and EF by telephone. A series of t-tests first compared the PSQI, EM, and EF levels between sexes at each time point. Then, we used general linear models to examine sex differences in the concurrent and prospective associations of PSQI with EM or EF, adjusting for sociodemographic and health covariates. Prospective models additionally controlled for T1 EM or EF and PSQI score differences between T1 and T2.
Results: Females exhibited poorer sleep quality compared to males, consistently over time (T1: t=3.43, p< 0.001, T2: t=3.96, p< 0.001). Females demonstrated significantly higher EM z-scores than males (T1: t=6.24, p< 0.001, T2: t=6.91, p< 0.001); no significant sex differences were observed in EF z-scores. Concurrently, poorer sleep quality was associated with lower EM and EF, adjusting for sex (EM: B =-0.04, SE=0.01, p=0.012; EF: B=-0.02, SE=0.01, p=0.019), although these associations became not significant in fully adjusted models. Prospectively, poorer sleep quality at T1 was associated with lower EM at T2 in the fully adjusted model (B=-0.41, SE=0.02, p=0.012), but there was no association with EF. There was no significant interaction between sleep quality and sex in either concurrent or prospective models.
Conclusion: The effect of PSQI scores differed between EM and EF, indicating that the importance of sleep quality may vary across cognitive function domains. No interaction with sex was found, suggesting that the importance of sleep quality in cognitive function may be universal across males and females. Future analyses will include actigraphy sleep data to explore sex differences in the objective sleep—cognition link.

TIME ESTIMATION DURING NOCTURNAL SLEEP AMONG YOUNG ADULT WOMEN AND MENOPAUSAL WOMEN

Sayaka Aritake-Okada[1], An Saotome[1], Mamika Nakazawa[2], Yumi Arai[2], Momo Fushimi[1]

[1] Saitama Prefectural University, Graduate School of Health Sciences and Social Work, [2] Saitama Prefectural University

Introduction: Previous studies reported abnormalities in time estimation ability (TEA) in patients with insomnia. Recent research indicates the possibility that menopausal women also exhibit impaired TEA. This study examined subjective sleep parameters (sleep duration, sleep latency etc.) and the relationship among these parameters, objective sleep structure, and body temperature during nocturnal sleep in menopausal and young adult women, to elucidate the psychophysiological mechanisms of menopausal sleep.
Methods: This study was approved by the ethical committee of Saitama Prefectural University (No.24057). A sample of 19 female volunteers (12 menopausal women: mean 52.92±2.73 years, 7 young adult women in the luteal phase: mean 21.83±4.18 years) participated in two-time estimation (TE) trials (first half [FH] and latter half [LH] of the sleep period) during the approximately 7-hour nocturnal sleep period. In each TE trial, participants underwent a structured interview regarding the perceived sleep time(sub-ST) of time passed since before bedtime or first TE trial. Timing of TE trials was executed at the following conditions: participants slept longer than 150 minutes; stage 2 sleep continued for more than 3 minutes; and spontaneous movement arousal occurred in each sleep period.
Results: Objective sleep time did not significantly differ between the FH and LH sleep periods in young women (FH: 227.00±9.73 minutes, LH: 196.67±14.46 minutes, p= 0.345) and menopausal women (FH: 210.82±7.40 minutes, LH: 205.27 ± 6.09 minutes, p= 0.929). Sub-ST significantly decreased according to sleep progression in young women (FH: 330.17±17.77 minutes, LH: 125.00±18.03 minutes, p= 0.028). The amount of slow wave sleep (SWS) showed similar to the time distributions of sub-ST in young women. Sub-ST in menopausal women was not significantly different between the two time periods (FH: 209.45±25.23 minutes, LH: 193.64±19.97 minutes, p= 0.754). Time distribution of SWS in menopausal women differed from those in young women.
Conclusion: Young women overestimated their actual sleep time in FH and underestimated their LH sleep time according to the time profiles of SWS. However, menopausal women estimated each FH and LH sleep period with some degree of accuracy. The amount and time distribution of sleep stage, particularly SWS, may play a role in TEA in both young and menopausal women.

CHANGES IN REM AND NREM SLEEP SURROUNDING CRAWLING ACQUISITION IN INFANTS

Sydney Thirkell[1], Melissa Horger[2], Sarah berger[3]

[1] University of Massachusetts Amherst, [2] University of Massachusetts, Amherst, [3] The City University of New York

Introduction: Sleep during motor milestone development is disrupted in infancy, yet the precise causes and effects remain unclear. In rodents, REM supports sensorimotor development through twitches (Sokoloff et al., 2015). Similarly, REM sleep in human infants is hypothesized to play a role in neural reorganization (Cao et al., 2020). NREM sleep, in contrast, aids in procedural memory consolidation, playing a more immediate role in motor learning (Stuart et al., 2007). This study is the first to investigate how REM and NREM sleep change around naturalistic motor learning: the acquisition of crawling.

Methods: Daily motor milestone diaries (Berger & Moore, 2021) and a commercially available video baby monitor (Nanit) were used to collect naturalistic sleep data time-locked to skill onset. Overnight videos were requested for the nights before, of, and after the onset of crawling (>10ft). Sleep states (REM, NREM, indeterminate, and wake) were behaviorally scored using criteria congruent with prior videosomnography research (Anders & Keener, 1985; Grigg-Damberger, 2007).
Results: Fourteen infants (M age = 8.26 months; 9 males) were included in the analysis. Two repeated measures ANOVAs were run on the proportion of the night spent in REM and NREM. The proportion of REM did not show a significant change over time ($F(2,32)=1.223$, $p=0.308$), though it steadily increased from the night of acquisition to the night after crawling. The proportion of NREM varied significantly over the acquisition of crawling ($F(2,32)=4.131$, $p=0.0254$). Pairwise comparisons of estimated marginal means identified a significant difference between the night of onset (M=0.46; SD=0.05) and the night after (M=0.45; SD=0.05) (p=.02).
Conclusion: The increase in NREM the night of acquisition may reflect its immediate role in consolidation, while the increase in REM the night after may reflect neural reorganization as the novel skill is practiced. These findings provide the first analysis of sleep states surrounding motor milestone acquisition in a naturalistic observational setting. Future research should explore the relationship between sleep disruptions and developmental outcomes in infancy.

A SLEEP-READING PUZZLE IN EARLY ADOLESCENCE

Hatty Lara[1], Katherine Marczyk Organe[2], Trent Petrie[3], Scott Martin[3], Christy Greenleaf[4], Jessica Dietch[5], Daniel Taylor[6]
[1] The University of Arizona, [2] Cook Children's Sleep Center, [3] The University of North Texas, [4] The University of Wisconsin–Milwaukee, [5] Oregon State University, [6] University of Arizona

Introduction: Sleep is associated with cognitive development and academic performance, particularly in reading and English Language Arts (ELA) performance. During early adolescence (ages 11-14 years), biological and social factors cause changes in sleep patterns which can impact key cognitive functions like memory, attention, and language processing. These functions are critical for developing reading and language skills, which are foundational for academic success. The present study examines how specific sleep variables predict reading/ELA scores in early adolescence.
Methods: Young adolescents (N= 296, Mage=12 years old, SD=.69, Female=151) attending 1 of 6 public middle schools in the Denton Independent School District, in Denton, TX completed the district's Texas Assessment of Knowledge and Skills (TAKS) exam. Their reading/ELA scores were provided by the school district. Information on student-reported sleep was obtained by student self-report on the Pittsburgh Sleep Quality Index (PSQI). Within the PSQI we looked at the following sleep variables: 1) sleep quality (i.e., perception of how restful sleep is), 2) sleep latency (time between "lights off" to sleep), 3) sleep efficiency (time asleep/time in bed), and 4) sleep disturbances (i.e., trouble falling asleep and/or staying asleep).
Results: We ran hierarchical multiple regression models to test ethnicity, sex, and grade as model 1 then added the four sleep variables as model 2 to see if they improve the prediction of participants' reading/ELA scores. Model 1 was significant (R^2 =.14, $F(5, 290) = 15.5$, $p <.001$) Model 2 was also significant ($R2=0.18$, $F(5, 290)=7.72$, $p<.001$). We found ethnicity (Hispanic v non-Hispanic) significantly predicted reading/ELA scores ($\beta=-.25$, $p<.001$) along with grade ($\beta=.23$, $p<.001$). For sleep variables, we found sleep latency ($\beta=.19$, $p=.003$) significantly predicted reading/ELA scores.
Conclusion: These results suggest Hispanic participants scored lower in the reading/ELA section of the TAKS test. Additionally, higher grades were associated with better performance. Interestingly, higher sleep latency was associated with higher reading/ELA scores. These findings suggest that both demographic factors and sleep variables influence reading/ELA scores. Our findings are preliminary, future analysis will look at how sleep compares between various race/ethnicity groups and sex using a modified total PSQI score followed up by sleep subcomponents.

OBJECTIVE AND SELF-REPORTED SLEEP RELATE DIFFERENTLY TO COGNITIVE MEASURES IN NEUROTYPICAL CHILDREN AND ADOLESCENTS

Emmet Klein[1], Gabrielle Deutsch[1], Chelsea Cadle[1], Maninder Kalra[2], Paola Malerba[1]
[1] Nationwide Children's Hospital, [2] Division of Pulmonary and Sleep Medicine, Nationwide Children's Hospital

Introduction: The relation between sleep and cognitive/behavioral measures in youth is not fully understood. Measures of sleep health and polysomnography (PSG) might speak to complementary sleep properties that relate to cognition differently. To better understand comparisons of self-reported vs. PSG-measured sleep with cognitive/behavioral measures, we acquired subjective and objective sleep measures paired to neurocognitive battery and emotion regulation reports in typically developing youth.
Methods: We recruited neurotypically developing children and adolescents aged 8-19. Participants completed one overnight PSG, measures of cognition (reaction time, processing speed (PSI)), emotion regulation (BASC-3 – internalizing problems), sleep (Epworth Sleepiness Scale – Children/Adolescents), and filled out a daily sleep diary the week before PSG. We quantify self-reported sleep health with the recently introduced Sleep Health Composite (SHC). From PSG, we extract total sleep time (TST) and derive Arousal Index (AI; arousals per hour of sleep) as an objective measure of sleep fragmentation. We group participants based on AI (normal AI< 14 for participants < 12y.o., AI< 10 for participants ≥12y.o.; otherwise, abnormal) or SHC (good (1-3); poor (4-6)). We compare internalizing problems, PSI, reaction time, and TST in participants with normal vs. abnormal AI, and good vs. poor SHC, separately with independent sample t-tests.
Results: 48 participants completed all study measures (Avg. Age=13, S.D.=3, Female=28). Participants with poor SHC (n=13) showed similar PSI (p =.710), reaction time (p =.360), internalizing problems (p =.567), and TST (p =.143) compared to good SHC participants (n=35). Compared with abnormal AI participants (n=7), normal AI participants (n=41) showed no differences on internalizing problems (p =.750) or TST (p =.676), but showed reduced PSI (p =.039) and longer reaction time (p <.001).
Conclusion: We found no explicit relation between a subjective measure of sleep health and cognitive/behavioral measures in

typically developing children. In contrast, an objective measure of sleep fragmentation showed significant relationships with processing speed and reaction time. This needs replication, due to an imbalance between normal and abnormal arousal index in our sample. Our findings support the relevance of objective lab-based sleep measures in studies of sleep and cognition in youth.

DAY-TO-DAY COGNITIVE VARIABILITY IN EXECUTIVE FUNCTION BUT NOT HIPPOCAMPAL DEPENDENT MEMORY IN YOUTH WITH OBSTRUCTIVE SLEEP APNEA

Katharine Simon[1], Tricia Morphew[2], Shun Iwata[1], Lia Gault[1], Spencer Polk[1], Lois Sayrs[2], Neal Nakra[2]
[1] University of California, Irvine, [2] Children's Hospital of Orange County

Introduction: Obstructive sleep apnea in development leads to behavior dysregulation, memory deficits, and emotional instability. Adenotonsillectomy is a common surgical treatment that improves sleep-disordered-breathing symptoms, health, and cognition. However, most studies exploring OSA's impact on cognition are obtained cross-sectionally. How surgery impacts day-to-day cognition in youth is unknown at short and long-term intervals. Currently, we are repeatedly and remotely tracking pediatric patients before and after surgery and healthy age/sex matched controls.
Methods: Using a measurement burst design, we tracked patients over nine months: before and twice post-surgery (controls are time matched). Eight pediatric patients (Mage=11.375, SD=1.4. F=4) and eight age/sex matched controls are enrolled. Our mobile health platform, HowRU, administers twice-daily cognitive tasks (hippocampal-dependent word pair associates and executive function operation span at easy and difficult levels), along with sleep diaries and mood assessments. Participants also use Muse and Garmin wearables to track sleep neurophysiology and physical activity. Baseline data are analyzed using a linear regression within the GLMM framework, accounting for the multilevel structure of the data, to examine daily variability in cognitive performance.
Results: Cognitive performance patterns in the baseline period did not significantly differ between patients and controls. For executive function, significant learning effects were observed, improving across difficulty levels after the first day. We found an interaction between easy performance and sleep, with greater sleep duration negatively impacting performance. Neither group showed a circadian-effect on performance. For hippocampal-dependent memory, neither group exhibited learning effects or day-to-day performance variability. However, both groups demonstrated sleep-dependent consolidation, with no significant overnight decline from encoding.
Conclusion: Day-to-day analyses reveals distinct performance patterns in executive function but not hippocampal-dependent tasks. Executive function learning effects were observed. This discrepancy in performance may stem from the heightened sensitivity of executive function to fragmented sleep, whereas hippocampal-dependent memory appears less affected, provided sufficient sleep is obtained. Our preliminary findings are promising, suggesting a nuanced understanding of the impact of fragmented sleep in youth. These findings suggest that youth with OSA experience subtle cognitive disruptions linked to sleep fragmentation, underscoring the need for targeted interventions.

TOTAL SLEEP DEPRIVATION DISRUPTS WORKING MEMORY UPDATING

Courtney Kurinec[1], Anthony Stenson[2], John Hinson[1], Paul Whitney[1]
[1] Washington State University, [2] Eastern Oregon University

Introduction: Total sleep deprivation (TSD) leaves the ability to maintain information in working memory (WM), i.e., the focus of attention, relatively unaffected. However, its effect on the ability to update information into and out of WM is less clear, in part because many of the tasks used to assess WM updating do not differentiate between maintenance and updating processes. Using a task designed to isolate WM updating from WM maintenance, we anticipated that TSD disruptions to WM updating would impair the ability to flexibly adapt to environmental demands to maintain up-to-date information in the focus of attention.
Methods: N=16 healthy adults completed a 4-day (3-night) in-laboratory study. After a baseline night with a 9h sleep opportunity, participants were randomly assigned to either 39h TSD (n=9) or well-rested control (WRC; n=7). Participants completed a modified delayed match-to-sample (DMS) task approximately 15 minutes after a sham stress test at baseline (session 1) and again 24h later (session 2). On each trial of the DMS, participants encoded an initial pair of figures. They were then shown a second pair of figures and instructed to either begin maintaining the second pair instead or ignore it and continue maintaining the first pair. After a short delay, they saw a single probe figure and had to determine if it matched what should be held in WM.
Results: Mixed-effects ANOVA on instruction (update or ignore), session (1 or 2), condition (TSD or WRC), and their interactions revealed a significant session by condition interaction (p=0.006) and a significant effect of instruction (p=0.013). TSD participants had poorer accuracy in session 2, when sleep-deprived, than WRC participants (p=0.034) and their own rested baseline (p=0.002). In general, participants had better probe accuracy when they had to maintain the second versus first pair in WM (p=0.013).
Conclusion: TSD impaired the ability to recognize to-be-maintained information in WM when told to update or ignore the new pair, indicating that TSD disrupts the ability to appropriately update information. As WM updating is critical in a number of settings, TSD may compromise the ability to maintain situational awareness in both laboratory and real-world tasks (e.g., driving).

THE EFFECT OF OBSTRUCTIVE SLEEP APNEA ON SLEEP NEUROPHYSIOLOGY AND COGNITION IN SCHIZOPHRENIA

Garry Cho[1], Samer Faris[1], Rick Wassing[2], Tancy Kao[1], Delwyn Bartlett[1], Isabella Valenzuela[1], Grace Garden[1], Jian Eu Tai[1], Premala Sureshkumar[3], Nathaniel Marshall[1], Brendon Yee[1], Timothy Lambert[3], Ronald Grunstein[4], Angela D'Rozario[1]

[1] The Woolcock Institute of Medical Research, [2] The Woolcock Institute of Medical Research, Sydney, Australia, [3] Collaborative Center for Cardiometabolic Health in Psychosis (ccCHiP), Sydney, Australia, [4] Woolcock Institute of Medical Research, Macquarie University CPC-RPAH Clinic, Royal Prince Alfred Hospital and University of Sydney, Sydney, Australia

Introduction: People living with schizophrenia are at high risk of developing obstructive sleep apnea (OSA). Sleep spindle deficits and impaired cognitive performance are commonly reported in schizophrenia, and in non-schizophrenia OSA populations. The effects of comorbid OSA on spindles and cognition in schizophrenia are unclear. We aimed to establish whether abnormal sleep neurophysiology and cognitive deficits in people with schizophrenia could in part be attributable to co-morbid OSA.
Methods: We measured sleep with 256-channel high-density EEG overnight polysomnography in two groups of people with a range of OSA severity, defined by the Apnea Hypopnea Index (AHI), matched for age and sex: 1) people with schizophrenia (n=31) and 2) without schizophrenia (n=30). Participants completed a cognitive test battery that assessed the domains of executive function and attention, and sleep-dependent procedural and declarative memory. Established algorithms detected spindles during NREM sleep and EEG spectral power was computed. General linear models were used to test the fixed effects (Group), and the interaction between Group and AHI for cognitive (adjusted for sex, age, education and subjective sleepiness) and spindle (adjusted by age and sex) outcomes.
Results: The schizophrenia group had significantly worse overnight procedural memory consolidation (B=-16.78;R2=0.12; pgroup< 0.05) and executive function (mean execution time on Tower of London: B=12.55,R2=0.26, p [group]< 0.01) and lower spindle density (Cz: t=2.12, p< 0.05), when compared with the no schizophrenia group. In the schizophrenia group, OSA had no effect on cognitive performance in any domain or spindle density (all p>0.05). High-density EEG analysis showed lower absolute sigma (12-15 Hz) EEG power in a cluster overlying the central region in the schizophrenia group (cluster size=114; p[corrected]=0.018). OSA had no effect on spindle density or sigma power in schizophrenia.
Conclusion: Our preliminary analyses shows impaired cognitive performance and spindle deficits in schizophrenia which does not appear to be attributable to co-morbid OSA. Future work will examine the relationships between spindles, cognition and OSA in this population and evaluate any potential recovery of abnormal sleep neurophysiology in those treated with CPAP therapy.

INFRASLOW RHYTHMS DURING SLEEP AND THEIR RELATIONS TO MEMORY CONSOLIDATION IN SCHIZOPHRENIA

Dimitrios Mylonas[1], Bryan Baxter[1], Katherine Ostrow[2], Dara Manoach[1]

[1] Harvard Medical School / Mass General Hospital, [2] Mass General Hospital

Introduction: Sleep spindles, defining oscillations of stage 2 (N2) non-rapid eye movement sleep (NREM), and their coordination with other NREM oscillations mediate sleep-dependent memory consolidation. Schizophrenia patients have spindle deficits that correlate with impaired memory consolidation. Novel findings from humans and rodents show that spindle activity is organized in an infraslow rhythm (~0.02 Hz). Although this temporal organization of spindles correlates with memory consolidation, it has not yet been investigated in schizophrenia. This study investigated infraslow rhythms and their relations to memory consolidation in healthy controls and schizophrenia patients.
Methods: To date we have analyzed archival data from 16 patients with schizophrenia (range: 24-60 yo) and 16 demographically matched healthy controls. Memory consolidation was measured using the Motor Sequence Task. The power and frequency of the infraslow rhythm for each subject were calculated based on the frequency decomposition of the spectrogram of each frequency bin from 1-35 Hz in N2.
Results: Spindle frequency activity (12-15 Hz) fluctuated in the infraslow band (Controls: 0.014±0.008 HZ, Schizophrenia: 0.016±0.011 Hz) and did not differ by group (p=.56). Infraslow rhythm power was reduced in schizophrenia (t(30)=2.81, p=.01). Memory consolidation corelated with the power of the infraslow rhythm only in schizophrenia (r=.64, p=.01) and this relation differed by group (p=.03).
Conclusion: The power of the infraslow rhythm is reduced in schizophrenia. The infraslow rhythm is thought to be generated in the locus coeruleus, which is the main source of noradrenaline in the brain. Our findings suggest that the noradrenergic system may affect the temporal organization of spindle activity in schizophrenia. Higher infraslow rhythm power predicted better memory consolidation in schizophrenia, suggesting that this temporal organization is relevant to memory. We plan to conduct mediation analysis to determine whether infraslow rhythmicity contributes to memory independently of spindles. Additionally, analyses of two archival datasets are underway to further characterize the infraslow rhythm and establish its clinical relevance in schizophrenia.

THE ROLES OF SLEEP AND CREATIVITY IN SCIENCE LEARNING AND ACADEMIC ACHIEVEMENT

Corinne Fitzsimmons[1], Alexander Beaujean[1], Michael Scullin[1]

[1] Baylor University

Introduction: While there is a literature indicating that sleep, creativity, and academic achievement are correlated, the relationships between these constructs are not yet understood. Using an integrative approach, we applied six theoretical models to test if student sleep and creativity are predictive of learning outcomes (controlling for differences in demographics and intelligence) and whether sleep mediates the possible relationship between creativity and learning.
Methods: First-year pre-health and science major students (N=489, 72.2% female, 46.2% white) completed questionnaires pertaining to sleep quality (PSQI), circadian preference (MEQ), social jetlag (midpoint difference of sleep from week to weekend), mental health (anxiety and depression), and creative achievement. They also performed seven assessments of creativity that measure convergent and divergent thinking (i.e.,

processes underlying creative achievement), assessments of fluid and crystallized intelligence, and assessments of organic chemistry and anatomy learning following reading passages and completing virtual lectures (science learning tasks). High school SAT/ACT scores and first-year cumulative GPA were obtained from university records. Structural equation modeling was used to evaluate the relationship between sleep, creativity, and learning outcomes.
Results: The model predicting learning from sleep and creativity, controlling for intelligence and covariates fit relatively well (Comparative Fit Index =.96, Root Mean Square Error of Approximation =.041, Standardized Root Mean Square Residual =.03). Sleep quality and social jetlag predicted GPA (β=-.174, p<.001; β=.097, p=.02, respectively). Convergent thinking predicted organic chemistry (β=.314, p=.028) and anatomy learning (β=.704, p<.001). Fluid intelligence also predicted organic chemistry learning (β=.146, p=.009). Crystallized intelligence (vocabulary score) predicted anatomy learning (β=.097, p=.047). Other predictors of GPA included creative achievement (β=-.137, p=.001), crystallized intelligence (ACT; β=.275, p<.001), and sex (β=.086, p=.047). The model testing sleep quality, social jetlag, sleepiness, and circadian preference as mediators of the creativity and learning relationship was not supported.
Conclusion: Sleep and creativity predict different aspects of learning and academic achievement.

SLEEP AND DIRECTED FORGETTING OF EMOTIONAL WORDS

Laura Kurdziel[1], Carie Fiedler[1]
[1] Merrimack College

Introduction: Sleep has been demonstrated to selectively improve directed remembering, without enhancing consolidation for information that was directed to be forgotten (Saletin, Goldstein & Walker, 2011). Sleep has also been shown to prioritize memory consolidation for emotional information (Baran et al., 2012; Wagner, Gais & Born, 2001). The question remains whether these two signals of relevance, valence and direction, are differentially impacted by sleep, or interact during the consolidation process. This study aimed to determine whether sleep enhanced directed forgetting could be observed for emotional information, and was an in-person follow-up to a study conducted online.
Methods: The task was a modified version of the directed forgetting paradigm used by Saletin, Goldstein, & Walker (2011). Participants were shown 100 words (50 negative, and 50 neutral) and were directed to either remember or forget each word. After encoding participants completed an immediate recognition task. Following a 12-hour delay, participants were asked to freely recall any of the words they saw on the original list. Participants either encoded in the morning (wake group), or encoded in the evening (sleep group). The sleep groupwore a sleep profiler to record sleep during the delay interval.
Results: At immediate recognition, there was a significant main effect of valence (F(1, 49)= 7.218, p=0.01) and instruction (F(1,49)=67.186, p< 0.001) with negative and remember words being significantly better recognized than neutral or forget words. However, following a 12 hour delay, there were no effects of sleep (F(1,50)=0.62, p=0.435), or valence (F(1,50)=0.274, p=0.603) on free recall. There was however a significant effect of instruction (F(1,50)=65.773, p< 0.001) with remember words being better recalled. Further, negative foils were more commonly recalled than neutral foils (F(1,50=14.081, p< 0.001). In the sleep group, the number of negative foils recalled was significantly associated with REM time (r=0.744, p< 0.001).
Conclusion: In this study, sleep, nor valence was not shown to benefit either directed remembering or forgetting. Rather, only the direction impacted memory for words after a delay.

SLEEP AND EMOTIONAL MEMORY: TRANSLATING NEURAL RESPONSE AT ENCODING TO CONSOLIDATED MEMORY IN TRAUMA-EXPOSED MEN AND WOMEN WITH AND WITHOUT PTSD

Anne Richards[1], Anthony Santistevan[2], Leslie Yack[1], Kim Felmingham[3], Steven Woodward[4], Daniel Mathalon[2], Thomas Neylan[1]
[1] University of California, San Francisco, [2] San Francisco VA Health Care System, [3] University of Melbourne, [4] National Center for PTSD- Dissemination & Training Division

Introduction: Growing evidence suggests that sleep plays an important role in PTSD outcomes, potentially due to its influence on emotional memory consolidation. This study sought to test the hypotheses that memory for affective visual stimuli was mediated by neural reactivity towards these stimuli and that this mediation was moderated by sleep neurophysiology.
Methods: 44 participants (21 female, 38 veterans) with variable PTSD severity (MCAPS=16, SD=11) viewed 75 negative and 75 neutral IAPS images while electroencephalography (EEG) was recorded. After viewing the images, participants had a 120-minute polysomnography-measured nap opportunity, from which time spent in stages wake, N1, N2, N3, and REM was calculated. Memory accuracy for the images was evaluated after the nap. Generalized additive models were used to model the late positive potential (LPP)—a sustained positivity in the event-related potential following affective stimuli. Moderated mediation analyses were preformed to investigate if emotional memory accuracy (d') was mediated by the LPP and to test if this mediation was moderated by properties of sleep.
Results: Mediation analyses demonstrated that memory accuracy for the stimuli (d') was partially mediated by the LPP (p< 0.05) and that this mediation was moderated by the proportion of time spent in sleep stages REM and N3 (p< 0.05). Specifically, the indirect effect increased in magnitude as the proportion of time spent in N3 and REM sleep increased, indicating greater memory for negative compared to neutral images for those who spent proportionately more time in these sleep stages. PTSD effects on LPP magnitude were observed, with blunting of LPP difference (negative vs. neutral) in PTSD. Sex effects in memory for negative vs. neutral images were also observed, although sleep moderation effects were consistent in both sexes and in both PTSD groups.
Conclusion: The late positive potential mediates an emotional memory benefit which is moderated by the proportion of time

spent in deep (N3) sleep and REM. These findings highlight how sleep physiology may influence the consolidation of information encoded during wake. Further research is critical to understand these effects in the context of biological sex and PTSD group differences in emotional memory.

SOCIAL ENVIRONMENT AS A POTENTIAL MODERATOR OF THE RELATIONSHIP BETWEEN SLEEP INERTIA, HYPERSOMNIA, AND COGNITION

Edith-Marie Green[1], David Plante[2], Laurel Ravelo[3], Erika Hagen[3], Paul Peppard[1]

[1] University of Wisconsin-Madison, [2] University of Wisconsin–Madison, [3] University of Wisconsin- Madison, Department of Population Health Sciences

Introduction: Literature suggests associations of both sleep inertia and hypersomnia with cognitive function and social environment with cognition function. However, the social environment has not been investigated as a potential moderator of the association of sleep with cognition. We examined both sleep parameters as predictors of poorer cognitive function, with social environment variables as potential moderators, in the Wisconsin Sleep Cohort study.

Methods: Survey data was collected from the ongoing Wisconsin Sleep Cohort (n=505, 45% female, mean [SD] age 74 [6.7] years). The sleep measures were the Hypersomnia Severity Index (HSI) and the Sleep Inertia Questionnaire (SIQ). Cognition measures were assessed in a 30-45 minute battery of tests that included symbol digit modalities, trail making, a pegboard task, digit cancellation, the audio verbal learning test (AVLT), and oral word fluency. Separate multiple linear models were used for each cognitive measure. Measures of the social environment included support and strain scores for participants' relationships with both friends and family. Both type and quality of relationships were evaluated to explore variations in moderating effects. Social environment questions came from the Midlife in the United States (MIDUS) study. Models were adjusted for age, race, sex, self-reported health status, and education and were fit using PROC GLMSELECT in SAS.

Results: Support in relationships with friends significantly (p=0.007) interacted with SIQ such that higher levels of friend support was associated with a mitigation of the reduction in pegboard task performance associated with greater sleep inertia. Borderline significance was found for family support and family strain as potential moderators of associations between SIQ and cognition. All other interactions between relationship factors, hypersomnia, and SIQ predicting cognitive function were not statistically significant.

Conclusion: Some social environment measures were associated with moderation of the relationship of SIQ and cognition. Subsequent research could explore potential underlying mechanisms and what specific aspects of these social environment scores are salient.

A CO-TWIN CONTROL STUDY OF SLEEP QUALITY AND COGNITION

Tina Vo[1], Carol Franz[1], Nathan Gillespie[2], William Kremen[1], Michael Lyons[3], Chandra Reynolds[4], Jeremy Elman[1], Matthew Panizzon[1]

[1] University of California, San Diego, [2] Virginia Commonwealth University, [3] Boston University, [4] University of Colorado, Boulder

Introduction: Sleep quality (SQ) is associated with cognitive performance; however, it remains unclear if this association is causal, and consequently, whether SQ is a modifiable risk factor for cognitive aging. Leveraging data from the Vietnam Era Twin Study of Aging (VETSA; N =1036, Mage =67.46, range=61.37-72.13, 304 monozygotic (MZ) pairs, 214 dizygotic (DZ) pairs), we investigated the causal relationship between sleep and cognition, accounting for genetic and shared environmental confounding.

Methods: Using a Co-Twin Control (CTC) design, we examined whether sleep-cognition associations reflect causal effects versus genetic and environmental confounding, leveraging that MZ twins share 100% of genes while DZ twins share 50%. Measures included sleep quality (Pittsburgh Sleep Quality Index total score), general cognitive ability (GCA), and factor scores across episodic memory, visual-spatial memory, executive function, fluency, and processing speed. SQ-cognition associations were decomposed into between-pair effects (comparing twin pair averages) and within-pair effects (comparing co-twins) to capture familial confounding versus potential causal effects.

Results: At the individual level, poorer SQ predicted worse performance (β = -0.02 to -0.03, all ps <.05). Within-pair effects (β = -0.02 to -0.05, all ps <.05) indicated the twin with poorer SQ performed worse, showing stronger effects in DZ (β = -0.02 to -0.06) than MZ twins (β = -0.001 to -0.02), except for processing speed. Weaker within- than between-pair effects suggested partial genetic confounding. Potential causation was observed for SQ-GCA and SQ-visual-spatial relationships as effects persisted regardless of genetic relatedness. SQ-episodic memory and SQ-semantic fluency associations suggested both sources of confounding as effects were only observed in the full sample. The remaining domains suggested genetic confounding as effects dissipated with increasing genetic relatedness.

Conclusion: Poorer SQ is associated with worse cognitive performance, though the relationship is complex. In some domains, poorer sleep may causally impact cognition, independent of genetic relatedness, albeit effects are small. In others, associations may reflect sources of confounding, with disrupted sleep and cognition representing symptoms of shared neurodegenerative or pathological processes. These findings emphasize the need for a nuanced approach to determine when sleep interventions may be most effective.

FRONTAL SLEEP SPINDLES, IQ, AND SLEEP DEPENDENT MEMORY CONSOLIDATION IN 22Q11.2 DELETION CARRIERS

Kathleen O'Hora[1], Hoki Fung[2], Charles Schleifer[2], Rune Bøen[1], Leila Kushan-Wells[2], Jennifer Xu[3], Elizabeth Bondy[2], Natasha Reddivalam[2], Jared Saletin[4], Carrie Bearden[1]

[1] University of California, Los Angeles, [2] Department of Psychiatry and Biobehavioral Sciences, Semel Institute for Neuroscience and Human Behavior, University of California, Los Angeles, [3] UCLA, [4] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: 22q11.2 deletion (22qDel) is a recurrent copy number variant that greatly increases risk for Schizophrenia and is associated with lower IQ. Recent work by our group has shown diminished sleep dependent memory consolidation (SDMC) in 22qDel carriers, but it is unclear whether this is associated with sleep spindle dysfunction, nor whether sleep spindles are associated with IQ, as in idiopathic schizophrenia.
Methods: 22qDel carriers (n=20, Mage=20.1±6.1, 10F) and typically developing (TD) controls (n=19; Mage=18.8±3.8, 12F) completed multiple nights (149 nights total; 1-8 nights per subject; median=3 nights) of sleep EEG recordings with a wearable headband (Dreem 3), along with the Wechsler Abbreviated Scale of Intelligence (WASI-II), and a motor sequence SDMC task. Unique sleep spindles were detected across a wide frequency range (10-16Hz) from the F8-F7 derivation during non-rapid eye movement sleep using Luna. We examined group differences in spindle density at each frequency (0.5Hz bins) using linear mixed effects models, accounting for multiple nights' data. We examined if spindle properties averaged across nights (amplitude, density, duration) were related to individual differences in cognition (SDMC, IQ) within group, and whether group moderated such effects. All models controlled for age and sex.
Results: 22qDel Carriers exhibited an altered frequency distribution of sleep spindles, with a peak frequency of 12.5 Hz, compared to the TD group (peak at 11.5 Hz). Spindle density was significantly different between groups at 12.5Hz (b= -0.55, p= 0.02). No group differences in spindle amplitude or duration were detected at this 12.5 Hz target frequency (p's > 0.77). Group moderated (b=-1.7, p=0.05) an association between spindle amplitude and SDMC, such that smaller spindle amplitude was associated with better SDMC in controls (b=-2.03, p< 0.01) but not 22qDel carriers (b=-0.34, p=0.49). Unexpectedly, there were no significant relationships between any spindle metric and IQ (all p's >0.14).
Conclusion: These results indicate 22qDel carriers exhibit differences in the intrinsic frequency and functional outcomes of frontal sleep spindles. These differences may reflect underlying differences in thalamocortical circuitry. Our future work will include investigating the relationship between SDMC and spindle-slow oscillation coupling.

EXAMINING PROPOSITIONAL LEARNING AMONG PATIENTS WITH INSOMNIA DISORDER

Shengzi Zeng[1], Tony Cunningham[1], Xiaoqing Hu[2]
[1] Beth Israel Deaconess Medical Center, [2] The University of Hong Kong

Introduction: Adaptive decision-making relies not only on recognizing which stimuli co-occur (e.g., whether stimulus A is associated with a positive or negative outcome B) but also on understanding the nature of their relationship (e.g., whether A causes or prevents B). For instance, when encountering the statement "acetaminophen reduces pain", individuals are more likely to make informed decisions if they remember the causal relationship between acetaminophen and pain, rather than simply recalling their association without understanding the relationship. In this study, we investigated whether sleep plays a role in adaptive evaluative choices and whether it depends on integrating memories for both stimulus co-occurrences and their relationships among patients with insomnia disorder and healthy participants.
Methods: Thirty-four patients with insomnia disorder (ID, mean age = 24.90) and 38 healthy participants (HC, mean age = 24.00) learned about hypothetical pharmaceutical products that either caused or prevented positive or negative health conditions. Evaluative choices and explicit memory were assessed at three time points: immediately after learning (pre-sleep), the following morning after sleep (post-sleep), and seven days later (delayed session).
Results: The impact of product–condition relations on evaluative choices significantly increased from pre- to post-sleep in the ID but not HC group, resulting in a significant group difference at post-sleep testing. Additionally, the influence of product–condition co-occurrences decreased from post-sleep to the delayed session in the ID group but remained relatively stable in the HC group. Explicit memory performance showed no significant differences between groups across sessions.
Conclusion: These findings present an unexpected pattern, diverging from prior studies comparing daytime wake and nighttime sleep conditions in healthy participants. Notably, ID showed a pronounced increase in reliance on relational information from pre- to post-sleep, whereas HC exhibited only a modest, non-significant change. Specifically, after a night of sleep, decisions made by individuals with insomnia were more strongly influenced by the causal relationship (e.g., a medication prevents illness) compared to their healthy counterparts. Importantly, these group differences could not be attributed to explicit memory performance. Further investigation is needed to explore the mechanisms underlying these group differences and their potential implications for interventions.

EFFECTS OF PARAFACIAL ZONE MEDIATED ENHANCEMENT OF SLOW-WAVE SLEEP ON HIPPOCAMPAL SYNAPTIC PLASTICITY

Heinrich Gompf[1], Christelle Anaclet[1]
[1] University of California, Davis

Introduction: Sleep deprivation attenuates behavioral learning and memory as well as its physiological proxy, hippocampal CA1 long term potentiation (LTP). Molecular signatures of synaptic plasticity are also affected. Here we examine the role of slow-wave sleep (SWS) by specifically only promoting this stage using chemogenetic activation of the brainstem parafacial zone (PZ). We do this in adult, aged, and aged Alzheimer's (APP/Psen1) mice to examine the beneficial role of SWS in learning and memory as well as neurodegenerative disease.
Methods: Vgat-Cre mice were used except for the Alzheimer's mouse model which was a double-transgenic Vgat-Cre;APP/

Psen. Chemogenetic activation of PZ Vgat neurons triggered at least 3 hours of uninterrupted SWS for each experiment. Behavioral: training completed 1 hr before SWS enhancement, testing 24 hrs later. Hippocampal LTP and RNA-Seq: SWS enhancement for 3 hrs just prior to sample (slice or nuclei) preparation.
Results: Generally "improved" learning and memory followed enhanced SWS in each measure, and this was more evident in aged and aged Alzheimer's mice than in younger mice.
Conclusion: SWS is leads to beneficial gene expression, synaptic plasticity and behavioral outcomes.

PERINEURONAL NET REMOVAL IN RAT PREFRONTAL CORTEX ALTERS RIPPLE SPINDLE COUPLING IN NREM SLEEP AFTER COCAINE

Barbara Sorg[1], Jonathan Ramos[1], Jereme Wingert[1], Sebastian Reynolds[1]
[1] Legacy Research Institute

Introduction: Environmental stimuli become paired with exposure to drugs of abuse and play an important role in the maintenance of drug memories. In the medial prefrontal cortex (mPFC), parvalbumin (PV) interneurons regulate pyramidal cells critical for cocaine memory consolidation. The majority of PV neurons are surrounded by a perineuronal net (PNN), an extracellular matrix structure essential for supporting fast firing rates and precise spike timing of PV neurons. These qualities of PV cells help generate oscillations and mediate coupling within and between brain regions, which plays an important role in memory consolidation. Removal of PNNs and associated extracellular matrix with chondroitinase ABC (ABC) disrupts acquisition and consolidation of cocaine-associated memories, but it is not known why this occurs.
Methods: After microinjection of either saline (control) or ABC into the mPFC of male Sprague Dawley rats, electrodes were implanted into the mPFC and hippocampal dorsal CA1 (dHIPP). Rats were given intravenous infusions of saline paired with one cue light or cocaine paired with a second cue light over eight alternating days. On the last day, rats were presented both cue lights in a pseudo-randomized order. After each daily session, rats remained in the apparatus for 2 hr to track spindle-ripple coupling during non-REM (NREM) sleep.
Results: Gamma power was elevated in response to the cocaine cue in control but not in ABC-treated rats. While all rats exhibited event-related phase resetting in response to the cocaine cue light presentation, mPFC-dHIPP theta phase coupling was reduced after ABC, and there was a strong trend toward decreased coupling between dHIPP theta phase/mPFC gamma amplitude. During NREM sleep, ABC treatment produced greater frequency of mPFC ripples and a strong trend toward enhanced spindle/ripple coupling. We are currently examining coupling of mPFC ripples with slow oscillations and delta waves.
Conclusion: These findings suggest that consolidation of memory may be compromised by altered dHIPP/mPFC coupling and hypersynchrony of spindle-ripple coupling during NREM sleep.

SEX DIFFERENCES IN CIRCADIAN-LINKED AND LEARNING BEHAVIORS AMONG MICE IN SOCIALLY-HOUSED AUTOMATED HOME CAGES

Philip Zendels[1], Briana Bernstein[2], Liliana Sisto[3], Leslie Aksu[4], DaNashia Thomas[1], Dalisa Kendricks[5], Jesse Cushman[6], Dondrae Coble[1], Chandra Jackson[1]
[1] National Institute of Environmental Health Sciences, [2] Georgetown University Medical Center, [3] McGill University, [4] NIEHS, [5] National Institute of Environmental Health Science, [6] NIH/NIEHS

Introduction: Women often report more sleep and circadian misalignment due to biological (e.g., hormones) and/or social (e.g., scheduling demands) factors. Mice are effective model organisms to assess circadian-linked behaviors associated with learning and human sleep due to similarities in sleep cycles. Singly-housed female mice are reported to spend more time awake than male mice and perform learning tasks differently. Despite mice being innately social animals, limited research exists examining circadian-linked behavior in socially-housed mice. Automated home cages allow for continuous monitoring of mice across the circadian cycle. In this study, we aimed to use an automated home cage with socially housed mice to provide naturalistic representation of mouse circadian-linked and learning behaviors that may represent underlying sex differences in human sleep and circadian rhythms.
Methods: We investigated sex differences in the circadian-linked and learning behaviors between male and female mice. Seventeen socially-housed C57BL/6J mice (9 Male; 8 Female) were continuously monitored using the TSE Intelligcage system. Mice were monitored across 15 days (12:12 light-dark cycle). Animals and cage-interactions (i.e., corner visits indicating circadian-activity; nosepokes indicating learning; and water licks indicating learning) were individually tracked. Water ports with various restrictions (e.g., nosepokes; restricted corner access) assessed learning. We created actograms and learning graphs by tracking mouse interactions and conducted independent sample t-tests to compare both sexes over time and for four hours of diurnal activity each day.
Results: Both sexes displayed more nocturnal than diurnal activity and biphasic activity. Across the 24-hour day, sex differences emerged with visit durations (females=longer, $p < 0.01$), licking (males=more, $p < 0.01$) and lick duration (males=longer, $p < 0.001$). During the day (rest), females demonstrated higher nosepokes ($p < 0.01$), visits ($p=0.02$), and licking ($p < 0.01$) than males. Females also demonstrated lower accuracy for water port visits ($p < 0.05$), though total visits considered accurate were comparable to males.
Conclusion: Consistent with disturbed sleep in women, female mice demonstrated more daytime activity. Differences in female circadian-linked behaviors may indicate biological basis for higher frequencies of some sleep and circadian disorders among women compared to men. Female mice appeared to exhibit more exploratory learning behaviors, but learning based on accuracy was otherwise comparable between sexes.

EFFECTS OF EARLY-ADULTHOOD SLEEP DISRUPTION ON LONGITUDINAL SPATIAL LEARNING, NEUROINFLAMMATION, AND LATE-LIFE TAU PATHOLOGY IN THE PS19 MOUSE MODEL

Kerly Lozano[1], Haris Hillery[1], Ronit Witztum[1], Sara Farahat[1], Kenny Vetter[1], Ward Pettibone[1], Korey Kam[2], Andrew Varga[2]

[1] Icahn School of Medicine at Mount Sinai, [2] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Sleep disruption is thought to exacerbate tau hyperphosphorylation and neurodegeneration. This study aimed to investigate how early-adulthood sleep disruption (SD) affects late life spatial memory, tau pathology, neurodegeneration, neuroinflammation, and sleep architecture in PS19 tauopathy mice.
Methods: PS19 (MAPT P301S) mice and wildtype (WT) littermates were exposed to chronic SD using an automated stimulus every 10 seconds for 18 hours daily (ZT 0–18) over eight weeks between 2 and 4 months of age. Control groups were allowed ad libitum (AL) sleep. Sleep architecture was analyzed via 24-hour EEG/EMG. Spatial memory was assessed at 6, 8, and 10 months using the Barnes Maze performance test. Brains were collected between 10–14 months and hippocampal sections were stained for AT8 (phospho-tau) and Iba1 (microglia). Hippocampal CA1 and dentate gyrus (DG) cell layer thickness and lateral ventricle area/volume were quantified using QuPath software.
Results: Sleep architecture analyses confirmed that SD impacted both genotypes equivalently, with significantly reduced total sleep time (TST) ($p< 0.01$), shorter REM ($p< 0.01$) and NREM ($p< 0.01$) bout lengths, and increased arousal indices ($p< 0.001$). At 8 months of age, PS19/AL mice had significantly worse Barnes maze performance compared to all other groups ($p=0.03$), and PS19/SD showed preserved spatial memory at 8 and 10 months compared to PS19/AL. SD showed no impact on WT controls. Despite early-adulthood SD, hippocampal tau pathology (AT8+ neurons) was similar between PS19/SD and PS19/AL (SD: 462 ± 268 vs. AL: 284 ± 98, $p=0.54$). However, hippocampal microglial activation (Iba1 staining cells/ROI) was significantly elevated in PS19/SD vs. PS19/AL (SD: 851.5 ± 151.9 vs. AL: 479.2 ± 81.3, $p=0.039$). Thinner CA1 and DG cell layers and larger ventricles were observed in PS19 mice vs WT, but no differences in these markers of neurodegeneration between SD and AL groups in PS19 mice were observed.
Conclusion: Contrary to expectations, early-adulthood SD preserved spatial memory in PS19 without significantly impacting hippocampal tau tangle load or metrics of neurodegeneration. We did observe significantly increased PS19 hippocampal microglial density in late life following early adulthood SD, but whether this is an epiphenomenon or somehow protective for cognition warrants further investigation.

ATTENTION-RELEVANT ALTERATIONS OF CORTICAL AND SUBCORTICAL NEURAL OSCILLATIONS IN RESTED AND SLEEP-DEPRIVED MICE

Eden Maness[1], Megan MacIver[1], Bernat Kocsis[1], Robert Strecker[1], James McKenna[1], James M McNally[2]

[1] Harvard Medical School, [2] VA Boston Healthcare System-Harvard Medical School

Introduction: Consciousness is comprised of a multitude of brain states that reflect varying degrees of exteroceptive awareness and rely on specialized functional neural networks that flexibly respond to the demands of the external world. Fast neural oscillations, such as those in beta (15-30 Hz) and low gamma (30-80 Hz) frequency bands, are prominent in mammalian salience- and attention-associated brain areas during goal-directed behaviors and reflect top-down and bottom-up information processing, respectively. However, how these oscillations vary on a millisecond scale across the attentional timespan, as well as how they are disturbed following sleep deprivation (SD), are not well understood.
Methods: To investigate time-dependent and cognition-relevant changes in neuroelectric activity in mice, local field potential (LFP) electrodes are implanted in various attention- and salience-associated brain regions prior to inclusion in the behavioral protocols. Once trained, these intracerebral multi-site LFPs are measured during self-initiated attentional performance to assess near-instantaneous, moment-to-moment changes in oscillatory activity as animals switch between task-off and task-on behaviors. These recordings are done when mice are rested as well as when they are deprived of sleep.
Results: When mice are not sleep-deprived, preliminary findings reveal an enhancement of beta and low gamma oscillations as well as a robust reduction in high gamma power (>80 Hz) – which is associated with internally-focused cognitive operations and external disengagement – during correct trial performance. These findings highlight a possible reprioritization of task-related network activity to produce a signal-to-noise ratio that underlies optimal signal-driven performance as animals anticipate information-bearing cues. Current manipulations involve depriving mice of sleep prior to task performance to better understand how variations in fast oscillations during attentional effort are disturbed following sleep loss and correlate with SD-induced performance impairments.
Conclusion: So far, these findings suggest rapid changes in neural dynamics as animals shift between behavioral states, including varying levels of exteroceptive awareness and external focus. Through these ongoing efforts, we endeavor to identify electrophysiological biomarkers of normal vigilance that can provide insights into attentional processing under normal conditions and inform potential treatments to mitigate oscillatory and behavioral disruptions caused by poor sleep.

UTILITY OF A SMARTPHONE ASSESSMENT OF ALERTNESS AND DECISION MAKING FOR REAL WORLD NIGHTTIME WAKING STUDIES

Paul Maruff[1], Hannah Cummins[2], Lisa Bransby[2], Yen Ying Lim[2]
[1] Cogstate, [2] Monash Univeristy

Introduction: Development of novel sleep promoting drugs requires demonstration that individuals sleeping, after having taken the drug at therapeutic doses, can be awoken by an unforeseen important event. Overnight waking studies require a small number of individuals be admitted to a research units where they are woken from drug-induced sleep and must perform tests of concentration and rapid decision making. This study examined the extent to which a validated cognitive assessment integrated into individuals' smartphones could be used to study unexpected nighttime waking in a real-world setting.
Methods: Middle-aged adults without sleep disorders were recruited to a study where they downloaded the Cogstate Brief Battery (CBB) to their personal smartphone and completed this twice during the daytime. They were instructed to sleep with the smartphone beside their bed, and that at sometime in the second week between 12am and 4pm they would receive a call on that smartphone. The smartphone would then display a link to initiate the cognitive assessment. This was repeated in the third week, so individuals completed the CBB in two overnight waking sessions.
Results: Of 52 people who volunteered, 98% woke at the call. Of these 100% performed the smartphone test with rate of missing data low (6%). Performance accuracy on each test was not meaningfully different between the daytime and nighttime-waking conditions (d's< 0.2). Speed of psychomotor function (d=1.21) and visual attention (d=-1.22) was slower in the nighttime waking condition. Speed of learning and decision making was not influenced by time of testing (d's< 0.2),. There were no differences in performance on any test between the two nighttime waking sessions, with test-retest reliability of each performance speed measure >0.7.
Conclusion: Smartphone-based cognitive assessment is a practical and usable method for examination of effects of pharmacological interventions on cognition in overnight waking studies. This method could allow studies to be conducted as part of larger trials with samples that better represent those who will ultimately use the drug.
Support (if any): The Cogstate Brief Battery was provided by Cogstate Ltd Melbourne. Paul Maruff is a part time employee of Cogstate

SLEEP AND PERFORMANCE ON TESTS OF PATTERN SEPARATION AND THE CAMBRIDGE NEUROPSYCHOLOGICAL TEST AUTOMATED BATTERY (CANTAB)

Aina Roenningen[1], Devan Gill[2], Brianne A. Kent[1]
[1] Simon Fraser University, [2] Adler University

Introduction: Sleep disturbances are considered both a risk factor and symptom of dementia. The present research aimed to identify cognitive tests that are associated with sleep quality or quantity, focusing on cognitive tests designed to evaluate the earliest cognitive changes in dementia.
Methods: We recruited younger (n=89) and older (n=40) adults and remotely monitored their sleep patterns for 7 consecutive days using wrist actigraphy and sleep diaries. On day 7, participants completed a battery of cognitive tests, which included the Prodromal Alzheimer's and MCI battery from the Cambridge Neuropsychological Test Automated Battery (CANTAB) and the Mnemonic Similarity Task (MST), which is a test designed to assess pattern separation. The Psychomotor Vigilance Task (PVT) was used as a positive control measure for all participants. The older adults were also assessed with the Montreal Cognitive Assessment (MoCA).
Results: Multiple linear regression models on the overall sample controlling for gender and age revealed that age was the strongest predictor of performance on MST and CANTAB DMS. Multiple linear regression models in the separate samples showed that sleep (i.e., total sleep time and sleep efficiency), MoCA score, and the interaction between gender and sleep were significant predictors for older adult's performance on the MST and CANTAB DMS. The regression analyses in the younger cohort revealed only significant effects of sleep efficiency on CANTAB PAL.
Conclusion: Performance on cognitive tests designed to assess pattern separation are sensitive to sleep patterns and the early cognitive changes associated with dementia, and should be evaluated for potential use as clinical trial outcome measures for sleep-promoting treatments in older adults.

OPTIMIZING CLOSED-LOOP AUDITORY STIMULATION TIMING TO MAXIMIZE PROCEDURAL MEMORY CONSOLIDATION

Jing Zhang[1], Bryan Baxter[2], Katherine Ostrow[3], Dara Manoach[4]
[1] Harvard Medical School/ Massachusetts General Hospital, [2] Harvard Medical School / Mass General Hospital, [3] Mass General Hospital, [4] MGH/HMS

Introduction: Closed-loop auditory stimulation during sleep (CLASS) enhances slow oscillations (SOs) by delivering short sound bursts synchronized to specific oscillations, such as SOs and spindles, which in turn boosts memory. The current study investigated the timing of stimulation in relation to NREM sleep oscillations to determine which timing was associated with better procedural memory consolidation. Based on prior literature on declarative memory, we hypothesized that stimulation during the SO upstate would lead to better memory.
Methods: Thirty-one healthy adults (15 F, Mage= 28.42 ± 4.92) completed up to three afternoon naps in the lab with EEG monitoring. During each visit, 50 ms bursts of pink noise were delivered during the upstate, downstate, or a randomly timed phase of detected SOs. Participants performed the finger-tapping motor sequence task (MST) before and after each nap to assess procedural memory consolidation. Over-nap improvement in the MST was modeled based on SO phase, SO amplitude, and sigma amplitude during stimulation. Theta phase and amplitude were included on an exploratory basis. We used linear mixed-effects models with a random effect for participants to account for repeated measures.

Results: MST improvement over the nap did not differ across conditions (F(1,3)=0.04, p=0.99,). Theta and sigma amplitudes during stimulation were significant predictors of memory consolidation (theta: B = 18.0, t = 2.19, p =.03; sigma: B = 158.3, t = 2.09, p =.04). These findings did not meet correction for multiple comparisons. Contrary to expectations, the SO phase (rho = 0.17, p=.49) and amplitude (B = -.005, t = -.07, p =.94) did not predict memory consolidation.

Conclusion: These preliminary findings suggest that higher theta and sigma activity during stimulation influence the effects of CLASS on procedural memory consolidation. Theta and sigma may contribute to this effect via cross-frequency coupling, but further analysis is needed to investigate this possibility. Additionally, theta and sigma may support memory processes differently from SOs, potentially due to distinct neural mechanisms involved in procedural versus declarative memory consolidation. Further research and replication are needed to clarify the specific roles of theta and sigma in memory consolidation within the context of CLASS.

EXTENDING OVERNIGHT FASTING TO IMPROVE CARDIOMETABOLIC HEALTH IN MIDDLE AGE AND OLDER ADULTS

Daniela Grimaldi[1], Kathryn Reid[1], Sabra Abbott[1], Kristen Knutson[1], Phyllis Zee[1]

[1] Northwestern University Feinberg School of Medicine

Introduction: Circadian rhythms play a fundamental role in regulating cardiometabolic function, with food intake serving as a key metabolic synchronizer. Emerging evidence suggests that time-restricted eating maybe a promising approach for improving cardiometabolic health. In this study we investigated the effect of a 6-week extended overnight fasting (EOF) intervention on glucose regulation, nighttime heart rate variability (HRV) and day-to-night change in blood pressure (BP) and heart rate (HR) in middle and older aged adults, a population particularly vulnerable to cardiometabolic disruptions.
Methods: Twenty-six adults (age: 58±8 years, BMI: 31±4 kg/m², post-menopausal if female, HbA1c < 6.5%) with a habitual overnight fast (OF) of ≤13 hours were randomized to either a 6-week EOF intervention (n=14, 57±7 years, 10 female) or control group (n=11, 60±9 years, 8 female). The EOF group had OF extended by 3 hours (12-16 hours OF) with the last meal consumed ≥3 hours before bedtime, while controls maintained their usual eating schedule. Participants were instructed to maintain their habitual sleep schedule, caloric and macronutrient intake throughout the study period. Assessments occurred during 3-day/2-night laboratory stays at baseline and post-intervention, including a morning 3-hour oral glucose tolerance test (OGTT), overnight HRV, 16.5-hour ambulatory BP and HR monitoring initiated in the afternoon, and polysomnography. Between-group differences in metabolic parameters, nighttime HRV, day-to-night BP and HR dipping, and sleep parameters were analyzed with age as a covariate.
Results: In response to the OGTT, the EOF group showed lower glucose levels ($p < 0.0001$) and higher 30-minute insulinogenic index ($p=0.032$), a measure of beta-cell function. EOF group exhibited reduced low-frequency to high-frequency ratio from HRV ($p < 0.0006$), and showed heightened day-to-night diastolic BP and HR dipping ($p=0.042$ and $p=0.028$, respectively). Sleep architecture remained unchanged between groups.
Conclusion: Six weeks of EOF improved regulation of glucose, nighttime autonomic balance and day-to-night dipping of diastolic BP and HR in middle and older-aged adults. These findings highlight the importance of the inclusion of circadian-aligned eating patterns in lifestyle interventions to enhance cardiometabolic function and health, particularly in older adults.

MULTI-LEVEL PHENOTYPIC MODELS OF CARDIOVASCULAR DISEASE AND OBSTRUCTIVE SLEEP APNEA COMORBIDITIES

Trung Le[1], Abhay Sharma[1], Phat Huynh[2]

[1] University of South Florida, [2] North Carolina A&T

Introduction: Cardiovascular diseases (CVDs) are prevalent among obstructive sleep apnea (OSA) patients, presenting significant challenges in predictive modeling due to the complex interplay of comorbidities. Current methodologies predominantly lack the dynamic and longitudinal perspective necessary to accurately predict CVD progression in the presence of OSA.
Methods: This study addresses these limitations by proposing a novel multi-level phenotypic model that analyzes the progression and interaction of these comorbidities over time. Our study utilizes a longitudinal cohort from the Wisconsin Sleep Cohort, consisting of 1,123 participants, tracked over several decades. The methodology consists of three advanced steps to capture the nuanced relationship between these comorbid conditions: (1) performing extensive feature importance analysis using tree-based models to highlight the predominant role of variables in predicting CVD outcomes. (2) developing a logistic mixed-effects model (LGMM) to identify longitudinal transitions and their significant factors, enabling detailed tracking of individual trajectories; (3) and utilizing t-distributed Stochastic Neighbor Embedding (t-SNE) combined with Gaussian Mixture Models (GMM) to classify patient data into distinct phenotypic clusters. In the analysis of feature importance, clinical indicators such as total cholesterol, low-density lipoprotein (LDL), and diabetes emerged as the top predictors, highlighting their significant roles in CVD onset and progression.
Results: The LGMM predictive models exhibited a high diagnostic accuracy with an aggregate accuracy of 0.9556. The phenotypic analysis yielded two distinct clusters, each corresponding to unique risk profiles and disease progression pathways. One cluster notably carried a higher risk for major adverse cardiovascular events (MACEs), attributed to key factors like nocturnal hypoxia and sympathetic activation. Analysis using t-SNE and GMM confirmed these phenotypes, showing marked differences in progression rates between the clusters.
Conclusion: The study highlights key predictive biomarkers and phenotypic patterns representing risk profiles and disease progression pathways of OSA comorbid with CVDs. Specifically, distinct patient clusters of CVD outcomes within the OSA populations have been identified. These clusters differentiate patients by severity and rapidity of disease progression. Future studies focus on expanding these findings through larger, more diverse cohorts and integrating additional predictive markers contributing to the complex etiology of CVDs and OSA.

Introduction: The current project builds upon existing literature suggesting that light exposure may play a role in metabolic function by examining the relationship between objectively measured 24-hour light exposure patterns and diabetes in middle-age to

older adults. The hypothesis is that those with diabetes will be more likely to experience low daytime light or high nighttime light levels.
Methods: The study included cross-sectional data from the CARDIA sleep ancillary study at Year 35. For seven days participants wore a wrist actigraphy monitor with an integrated light sensor and completed a sleep log. Data was collected in 30-second epochs and manually scored for rest intervals. Light variables include time above threshold for the 24-hour day, sleep intervals using 10, 100, 1000 lux thresholds. Diabetes was defined as fasting glucose ≥126 mg/dL or medication use. Logistic regression was used with diabetes as the outcome and light as the exposure. Model 1 adjusted for age, sex, race, field center, education, employment; Model 2 further adjusted for actigraphy measures (total sleep time, sleep fragmentation, sleep midpoint and 24-hour activity level).
Results: Data are from 861 participants with a mean age of 61.5±3.6 years, 63.1% female, 59.0% White, 57.4% employed, and 20.3% with diabetes. Participants with diabetes are 65.1% female, 37.1% White, and 49.1% employed. Those with diabetes spent less time above 1000 lux across the 24-hour day (45.3 (±46.6) mins vs. 59.3 (±53.2) mins), and more time above 10 lux during sleep intervals (8.76±25.5 vs 4.12±11.2 mins). Participants who spent the least time above 100 lux and 1000 lux during the 24-hour day had a higher odds of having diabetes (OR=1.79, 95% CI=(1.04, 3.07); OR=2.25, 95% CI=(1.28, 3.95), respectively) compared with those who spent the most time above specified threshold. Further adjustment (Model 2) attenuated the association.
Conclusion: Habitual light exposure patterns across the 24-hour day are associated with diabetes. Specifically, people with diabetes spend less time in bright light, which seems to be due to how much, how well and when they are sleeping and/or how active they are.

TIME OF EATING ASSOCIATED WITH BLOOD PRESSURE IN HEALTHY MIDDLE-AGED AND OLDER ADULTS

Kathryn Reid[1], Daniela Grimaldi[1], Sabra Abbott[1], Kristen Knutson[1], Marguerite McGuire[2], Sandra Bajc-Dimitrov[2], Phyllis Zee[1]
[1] Northwestern University Feinberg School of Medicine, [2] Northwestern University

Introduction: Recent studies suggest the duration of the overnight fast and how late we eat is related to health. The goal of this analysis was to examine the relationship between time of eating with blood pressure (BP) measures including mean arterial pressure (MAP) which is a key factor in supplying blood to body tissues. We will test the hypothesis that a longer overnight fasting period and longer duration between last meal and bedtime will be associated better BP measures in healthy middle-age and older adults.
Methods: This cross-sectional study recruited adults aged 35-75 years from the community. Participants had height, weight, %body fat (Bioelectrical Impedance Analysis), HbA1c (point of care) and blood pressure measured (average of 3 daytime measures after 5-minute seated) and completed questionnaires related to demographics, sleep and eating habits. Exposure variables included overnight fast duration (OF) and duration between last meal and bedtime (LMBT). The outcome variables were mean arterial pressure (MAP), systolic (SBP) and diastolic DBP) blood pressure. Multivariate regression models were used controlling for age, sex, %body fat, sleep duration.
Results: Data are from 405 participants with a mean (±stdev) age 52.09±10.2 years and 75.1% female. Means (±stdev) were: 30.4±6 kg/m2 for body mass index, 5.5±0.4% for HbA1c, 36.7±9.1% for % body fat, 125.05±17.5 mmHg for SBP, 80.67±10.3 mmHg for DBP, and 95.5±11.9 mmHg for MAP. Mean OF duration was 11.85±1.7 hours and LMBT duration was 2.64±1.4 hours. OF was negatively associated with SBP (r -0.11, p=0,03) and MAP (r -0.103, p=0.04) which was no longer significant after adjustment. The LMBT duration was negatively related to SBP (r -.013 p=0.009), DBP (r -0.10 p=0.03) and MAP (r -0.12, p=0.013). However, after adjustment only SBP and MAP remained significant (b=-1.42 p= 0.013 and b=-0.84, p=0.034, respectively).
Conclusion: These results suggest that in middle-aged and older adults that a longer interval between last meal and bedtime is associated with better blood pressure measures.

MODULATION OF THE PERIPHERAL ENDOCANNABINOID SYSTEM ACTIVATION ON SLEEP AND GUT MICROBIOME

Choa Sung[1], Meagan Marks[1], Resat Cinar[1], Andrew Kesner[1], Katherine Maki[1]
[1] National Institutes of Health

Introduction: The endocannabinoid system (ECS) regulates both sleep and gut physiology. Cannabinoid receptor (CB1R) activation in central nervous system via exogenous cannabinoids has been linked to changes in sleep dynamics, but the role of peripheral CB1R activation in sleep remain unclear. The gut microbiome can modulate the intestinal ECS tone through changes in bacterial lipopolysaccharide levels and composition. Using a peripherally restricted CB1R agonist (CB13), we examined the effect of ECS on the gut microbiome and sleep architecture.
Methods: Nineteen C57BL/6J mice received intraperitoneal injections (1 mg/kg) of CB13 or vehicle for 6 days, with monitoring continuing for 6 days post-intervention. EEG/EMG recordings and fecal samples were collected at baseline, end-intervention, and end-recovery. Sleep was quantified as REM and NREM sleep hours during the 12-hour light period. Gut microbiome composition was assessed using shotgun metagenomic sequencing. Linear mixed-effects models analyzed the effects on sleep and alpha diversity (Shannon index) with Tukey post-hoc tests when appropriate. Correlations examined NREM and Shannon diversity associations at end-intervention and end-recovery. Unadjusted $p < 0.05$ was considered significant.
Results: Time had a significant effect on NREM and REM sleep (p=.034, p<.0001, respectively), but no intervention effects were observed (NREM: p =.535; REM: p =.746). Peripheral ECS activation influenced global microbiome characteristics (Shannon:

group x time p <.001). Mean Shannon diversity was lower in the CB13 group, significantly at end-intervention (p =.010), but not at end-recovery. Group-specific relationships between NREM and Shannon indicated a strong negative association at end-intervention (r = -0.784, p =.037) that switched to a positive association at end-recovery (rho = 0.75, p =.14). The strength or direction of associations were not reflected in controls.
Conclusion: These findings suggest peripheral ECS activation influences alpha diversity, and that the gut microbiome may modulate NREM sleep via ECS pathways, highlighting the potential importance of studying microbial-mediated ECS mechanisms in sleep. Our ongoing research explores ECS pathways and the impacts of alcohol vs. alcohol and cannabis co-use on sleep and the microbiome.

BREATHING PATTERNING VARIATION DURING POLYSOMNOGRAPHY ACROSS TIME AND SLEEP STAGE

Anna May[1], Thomas Ciardi[2], Farhad Kaffashi[2], Kenneth Loparo[2], Kingman Strohl[3]
[1] VA Northeast Ohio Healthcare System, [2] Case Western Reserve University, [3] University Hospitals Cleveland Medical Center

Introduction: Sleep stages effect breathing patterning with more variation in tidal volume and respiratory rate during rapid eye movement (REM) compared to non-REM sleep. Variation of these metrics across the night, however, is not well-elucidated. We hypothesize that breathing variability in stage N2 is more stable over time compared to REM.
Methods: A retrospective cohort of 2081 polysomnography (1512 diagnostic and 569 titration) polysomnographies in 2014 people from the Department of Veteran Affairs Northeast Ohio Healthcare system (1/1/2010–12/31/2020). Participant demographics at the time of study were assessed using the integrated electronic medical record. Sleep studies were scored for sleep stage by the Stanford University automated scoring algorithm. Studies were included in analyses if at least 15 minutes of usable data for at least one sleep stage was available for analysis. Five-minute contiguous intervals of breathing during wake, N2, and REM sleep were separately analyzed for coefficient of variation (CV) of inspiratory time as a measure of breathing patterning. Linear fits of CV were used to analyze change over time within each sleep stage. Sensitivity analysis included using median absolute deviation of CV and CV of expiratory time and total breath time. We also evaluated differences between diagnostic and titration studies.
Results: Participants were average age 58.2±13.2 years, 92.4% male, mean body mass index of 33.2±6.5 kg/m2. For inspiratory time, N2 had lower linear trend over time compared to both wake and REM (β=-0.0006 for N2, β=0.0113 for wake, β=-0.0157 for REM). Trends were similar for expiratory time and total breath time. Results for expiratory and total breath time were similar to main analyses. Diagnostic studies had higher linear trend for all sleep stages evaluated compared to titration. Median absolute deviation was lowest for N2 compared to wake and REM in both diagnostic and titration studies.
Conclusion: Breathing patterning has greater stability over time within every sleep stage in titration compared to diagnostic sleep studies. N2 has less breathing patterning variation over time than wake or REM sleep.

FACILITY-MEASURED NOCTURNAL HYPOXEMIA AND SLEEP IN LONG COVID: AN OBSERVATIONAL STUDY

Haoqi Sun[1], Rammy Dang[1], Monika Haack[1], Kristine Hauser[1], Jennifer Scott-Sutherland[1], M. Brandon Westover[1], Sairam Parthasarathy[2], Susan Redline[3], Robert Thomas[1], Janet Mullington[1]

Introduction: Persistent post-acute sequelae of SARS-CoV-2, i.e., long COVID, is a heterogeneous syndrome involving multiple organ systems. While lower blood oxygen is expected when SARS-CoV-2 infects the lungs, hypoxia without pulmonary symptoms can continue after the acute phase. Ventilation and blood oxygen are more vulnerable during sleep, but nocturnal hypoxemia has not been studied in long COVID in a facility setting using polysomnography (PSG). Here, we characterized blood oxygen levels during sleep.
Methods: This was an observational study with 50 participants (25 long COVID, 25 age-sex-matched healthy controls) using in-laboratory overnight PSG. The long COVID participants were recruited via advertisement and postings on ClinicalTrials.gov (NCT03377543, NCT05606211) and referrals from Beth Israel Deaconess Medical Center, Boston, MA. The controls were a convenience sample of past healthy participants. We calculated the average SpO2, average SpO2 after removing desaturations, hypoxic burden using all desaturations, and respiratory rate. We studied these metrics in different sleep periods and stages. We adjusted for body mass index since it is negatively associated with SpO2. We used the Bonferroni multiple tests correction.
Results: The average SpO2 was lower in long COVID: 1.0% lower after sleep onset until lights on (p = 0.004) and 0.7% lower during REM (p = 0.002); average SpO2 after removing desaturations was also lower in long COVID: 1.3% lower after sleep onset until lights on (p = 0.002), 0.9% lower during REM (p = 0.0004), and 1.4% lower during NREM (p = 0.003); and respiratory rate was 1.4/minute higher in long COVID during REM (p = 0.005). Hypoxic burden showed no difference.
Conclusion: The results suggested that long COVID have a persistent lower nocturnal blood oxygen saturation. The findings highlight the need for further research to better understand how long COVID affects sleep and health.

NOCTURNAL BLOOD PRESSURE AS AN EMERGING BIOSIGNAL IN SLEEP

Yeilim Cho[1], Justyna Swierz[2], Rishi Ananth[3], Swati Levendovszky[3], Vishesh Kapur[3], Brian Palen[4], Miranda Lim[5], Elaine R. Peskind[6], Jeffrey J. Iliff[7]

[1] VA Puget Sound, [2] VISN20 MIRECC, [3] University of Washington, [4] Veterans Affairs, [5] Oregon Health & Science University, [6] University of Washington, School of Medicine, Department of Psychiatry and Behavioral Sciences, [7] VISN [20] Mental Illness Research, Education, and Clinical Center

Introduction: Sleep blood pressure (BP) is an important cardiovascular marker. A sporadic BP measurement by traditional oscillometric ambulatory BP monitoring cannot capture dynamic BP fluctuation occurring in sleep. Acute BP surges accompanying an pathological sleep event such as an obstructive sleep apnea (OSA) may provide clinically meaningful information. Based on the inverse relationship between BP and pulse transit time (PTT), PTT can be used to track BP changes. In this study, we tested the hypothesis that individuals with OSA would exhibit variable nocturnal BP fluctuations.
Methods: We included study participants enrolled in a prospective study that aims to investigate the brain glymphatic function in Veterans with OSA. All participants underwent a home sleep study using a system that records PTT via electrocardiography (ECG) and photoplethysmography (PPG). We derived a nocturnal BP fluctuation index (NBPFI), defined as the number of events per hour with systolic BP increase more than 12 mmHg from baseline in association with OSA events. We categorized NBPFI into OSA events with and without accompanying significant desaturation (>=4%). We evaluated the association between NBPFI normalized by AHI and its association with total time spent with oxygen desaturation below 90% (T90%).
Results: Among 7 participants enrolled, 5 participants achieved successful PTT-based BP recording (mean age± SD =53.4 years old±6). All participants had moderate to severe OSA with a mean apnea-hypopnea index (AHI) of 42/hr. ±18 and mean T90% of 27min±20. Regarding the BP surge, the mean maximal BP surge was 28±1.8 mmHg and mean absolute maximal systolic BP was 152 mmHG±23. All participants exhibited NBPFI (rages from 14 to 36/hr.) with mean of 22.9/hr±9.2 with mean NBPI related to without (18.2/hr. ±9.2) and with hypoxia (2.1/hr±2.0). A trend of inverse association was observed between NBPFI normalized by AHI and T90% but not statistically significant.
Conclusion: We found highly variable BP surge patterns in response to OSA events. There appears to be an inverse relationship between the degree of hypoxemia and BP surge events. Future work should investigate how and whether OSA related BP surge events would be related to brain glymphatic function.

Introduction: Suicidal self-directed violence (SSDV) has been previously associated with Toxoplasma gondii (T. gondii) IgG positivity and intensity, blood levels of quinolinic acid (QUIN, positively), picolinic acid (PIC, negatively) and kynurenic acid (KYNA, negatively), and sleep disturbance (insomnia, daytime sleepiness, positively). We examined associations between T. gondii IgG serointensity, excitotoxic and neuroprotective kynurenines and their ratios, and sleep disturbance in U.S. Veterans enrolled in mental health treatment.
Methods: Veterans from three Veterans Affairs Medical Centers participated in the study (N=407, mean age = 45.6 ± 11.6 years; 74.7% men). Of these, 203 had a history of SSDV, while 204 had no history of self-directed violence (SDV). T. gondii IgG was measured with ELISAs. QUIN and PIC were analyzed with GC-MS, KYNA with UPLC-MS/MS. Sleep disturbance was estimated using Pittsburgh Sleep Quality index (PSQI). Statistics included ANCOVAs and logistic regressions.
Results: High T. gondii serointensity (classified as high-top quartile) was significantly associated with daytime dysfunction due to sleepiness ($p < 0.05$) in SSDV positive Veterans. This relationship remained significant after adjusting for socioeconomic factors status. T. gondii seropositivity was significantly associated with QUIN positively and PIC/QUIN, and KYNA/QUIN negatively ($p< 0.05$). In turn, QUIN was positively associated with daytime dysfunction due to sleepiness ($p=0.007$) and KYNA/QUIN and PIC/QUIN ratios were negatively associated with sleep disturbance, sleep latency, daytime dysfunction, and PSQI total score ($p< 0.05$).
Conclusion: Limitations include the cross-sectional design, low seropositivity, lack of data on sleep apnea and actual recording of sleep, and multiple comparisons. Sleep- wake dysregulation was positively associated with T. gondii serointensity and QUIN, and negatively with neuroprotective kynurenine ratios. These findings warrant replication in larger, longitudinal studies with direct measuring of sleep parameters.

ODDS RATIO PRODUCT IS ASSOCIATED WITH BLUNTED HEART RATE VARIABILITY INDEPENDENT OF CORTISOL LEVELS IN ADOLESCENTS

Anthony Rahawi[1], Jidong Fang[1], Susan Calhoun[1], Alexandros Vgontzas[2], Duanping Liao[1], Edward Bixler[1], Julio Fernandez-Mendoza[1]

[1] Penn State College of Medicine, [2] Sleep Research and Treatment Center, Penn State College of Medicine

Introduction: We previously showed that the odds ratio product (ORP), an EEG measure of sleep depth, was associated with lower heart rate variability (HRV), an EKG measure of cardiac autonomic modulation (CAM). Specifically, ORP was associated with decreased low-frequency (LF) and standard deviation between normal sinus rhythms (SDNN) in adolescents. Cortisol, a glucocorticoid of the HPA axis, is secreted in response to stress and is associated with short sleep. As both HRV and cortisol can reflect physiologic responses to stressors, we examined whether the association of in-lab ORP with at-home HRV is independent of in-lab cortisol levels.

Methods: We studied 310 adolescents from the Penn State Child Cohort (Md age=16y; 46% female, 24% racial/ethnic minority). We extracted ORP during NREM sleep from 9-hour, in-lab polysomnography (PSG), evening and morning cortisol levels from saliva samples at 19:00 before PSG and 7:00 following PSG, and LF and SDNN from Holter EKG monitoring during the 24-h after PSG. Stepwise linear regression models first examined the association between ORP with 24-h LF and SDNN. Thereafter, evening or morning cortisol levels were added to the models. Finally, the interaction terms were included in the models. Covariables included sex, age, race/ethnicity, obesity, metabolic syndrome, PSG-measured sleep apnea, insomnia symptoms, and actigraphy-measured sleep duration.

Results: Commensurate with prior findings, higher ORP was associated with lower LF (daytime P=0.041; nighttime P=0.005) and SDNN (nighttime P=0.029). Higher ORP remained associated with lower LF and SDNN after adjusting for evening (LF: daytime P=0.041, nighttime P=0.005; SDNN: nighttime P=0.030) or morning cortisol levels (LF: daytime P=0.043, nighttime P=0.005; SDNN: nighttime P=0.030). The interaction terms between ORP and cortisol levels on LF or SDNN were not statistically significant (all-Ps>0.10). Neither evening nor morning cortisol levels were associated with ORP, LF or SDNN (all-Ps>0.10); yet, evening cortisol levels were associated with shorter PSG-measured sleep duration (P=0.01).

Conclusion: The association between NREM sleep depth and CAM is independent of acute cortisol levels in adolescents. Future studies should examine whether chronic activation of the HPA axis synergistically impacts the association between sleep depth, sleep duration and CAM in adolescents.

EFFECTS AND GENDER DIFFERENCES OF COMBINED HAND AND FOOT BATHING ON HEAT DISSIPATION, DAYTIME SLEEP STRUCTURE, SUBJECTIVE EVALUATION

An Saotome[1], Maki Hagita[2], Rinna Saito[2], Yuka Fujiki[2], Momo Fushimi[1], Sayaka Aritake-Okada[1]

[1] Saitama Prefectural University, Graduate School of Health Sciences and Social Work, [2] Saitama Prefectural University, School of Health Sciences

Introduction: Partial body bathing, such as foot bathing, is often used in nursing care and caregiving to improve sleep quality. However, previous studies have focused on subjective evaluation methods, and limited attention has been paid to objective evaluation and the physiological mechanisms underlying these bathing practices. We investigated the relationships among heat dissipation caused by combined hand and foot warm bathing, changes in body temperature, objective sleep structure, and subjective evaluation, as well as examining potential gender-related differences in these parameters among healthy subjects. This study was approved by the ethical committee of Saitama Prefectural University.

Methods: Thirty healthy adults (14 men, 16 women; mean age, 21.47±1.50 years) participated in a 2-day experiment involving a baseline condition (35 ºC) and warm bath condition (40 ºC) using a crossover design. In each condition, participants took a 15-minute hand and foot bath during the day, followed by 1-hour daytime polysomnography. We measured distal skin temperatures (hands and feet) and proximal skin temperatures (subclavian region and forehead) to determine the distal–proximal skin temperature gradient (DPG). Participants completed a visual analogue scale assessment for subjective evaluation after sleep. A registered polysomnographic technologist scored the sleep stages in 30-second epoch periods according to the Scoring Manual of the American Academy of Sleep Medicine.

Results: The DPG during bathing, after bathing, and during sleep were significantly higher in the warm bath than baseline condition ($p < 0.05$, respectively). The duration of slow-wave sleep (SWS) was longer in the warm bath condition (p=0.057), particularly at 20–40 minutes after bedtime (p=0.018). Warm baths improved subjective mental evaluation in women (mental fatigue: p=0.032, difficulty organizing thoughts: p=0.041) and subjective physical evaluation in men (arm sluggishness: p=0.049, backache: p=0.068). In the warm bath condition, stronger SWS was positively correlated with subjective mental evaluation improvement in women (mental fatigue: rho=-0.570, p=0.042, difficulty organizing thoughts: rho=-0.596, p=0.032).

Conclusion: A 15-minute combined hand and foot warm bath promoted heat dissipation and increased the duration of SWS. There were gender differences in the effects of warm hand and foot baths, with improved physical evaluation in men and improved mental evaluation scores in women.

THE ASSOCIATION BETWEEN PHYSIOLOGICAL AROUSAL AND SLEEP EEG MICROSTRUCTURE IN YOUNG ADULTHOOD AND MIDDLE AGE

Xinran Niu[1], Kristin Sanders[1], Elizabeth Kensinger[2], Jessica Payne[1]
[1] University of Notre Dame, [2] Boston College

Introduction: Sleep microstructure, characterized by distinct patterns of brain activity during different sleep stages, has been linked to various physiological and emotional processes. Slow-wave and rapid eye movement (REM) sleep are two prominent sleep stages that are known to influence physiological arousal through the parasympathetic nervous system activity. This study examines the association between microstructure features during slow-wave and REM sleep and heart rate deceleration (HRD) in response to emotional stimuli.
Methods: A total of 133 healthy young (ages 18–35) and middle-aged (ages 36–59) adults viewed a series of negative (e.g., a vicious looking snake) and neutral objects (e.g., a chipmunk), superimposed on neutral backgrounds (e.g., an avenue). During scene viewing, HRD was recorded to measure physiological arousal to negative and neutral scenes. All participants underwent one night of laboratory-monitored polysomnography (PSG), where REM count (total number of REMs across all REM sleep) and slow-wave count (total number of slow waves across all slow-wave sleep) were recorded.
Results: In middle-aged adults, a higher slow-wave count was associated with an increased HRD response to negative scenes (r=0.29, p=.051), but not neutral scenes (r=0.15, p=.319). In contrast, a higher REM count was linked to increased HRD responses to both negative (r=0.34, p=.044) and neutral scenes (r=0.40, p=.017). Correspondingly, a higher slow-wave count was associated with a steeper HRD response to negative versus neutral scenes (r=0.30, p=.044), while REM count did not predict this difference (r=0.07, p=.674). In young adults, however, neither slow-wave nor REM count were correlated with HRD responses (ps>.7).
Conclusion: Microstructure features during slow-wave and REM sleep may differentially influence physiological arousal responses in middle-aged but not younger adults. Slow-wave activities may enhance the discrimination between emotionally salient and neutral information, whereas REM sleep seems to exert a more generalized parasympathetic influence on physiological arousal. These age-related differences in the impact of sleep microstructure on physiological arousal highlight the importance of sleep for maintaining emotional well-being and longevity.

DREAM AFFECT AND SELF-REPORTED WAKING BEHAVIORAL RESPONSES: A LOGISTIC REGRESSION ANALYSIS

Garrett Baber[1], Nancy Hamilton[1], Matthew Gratton[1]
[1] University of Kansas

Introduction: Dreams are hypothesized to influence waking behavior through affective dream experiences. However, it remains untested whether positive affect (PA) and negative affect (NA) in dreams predict approach and avoidance behaviors in waking life. This study examines the relationship between self-reported dream affect and approach or avoidance behaviors toward the subject of the dream.
Methods: A total of 218 participants provided dream reports and rated their dreams' positive affect and negative affect on a 0–10 scale. Participants also reported whether the dream influenced them to approach or avoid (or neither/unsure) the subject of their dream in waking life. Binary logistic regression models were fitted to predict approach and avoidance behaviors separately, using either dream PA or NA as predictors. PHQ-9 total scores (excluding the suicidality item) were included as a covariate to account for amotivational symptoms. The correlation between PA and NA was -0.78, so the predictors were modeled separately to avoid multicollinearity.
Results: For avoidance, NA was positively associated with avoidance behavior (OR = 1.61, 95% CI [1.08, 2.50], p =.025), while PA was negatively associated with avoidance (OR = 0.50, 95% CI [0.30, 0.78], p =.004). PHQ-9 scores were not significant predictors in either model. For approach, PA was positively associated with approach behavior (OR = 1.45, 95% CI [1.06, 2.01], p =.021). NA was not a significant predictor of approach (OR = 0.99, 95% CI [0.73, 1.36], p =.962), nor were PHQ-9 scores in either model.
Conclusion: Dreams with high negative affect and dreams with low positive affect were more likely to elicit self-reported avoidance behaviors in waking life, while dreams with high positive affect were more likely to promote self-reported approach behaviors. Negative dream affect was not related to approach behaviors. Depressive symptoms did not influence these relationships. These findings indicate that the affective content of dreams may shape waking behaviors and suggest distinct pathways for avoidance and approach.

EFFECT OF SLEEP DURING REDUCED TEMPO TRANSITION PERIODS ON READINESS AND HEALTH DURING HIGH STRESS NAVAL OPERATIONS

Sean Deering[1], Peter Roma[1], Alice LaGoy[1], Andrew Kubala[1], Josue Uriarte[1], Dale Russell[2], Rachel Markwald[3]
[1] Naval Health Research Center, [2] US Air Force, [3] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA

Introduction: As U.S. Navy ships prepare for deployment, crews experience alternating periods (days to weeks) of fluctuating operational tempo, with in-port operations serving as recovery from and preparation for demanding at-sea missions. Poor sleep in-mission and its effects on operational readiness are well known and uncontrollable, so it is critical to understand the impact of sleep during in-port periods on subsequent in-mission readiness and health. This study examined relationships between sleep during in-port periods and markers of operational readiness and health during subsequent missions.
Methods: 309 personnel from eight Littoral Combat Ships participated in the study. Sailors were continuously monitored using commercial wearable sleep-trackers (Oura™ Ring, Generation 2 or 3) across 695 in-port operations and at-sea periods. For each

sailor, mean and standard deviation of total sleep time (TST) and sleep efficiency (SE) during each in-port period were computed, as well as mean of resting heart rate (HR, bpm) and heart rate variability (HRV; RMSSD in msec) across the subsequent at-sea mission period. Linear mixed-effects models with random intercept by individual, and age and gender covariates were used to assess relationships between sleep and number of in-port days with HR/HRV during subsequent high-stress mission periods.

Results: Analyses showed significant effects of daily TST in-port on subsequent HR and HRV responses (Fs > 8.9, ps <.003, R2 = 0.27-0.36), whereby more sleep in port associated with lower HR and higher HRV in mission. Analyses also revealed significant standard deviation of TST × in-port duration interaction effects (Fs > 5.0, ps <.03), whereby consistent TST in port associated with lower HR and higher HRV in mission, but longer periods of variable TST in port yielded increased HR and decreased HRV (all other effects, Fs < 2.4, ps >.13).

Conclusion: These data demonstrate the importance of sufficient sleep quantity and consistency during reduced-tempo transition periods as both recovery from and preparation for high-stress mission operations. This study aimed to clarify the value of sleep during in-port periods on personnel health and readiness at sea, potentially informing optimal timing and duration of transition periods to support operational readiness.

DO SELF-RATED STRESS LEVELS REFLECT GREATER SLEEP PROBLEMS? LINKING REPORTED STRESS TO SLEEP EFFICIENCY

Elijah Nichols[1], Matthew Gratton[1], Garrett Baber[1], Anna Quesada[1], Nancy Hamilton[1]

[1] University of Kansas

Introduction: The linkage between chronic stress and sleep disruption is often known, but the extent to which self-rated stress levels predict specific sleep-related problems remains unclear. This study examined whether individuals who self-report more severe stress demonstrate differences in total sleep time (TST), sleep efficiency (SE), and sleep architecture (i.e., time spent in each stage).

Methods: Data are from the Sleep Heart Health Study (SHHS, N=5,804). Stress was measured using the Sleep Habits Questionnaire (SHQ), a standardized self-report that measures the individual's sleep patterns and behaviors, as well as the severity of reported stress and its impact on sleep. Linear regression models evaluated the relationship between stress and various sleep parameters, including TST, SE, and time spent in Stages 1, 2, and 3–4 of sleep. Models were run both unadjusted and adjusted for covariates (age, sex, race).

Results: In unadjusted models, higher stress levels were associated with slightly longer TST (β=4.61, 95%CI [2.35, 6.87], p< 0.001, R^2=0.0028) and higher SE (β=0.93, 95%CI [0.56, 1.30], p< 0.001, R^2=0.0042). However, after adjusting for demographics, these associations were diminished and no longer statistically significant, TST (β= 1.83, 95% CI [-0.43, 4.09], p= 0.108, R^2=0.049) and SE (β= 0.33, 95% CI [-0.03, 0.68], p= 0.07, R^2=0.084), with overall model fit improving modestly after adjusting for covariates. Stress was not significantly associated with the percentage of time in Stage 1 (β= −0.06, 95%CI [-0.20, 0.08], p=0.43) or Stages 3–4 (~40.79 minutes, β= −0.60, 95%CI [-2.05, 0.85], p=0.42). A marginally positive association emerged for the percentage of time in Stage 2 (~59.67 minutes; β=0.40, 95%CI [0.00, 0.80], p=0.049).

Conclusion: The unadjusted models suggest that there is a positive association between an individual's self-reported stress and measures of objective sleep. However, the associations between self-reported stress and objective sleep measures are diminished after accounting for certain demographic factors. Future research should investigate interactions between perceived stress and other physiological or psychological factors within more diverse samples to better understand the nuanced stress-sleep relationship.

DEPRESSIVE AND DYSREGULATED: EXAMINING PERSONALITY FACTORS AMONG BEDTIME PROCRASTINATORS

Steven Carlson[1], Paula Williams[1]

[1] University of Utah

Introduction: Introduction. Bedtime procrastination, or the tendency to delay bedtime in the absence of external obligations, is consistently associated with insufficient sleep. Although technology use and difficulties with self-regulation are recognized as antecedents to this behavior, little is known of other psychological correlates of bedtime procrastination. Accordingly, the purpose of the present study is to explore the associations between bedtime procrastination and Five Factor Model personality traits (i.e., Neuroticism, Extraversion, Openness, Agreeableness, Conscientiousness). Further, we aimed to determine whether bedtime procrastinators had a unique pattern of associations with personality compared to evening chronotypes.

Methods: Method. 390 young adults (Mage = 24.4, SD = 6.5) completed a questionnaire battery consisting of self-reported measures of personality (NEO-PI-3) and chronotype (Morningness-Eveningness Questionnaire), followed by 14-daily assessments of bedtime procrastination and sleep diaries. Correlational and regression analyses were used to determine the associations among bedtime procrastination, chronotype, and personality scales (domain and facet scales).

Results: Results. Bedtime procrastination (r = -0.27), eveningness (r = -0.24), and later habitual bedtime (r = -0.21) were all negatively associated with Conscientious (ps < 0.001). Bedtime procrastination (r = 0.41, p < 0.001) and eveningness (r = 0.14, p = 0.005) were also associated positively with Neuroticism. Further, bedtime procrastination was negatively associated with Extraversion (r = -0.20, p < 0.001). Bedtime procrastination remained significantly associated with these domains after statistically adjusting for chronotype. Notably, bedtime procrastination was associated with all facets of the Conscientiousness, Neuroticism, and Extraversion domains, except for the Excitement Seeking facet of Extraversion. Facets of Openness (higher Aesthetics and Actions) and Agreeableness (lower Trust and Altruism, higher Modesty) were also associated with bedtime procrastination.

Conclusion: Discussion. Bedtime procrastination was associated with lower Conscientiousness, Extraversion, and higher Neuroticism. Notably, bedtime procrastination, but not chronotype, was negatively associated with Extraversion. These findings suggest that propensity to high negative affect and low positive affect (i.e.,

depressive tendencies) along with self-regulation difficulties may be relevant in the development of bedtime procrastination.

LONGITUDINAL EXAMINATION OF THE EFFECTS OF CYCLIC BREATHING ON SLEEP: A PILOT STUDY

Serge Onyper[1], Joseph Mocerine[1], Gabrielle-Catherine Cote[1], Amelia Burkhard[1]
[1] St. Lawrence University

Introduction: Breathwork techniques such as box breathing and paced breathing have been gaining popularity in clinical mental health settings as means to manage stress and enhance well-being. This study explored the impact of a novel controlled breathwork method, cyclic breathing, on sleep in college students. Cyclic breathing involves a double inhale (the first inhale being longer than the second) followed by a prolonged exhale. This is the first study to examine the effects of cyclic breathing on sleep.
Methods: 41 participants were randomly assigned to the intervention or control group and completed baseline measures of sleep (PSQI), anxiety, mood, and perceived control. Additionally, physiological measures—heart rate (HR), respiration rate, blood pressure (BP), and electrodermal activity (EDA)—were recorded while participants were exposed to an auditory stressor (a compilation of emergency and construction sounds played at 70-80dB for 5 minutes). Over the next 4 weeks, participants in the intervention group were instructed to practice cyclic breathing daily. Both groups completed modified CSD (Consensus Sleep Diary) daily. Finally, participants returned to the laboratory, where they were exposed to a different auditory stressor and instructed to breathe naturally and completed the same self-report measures as during the initial session and the CSM (Composite Scale of Morningness).
Results: Participants in the control group experienced declines in TST over the course of the study, unlike those in the intervention group. The intervention group also reported shorter SOL and lower TWT after one month compared to the control group. Physiological measures recorded during the second session indicated that the intervention group exhibited lower HR, lower EDA, and higher vagal tone when exposed to a stressor. The intervention did not significantly impact global self-reported measures of PSQI, stress, anxiety, or mood.
Conclusion: Our findings suggest that cyclic breathing may serve as a simple, accessible tool to enhance sleep and improve resilience to stress. Future research should explore factors influencing treatment adherence, as well as the potential for integrating cyclic breathing into broader interventions to support sleep health and overall well-being.

LUCID DREAMING: A POTENTIAL OUTLET FOR AN EXTERNAL LOCUS OF CONTROL

Otis Eads[1], John Richmond Sy[1], Ruth Brombach[1], Jessica Dietch[1]
[1] Oregon State University

Introduction: Lucid Dreaming, defined by a preserved sense of insight, thought, and control while dreaming, has been previously linked to internal locus of control, resilience and problem-solving. Lucid Dreaming may be important for individuals to exert a sense of agency in both dreams and daily life. This study therefore investigates how locus of control relates to lucid dreaming frequency.
Methods: Participants (N = 348, 75% Women, M = 22, SD = 6.3) recruited through Oregon State University's SONA system completed a survey assessing their sleep, locus of control, and dreaming. A moderation analysis was conducted in SPSS to determine whether lucid dreaming identity moderates the association between locus of control and lucid dreaming frequency.
Results: Some participants (n = 38) met criteria for and self-identified themselves as lucid dreamers. Lucid dreaming frequency was significantly higher on average for identifying lucid dreamers (about once a month) compared to non-lucid dreamers (less than once a year). Results of the moderation analysis indicated a significant interaction between locus of control and lucid dreaming identity (b = -0.06, SE = 0.03, p = 0.04). Higher external locus of control was associated with greater lucid dreaming frequency for lucid dreamers.
Conclusion: External locus of control was associated with higher lucid dreaming frequency for lucid dreamers but not for non-lucid dreamers. These findings suggest that individuals who experience an external locus of control during the day may use lucid dreaming to reclaim a sense of agency. Future research should continue to investigate the mechanisms of lucid dreaming experiences, especially related to resiliency and problem solving. Additionally, future research should investigate lucid dreaming experiences in people with an external locus of control to better understand new ways people may utilize lucid dreaming productively.

EXAMINING THE IMPACT OF LATE VERSUS EARLY MEAL TIMING ON MOOD IN A RANDOMIZED CROSSOVER TRIAL

Ioannis Lempesis[1], Jingyi Qian[1], Nina Vujovic[2], MaryClare Pikus[1], Frank Scheer[1]
[1] Brigham and Women's Hospital, [2] Brigham and Women's Hospital

Introduction: Among shift workers, there is an increased prevalence of mood-related disorders. Our previous work showed that simulated night shifts adversely affect mood. We have also shown that daytime meal intake only, versus daytime and nighttime, during simulated night shifts, mitigated such adverse effects. These observations indicate that aligning mealtime to the circadian system can benefit mood independent of mistimed sleep/wake schedules. However, whether changing the timing of food intake without changing the sleep/wake cycle influences mood regulation is unknown. We hypothesize that a later eating schedule worsens mood compared to an earlier one during day shifts.
Methods: We conducted a randomized, controlled, crossover trial (ClinicalTrials.gov NCT02298790) to determine the effects of late versus early eating while rigorously controlling nutrient intake, physical activity, sleep, and light exposure. We assessed eight mood perception measures hourly during two test days for both eating protocols to assess the effect of the first day and the fourth day of late eating. Mood was assessed using computerized visual analog scales (VAS). The main outcome for mood was "HAPPY" (from 0 sad to 100 happy). We also

assessed three measures for well-being ("SICK", "STRESSED", and "UNMOTIVATED"), and four for mental/physical sleepiness ("ALERT", "SHARP", "FRESH AS A DAISY", and "PHYSICALLY EXHAUSTED"). Measures were analyzed by linear mixed model.

Results: 15 participants (mean±SD; age, 36.06±10.8 years; 4 women; BMI, 29.05±2.47 kg/m2) completed this study and contributed mood data. During the test days, late eating decreased the daily average rating of "HAPPY" (p=0.0074). Consistently, late eating increased the daily average rating of "SICK" (p=0.0043). However, late eating decreased ratings of "UNMOTIVATED" (p=0.0003) and "PHYSICALLY EXHAUSTED" (p=0.0313). There was an interaction effect of protocol (late vs. early eating) and test day (first vs. fourth day) for "FRESH AS A DAISY" (p=0.0346) and "ALERT" (p=0.0021), being greater for late eating during the fourth day. The other measures were not significantly influenced.

Conclusion: These findings demonstrate that meal timing may affect mood. Future studies are required to examine if longer-term changes in meal timing affect mood and determine underlying mechanisms.

CARDIAC EVENT-INDUCED PTSD SYMPTOMS LINK TO CONTINUOUS HEART RATE IN CORONARY ARTERY DISEASE PATIENTS, INDEPENDENT OF SLEEP AND DIURNAL VARIATION

Maia ten Brink[1], Joseph Schwartz[1], Talea Cornelius[1], Ian Kronish[1], Ari Shechter[1], Keith Diaz[1], Sung Lee[1], Gabriel Sanchez[1], Redeana Umland[1], Gaspar Cruz[1], Richard Sloan[1], Sachin Agarwal[1], Donald Edmondson[1], Jeffrey Birk[1]

[1] Columbia University Irving Medical Center

Introduction: Elevated posttraumatic stress symptoms (PSS) affect among ~13% of coronary artery disease (CAD) patients after acute cardiac events. PSS have been separately associated with short sleep duration and elevated sympathetic nervous system activation (SNA), both of which increase risk for recurrent cardiovascular events. We investigated the association between PSS and heart rate (HR), indexing SNA, in the daily lives of recently discharged cardiac patients, independent of sleep and diurnal HR variation.

Methods: Patients were enrolled in the emergency room of a large urban hospital, had confirmed acute coronary syndrome (ACS) or prior CAD with suspected ACS, were taking >1 cardiovascular medication, and had elevated or non-elevated PSS (PTSD Checklist for DSM-5 [PCL] score ≥20 or ≤5) 1 month post-discharge. Participants completed two weeks of 24-hour electrocardiography monitoring (ZioPatch). Sleep and physical activity were monitored with actigraphy. Beta-blocker adherence was assessed via electronic pill caps. Three-level multilevel cosinor wave models tested associations between PSS and HR, adjusting for diurnal HR variation, sleep episode length, and other factors known to influence HR: physical activity, beta-blocker adherence, and demographic/medical covariates.

Results: Among 116 enrolled patients (34.4% women, 74% Hispanic, mean age 61 ± 11 years; 293,897 observations), 36.2% had elevated PSS (mean PCL = 33.1; non-elevated PSS mean PCL = 1.2). In adjusted models, there was no significant difference in HR for participants with elevated (77.1 bpm) vs. non-elevated PSS (73.6 bpm, p =.11). However, reporting 10 points higher on continuous PCL score (range 0-80) was associated with a 1.6 bpm higher HR (95% CI [0.44, 2.82], p =.007). Further, sleep episode length (-.28 bpm/additional hour, p =.0002) and diurnal variation (p =.0002) were related to HR but did not moderate the PSS effect (p >.21).

Conclusion: Early cardiac-induced PSS are associated with elevated HR, independent of sleep episode length and diurnal HR rhythm, physical activity, beta-blocker adherence, sex, age, race, cardiac risk, and medical comorbidities. Interventions targeting PSS after cardiac events as well as sleep-specific interventions may reduce chronic sympathetic arousal and thus cardiovascular risk in CAD patients.

IMPACT OF CIRCADIAN PHASE AND DISTINCTIVENESS ON FATIGUE AND EXCESSIVE DAYTIME SLEEPINESS: A NATIONWIDE STUDY

Hyo-Jin Park[1], Sun-Ku Han[1], Sang Min Paik[1], Jae Rim Kim[1], Woo-Jin Lee[1], Daeyoung Kim[2], Kwang Ik Yang[3], Min Kyung Chu[4], Chang-Ho Yun[5]

[1] Department of Neurology, Seoul National University Bundang Hospital, [2] Department of Neurology, Chungnam National University Hospital, Chungnam National University School of Medicine, [3] Sleep Disorders Center, Department of Neurology, Soonchunhyang University Cheonan Hospital, Soonchunhyang University College of Medicine, [4] Department of Neurology, Severance Hospital, Yonsei University College of Medicine, [5] Department of Neurology, Seoul National University Bundang Hospital, Seoul National University College of Medicine

Introduction: Chronotype influences daily functioning and sleep quality, often assessed through self-reported questionnaires. Oginska's Chronotype Questionnaire (ChQ) introduces a two-dimensional approach, evaluating circadian phase and distinctiveness (or amplitude). While strong circadian distinctiveness is linked to poorer sleep quality, its association with daytime fatigue and sleepiness remains underexplored. This study aims to examine the associations between chronotype dimensions and daytime functioning, focusing on both circadian phase and distinctiveness.

Methods: We analyzed 1,779 participants (mean age: 43.1 ± 12.9 years; range: 19–65 years; 918 males) from a 2018 nationwide Korean survey on sleep and headache. Chronotype was assessed using the ChQ, classifying participants as morning, intermediate, or evening types based on the 25th and 75th percentiles of the Morningness-Eveningness score, and as strong or weak distinctiveness based on the median Distinctiveness score. Fatigue and excessive daytime sleepiness (EDS) were measured using the Fatigue Severity Scale (FSS) and the Epworth Sleepiness Scale (ESS), respectively. Multivariable logistic regression models were used to analyze associations between chronotype dimensions and daytime functioning, adjusting for potential confounders.

Results: Among participants, 27.3% were classified as morning type, 48.5% as intermediate type, and 24.2% as evening type. Additionally, 60.20% showed strong circadian distinctiveness. Significant fatigue (FSS ≥ 36) was observed in 501 participants (28.2%). On multivariable analysis, morning chronotype

was associated with lower odds of fatigue (OR [95% CI], 0.572 [0.439–0.746], p< 0.001), while strong distinctiveness was associated with higher odds (1.362 [1.097–1.689], p=0.005). Combining both dimensions, strong and weak morning chronotypes had lower odds of fatigue compared to intermediate types (0.671 [0.492–0.916], p=0.012 and 0.439 [0.293–0.657], p< 0.001, respectively). EDS (ESS ≥ 11) was reported in 12.3% of participants. Morning chronotype was associated with lower odds of EDS (OR [95% CI], 0.668 [0.466–0.957], p=0.028), while strong distinctiveness was linked to higher odds (1.685 [1.236–2.298], p=0.001). Combining both dimensions, only weak morning chronotype showed significantly lower odds of EDS compared to intermediate types (0.505 [0.287–0.889], p=0.018).
Conclusion: This study highlights the importance of evaluating both circadian phase and distinctiveness in chronotype research. Integrating these dimensions provides a more comprehensive understanding of chronotype's impact on daytime functioning.

THE ASSOCIATION BETWEEN RACISM AND INSOMNIA AMONG ASIAN AMERICANS

Sunmin Lee[1], Susan Redline[2], Suzanne Bertisch[3], Chun-Kai Shih[1], Truc Tran[1], Young Joo yoo[1], Yuxin Ji[1], Sue Thai[1], Ichiro Kawachi[4]
[1] University of California, Irvine, [2] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [3] Brigham and Women's Hospital, Harvard Medical School, [4] Harvard Chan School of Public Health

Introduction: Studies have found that experiences of racial/ethnic discrimination may adversely affect sleep outcomes. However, no studies have examined the association between anti-Asian racism stemming from the COVID-19 pandemic and its impact on insomnia among Asian Americans.
Methods: The cross-sectional study consisted of 256 Chinese-, 256 Korean- and 267 Vietnamese Americans ages 30 years or older residing in Southern California. Anti-Asian racism was assessed by using a 6-item scale that included the following questions. How often have you: (i) witnessed someone blaming Asian people for the Coronavirus pandemic?; (ii) been treated differently or mistreated because someone suspected you of having Coronavirus?; (iii) avoided wearing a mask because you are worried about experiencing anti-Asian racism?; (iv) avoided going out in public because you are afraid of someone committing a crime against you because you are Asian?; (v) been subjected to racial slurs or jokes in person or online because you are Asian?; and (vi) How often have other people acted uncomfortable around you or avoided you because you are Asian? The Anti-Asian racism scale had high internal consistency (Cronbach's alpha=0.82). Responses were summed to create a total score. Insomnia was assessed by using the Insomnia Severity Index and dichotomized as moderate/severe insomnia (Score ≥ 15) vs. no/subthreshold insomnia.
Results: Mean age of the study population was 55 year and 56% identified as female sex. Fifteen percent of the study population reported moderate/severe insomnia. One unit increase in the anti-Asian racism scale was associated with 2.18 times the odds of having moderate/severe insomnia (95% Confidence Interval (CI): 1.40-3.38), adjusting for age, sex, Asian subgroup, marital status, education employment status, income, and type of health insurance. When depression (assessed by CES-D) was further adjusted, the association attenuated (OR=1.60, 95% CI: 1.00-2.56). In an exploratory analysis, Korean group had the highest association (OR=4.19; 95% CI: 1.92-9.12), followed by Vietnamese (OR=4.00; 95% CI: 1.50-10.70), and Chinese (OR=0.98; 95% CI: 0.44-2.22) (interaction p-value= 0.05).
Conclusion: Anti-Asian racism associated with the COVID-19 pandemic was significantly associated with insomnia. Future prospective analysis is needed to understand the causal pathways linking anti-Asian racism and insomnia among Asian Americans.

THE ASSOCIATION BETWEEN PERCEIVED STRESS AND INSOMNIA AMONG ASIAN AMERICANS

Sunmin Lee[1], Ichiro Kawachi[2], Suzanne Bertisch[3], Chenghui Wang[1], Vyvy Truong[1], Yizhi Wang[1], Tianlang Chen[1], Susan Redline[4]
[1] University of California, Irvine, [2] Harvard Chan School of Public Health, [3] Brigham and Women's Hospital, Harvard Medical School, [4] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Studies have found that perceived stress is associated with sleep outcomes. However, there is a lack of data examining the association between perceived stress and insomnia among community-dwelling Asian Americans. We investigated the association between perceived stress and insomnia among 779 community-dwelling Asian Americans.
Methods: The cross-sectional study consisted of 256 Chinese-, 256 Korean- and 267 Vietnamese Americans ages 30 years or older residing in Southern California. We assessed perceived stress using a 4-item Perceived Stress Scale (PSS) (Range 0-16; Cronbach's alpha = 0.62). A summed continuous total score was calculated. Insomnia was assessed by using the Insomnia Severity Index (ISI) and dichotomized as having moderate/severe insomnia (ISI score ≥ 15) vs. no/subthreshold insomnia. Logistic regression analysis examined associations between perceived stress and insomnia.
Results: Mean age of the study population was 55 years, and 44% identified as male sex. In total, 15% of the study population met the criteria for moderate/severe insomnia. One unit increase in the perceived stress scale was associated with 1.20 times higher odds of moderate/severe insomnia (95% Confidence Interval (CI): 1.10-1.30), adjusting for age and sex. When this association was further adjusted for the Asian subgroup, marital status, education, employment status, income, and type of health insurance, the association did not change substantively (OR=1.16, 95% CI:1.06-1,28). However, with further adjustment for depression (assessed by the Center for Epidemiologic Studies Depression Scale (CES-D)), the association was no longer significant (OR = 0.99; 95% CI: 0.88-1.10). This association did not differ by the Asian subgroup.
Conclusion: Higher levels of perceived stress were associated with higher odds of insomnia among Asian Americans after adjusting for sociodemographic variables. Adjustment of depression resulted in attenuation of the association. Whether depression mediates or confounds the association between perceived stress and insomnia should be examined in the prospective analysis.

SLEEP QUALITY AND SOCIAL INTERACTION: THE MODERATING ROLE OF ATTACHMENT STYLE

Giovanni Alvarado[1], Cara Palmer[1]
[1] Montana State University

Introduction: Longitudinal research has consistently linked poor sleep health (e.g., short sleep duration, poor efficiency, and irregular sleep) to the onset of psychiatric symptoms and disorders. One important mechanism thought to be responsible for these associations is altered emotional and social functioning, such as decreased motivation for social engagement, fewer peer relationships, and lower positive affect. However, individual differences that may exacerbate the effects of poor sleep are still largely unexplored. Anxious attachment (difficulties with trust and low self-esteem in relationships) and avoidant attachment (negative view of others, avoidance of emotional intimacy) are related to more interpersonal conflict and altered emotional experiences in relationships, and may result in exaggerated sleep-related socioemotional impairment. The current study examined whether attachment moderates the relationship between sleep quality and daily socioemotional experiences.
Methods: Participants included 68 young adults who completed the Pittsburgh Sleep Quality Index, Experiences in Close Relationships-Revised questionnaire, and daily self-reports capturing experiences of social emotions and social approach/avoidance behaviors over two weeks.
Results: Preliminary analyses indicated that anxious attachment was related to poorer sleep quality (r = -.28, p <.02). Poorer sleep quality was also related to fewer daily social approach behaviors (r = -.28, p =.02), and marginally more daily reports of guilt/shame, social rejection/social anxiety, and less feelings of love/affection towards others (p's =.07-.08). Regression analyses indicated that attachment anxiety moderated the effect of sleep quality on daily feelings of envy/jealousy (b = -.22, SE =.09, p =.02). Poor sleep quality was associated with more daily envy/jealousy (b =.55, SE =.27, p =.04), but effect was only significant for those with high levels of attachment anxiety (p =.01).
Conclusion: Results suggest that poor sleep quality is related to anxious attachment and daily social behaviors/emotions. In addition, sleep disturbances are related to more envy/jealousy in social relationships, but only for those with higher trait relationship anxiety. This study provides preliminary evidence that the effect of sleep on social emotions may depend on individual differences in relationship styles, and that those with insecure attachment may be most at risk of the socioemotional effects of poor sleep.

NO ADDED BENEFIT OF TARGETED MEMORY REACTIVATION DURING NAPS ON NEGATIVE MEMORY RESCRIPTING

Olivia Larson[1], Luna Sato[1], Sirisha Krishnamurthy[1], Ruda Lee[1], Qiyao Wang[1], Elizabeth Siefert[1], Philip Gehrman[1], Anna Schapiro[1]
[1] University of Pennsylvania

Introduction: Memories for negative life experiences play a key role in our mental health and are processed by the sleeping brain. Here, we attempted to bias the sleeping brain towards processing a more adaptive version of a negative autobiographical memory during a nap using targeted memory reactivation (TMR).
Methods: Forty-seven participants (23.6±5.5 years old; 68% female) provided details about one negative and one neutral life experience and provided self-report ratings on arousal to each memory (0=very calm; 10=very aroused) and distress to the dominant emotion associated with their negative memory (0=no distress; 10=extreme distress). They completed an imagery rescripting intervention for their negative memory during which they heard a repetitive sound cue and a similar procedure for their neutral memory during which they heard a different cue. All participants were then allowed a 2-hour PSG-monitored nap opportunity in the lab and were randomized to hear either the sound cue associated with their negative (n=22) or neutral (n=18) memory (i.e., to have one memory "targeted" for reactivation); participants who got less than 15 minutes of non-REM sleep were reclassified into a "wake" group (n=7). After the nap and one week later, participants repeated arousal and distress ratings.
Results: Arousal to both negative and neutral memories decreased after the interventions and nap period (β=-1.64, p< 0.0001) and remained lower one week later (β=-1.51, p< 0.0001), but this did not depend on whether the memory was cued via TMR. Similarly, emotional distress decreased after imagery rescripting (β=-2.98, p< 0.0001) and decreased further after the nap period (β=-1.00, p=0.04), but this reduction did not depend on TMR cueing. Participants in the wake group appeared to show a different pattern in which distress to dominant emotions increased after the nap period, but this difference was not significant in the current sample.
Conclusion: TMR did not enhance the arousal- and distress-reducing effects of imagery rescripting, but a nap did appear to further reduce emotional distress. Further research on the benefits of sleep and TMR on processing negative autobiographical memories is warranted.

ACTIGRAPHY-BASED SLEEP PARAMETERS AND HEALTH CORRELATES IN VETERANS WITH GULF WAR ILLNESS

Charity Breneman[1], Nathaniel Allen[2], Kamila U. Pollin[3], Matthew Reinhard[3]
[1] Henry M Jackson Foundation for the Advancement of Military Medicine, Inc., [2] War Related Illness and Injury Study Center, Department of Veterans Affairs, [3] War Related Illness and Injury Study Center (WRIISC), Department of Veterans Affairs

Introduction: During military service, sleep/wake patterns are often altered due to irregular or unpredictable operational schedules, non-conducive sleeping conditions (e.g., threatening environments), and/or time zone changes. The lack of consistency in sleep-wake patterns during military service may precipitate sleep disturbances post-military. This analysis examined the associations between objective sleep parameters and self-reported measures of health in veterans with Gulf War Illness (GWI).
Methods: Participants included 86 veterans with GWI (Mage= 54.1±7.1 y, 87.2% male) who wore an actigraphy monitor on

their non-dominant wrist for 24 hours per day for seven consecutive days during a baseline assessment. Actigraphy data were manually scored using the manufacturer's software to derive parameters of sleep timing, duration, and quality/continuity (time in bed [TIB], midpoint of sleep, total sleep time [TST], sleep efficiency [SE], wake after sleep onset [WASO], number of awakenings (NWAK), motor activity counts [MAC], and mean motor activity during TIB [AMEAN]). Participants completed several questionnaires: Patient Health Questionnaire (depression), Posttraumatic Symptom Checklist (PTSD), PROMIS® Adult Short Form v1.0 – Pain Interference, and Pittsburgh Sleep Quality Index. Associations between objective sleep parameters and self-reported measures of health were examined using Spearman's rank correlations.
Results: Many of the participants (n=62; 72.1%) slept less than six hours per night with some sleeping less than five (n=36; 41.9%). Participants on average slept 5.3±1.6 h (SD), had 27.6±10.4 awakenings, 83.8±33.2 min of WASO, and a SE of 72.7±8.3% per night. Spearman correlations revealed that MAC and AMEAN were positively related to self-reported sleep quality (rho= 0.35, 0.33, respectively), depression (rho= 0.27, 0.30), PTSD (rho= 0.22, 0.28), and pain interference (rho= 0.26, 0.24; p< 0.05 for all). WASO and SE were also significantly related to subjective sleep quality (rho= 0.27, -0.31; p< 0.01).
Conclusion: Objective parameters of poor sleep quality and continuity (MAC, AMEAN, WASO, SE) were associated with poor self-reported sleep quality and greater symptoms of depression, PTSD, and pain interference in veterans with GWI. Future research will assess variability in sleep timing and profiles of sleep characteristics and their impact on functional health outcomes.

RELIGIOUS INVOLVEMENT AND SLEEP HEALTH IN MIDDLE-AGED AND OLDER ADULTS

Spencer Nielson[1], Natalie Dautovich[1], Joseph Dzierzewski[2]
[1] Virginia Commonwealth University, [2] National Sleep Foundation

Introduction: Previous studies found that religious involvement, both public (e.g., religious attendance) and private (e.g., prayer) activity, is associated with better sleep, including increased sleep duration and quality. Furthermore, some evidence suggests that this connection may be modified by depressive symptoms. However, little is known about how religiosity is associated with other aspects of sleep health, such as global sleep health, sleep regularity, and insomnia symptoms, and whether anxiety symptoms impact this association. This study sought to explore how public and private religious involvement are associated with sleep health factors and whether anxiety symptoms moderate these associations.
Methods: Participants (N=370) were middle-aged and older adults (Mage=62.8, 60.3% female) who participated in an online study that included questionnaires measuring religious attendance, private religious involvement, global sleep health, insomnia symptoms, sleep regularity, daytime sleep-related impairment, and anxiety symptoms. Bivariate correlations examined direct associations between variables while SPSS PROCESS macro was used to determine whether anxiety moderated associations between religiosity and sleep.
Results: More religious attendance was correlated with poorer sleep health, higher insomnia symptoms, lower sleep regularity, and increased daytime sleep-related impairment (all p's <.01). Higher private religious involvement was correlated only with increased sleep regularity (p <.01). Anxiety moderated the associations between religious attendance and sleep factors such that those with high anxiety symptoms showed a positive association between religious attendance and better sleep, while those low in anxiety symptoms had a negative association. Similarly, anxiety moderated the association between private religious involvement and sleep regularity, such that those high in anxiety symptoms had a significantly stronger positive association than those low in anxiety symptoms.
Conclusion: Overall, public religious involvement was associated with poor sleep, while private involvement was associated with better sleep health. Anxiety may impact the religiosity-sleep association as those high in anxiety symptoms had a positive association between religious involvement and sleep health, while those low in anxiety had the opposite, a negative association. These results suggest that different factors of religiosity may be uniquely associated with aspects of sleep health, and that anxiety may be an important underlying factor of this association.

EVOLVING REM SLEEP ABNORMALITIES FOLLOWING EXPERIMENTAL TBI

Xoshill Saldana[1], Ehsan Mirzakhalili[1], Victoria Johnson[1], John Wolf[1], Alexandra Ulyanova[1]
[1] University of Pennsylvania

Introduction: Disrupted sleep is a common symptom following traumatic brain injury (TBI). It can last for months and impair the recovery process. Sleep disturbances can also contribute to memory dysfunction and induce adverse changes in cognitive performance. Understanding the mechanisms of sleep abnormalities triggered by TBI is essential for managing functional recovery and improving the quality of life in patients with TBI.
Methods: Continuous video EEG monitoring was used to investigate sleep patterns after experimental TBI. Injury Model: Controlled cortical impact (CCI) injury was induced in a large animal model (swine). It produced clinically relevant focal and diffuse pathologies previously described in human post-mortem TBI tissue. Electrodes Implantation: MRI-based Brainsight neuronavigation system was used to guide 64-channel silicon depth electrodes into the ipsilateral cortex and hippocampus of pigs two (n=3) and four (n=1) months after CCI and sham (n=2) injuries. Four skull ECoG screw electrodes were also placed on the contralateral and ipsilateral hemispheres to the CCI injury site. Wireless EEG System: Neuralynx CUBE2 head stage was used to acquire 30kHz EEG signals and wirelessly record them with the Digital Lynx 4SX system. Sleep Analyses: 2D pose estimation software YOLO was used for video-based activity tracking in home cages. Animals' velocity synchronized with EEG was used to identify sleep-wake cycles. The measure of animals' movement and spectral analyses of cortical delta, cortical gamma, and hippocampal theta oscillations were used to stage sleep (awake, NREM, and REM).
Results: Two months after the CCI injury, an increase in animals' movement during sleep was identified. Moreover, tiny twitches in the animals' bodies were present during REM sleep. Additionally, sharp-wave ripples and high-frequency oscillations,

hallmark hippocampal oscillations present only during awake state and NREM sleep, were also present during REM sleep two months after the CCI injury. These symptoms were even more pronounced at four months after the CCI injury.
Conclusion: These results may indicate the development of parasomnias (REM sleep without atonia) after TBI. Further investigation will be vital to understand how progressive changes in REM sleep might evolve in parallel with other TBI-associated pathologies.

THE MEDIATING ROLES OF DYSFUNCTIONAL BELIEFS AND PRE-SLEEP AROUSAL IN THE SELF-COMPASSION-SLEEP QUALITY LINK

Arash Assar[1], Niloufar Lueke[2], Anjolii Diaz[3], Ivan Vargas[1], Patrick Myers[2], Kamryn Graveman[2], Hailey Krantz[2], Frankie Rae Davis[2]
[1] University of Notre Dame, [2] Austin Peay State University, [3] Ball State University

Introduction: Sleep disturbances affect a significant portion of college students in the United States, with 60% meeting the criteria for poor sleep quality (Becker et al., 2018). Identifying modifiable psychological factors, such as self-compassion, to alleviate these issues is essential. While self-compassion has emerged as a promising resource linked to improved sleep, the cognitive pathways contributing to this association remain unclear. Theoretical models of insomnia emphasize the role of dysfunctional interpretive processes—including unrealistic attitudes, beliefs, and expectations about sleep—and psychophysiological arousal as mechanisms maintaining sleep disturbances (Lundh & Broman, 2000; Harvey, 2002). For instance, poor sleepers often engage in maladaptive strategies, such as thought suppression, worry, rumination, and imagery control, which perpetuate arousal and interfere with sleep onset and maintenance (Espie et al., 2006). Self-compassion, characterized by treating oneself with kindness and understanding during difficult times (Neff, 2003), may mitigate dysfunctional control strategies through its facilitation of adaptive coping (Allen & Leary, 2010) and emotion regulation strategies, such as tolerating negative emotions (Diedrich et al., 2017). Building on models emphasizing dysfunctional cognitive processes in sleep disturbances, this study examined self-compassion as a modifiable factor in these pathways.
Methods: 221 undergraduate students (M = 19.88, SD = 1.50) completed measures of self-compassion, dysfunctional sleep beliefs and attitudes, pre-sleep arousal, and sleep quality.
Results: A serial mediation model examined whether dysfunctional sleep beliefs and attitudes (M1) and pre-sleep arousal (M2) sequentially mediated the relationship between self-compassion (X) and poor sleep quality (Y). Self-compassion had an indirect association with poor sleep quality through dysfunctional sleep attitudes and beliefs and pre-sleep arousal (X→M1→M2→Y; completely standardized indirect effect = -.05, SE =.01, 95% CI [-.08, -.02]). The non-significant direct effect of self-compassion on sleep quality with mediators suggests full serial mediation (direct effect = -.02, p =.772, 95% CI [-.66,.50]).
Conclusion: Self-compassion may reduce unrealistic expectations and maladaptive beliefs about sleep, lowering cognitive and physiological arousal before bedtime and ultimately improving sleep quality. Although the observed effect size was small, these findings highlight the potential of self-compassion as a modifiable factor in targeted interventions addressing cognitive and psychophysical sleep disruptions.

CAFFEINE AND BRIGHT LIGHT EFFECTS ON MOOD OUTCOMES DURING EVENING HOURS

Korey Smith[1], Rachel Markwald[1], Evan Chinoy[1], Andrew McHill[2]
[1] University of Colorado Boulder, [2] Oregon Institute of Occupational Health Sciences, Oregon Health & Science University, Portland, Oregon, USA

Introduction: Nighttime caffeine administration and bright light exposure has been shown to reduce melatonin levels, increase core body temperature, and increase alertness and performance. The effects of nighttime caffeine and bright light exposure on mood however is less understood. Here we examined the effects of evening caffeine administration and bright light exposure individually and in combination on mood outcomes in the evening hours.
Methods: Five healthy adults (3 females) aged (24±4 years) participated in a randomized, double-blind, placebo-controlled, crossover research design. Participants were studied in the Sleep and Chronobiology Laboratory on four separate visits. Following an initial constant routine to assess circadian phase, participants were assigned to one of four treatment conditions including caffeine (2.9 mg/kg) or placebo (rice-filled powder) 3h prior to habitual bedtime plus 3h of bright (~3000 lux) or dim light (1.5 lux) exposure starting at habitual bedtime. Mood was assessed including 17 mood variables, using Visual Analog Scales (VAS) during treatment.
Results: Participants reported being more interested and more friendly when receiving caffeine versus placebo ($p < 0.05$) and during exposure to dim versus bright light ($p < 0.05$). Furthermore, participants reported feeling less sad during the dim-light-caffeine versus the dim-light-placebo ($p < 0.05$) and bright-light-caffeine ($p < 0.05$) conditions.
Conclusion: These findings show that mood outcomes were generally more positive (i.e., more interested, more friendly, and less sad) after receiving caffeine in the evening hours, but that mood was generally less positive during exposure to bright light. Our findings for caffeine are consistent with prior research showing that caffeine elevates mood during daytime and nighttime. Previously, bright light has been shown to have beneficial effects on mood during the morning/daytime. Our findings suggest that the effects of bright light exposure on mood may be dependent upon the biological time of day, with evening exposure being less favorable. The latter is consistent with epidemiological findings that artificial light at night is associated with mood disorders.

CHRONIC STRESS-MEDIATED DYSREGULATIONS OF BASAL FOREBRAIN GABAERGIC NPAS1+ NEURONS AND IMPLICATIONS IN STRESS-INDUCED SLEEP AND PSYCHIATRIC DISEASES

Tim Troppoli[1], James McKenna[2], Ritchie Brown[3]
[1] Veterans Affairs Boston Healthcare - Harvard Medical School, [2] Harvard Medical School, [3] VA Boston Healthcare System

Introduction: American Servicemembers are routinely exposed to prolonged periods of intense stress during deployment and combat exposure. These stressors are critical risk factors for the pathogenesis and severity of psychiatric disease—a leading cause of permanent disability within VA that significantly increases risk of suicide. However, the identity of the regions, cell types, and mechanisms integrating the effect of stress on sleep disruption remain poorly characterized, thus hindering the development of effective treatments. I have previously found that BF Npas1+ neurons project to numerous brain regions implicated in arousal, reward, and the stress response, and disrupt normal sleep behavior and oscillatory activity when chemogenetically activated, and are therefore potential mediators for stress-induced sleep disruption and psychiatric disease.
Methods: I explored this using a chronic multimodal stress paradigm (10 days, 4h/day) in mice. Mice were implanted with EEG and EMG electrodes to monitor sleep behavior and oscillations before and during the 10 days of stress. Stress-sensitive mice were identified by a reduction in their sucrose preference. Immunohistochemistry was performed in basal forebrain tissue for the transcription factor NPAS1 and the immediate early gene cFOS.
Results: Preliminary findings indicate that Npas1+ neurons in the basal forebrain (BF) are potently activated by stress (30-40+% cFOS-expressing), correlating with disruptions in sucrose preference. These stress-sensitive mice tended to spend less time awake (n=8, p=0.13) and in NREM sleep (p=0.09) during the light-(active) period, with more dramatic shifts seen in the dark-(inactive) period with wake ($p< 0.05$) and NREM sleep ($p< 0.01$). Individual wake and NREM bouts tended to be less frequent after stress. Furthermore, slow and delta wave decreased following stress, correlating to the degree of increased NREM sleep. Sleep-spindle density also significantly decreased following chronic stress. Notably, the proportion of cFOS-expressing Npas1+ neurons correlates with the post-stress change in wake (p=0.07), and with NREM (p=0.04) and REM sleep (p=0.01).
Conclusion: I conclude Npas1+ basal forebrain neurons are potently activated by stress and may play a key role in stress-induced sleep and psychiatric illness.

EFFECTS OF STRESSFUL LIFE EVENTS AND EMOTIONAL SUPPORT ON INSOMNIA AMONG RURAL AND URBAN LATINOS

Ziyi Ding[1], Joon Chung[2], Dunia Mejia[3], Jasmine Rubio[1], Camila Pow-Sang[1], Stacyca Dimanche[1], Mary Carrasco[4], Laurent Garchitorena[1], Carolina Scaramutti[2], Michael Grandner[5], Ferdinand Zizi[1], April Rogers[6], Alberto Ramos[2], Girardin Jean-Louis[7], Azizi Seixas[7]
[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Miami, [3] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [4] Lincoln Memorial University Debusk College of Osteopathic Medicine, [5] University of Arizona College of Medicine, [6] St. John's University, [7] University of Miami Miller School of Medicine

Introduction: Sleep difficulties are prevalent among Latinos in the United States. Individuals with insomnia have been shown to experience a greater number of stressful life events compared to those without insomnia, yet social support may be a counter-balancing factor. The purpose of this study was to examine associations between stressful life events and emotional support and insomnia.
Methods: A population-level sample (N = 603) from DORMIR that focuses on the causes of insufficient sleep in rural and urban areas of Florida was utilized. Stressful life events were assessed based on the number of major stressors experienced within the last year (e.g. marital separation, loss of spouse). Emotional support was measured using the PROMIS Emotional Support 4, with higher scores indicating greater perceived emotional support. Severity of insomnia was assessed using the Insomnia Severity Index (ISI), where higher scores reflect more severe insomnia. Linear regression analyses were performed to assess the effects of both stressful life events and emotional support on ISI scores, adjusting for covariates including age, gender, education, race, Hispanic ethnicity, marital status, employment, income, and language.
Results: The number of stressful life events was positively associated with ISI score ($\beta = 1.05$; 95% Confidence Interval [CI]: 0.48 to 1.62; $P < 0.001$), while emotional support was negatively associated with ISI score ($\beta = -0.30$; 95% CI: -0.42 to -0.17; $P < 0.001$). Spanish-speaking individuals are associated with significantly higher ISI scores compared to English-speaking individuals ($\beta = 1.70$; 95% CI: 0.69 to 2.69; $P < 0.001$).
Conclusion: Stressful life events and emotional support are key predictors of insomnia among rural and urban Latinos, with more stress associated with higher ISI scores and greater social support associated with lower ISI scores. Spanish-speaking individuals tend to have higher levels of insomnia severity compared to English-speaking individuals. Further studies are needed focusing on whether other factors mediate the effects of stress and emotional support on insomnia.

ANXIETY AND SOCIAL SUPPORT ASSOCIATE WITH INSOMNIA AMONGST ENGLISH AND SPANISH SPEAKING HISPANICS IN FLORIDA

Camila Pow-Sang[1], Joon Chung[2], Ziyi Ding[1], Laurent Garchitorena[2], Jasmine Rubio[2], Dunia Mejia[3], Stacyca Dimanche[2], Mary Carrasco[2], Carolina Scaramutti[2], April Rogers[4], Alberto Ramos[2], Girardin Jean-Louis[5], Ferdinand Zizi[1], Azizi Seixas[5], Ricardo Osorio[6]
[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Miami, [3] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [4] St. John's University, [5] University of Miami Miller School of Medicine, [6] Department of Psychiatry, New York University Grossman School of Medicine

Introduction: Sleep health is critical for overall health and mental well-being. Both anxiety and social support can influence one's sleep quality, as high levels of anxiety and inadequate

levels of social support are associated with worsening sleep outcomes leading to declining insomnia levels. There is a lack of research and literature regarding the association between anxiety and social support on insomnia as it pertains to the Insomnia Severity Index (ISI). This study aims to evaluate the associations of anxiety and social support with insomnia amongst English and Spanish speaking Hispanics in Florida.
Methods: Survey data were collected from Determinants, Outcomes, Responses, and Markers of Insufficient Sleep in Rural-Urban (DORMIR) study, a cross-sectional study at the University of Miami Miller School of Medicine. A linear regression analyses was built to regress ISI on the PROMIS Emotional Distress Anxiety (Short Form 8a) and PROMIS Emotional Support Scale (Short Form 4a), adjusting for age, sex, race/ethnicity, Hispanic origin, marital status, employment, education, income, Body Mass Index (BMI), and whether the respondent participated using the English or Spanish version of the questionnaires among 603 participants.
Results: The average age amongst the English and Spanish speaking participants was 41.57 ± 16.65 with a total of 223 individuals in the Spanish-speaking sample and 380 in the English-speaking sample. The study has a total of 399 (66.2%) females and 204 (33.8%) males. A one-unit increase in anxiety scores was associated with a 0.32 increase in ISI scores (b [95% Confidence Interval (CI)]: 0.32 [0.24, 0.39], p< 0.001). A one-unit increase in social support was nearly associated with a -0.11 decrease in ISI scores (b [95% CI]: -0.11 [-0.23, 0.01], p=0.069).
Conclusion: Higher anxiety levels are associated with worsening ISI scores, while an increase in social support scores may associate with lower ISI outcomes amongst the English and Spanish speaking sample. Anxiety and social support independently were associated with ISI outcomes. Additional research is needed to assess the relation between anxiety levels and social support to enhance overall ISI scores and overall sleep quality.

FOSTER PARENT EMOTIONAL INVESTMENT ASSOCIATED WITH SLEEP HEALTH IN THEIR CHILDREN

Morgan Endlein[1], Robyn Fielding-Jones[1], Candice Alfano[2], Eleanor McGlinchey[3], Carol Ripple[4], Amy Wolfson[1]
[1] Loyola University Maryland, [2] University of Houston, [3] Fairleigh Dickinson University, [4] Pajama Program

Introduction: Healthy foster parent-child relationships are critical for children's overall health (Frosch et al., 2021). With parents playing a significant role in children's bedtime routines and sleep health, understanding foster parents' emotional investment in children under their care is important. Emotional investment includes foster parents' willingness to commit to the child's health and wellbeing and think of them as part of their family. While studies have examined sleep health and bedtime routines in this child population, foster parents' emotional investment has been unexplored. This study examined associations between foster parents' emotional investment and children's sleep health.
Methods: Foster parents (n = 218) were recruited to complete a Qualtrics questionnaire through open/closed Facebook groups for US foster parents (focus on child ages 3-11). The Foster Parent Emotional Investment Scale (FPEIS) was developed to measure foster parents' emotional investment in the children under their care. Similarly, the Revised Inventory of Parental Attachment (RIPA) Trust subscale assessed trust between the parent and child (Johnson et al., 2003). Sleep health was assessed using the PROMIS Sleep Disturbance, Bedtime Routines Questionnaire (BRQ), sleep quality scale, and the use of sleep comfort objects (Forrest et al., 2018). Associations between sleep health and emotional investment was assessed.
Results: The 13-item FPEIS scale had strong internal consistency (Cronbach's alpha =.70). Pearson correlations revealed that higher parental emotional investment was associated with consistent bedtime routines (r =.42), fewer night wakings (r = -.53), higher sleep quality (r =.45), fewer sleep problems (r = -.39), and reduced need for sleep comfort objects (r = -.34), p's <.01. Additionally, greater parental trust correlated with consistent bedtime routines (r =.47) and fewer night wakings (r = -.36), p's <.01.
Conclusion: The FPEIS scale demonstrates the importance of foster parents' emotional investment in foster children and its association with children's sleep health. Moving forward, interventions related to emotional investment and sleep health education programs are necessary to ensure that foster families understand their roles in children's health and wellbeing and have the tools to establish healthy sleeping habits to decrease sleep challenges for children in the foster care system.

SLEEP AND EMOTIONAL MEMORY OF PRESCHOOL CHILDREN ADOPTED FROM FOSTER CARE: A COMPARISON WITH A COMMUNITY SAMPLE

Karolina Rusin[1], Annika Myers[2], Megan Rech[2], Rebecca Spencer[1], Candice Alfano[2]
[1] University of Massachusetts, Amherst, [2] University of Houston

Introduction: Sleep is an active state that plays a critical role in memory consolidation, learning, and emotional processing. Children exposed to early-life adversity/trauma demonstrate disproportionately elevated rates of sleep disturbance, which contribute to greater risk for development of cognitive and emotional problems. Yet, sleep and cognition among children who experience early adversity/trauma remains understudied. This study examined, for the first time, objectively measured differences in sleep and sleep-related emotional memory between children with and without foster care histories.
Methods: Data were collected from two groups of 3- to 5-year-old U.S. children (M= 4.38 years, SD=0.78 years): children adopted from foster care (N=32) and a community sample (N=35). Demographic variables did not significantly differ between the two groups. Sleep was measured objectively using actigraphy and subjectively via Children's Sleep Habits Questionnaire (CSHQ), and the Nap Transition Questionnaire (NTQ). To assess emotional memory, participants remotely viewed a video story containing neutral and negative elements and completed evening (immediate) and morning (delayed) recall tasks. Adverse childhood experiences (ACEs) were assessed using the ACE questionnaire.
Results: As expected, the adopted sample experienced more ACEs (M=3.9; Range: 1-9) than the community sample (M=0.17; Range: 0-2). Children adopted from foster care had significantly shorter actigraphy-based sleep duration (t(45)=2.1004, p<.05)

and worse sleep quality, including higher WASO (t(45)=-3.0326; p<.01), and lower efficiency (t(45)=4.0247; p<.001). Further, the adopted sample scored higher on the CSHQ Parasomnia subscale (t(59)=2.064; p<.05), which was significantly correlated with ACEs (r(59)=0.398; p<.01). However, the community sample had a later sleep midpoint (t(41)=2.348; p<.05) and a lower nap frequency across the week (t(54)=-2.5526; p<.05). There were no significant differences in total memory scores or negative bias on the emotional memory story task between the groups.
Conclusion: Findings corroborate prior work demonstrating that children with early-life adversity/trauma (e.g., those adopted from foster care) experience poorer nocturnal sleep health, assessed both objectively and subjectively. Moreover, ACEs may contribute to higher rates of parasomnias. Future studies should examine emotional memory performance in a larger sample and in a controlled setting.

PERCEIVED SAFETY AND INSOMNIA SEVERITY: EXPLORING THE ROLE OF PHYSICAL AND EMOTIONAL ABUSE IN INSOMNIA

Carolina Scaramutti[1], Joon Chung[1], Ziyi Ding[2], Dunia Mejia[3], Jasmine Rubio[2], Camila Pow-Sang[2], Stacyca Dimanche[2], Mary Carrasco[4], Laurent Garchitorena[2], April Rogers[5], Debbie Chung[6], Ferdinand Zizi[2], Alberto Ramos[1], Girardin Jean-Louis[7], Azizi Seixas[7]
[1] University of Miami, [2] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [3] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [4] Lincoln Memorial University Debusk College of Osteopathic Medicine, [5] St. John's University, [6] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [7] University of Miami Miller School of Medicine

Introduction: Feeling unsafe is antithetical to healthy sleep. This study aims to explore the relationship between reports of physical or emotional abuse, and insomnia severity as measured by the Insomnia Severity Index (ISI) in a diverse population of Latin American and Hispanic individuals residing in both rural and urban communities in Florida.
Methods: The Determinants, Outcomes, Responses, and Mechanisms of Insufficient Sleep in Rural-Urban Settings (DORMIR) study investigates the relationship between insufficient sleep and cardiovascular health. Of 603 respondents, 381 (63.2%) responded in English and 222 (36.8%) responded in Spanish. Respondents of 23 different national origins are represented. The average age was 41.6 ± 16.6 years, and there were 399 females, 204 males. A 'Safescore' was computed by adding responses to 4 domains from the Social Needs Screening Tool (AHC), answered on a 5-point scale (never, rarely, sometimes, fairly often, frequently) measuring frequency of how often 'anyone', including family and friends: i) "physically hurt you"; ii) "insult or talk down to you"; iii) "threaten you with harm"; iv) "scream or curse at you". Scores range from 0-20 (higher is less safe). A linear regression was conducted to examine the relationship between the AHC Safescore and Insomnia Severity Index (ISI), adjusting for age, sex, race/ethnicity, marital status, education level, employment status, Body Mass Index, income, and whether the questionnaire was responded to in English/Spanish.
Results: A 1-unit increase in the Safescore was associated with a 0.46 increase in ISI scores (β [95% Confidence Interval] (95% CI) = 0.46 [0.24, 0.67], p< 0.001). Of the 4 domains, "insult or talk down to you" and "scream or curse at you" were the primary drivers of the statistical signal. Per increase in frequency of "insult or talk down to you" and "scream or curse at you", ISI scores are estimated to increase by 1.66 and 1.33 points, respectively (1.66 [0.64, 2.67], p< 0.001; 1.33 [0.76, 1.90], p< 0.001).
Conclusion: Emotional safety concerns were associated with greater insomnia severity. Future interventions should focus on creating safe environments and providing targeted support to vulnerable populations.

SLEEPING TO COPE OR COPING TO SLEEP? EXPLORING THE ASSOCIATION BETWEEN SLEEP AND EMOTION REGULATION IN ADOLESCENCE

Todd Obilor[1]
[1] University of Washington

Introduction: Using path analysis, we examined bidirectional associations to determine the impact of sleep quality on the use of active or avoidant emotion regulation strategies and conversely, whether those emotion regulation strategies predicted sleep quality. Additionally, we analyzed whether sleep quality or emotion regulation strategies independently predicted psychopathology.
Methods: Data came from a longitudinal study of 226 children and adolescents with measures of sleep quality, emotion regulation, and internalizing and externalizing problems collected at ages 14 and 16. Analyses controlled for emotional and behavioral problems assessed at age 11.
Results: Findings demonstrated that sleep quality and emotion regulation strategies independently predicted internalizing and externalizing symptoms at ages 14 and 16. Sleep quality did not predict emotion regulation strategies, nor did these strategies predict sleep quality. However, sleep quality at age 14 predicted internalizing and externalizing symptoms at age 14 and internalizing symptoms at age 16. Avoidant emotion regulation strategies at age 14 predicted internalizing symptoms, while active strategies were negatively associated with internalizing symptoms at both ages.
Conclusion: These findings suggest that sleep quality and emotion regulation strategies independently influence adolescent psychopathology and could be key targets for prevention and intervention.

AIR POLLUTION AND PSYCHOSOCIAL STRESS EXPOSURES IN RELATION TO SLEEP HEALTH IN MIDDLE CHILDHOOD

Jonika Hash[1], Logan Dearborn[1], Christine Loftus[1], Catherine Karr[1], Adam Szpiro[1], Emily Barrett[2], Kaja LeWinn[3], Ruby Nguyen[4], Paul Moore[5], Brent Collett[6], Amanda Noroña-Zhou[3], Nicole Bush[3], Sheela Sathyanarayana[1]

[1] University of Washington, [2] Rutgers School of Public Health, [3] University of California, San Francisco, [4] University of Minnesota, [5] Vanderbilt University Medical Center, [6] Seattle Children's Hospital

Introduction: Prior studies raise concern for air pollution and psychosocial stressors as potential independent risk factors of poor sleep health in children. Chemical-by-non-chemical stress interaction frameworks further suggest that joint air pollution and psychosocial stress exposures could exacerbate this risk, but such interactions are poorly understood. We examined independent and interactive associations of air pollution (PM2.5, NO2, and O3 exposures during early infancy and early childhood) and psychosocial stressors (adverse childhood experiences/ACEs) with sleep health outcomes in middle childhood.
Methods: Participants included 1,166 children from a three-cohort consortium (ECHO-PATHWAYS) with available air pollution and sleep data. Of these, 719 from a single cohort (CANDLE) additionally had ACEs data. Spatiotemporal prediction modeling was used to estimate PM2.5 (μg/m3), NO2 (ppb), and O3 (ppb) at children's residential locations, time-weighted across early infancy (0–6 months) and early childhood (6 months–6 years) exposure periods. ACEs were measured via retrospective parent report of children's cumulative lifetime exposures (up to age 8–9 years) to eight ACE types. Sleep outcomes were measured via children's self-report on the PROMIS sleep disturbance and sleep-related impairment questionnaires at age 8–9 years. Analyses fit linear regression models and adjusted for a priori-selected confounders.
Results: In the ECHO-PATHWAYS cohort, greater NO2 exposure during early infancy associated with lower sleep-related impairment in middle childhood (β=-0.31, 95% CI [0.01, 0.61]). In CANDLE only, the NO2-by-ACEs interaction term was significant for the early infancy (β=0.43, 95% CI [0.08, 0.78], p=.02) and early childhood (β=0.41, 95% CI [0.08, 0.73], p=.02) NO2 exposures periods on sleep-related impairment in middle childhood: Greater NO2 associated with lower sleep-related impairment at lower ACE levels, but at higher ACE levels, greater NO2 associated with greater sleep-related impairment.
Conclusion: This study adds novel evidence of independent NO2 and interactive NO2-by-ACEs associations with sleep-related impairment. Other findings were null and inconsistent with prior research.

THE RELATIONSHIP OF SLEEP HYGIENE, SLEEPINESS, AND SLEEP QUALITY TO MENTAL HEALTH (BURNOUT, DEPRESSION, ANXIETY, AND STRESS) AMONG COLLEGE STUDENTS

Jennifer Peszka[1], Elaine Schomburg[1], Katherine Scalzo[1], Max Nierstheimer[1], Avery Fry[1], Cecelia Schneider[1], Bruce Moore[2], David Mastin[2]
[1] Hendrix College, [2] University of Arkansas Little Rock

Introduction: Student burnout has been reported from 10.3% to 71.0% and mental health symptoms have worsened for young adults in recent years. Disturbed sleep has been linked with burnout and mental health issues (e.g. reduced engagement, poor academic achievement, low self-efficacy, low self-esteem, sleep disorders, and suicidal ideation) and may increase vulnerability. Sleep hygiene, behaviors related to quality and quantity of sleep (e.g. consistent bedtimes, comfortable sleeping conditions, and technology use during and before bed), may provide an avenue to treat or protect from burnout, depression, anxiety, and stress. We assessed the relationship between sleep hygiene, sleepiness, sleep quality, and mental health in college students and examined specific modifiable sleep hygiene behaviors as potential targets for intervention.
Methods: 104 undergraduate students (M = 20.4 years, SD = 1.32, 77 females, 23 males) completed online questionnaires: Pittsburg Sleep Quality Index, Epworth Sleepiness Scale, Sleep Hygiene Index-Technology, Copenhagen Burnout Personal Subscale, School Burnout Inventory, Depression Anxiety Stress Scale, and Mental Toughness Questionnaire.
Results: Sleep Quality and Sleepiness: Greater sleep disturbance was significantly related to greater personal burnout, school burnout, depression, anxiety, and stress, rs (59)=.233 to.537, all ps <.05. Greater sleepiness was significantly related to more personal burnout, r(73)=0.338, p=.002, anxiety, r(76)=0.396, p<.001, and stress, r(74)=0.349, p=.001. Sleep Hygiene: Poor sleep hygiene was related to greater personal burnout, r(72)=.365; p<.001, school burnout, r(71)=.336; p=.002, and lower mental toughness, r(72)= -.237; p=.021. Poorer mental health was significantly related to the specific sleep hygiene behaviors of long naps, irregular bedtimes, extended time in bed, negative emotions before bed, and anxiety in bed. Frequent technology use in bed predicted all negative mental health measures, rs (72)=.202 to.334, all ps<.05.
Conclusion: We found a relationship between sleep, sleep hygiene, burnout, and mental health. Sleep disturbance and maladaptive sleep hygiene were significantly related to poorer mental health in these students. The sleep hygiene behaviors identified here (especially technology use during bedtime) are modifiable with cognitive and behavioral interventions and could be avenues for reducing mental health vulnerability in this student population.

STRESS-RELATED NEURAL MECHANISMS LINKING EARLY ADVERSITY TO SLEEP DISTURBANCES: THE ROLE OF AMYGDALA REACTIVITY

Nicholas Harris[1], Christine Peng[2], Brant Hasler[2], Layla Banihashemi[3]
[1] UPMC Children's Hospital of Pittsburgh/Western Psychiatry Hospital, [2] University of Pittsburgh, [3] Western Psychiatric Hospital

Introduction: Early life adversity (ELA) in childhood is associated with poorer adulthood sleep quality, though the underlying mechanisms remain unclear. ELA in rodent models induces alterations in stress-related neurocircuitry related to neuropsychiatric phenotypes including sleep disturbances. However, this circuitry remains less explored in humans. To investigate these relationships, we assessed stressor-evoked activity in proximal

stress control regions and sleep quality in young adults with differential exposure to ELA.

Methods: Participants (n=97, 21-35 years) were recruited with graded exposure to ELA as quantified by the Childhood Trauma Questionnaire (CTQ). Poor sleep quality was measured with the Pittsburgh Sleep Quality Index (PSQI). Each participant underwent fMRI during a Multi-Source Interference Task (MSIT), a Stroop-like mild cognitive stress task. In this task, participants identify the number that differs among three numbers in incongruent vs. congruent conditions, with performance titration by accuracy. Stressor-evoked activity is extracted from regions of interest (bed nucleus of the stria terminalis, BNST; subgenual nucleus of the anterior cingulate cortex, sgACC; paraventricular nucleus of the hypothalamus, PVN; amygdala) using incongruent vs. congruent contrasts. Linear mixed effect and moderation models assessed relationships between ELA, MSIT reactivity, and sleep.

Results: Early life adversity (CTQ) was associated with worse sleep quality (PSQI) (B_standardized/std=0.53, p< 0.001). In the MSIT, significant relative deactivation was demonstrated in the BNST, sgACC, PVN, and the basolateral amygdala (BLA). No linear bivariate associations were observed between CTQ and stress reactivity. However, the relationship between CTQ and BLA stress reactivity was moderated by PSQI score (B_std=-0.31, p=0.003). Participants with the worst sleep quality (>75% percentile for PSQI) (n=25) showed that higher CTQ was associated with greater stressor-evoked activity (greater relative deactivation) within the BLA (B_std=-0.30, p=0.038), an effect not seen with better sleep quality (< 25% percentile) (n=21, B_std=0.70, p=0.25).

Conclusion: In this study, ELA is associated with worse sleep and a greater stressor-evoked activity in the basolateral amygdala in adults. A better understanding of subcortical stress-related neurocircuitry interactions with sleep may inform future work on intermediary targets for neuropsychiatric interventions. Future studies will assess importance of risk/resiliency factors in ELA-related sleep and stress-related neural reactivity measures.

SLEEP DURATION AND HIPPOCAMPAL-DEPENDENT MEMORY TRAJECTORIES SHAPED BY EARLY SUBCLINICAL DEPRESSIVE SYMPTOMS IN PRE-ADOLESCENTS

Katharine Simon[1], Katherine A. Duggan[2], Jayla Harris[3], Jessica Borelli[3], Amir Rahmani[3], Uma Rao[3], Sara Mednick[1]

[1] University of California, Irvine, [2] North Dakota State University, [3] UC Irvine

Introduction: Preadolescence is a vulnerable time for the onset of depressive symptoms and early depressive symptoms confer a heightened risk for long-term depression. The adolescent transition period is also marked by dynamic shifts in sleep patterns that manifest as delayed and variable bedtimes, increased sleep onset latency, and reduced homeostatic sleep pressure. Sleep supports cognition and mood, with impairment reported with insufficient sleep (e.g., short sleep duration, variable timing). However, less is understood about the impact on hippocampal dependent memory of poor sleep and depressive symptoms during the adolescent transition.

Methods: Data included thirty-four 9-to-13-year-olds (M = 11.75, SD = 1.63, F = 16) in a measurement burst longitudinal study spanning one year. Every four months, for seven consecutive days, participants completed daily sleep diaries, a word-pair task (hippocampal-dependent), and questionnaires on depressive symptoms. Participants wore Garmin Vivo Smart 5 watches to monitor sleep patterns. We conducted a group-based trajectory model estimation to identify and cluster subpopulations of participants based on longitudinal changes in sleep and sleep-dependent memory.

Results: Preliminary analyses revealed that baseline subclinical depressive symptoms served as a key factor in clustering youth and were associated with the rate of decline in total sleep time across the age range. Youth with higher initial depressive symptoms exhibited a steeper decline, and slope clusters were predicted by these initial depressive symptoms. Regarding sleep-dependent memory, baseline depressive symptoms again clustered youth and their performance. Youth with lower depressive symptoms followed a quadratic trajectory in performance over the year, whereas youth with higher depressive symptoms showed a flat trajectory in sleep-dependent performance change and reduced ability to distinguish between targets and false alarms.

Conclusion: Our initial trajectory analyses suggest that depressive symptoms may serve as an early vulnerability marker. Baseline subclinical depressive symptoms emerged as a predictor for the rate sleep duration declined across pre-adolescence. Further, they predicted overnight sleep-dependent memory performance change, suggesting possible potential consolidation issues for those with higher symptoms. Monitoring daily and longitudinal changes in sleep offers valuable insight into the longitudinal interplay between sleep and depressive symptoms, which can be used for future intervention development.

RELATIONSHIP BETWEEN SLEEP HEALTH OF RURAL COLLEGE FRESHMAN AND SCREEN TIME

Hershel Robert Nemer[1]

[1] Montana State University

Introduction: College students face sleep issues, including difficulty maintaining consistent sleep schedules and not getting enough sleep. Rural students face unique challenges compared to their peers, including adjusting to a louder, faster-paced lifestyle and a more affluent environment, all of which may cause increased stress and ultimately impact sleep. Excessive screen time usage also impacts sleep negatively. Combined with the challenges of transitioning to a college environment, sleep for rural college freshmen is likely to be impacted by screen time. Although numerous studies have been conducted on screen time, including some involving sleep, there is a gap in research regarding sleep health of rural freshmen in the United States. In this study we hypothesized that more phone use within two-hours before bedtime is associated with shortened sleep duration, poorer sleep quality, and later sleep timing for freshmen in college from rural areas. Twenty freshmen (aged 18 to 24) from rural backgrounds were recruited, all of which enrolled in a public university in the Western United States. Objective measures of sleep quantity and quality using GENEActiv wearable devices were collected over the course of one month. Key sleep measures include nocturnal sleep duration (measured by total

sleep time), sleep quality (measured by wake-after-sleep-onset), sleep timing (measured by midpoint of nocturnal sleep), and daytime naps. We also collected data on hourly phone screen time use records and most-used applications during the study period. In addition, participants reported their prior screen time use (ABCD Youth Screen Time Survey) and sleep health before college. A one-on-one interview was conducted with the participants to collect qualitative information on any influential factors of their sleep and phone use, such as exams, social activities, and illnesses. We plan to examine the between-person and within-person associations of phone screen time and sleep factors with a multilevel regression analysis. Regression model results will provide insights on the effect of phone use on sleep health for college students from rural areas. The qualitative and quantitative data will be combined to develop actionable recommendations for improving sleep health among rural college freshmen as they adjust to college life.

THE IMPACT OF DEPRESSION ON SLEEP AMONG HIGH SCHOOL STUDENTS IN JAMAICA

Anuradha Ramdas[1], Jasmine Davis[1], Josef Thomas[2], Gerren Austin[2], Avril Dailey[2], Ken-Garfield Douglas[2], Janelle Greene[2], Marvin Reid[2], Winston De La Haye[2], Denise Vidot[1]
[1] University of Miami, [2] University of the West Indies

Introduction: Depression is associated with sleep disorders such as insomnia; reported to create a cycle that makes it difficult to get an adequate amount of sleep. As adolescents (ages 10-19) develop, adequate sleep is an important component of mental and physical well-being. We examined this relationship among Jamaican high school students.
Methods: The study included a 3-stage stratified cluster sample of 358 students (12-to-19-years) from a high school in Kingston, Jamaica. Participants completed a web-based questionnaire including the Patient Health Questionnaire 9, Car, Relax, Alone, Forget, Friends, Trouble (CRAFFT) Screening Tool, and Gaming Addictions Scale for Adolescents. Chi-square tests compared proportions.
Results: From this sample (N=358; mean age: 14.8 years), 33.5% reported mild depression and 46.6% moderate depression. Over half (57.2%) of students with depression reported issues with sleeping ($p< 0.0001$). Sleep issues were reported in 64.4% of females compared to 55.4% of males ($p=0.261$). Students in single parent households reported sleep issues more often than two-parent households (69.0% vs 48%; $p=0.010$). There was a higher prevalence reported inadequate sleep among students in grades 10-13 (62.4%) compared to 1-9 (58%) in grades 1-9 ($p< 0.05$).
Conclusion: Jamaican students with sleep difficulties were more likely to have mild to moderate depression. Females, older students, and those in single-parent households were also more likely to have problems with sleep. Further investigation is needed to better understand the relationship between depression and sleep in Jamaican adolescents.

EXAMINING THE DAILY ASSOCIATIONS BETWEEN LONELINESS, RUMINATION, AND SLEEP OUTCOMES IN A COMMUNITY SAMPLE OF ADOLESCENTS

Christy Bui[1], Kathryn Lemery-Chalfant[1], Sierra Clifford[1], Leah Doane[1]
[1] Arizona State University

Introduction: Sleep is vital for mental and physical health, yet it is often influenced by psychological and social factors. Loneliness and rumination, key predictors of emotional distress, are consistently linked to poor sleep outcomes. Indeed, the U.S. Surgeon General recently identified loneliness as a growing public health epidemic, emphasizing its profound impact on health, including disruptions to sleep. Much research has focused on trait-level links between loneliness, rumination, and sleep, however, emerging evidence suggests the possibility for daily links. Therefore, the current study examined daily within-person links between these socioemotional challenges and adolescent sleep outcomes.
Methods: Participants were twins who participated in the 13-year study wave (twin M=13.53, SD=1.03) of a broader longitudinal study (N=389; 50.3% female; 57.2% non-Hispanic White; 27.6% Hispanic/Latino). Twins completed questionnaires, and wore wrist-based actigraph accelerometers while completing daily diaries for approximately one week (M=6.70, SD=1.28). Actigraph sleep indicators included duration, efficiency, and wake after sleep onset [WASO]. Loneliness was assessed daily using a single item from the PANAS and rumination with the question, "Overall today, how much did you focus on your problems/stress?". Three-level multilevel models were fit in Mplus v.8.10.
Results: After controlling for between-person loneliness and rumination, day-level loneliness and rumination were not significant predictors of nightly sleep duration, efficiency, or WASO (βs=-.01–.03, ps>.05). However, loneliness and rumination were significantly lower on weekends (βs=-.09 to -.03, ps<.001), suggesting that adolescents tend to experience less loneliness and rumination on weekends compared to weekdays. Additionally, variances were significant (βs=.30–2.88, ps<.001), indicating substantial day-to-day variability in loneliness and rumination.
Conclusion: Daily fluctuations in loneliness and rumination may not significantly impact sleep that night in adolescents, with stable traits, such as chronotype or baseline anxiety levels, more likely to influence sleep outcomes. However, loneliness and rumination were lower on weekends, possibly reflecting reduced academic and cognitive demands and more opportunities for connection with peers. Significant day-to-day variability in loneliness and rumination highlights their dynamic nature. Future research should examine the potential moderating factors of social support on these daily links to understand if such associations vary across subgroups.

THE IMPACT OF THE TRANSDIAGNOSTIC INTERVENTION FOR SLEEP AND CIRCADIAN DYSFUNCTION ON ADOLESCENT MENTAL HEALTH

Justin Ison[1], Audrey Hardey[1], Isabella Wright[1], Kara Duraccio[1], Daniel Kay[1]

[1] Brigham Young University

Introduction: Sleep and circadian rhythm problems may worsen adolescent mental health; sleep disorders in adolescents are often linked to anxiety, depression, and attention difficulties. Interventions, such as the Transdiagnostic Intervention for Sleep and Circadian Dysfunction (TranS-C), have been found to be effective at improving adolescent sleep health, and a small pilot study demonstrated that TranS-C may improve mental health symptoms in adolescents with ADHD. As a secondary aim of a larger study examining the effectiveness in TranS-C in improving sleep in night-owl adolescents, we evaluated whether this sleep intervention would significantly improve emotional regulation abilities and reduce symptoms of depression, stress, anxiety, and suicidality in adolescents.
Methods: 31 adolescents and their parents completed a six-week TranS-C sleep intervention; at baseline and immediately following the intervention, adolescents completed the following measures: the Emotional Regulation Questionnaire (ERQ), the Difficulties in Emotion Regulation Scale (DERS), the Depression Anxiety and Stress Scale (DASS), the Columbia-Suicide Severity Rating Scale (C-SSRS), and the Pittsburgh Sleep Quality Index (PSQI). Paired-sample t-tests and non-parametric repeated-sample comparisons were used to evaluate how emotional regulation abilities and depression, anxiety, stress, and suicidality symptoms changed after the course of the sleep intervention.
Results: No statistically significant changes were found in emotional regulation ability, anxiety, stress, depression, or suicidality from pre-post ($p > .05$). Since no changes were found, it was examined if sleep improvement (change in PSQI total score) served as a moderator in mental health improvement; the presence of sleep improvement as part of the sleep intervention did not serve as a statistically significant moderator ($p > .05$).
Conclusion: Sleep interventions alone may not be a powerful enough intervention target to improve emotional regulation ability, anxiety, stress, depression, or suicidality. Future research should look at whether combining sleep treatment with evidence-based mental health interventions enhances the overall effectiveness of mental health treatment.

DAILY ASSOCIATIONS BETWEEN RELATIONSHIP STRESS AND SLEEP ARE MODERATED BY A HISTORY OF INTERPERSONAL VIOLENCE IN YOUNG ADULTS WITH REGULAR ALCOHOL USE

Karen Jakubowski[1], Nina Oryshkewych[1], Maria Guzman[1], Meredith Wallace[1], Sarah Pedersen[1], Brant Hasler[1]
[1] University of Pittsburgh

Introduction: Interpersonal violence (IPV) includes physical, sexual, or emotional abuse from a romantic partner or non-partner. IPV is related to poor health and social functioning, but little research has examined sleep outcomes. Moreover, most studies focus on childhood abuse history (vs. more proximal abuse during young adulthood) and do not consider IPV history in combination with day-to-day relationship stress. We tested interactive and independent effects of IPV history and daily relationship stress on same-night shorter total sleep time (TST), lower sleep efficiency (SE), longer sleep onset latency (SOL), and later sleep timing (midpoint) via ecological momentary assessment (EMA) among young adults.
Methods: 292 regular drinkers aged 21-30 (64% female; 64% White) from two studies of alcohol use and health self-reported demographics and current/past-year IPV history, and participated in an 18-day EMA protocol. Participants reported daily sleep (TST, SE, SOL, midpoint); cannabis use (yes/no); alcohol use (total drinks); and stress with family, partner/spouse and friends (each rated: 0=not at all to 3=very much; also summed to 0-9 overall score). We fit mixed-effects models and estimated within-subject effects, including: (1) interaction of daily stress variables and IPV history on sleep outcomes that night, and (2) main effects of daily stress variables and IPV history on sleep outcomes that night. All models included time-invariant (age, study, income, sex, partner status) and time-variant covariates (weekend, cannabis, alcohol, pre vs. post-pandemic).
Results: Participants with IPV history (12%) reported a stronger effect of overall relationship stress on SOL [B(95%CI)=0.02(0.00-0.03), p=0.041 for interaction]. Considering main effects, higher overall relationship stress on a given day [B(95%CI)=0.01(0.00-0.02), p=0.023], particularly friend stress [B(95%CI)=0.02(0.00-0.03), p=0.011], was associated with longer SOL that night. Participants with (vs. without) a history of IPV reported later sleep midpoint [B(95%CI)=0.47(0.10-0.85), p=0.012] on a given day.
Conclusion: Daily relationship stress and IPV history are related to disturbances in sleep initiation and timing in a well-characterized sample of young adults. Results highlight the importance of querying trauma and stress, and how these experiences impact cognitions, feelings, and behaviors around sleep, in order to comprehensively identify and address contributors to sleep problems in behavioral sleep medicine interventions.

GENDER DIFFERENCES IN MENTAL HEALTH, SLEEPINESS, AND SLEEP QUALITY IN COLLEGE STUDENTS

Alexandria Reynolds[1], Joshua Hughes[1], Sam Walther[1], Emily Stripling[2], Michael Oliver[2]
[1] University of South Carolina, [2] Belmont University

Introduction: Studies have shown that women may have an increased sleep duration need compared to men. Additionally, college life presents additional stressors and challenges that impact sleep duration and quality, and mental health in college students. The purpose of this study was to investigate sleep, mental health, and gender factors in college students.
Methods: Participants included 361 (male=62) full-time undergraduate students (mean age=19.93, SD=2.49 years). Participants completed an online survey that consisted of a series of questionnaires that examined demographics, depression, anxiety, and stress symptoms (Depression Anxiety Stress Scale, DASS-21), sleepiness (Epworth Sleepiness Scale, ESS), fatigue (Multidimensional Assessment of Fatigue, MAF), sleep hygiene (Sleep Hygiene Index, SHI), and sleep quality and duration (Pittsburgh Sleep Quality Index, PSQI).
Results: Preliminary data comparison tests were conducted. There were no gender differences in sleep duration (Mfemale=7.057, Mmale=6.93; p=.477), but women demonstrated worse sleep quality (Mfemale=6.80 vs Mmale=5.72; p=.020), more stress symptoms (Mfemale=19.73 vs Mmale=16.49, p=.037), greater

sleepiness (Mfemale=6.86 vs Mmale=5.52; p=.032), and greater fatigue (Mfemale=24.02 vs Mmale=18.77; p=.048) compared to men. There were no differences in depression or anxiety symptoms. Women also demonstrated poorer sleep hygiene habits than men (Mfemale=21.77 vs Mmale=19.37, p=.019).
Conclusion: Preliminary results showed that female college students obtained about the same sleep duration as men, however, their increased sleepiness, fatigue, and stress symptoms indicated that they experienced a more negative impact compared to men. It is unclear if the negative experiences were a result of worse sleep hygiene practices, greater perceived stress, or other factors. However, it is likely that women generally have a greater sleep need compared to men and simply increasing sleep duration is not the solution. Further, women may need to increase both quantity and quality of sleep to experience better mental and physical health. This study was limited by observational data collection, and further study is warranted to determine causal relationships. Additional work is being conducted at other institutions in the Southeast to determine if these trends are generalizable to other colleges.

EFFECTS OF COMMUNITY VIOLENCE ON PEDIATRIC SLEEP HEALTH: A SYSTEMATIC REVIEW

Hannah Scheibner[1], Eileen Condon[1], Kelley LaFleur[1], Nancy Redeker[2]
[1] University of Connecticut School of Nursing, [2] University of Connecticut

Introduction: Sleep is vital for child health and development and sets the foundation for lifelong health. Children living in disadvantaged neighborhoods are more likely to be exposed to community violence, which may disrupt sleep health through noise, anxiety, fear, stress, and hypervigilance. The purpose of this systematic review is to examine the associations between community violence and pediatric sleep health.
Methods: We systematically searched four electronic databases (CINAHL, SCOPUS, PubMed, Embase) using terms related to sleep, community violence, and pediatrics and screened for relevant articles that explored associations between community violence and pediatric sleep health. At least two reviewers screened all articles. We included English-language articles that addressed the relationship between community violence and sleep in pediatric populations. We did not place a time limit on our inclusion. We organized the results based on the B-SATED definition of pediatric sleep health.
Results: We screened 2,271 papers and included 29 eligible studies. Studies focused on sleep behaviors (n=4), sleep satisfaction/quality (n=17), alertness/sleepiness (n=7), timing (n=7), efficiency (n=10), and duration (n=12). Most studies included adolescents (n=19), while others included children in infancy (n=1), early childhood (n=2), and across a wide range of ages (n=7). The authors of most studies used self-report measures of sleep and community violence, and measures had varying reliability and validity. Some studies had small samples. Community violence exposure was negatively associated across all sleep health dimensions, particularly satisfaction, duration, and alertness. Evidence was weaker for behaviors, timing, and efficiency.
Conclusion: Exposure to community violence is negatively associated with all pediatric sleep health dimensions, especially satisfaction, duration, and alertness. Consistent definitions and measures of sleep dimensions and community violence are needed to promote rigor, reproducibility, and comparisons across studies. Future research should focus on infants and children under 6 years of age, covariates including potential risk and protective factors, sleep behaviors, timing, and efficiency. Policy changes and community, school, and individual-level interventions may help buffer the harmful effects of community violence on pediatric sleep health to promote health equity, but more research is needed.

SLEEP QUALITY AND PARENTAL STRESS IN MOTHERS OF CHILDREN WITH COMPLEX CHRONIC CONDITIONS

Ana Carolina Coelho[1], Simone Brasil de OLiveira Iglesias[1], Sergio Tufik[2], Gustavo Moreira[3]
[1] Universidade Federal de São Paulo, [2] Universidade de Federal de São Paulo, [3] Sleep Institute, Associação Fundo de Incentivo à Pes quisa

Introduction: In recent years, there have been advancements in the diagnosis and treatment of acute and rare diseases. As a result, these diseases have become persistent throughout life, leading to long-term disability and the emergence of a subset of children with complex chronic conditions (CCC). The families of these children experience the burden of care transfer, which impacts their health and well-being, resulting in high levels of parental stress and sleep disturbances.
Methods: Cross-sectional observational quali-quantitative evaluation assessment involving primary caregivers of children and adolescents with CCC. Exclusion criteria encompassed CCC patients who deceased, were readmitted, or were unreachable by phone. Questionnaires covered main caregiver sociodemographic data. Pittsburgh Sleep Quality Index (PSQI) and Parental Stress Scale were employed. Analyses comprised descriptive statistics with mean, standard deviation, percentage, tests for normality, one-way ANOVA with post hoc analysis and ANCOVA.
Results: The sample comprised 31 caregivers of children and adolescents with CCC and 31 caregivers of healthy children. Among primary caregivers of children with CCC, 93% were female, a mean PSQI score of 7.6, an average total sleep time of 5 hours and 45 minutes, and sleep latency of 37 minutes. Among caregivers of healthy children, 90% were female, a mean PSQI score of 6.8, an average total sleep time of 6 hours and 27 minutes, and sleep latency of 16 minutes. Comparisons between the groups showed significant differences in daytime caregiving time (7.0 vs 2.8 hours), total parental stress scale scores (7.6 vs 6.8), parental stress domain scores (18.9 vs 13.8), and sleep latency (37.3 vs 16.6 minutes). The groups also differed in daytime caregiving time regardless of total sleep time (5 hours 45 minutes vs 6 hours and 27 minutes).
Conclusion: Families of children with CCC, compared to families of healthy children, spend more time on caregiving, experience higher parental stress, taking longer to fall asleep and have shorter total sleep durations.

POOR SLEEP QUALITY AND DURATION PREDICT INTRUSIVE MEMORIES IN WOMEN AFTER AN ANALOGUE TRAUMA

Emily Mantaro[1], Alyssa Alishoev[1], Meghna Julian Sebastian[1], Sunjeev Kamboj[1]

[1] University College London

Introduction: Disturbed sleep is a key component of posttraumatic stress disorder (PTSD) symptomology, and sleep disturbances and PTSD have a bidirectional association. In the context of a larger experimental intervention study we evaluated the impact of pre-trauma sleep on intrusive memory frequency and characteristics, including distress, vividness, and avoidance, in healthy women after analogue trauma exposure.
Methods: Using the trauma film paradigm as an experimental model of trauma exposure, healthy female participants (N = 120) reported baseline sleep characteristics using the Pittsburgh Sleep Quality Index and viewed a distressing film, then listened to either a 30-minute guided yoga nidra meditation or instrumental music. Intrusive memory frequency and characteristics (vividness, distress, avoidance and sense of 'nowness') were monitored in the acute period immediately after the film and over 1-week ('long-term').
Results: Worse sleep quality predicted greater acute memory avoidance and distress and greater acute and long-term vividness and nowness. Lower sleep duration was associated with greater avoidance of acute intrusions. Neither sleep quality nor duration was associated with intrusion frequency.
Conclusion: Sleep over the month prior to an analogue trauma predicted intrusive memory characteristics acutely and long-term, though its impact varied depending on the specific sleep metric —quality versus duration. In contrast with previous analogue and naturalistic trauma studies, while baseline sleep predicted intrusive memory characteristics, it did not predict the frequency of intrusive memories. This research further underlines the impact of baseline sleep on the development of psychological symptoms after trauma exposure and suggests that trauma memory characteristics, in addition to frequency of intrusions, are a potentially informative outcome in trauma-sleep studies. These findings may have implications for development of preventative interventions aimed at reducing the subjective impact of intrusive memories after stressful events and improving key sleep metrics in the immediate aftermath of such events.

MENSTRUAL PHASE-DEPENDENT CHANGES IN CBT ACROSS SLEEP MAY PREDICT NEXT-MORNING MOOD IN YOUNG ADULT WOMEN

Katrina Rodheim[1], niveditha Gandikote[1], Rebecca Spencer[2]

[1] University of Massachusetts Amherst, [2] University of Massachusetts, Amherst

Introduction: Core body temperature (CBT) varies across the menstrual cycle, with lower CBT in the follicular phase and higher CBT in the luteal phase. Evidence suggests women have poorer sleep and mood outcomes in the luteal phase, yet it is unclear whether this is influenced by temperature changes occurring during sleep onset. The present study assessed CBT across sleep onset and its influence on next-morning sleepiness and mood in young adult women.
Methods: Nine healthy young women (mean age = 19.78 = 1.86 years) participated in both follicular and luteal phases. Participants ingested a telemetric pill to continuously measure CBT. Polysomnography was recorded. CBT was averaged 3 hours before and after sleep onset in each phase. Upon awakening, participants completed the Stanford Sleepiness Scale and Positive and Negative Affect Schedule. Paired samples t-tests were performed to compare temperature, sleepiness and affect between phases. A linear mixed-effects model tested whether the difference in CBT from wake to sleep predicts sleepiness and mood upon awakening by phase.
Results: There was a significant difference in CBT after sleep onset between the follicular and luteal phase ($t(8)=-3.12$; $p=0.01$); CBT in the luteal was higher. There was no significant difference between CBT before sleep onset ($t(8)=0.017$; $p=0.98$), sleepiness ($t(8)=0.814$; $p=0.44$), or affect ($t(8)=-0.077$; $p=0.94$) between phases. However, there was a significant interaction between menstrual phase and wake/sleep CBT difference in predicting next-morning positive affect ($p=0.001$). In the follicular phase, greater wake/sleep CBT difference was associated with increased positive affect. In the luteal phase, greater wake/sleep CBT difference was associated with decreased positive affect. There was no significant interaction for sleepiness ($p=0.29$).
Conclusion: The differences in CBT during sleep in the luteal and follicular phases are consistent with prior work. Interestingly, the impact of CBT fluctuations on mood differed by menstrual phase. In the follicular phase, a larger difference in CBT might indicate better thermoregulation aligned with a stronger circadian rhythm, improving mood, while in the luteal phase, the same change in temperature may suggest less optimal thermoregulation resulting in poorer mood. Future analyses will incorporate sleep physiology and ovarian hormones that may clarify how phase-related temperature differences influence mood.

THE INTERPLAY BETWEEN MOOD AND SLEEP AT DIFFERENT PHASES OF THE MENSTRUAL CYCLE

Peremoboere Uzoigwe[1], Alessandra Shuster[2], Allison Morehouse[2], Andres Pena[2], Katharine Simon[2], Negin Sattari[2], Jing Zhang[3], Marie Gombert[4], Fiona Baker[4], Sara Mednick[2]

[1] University of California, Irvine, CA, [2] University of California, Irvine, [3] Harvard Medical School/ Massachusetts General Hospital, [4] SRI International

Introduction: Understanding the intricate relationship between menstrual phases, sleep, and mood remains a critical area of investigation. Existing literature often falls short by relying on small sample sizes or failing to comprehensively evaluate women using a within-subject design across multiple time points of the menstrual cycle. Furthermore, few studies incorporate assessments of daily mood, sleep, and hormonal fluctuations. This study addresses these gaps by examining how menstrual phases modulate the interplay between mood and sleep in healthy young women.
Methods: We collected daily sleep and mood self-report measures in 60 healthy young women (18-35 years old). Each

participant completed in-lab visits during four menstrual phases (Menses, Pre-Ovulation, Mid-Luteal, and Late-Luteal), and hormone levels were collected through saliva samples. Objective sleep was examined at each visit via polysomnography (PSG) recordings. Using Pearson's correlations, we examined the relationship between self-reported scores of positive, negative, and angry mood, hormone levels, and objective sleep at each menstrual phase.

Results: Key findings indicate that reduced Stage 2 sleep is associated with negative emotions (less positive and more negative mood, r=-0.48,p< 0.001), particularly during the Mid-luteal phase. Progesterone was positively correlated (r=.16,p=0.04) with negative mood, and progesterone and testosterone was positively correlated (r=.21,p=0.009,r=.23,p=0.017) with Stage 2 sleep across all menstrual phases. Furthermore, positive mood consistently correlated with increased REM sleep across all menstrual phases(MS:r=.35,p=0.04, PO:r=.56,p=0.001,ML:r=.29,p=0.04,LL:r=.40,p=0.03)

Conclusion: These results underscore the dynamic interdependence between menstrual cycle phases, mood, and sleep. Our findings suggest that hormonal fluctuations modulate these relationships, providing a nuanced understanding of sleep and mood variability in young women.

DO WOMEN NEED MORE SLEEP THAN MEN? A STUDY ON GENDER DIFFERENCES IN COLLEGE STUDENT SLEEP AND MENTAL HEALTH

Joshua Hughes[1], Sam Walther[1], Katherine Batterson[1], Emily Stripling[2], Michael Oliver[2], Alexandria Reynolds[1]

[1] University of South Carolina, [2] Belmont University

Introduction: College students in general tend to have poor sleep quality and face stressors that impact their sleep and mental health. Further, women may have a greater sleep need compared to their male counterparts. The purpose of this study was to investigate sleep, mental health, and gender factors in college students via objective and subjective data collection.

Methods: Participants included 32 (male=16) full-time undergraduate students enrolled in a Psychology of Sleep course. Participants wore a Philips Respironics Actiwatch Spectrum device during one week of typical sleep. After one week, participants completed an online survey that consisted of a series of questionnaires that examined demographics, depression, anxiety, and stress symptoms (Depression Anxiety Stress Scale, DASS-21), sleepiness (Epworth Sleepiness Scale, ESS), fatigue (Multidimensional Assessment of Fatigue, MAF), and sleep quality and duration (Pittsburgh Sleep Quality Index, PSQI).

Results: Preliminary data comparison tests were conducted. There were gender differences in sleep duration (Mfemale=7.31h, Mmale=6.47h; p=.011), but no differences in sleep efficiency (Mfemale=84.57% vs Mmale=82.66%), wake after sleep onset (Mfemale=55.88 min vs Mmale=49.84 min), or number of awakenings (Mfemale=26.35 vs Mmale=25.89). There were no significant differences in sleep quality (PSQI), although the scores did represent poor quality (Mfemale=7.50 vs Mmale=6.13). Results showed that women experienced significantly greater sleepiness (Mfemale=9.88 vs Mmale=5.94; p=.033), and approaching significance in terms of greater fatigue (Mfemale=20.22 vs Mmale=13.89; p=.056) compared to men. There were no significant gender differences in depressive symptoms (Mfemale=6.31 vs Mmale=5.31), but women experienced greater anxiety (Mfemale=8.81 vs Mmale=3.69; p=.017) and stress (Mfemale=13.44 vs Mmale=6.38; p=.018) symptoms.

Conclusion: Preliminary results showed that the female college students taking the sleep course were obtaining significantly more sleep than men, with similar quality and efficiency. However, their increased sleepiness, fatigue, anxiety, and stress symptoms indicated that they were experiencing a more negative impact compared to men. It is likely that women generally have a greater sleep need compared to men, however, simply increasing sleep duration is likely not the answer. This study was limited by observational data collection, and further study is warranted to determine causal relationships and future intervention plans to improve sleep in women.

LATENT SLEEP PROFILES AND THE ROLE OF PARENT-CHILD SLEEP INTERACTIONS IN CHILDREN WITH A HISTORY OF MALTREATMENT

Anthony Cifre[1], Paul Cirino[1], Amanda Venta[1], Eleanor McGlinchey[2], Candice Alfano[1]

[1] University of Houston, [2] Fairleigh Dickinson University

Introduction: Sleep is critical for child development, yet children with maltreatment history frequently experience sleep disturbances linked to poor academic performance, mental health issues, and substance abuse. Children adopted from foster care, often exposed to early adversity, are at increased risk for sleep and emotional difficulties. However, little is known about their distinct sleep patterns and associations with maltreatment. We aimed to identify latent sleep profiles among children adopted from foster care and examine whether parent-child sleep interactions predicted profile membership.

Methods: Participants were adoptive parents of 362 children (Mage = 5.50 years) who completed surveys assessing child sleep health, foster care history, and maltreatment. Sleep was measured using the Child Sleep Habits Questionnaire (CSHQ) and parent-child interactions around sleep using the Parent-Child Sleep Interactions Scale (PSIS). Latent profile analysis (LPA) was conducted in MPlus, with CSHQ subscales standardized as z-scores. Multinomial logistic regression examined predictors of profile membership, with the 'Good Sleep' (GS) profile as the reference group.

Results: Five sleep profiles were identified: GS (36.0%), 'Sleep Onset Delay Problems' (SODP; 16.0%), 'Pre-Sleep/Bedtime Sleep Problems' (PSBSP; 12.9%), 'Severe Sleep Disturbance Problems' (SSDP; 12.9%), and 'Broad Behavioral Sleep Problems' (BBSP; 8.6%). Most children (64%) fell into one of the disturbed sleep profiles, with over a fifth (21.5%) exhibiting pervasive sleep issues spanning multiple domains (BBSP and SSDP). Parent-child sleep interactions significantly predicted profile membership. Higher scores on the PSIS sleep conflict subscale increased the odds of membership in the BBSP (RRR = 4.11), SSDP (RRR = 3.89), and PSBSP (RRR = 2.51) profiles. Similarly, higher sleep dependence scores were associated with increased likelihood of membership in the SSDP (RRR = 6.86), PSBSP (RRR = 3.58), and BBSP (RRR = 1.98).

Conclusion: Findings identified five distinct sleep profiles, reflecting varied sleep challenges among children adopted from foster care. Most children exhibited some sleep disturbances, with the BBSP and SSDP profiles representing severe dysregulation. Parent-child sleep interactions, particularly sleep conflict and dependence, emerged as significant predictors of profile membership. Results emphasize the need for interventions targeting these interactions to address sleep disturbances and mitigate their impacts on well-being.

ASSOCIATIONS BETWEEN PARENT-CHILD RELATIONSHIP QUALITY DURING ADOLESCENCE AND SLEEP INTO ADULTHOOD AMONG INDIVIDUALS WITH A HISTORY OF FOSTER CARE

Darlynn Rojo-Wissar[1], Alyssa Vieira[2], Megan Rech[2], Candice Alfano[2], Stephanie Parade[1]
[1] Brown University & Bradley Hospital, [2] University of Houston

Introduction: Children in foster care (FC) face caregiver attachment disruptions, leading to hyperarousal and poor sleep that may persist even after achieving permanency. Caregiver-child relationship quality may protect against poor sleep by down-regulating hypervigilance and fostering a sense of safety, but this is understudied in this population. We examined associations between resident parent-child relationship quality (PCRQ) in adolescence and sleep from adolescence into adulthood in individuals with a FC history.
Methods: Participants were 178 individuals from the National Longitudinal Study of Adolescent to Adult Health who reported a FC placement history at Wave III (W3) of the study. Participants were in grades 7-12 during W1 (mean age=15.34 years, SE±0.21) and were 60% female, 60% White, 17% Black, 11% Hispanic, and 29% reported a resident parent receiving public assistance. At W1, participants rated PCRQ for their resident parent(s). For overall PCRQ, mother and father scores were averaged for two-parent households and the single score was used in single parent households. Insomnia symptoms and insufficient sleep duration were measured at W1, W3 (ages 18-26 [duration only]), W4 (ages 24-32), and W5 (33-43). Design-based analyses were conducted, including use of sampling weights. We used Poisson regression with robust variance, adjusting for demographic characteristics and wave.
Results: Neither overall PCRQ or maternal PCRQ in adolescence were associated with insomnia symptoms or insufficient sleep duration. However, each 1-point increase in paternal PCRQ during adolescence was associated with a 6% reduced risk for insomnia symptoms from adolescence into adulthood (Risk Ratio=0.94, SE=.03, p=0.025). Associations between PCRQ and sleep did not differ by wave.
Conclusion: Among individuals with FC histories, higher PCRQ with a resident father in adolescence was associated with reduced risk of insomnia symptoms over time. Lack of associations with overall PCRQ and maternal PCRQ highlights the need for additional research into the unique roles of fathers and other contextual factors on lifelong sleep health in people who experienced FC. This work will inform the tailoring of sleep interventions for this population.

DAY-TO-DAY ASSOCIATIONS BETWEEN STRESS MANAGEMENT AND SLEEP HEALTH IN SOCIOECONOMICALLY DISADVANTAGED FAMILIES

Lauren Covington[1], Benjamin Brewer[2], Destiny Mahmood[3], Nicholas Bendel[4], Emma Archer[3], Kiara Shay[1], Shannon Mayberry[3], Xiaopeng Ji[4], Freda Patterson[4]
[1] University of Delaware School of Nursing, [2] Virginia Tech, [3] University of Delaware College of Health Sciences, [4] University of Delaware

Introduction: Parenting toddlers is stressful and for caregivers experiencing low socioeconomic status (SES), stress can be exacerbated by insufficient resources. Cross-sectional examinations suggest that stressful life events and ineffective stress management relate to poor sleep. This evidence base fails to recognize that naturally occurring stressors, stress management and sleep are dynamic and are marked by fluctuations within-persons from one day to the next. Not known is the day-to-day experience of stress among toddler caregivers, and how daily stress management relates to caregiver sleep in low-SES family contexts. Therefore, this study aims to characterize the day-to-day experience and response to stressors in association with caregiver sleep health.
Methods: We enrolled 60 caregiver-toddler dyads who were eligible for federally funded programs (e.g., WIC, Medicaid). Using a micro-longitudinal design, we used 24/7 actigraphy to measure caregiver sleep health (duration, efficiency, timing) over two-weeks. Concurrently, caregivers completed daily electronic diaries reporting experienced stressors, their severity, stress management strategies and their effectiveness. Generalized Linear Models utilizing GEEs quantified the associations between caregiver stress and sleep health.
Results: Caregivers (90% mothers, 48% Black, 25% < high school educated) slept on average 417.12 (SD=76.88) minutes/night, had 83% (SD=5.64) sleep efficiency and an 11:15 pm bedtime. One-quarter of caregivers reported family/parenting issues as their primary stressor, with up to 90% taking a healthy action against stress (e.g., mindfulness-based techniques, distraction), yet 44% reported healthy strategies as ineffective in managing their stress. Mixed model results showed that caregiver sleep efficiency varied by stress management effectiveness (p=0.009), ranging from a low of -0.4% decreased sleep efficiency (ineffective strategies) up to a high of 1.5% increased efficiency (very effective strategies). Similarly, on days when caregivers reported high strategy effectiveness, their sleep duration increased by 48-minutes (p=0.034).
Conclusion: Our findings underscore the importance of perceived stress management effectiveness on sleep quality and quantity in low-SES contexts. Future work is needed to better understand how toddler caregivers are employing stress management strategies, and if targeting such strategies may positively affect caregiver sleep.

THE IMPACT OF A SLEEP AND CIRCADIAN INTERVENTION ON TRAUMA-RELATED SYMPTOMS IN ADOLESCENTS

Maryn Ringger[1], Afton Beard[1], Meredith Woolley[1], Sarah Kamhout[1], Kara Duraccio[1]

[1] Brigham Young University

Introduction: Post-traumatic stress disorder (PTSD) is a debilitating condition that commonly causes sleep disturbances. Interventions that target sleep disturbances have gained traction as a way to alleviate PTSD symptoms. Circadian misalignment (CM), the discrepancy between one's sleep patterns and biological clock, is a potential contributor to poor sleep, especially in adolescents. We examined if a sleep intervention (the Transdiagnostic Intervention for Sleep and Circadian Dysfunction (TranS-C)) improved trauma symptoms in adolescents with CM. We hypothesized that adolescents would experience reduced trauma symptoms after completing TranS-C.

Methods: Thirty-one adolescents ages 14-18 actively experiencing CM (had a weekday bedtime of after midnight) engaged in a six-week TranS-C sleep intervention. Both before and immediately after the intervention, participants completed the International Trauma Questionnaire (ITQ.) We used nonparametric Wilcoxon Signed-Rank tests to compare the presence of PTSD symptoms and trauma-related functional impairment before and after the sleep intervention.

Results: Post-test scores were significantly higher than pre-test scores across three subtests of the ITQ: Disturbance in Relationships ($p = .013$), Disturbances of Self-Organization ($p = .007$), and Affective Dysregulation ($p = .042$); all other subtests had no significant change.

Conclusion: These results are contrary to our hypothesis, suggesting that while the intervention aimed to address CM and improve overall sleep health, it may have inadvertently heightened participants' awareness of trauma-related symptoms. This could reflect increased emotional processing or sensitivity to trauma cues as a result of improved sleep quality facilitated by the intervention. Further research is needed to explore these unexpected findings, examine potential mediating factors, and refine the intervention to better address both sleep and trauma-related outcomes.

CAN DIGITAL CBT-I BE AS A SCALABLE WORKPLACE SOLUTION FOR INSOMNIA-RELATED PRODUCTIVITY LOSSES?

Jonny Russell[1], Marleigh Treger[2], David Kalmbach[3], Christopher Drake[4], Philip Cheng[5]

[1] Henry Ford Sleep Research Center, [2] Henry Ford Health, [3] Henry Ford Sleep Research, [4] Henry Ford Health System, [5] Henry Ford Health + Michigan State University Health Sciences

Introduction: Previous research demonstrated that insomnia significantly impairs work productivity, leading to substantial economic losses. Traditional Cognitive Behavioral Therapy for Insomnia (CBT-I) is effective in alleviating insomnia symptoms, but largely inaccessible due to the scarcity of trained providers and associated costs. Digital CBT-I (dCBT-I) offers a scalable and accessible solution, showing evidence in reducing insomnia severity. When investigating dCBT-I's effect on work productivity, existing studies have shown promise, but also have limitations, including homogeneous samples and insufficient follow-up data. This study examines whether dCBT-I can lead to meaningful improvements in overall work productivity.
Methods: The 658 participants in this study met the DSM-5 criteria for insomnia. Participants were randomized to complete six core sessions of dCBT-I (n=358), or receive six weekly emails of sleep education (n=300). Work productivity was measured using the Work Productivity and Activity Impairment Questionnaire specified to a specific health problem: insomnia (WPAI:SHP). The WPAI:SHP questionnaire was administered pre-treatment, post-treatment, and one-year follow up. Total work impairment was the primary outcome. Secondary analyses included presenteeism and absenteeism subscales. A meaningful improvement was operationalized as 15% improvement, which corresponds to 6 hours in a 40 hour work week.
Results: Total work impairment was reduced 16.5% (b = -16.5 ± 2.7 SE, p <.001) more in the dCBT-I condition compared to the SE condition at post-treatment. At the one-year follow up, reduction in total work impairment remained 12.9% (b = -12.9 ± 2.8 SE, p <.001) greater than the SE condition. Sensitivity analysis indicated dCBT-I participants were 2.7 times more likely to achieve a 15% reduction in work impairment (95% CI [1.7, 4.3]) post-treatment. No significant effects were found for absenteeism in the secondary analysis, but participants in the dCBT-I group were 2.2 times more likely to achieve a 10% reduction in presenteeism (95% CI [1.4, 3.5]).
Conclusion: This study demonstrates the potential for dCBT-I as a scalable solution to rescuing insomnia-related productivity losses. Our results demonstrated that dCBT-I may recover almost a full day of work productivity. Integrating dCBT-I into workplace occupational health programs may help companies recoup insomnia-related productivity losses while improving employees' sleep health.

EVALUATING THE CAUSAL IMPACT OF SLEEP-RESTRICTION ON COGNITIVE AND AFFECTIVE EMPATHY

Zlatan Krizan[1], Anthony Miller[1]

[1] Iowa State University

Introduction: Insufficient sleep is known to degrade neurobehavioral functioning, but its impact on social responses to others is not well-understood. One key social response is empathy, namely the ability to understand and share in others' mental states. Empathy refers to both cognitive appraisals (understanding others) and affective responses (feeling with others). While linked to sleep, the dearth of experimental studies limits current understanding of whether commonly-experienced levels of sleep loss cause changes in cognitive and affective empathy. In this vein, the current pre-registered experiment tested whether experimentally-induced sleep restriction diminished cognitive (emotion-recognition) and affective empathy (concern for others).
Methods: College-age adults (n=70, 52% female, 66% White) were randomly assigned to either maintain their typical sleep or curtail it (by shifting bed and wake times over two days). Empathy changes were measured with the Multifaceted Empathy Test using emotional faces where participants had to accurately classify the emotion (cognitive) and report their feeling of concern for each depicted individual (affective), before and after the sleep manipulation. Regression analyses tested the impact of sleep-restriction condition on post-manipulation empathy (alongside baseline empathy and sex as covariates), while actigraphy assessed sleep.
Results: Sleep-restriction was successful, on average leading to a 4.5 hours deficit among the restricted group. Regression analysis indicated that cognitive and affective empathy were significantly diminished among sleep-restricted participants, even after accounting for their baseline empathic responses and sex. As a result, sleep-restricted individuals ultimately showed significantly lower empathic accuracy (58% vs. 63%) and empathic concern (d=.50), confirmed by associations with measured sleep duration.
Conclusion: The findings provide novel and much needed evidence about the impact of commonly experienced levels of sleep loss on a core human capacity—the ability to understand and feel with others. Despite methodological limitations (e.g., simple stimuli), the findings provide important causal evidence suggesting sleep loss reduces both cognitive and affective empathy in young adults. This carries important theoretical implications for of how sleep shapes social behavior, but also applied ones for occupations which require empathizing in order to be effective (e.g., first-responders).

SLEEP'S IMPACT ON SOCIAL WELLNESS: A NATIONAL SLEEP FOUNDATION POPULATION STUDY OF BLACK AND HISPANIC ADULTS

Alysa Miller[1], Spencer Nielson[1], John Lopos[1], Joseph Dzierzewski[1]

[1] National Sleep Foundation

Introduction: A robust and compelling literature has documented the importance of social connectedness and community in Black and Hispanic populations. A growing body of research has documented that poor sleep may negatively impact peoples' social lives, including hindering social engagement with friends and family; however, less is known about the potential positive impact of good sleep health on social functioning. Given the lack of research on the positive social impact of sleep health in communities of color, the present study examined the positive effects of getting enough quality sleep on social functioning among Black and Hispanic American adults.

Methods: A random sample of 608 nationally representative Black and Hispanic American adults were recruited to complete a survey that was administered in English or Spanish. The survey consisted of demographic questions and items probing the potential impact of a good night's sleep on social functioning. Descriptive statistics were used to analyze rates of experiencing positive social functioning benefits due to good sleep health within both Black and Hispanic adults.
Results: The large majority of Black and Hispanic adults reported a positive social impact of getting enough sleep (80%) and getting good quality sleep (79%). When asked about the impact of a good night's sleep on their ability do all the activities with friends that they want to do, 82% of Black and Hispanic adults reported good sleep has a positive impact. Over eight out of every ten people (83%) reported that a good night's sleep had a positive impact on their ability to do the family activities they want to do.
Conclusion: Good sleep health has a large and profound impact on the social functioning of Black and Hispanic American adults—facilitating activities with both friends and family alike. Considering the centrality of social connectedness in communities of color, messaging around the beneficial effects of good sleep health on social functioning should be highlighted in efforts to promote sleep health for Black and Hispanic Americans.

HOW MANY NIGHTS ARE ENOUGH? A PRE-REGISTERED STUDY EXAMINING THE RELIABILITY OF SLEEP INTRAINDIVIDUAL VARIABILITY DERIVED FROM 10,412 NORMAL SLEEPERS

Josh Leota[1], Brett Messman[2], Flora Le[1], Summer Jasinski[3], Emily Capodilupo[3], Elise Facer-Childs[1], Joshua Wiley[1]
[1] Monash University, [2] The Pennsylvania State University, [3] WHOOP, Inc.

Introduction: Individual sleep/wake patterns are characterized by the intraindividual mean and variability, which captures night-to-night fluctuations. Although research has focused on mean sleep parameters, higher sleep duration and timing variability are associated with negative physical and mental health outcomes. Most accelerometry-based sleep studies assess 5–14 nights of data, which may be insufficient for reliable variability estimates. This pre-registered study quantifies how many nights are needed for reliable sleep intraindividual mean and variability estimates using accelerometry.
Methods: Participants (N = 10,412, M-age = 37.75 ± 10.65, 50% women) wore a validated wrist-worn biometric device (WHOOP strap) for one year (3,700,492 person-nights). Total sleep time (TST), sleep onset, mid-sleep, sleep offset, wake after sleep onset (WASO), and sleep percentage were derived from heart rate and accelerometer data. Reference intraindividual means (iM) and standard deviations (iSD) were calculated from all (363) nights. Reliability correlation coefficients compared reference values with 2–362 consecutive nights randomly selected per participant, with r ≥.80 considered reliable. 95% limits of agreement were calculated using the Bland-Altman method.
Results: Reliable estimates of sleep iM required 2–8 nights (TST: 8 nights; sleep onset, midsleep, sleep offset: 2 nights; WASO and sleep percentage: 4 nights). Reliable iSD estimates required substantially longer durations, 41–67 nights (TST: 43 nights; sleep onset, midsleep, sleep offset: 41 nights; WASO and sleep percentage: 67 nights). iSDs from 7- or 14-nights showed poor reliability (7-nights: r =.48–.57; 14-nights: r =.59–.68). 95% limits of agreement on absolute values for 14-night iSDs were, TST: -42.80–34.57 (min), sleep onset: -60.80–44.58 (min), midsleep: -52.22–37.34 (min), sleep offset: -61.45–45.74 (min), WASO: -25.07–19.24 (min), and sleep percentage: -3.56%–2.66%.
Conclusion: Eight nights of accelerometry data are sufficient to estimate intraindividual mean sleep, but ~6–10 weeks (41–67 nights) are needed to reliably estimate intraindividual sleep variability. These findings highlight the importance of tailoring study periods to the specific sleep metric of interest. Longer monitoring periods may improve diagnostic accuracy and inform evidence-based recommendations for sleep assessments in clinical and research settings.

PAIN AND SOCIAL ISOLATION AS MECHANISMS LINKING THE ASSOCIATION BETWEEN SLEEP HEALTH PROBLEMS AND FRAILTY IN OLDER ADULTS IN THE UNITED STATES

Muhammad Thalil[1], Alexis R. Santos[1], Soomi Lee[1]
[1] The Pennsylvania State University

Introduction: Sleep health problems are common among older adults and are associated with various aging outcomes, including frailty. Older adults with sleep health problems may also experience pain and social isolation which can lead to physical and psychological consequences that exacerbate frailty. In this study, we examined the pathways, such as physical pain and social isolation, through which sleep health problems may contribute to the development of frailty among older adults.
Methods: 963 community-dwelling older adults (65+) were included in this two-wave longitudinal study from the National Aging and Health Trends Study (NHATS, 2013-14). Sleep health problems, including dissatisfaction, poor daytime alertness, suboptimal sleep timing, inefficiency and inadequate sleep duration were self-reported. Frailty was assessed using Fried's frailty phenotype and included muscle weakness, slow gait speed, exhaustion, low physical activity and weight loss. The presence of any chronic pain, activity-limiting pain, and social isolation, assessed through the 6-item Social Network Index participation domains, were included as mediators. We used multivariable logistic regression models to examine the associations and the Karlson–Holm–Breen (KHB) method to assess the mediation.
Results: After adjusting for baseline frailty, socio-demographics, and chronic conditions, older adults with more sleep health problems had 29% higher odds of being frail (OR: 1.29, 95% CI: 1.09, 1.53). Those who reported any pain (OR: 2.14, 95% CI: 1.35, 3.41), activity-limiting pain (OR: 1.72, 95% CI: 1.09, 2.72), and social isolation (OR: 1.98, 95% CI: 1.23, 3.18) had higher odds of frailty. The results of the KHB analysis indicate that pain (10%), activity-limiting pain (15.4%) and social isolation (9.9%) mediated the association between sleep health problems and frailty.
Conclusion: Older adults with more sleep health problems were found to have an increased risk of frailty, with pain, activity-limiting pain and social isolation being potential pathways in this association. The findings highlight the importance of addressing these factors to delay age-related declines in older adults

experiencing sleep health problems. Interventions aimed at improving sleep quality, managing pain effectively, and reducing social isolation may help mitigate the progression of frailty.

SLEEP HEALTH PROFILES ON EMOTIONAL FUNCTIONING AND QUALITY OF LIFE OF LONG-TERM SURVIVORS OF PEDIATRIC HODGKIN LYMPHOMA

Miguel Navarrete[1], Melissa Hudson[2], Belinda Mandrell[3], Kevin Krull[3], Lauren Daniel[4]

[1] St. Jude Children's Research Hospital, [2] St. Jude Children's Research Hospital, [3] St. Jude Children's Research Hospital, [4] Rutgers University-Camden

Introduction: Sleep is a neurophysiologic and behavioral state essential for wellness. Pediatric cancer survivors are at elevated risk of developing sleep problems due to cancer and/or treatment-related factors, but their sleep health is understudied. We used unsupervised clustering to identify sleep health profiles in survivors and controls and evaluated differences in emotional function across sleep groups.
Methods: Long-term survivors (> 5 years from diagnosis) of Hodgkin lymphoma (n=224, mean±SD age=40±9.5) and matched community controls (n=184, age=38±11.4) completed sleep questionnaires. Following the SATED model, sleep health components were derived from PSQI responses indicating Satisfaction, Alertness, Timing, Efficiency, and Duration. Continuous sleep metrics were computed as Euclidean distances of associated PSQI items, and Latent Profile Analysis identified sleep profiles. Parametric bootstrapped likelihood ratio tests estimated the number of profiles and robustness was assessed using Adjusted Rand Index. The health-related quality-of-life (SF36) and Brief Symptom Inventory (BSI-18) evaluated emotional function, and ANOVAs, t-tests, and $\chi 2$ assessed group differences.
Results: Three sleep profiles were identified: good-sleepers (PSQI=3.6±1.8), average-sleepers (PSQI=6.9±2.9), and poor-sleepers (PSQI=10.2±3.2). Profile distribution was significantly different between survivors and controls ($\chi 2=19.2$, $p< 0.001$) with a larger proportion of survivors in the poor-sleeper profile (33.9%vs15.2%). Average-sleepers had worse Alertness than good-sleepers, with no difference compared to poor-sleepers ($F(2,405)=68.2$, $p< 0.001$). Good-sleepers had better Timing than poor-sleepers, with no difference compared to average sleepers ($F(2,405)=30.1$, $p< 0.001$). Differences between all three profiles were found in Satisfaction ($F(2,405)=85.7$, $p< 0.001$), Efficiency ($F(2,405)=110.7$, $p< 0.001$), and PSQI disturbances ($F(2,405)=71.4$, $p< 0.001$), but no differences in Duration ($F(2,405)=1.4$, $p=0.237$). Considering quality-of-life, survivors have worse bodily pain, general health, and physical and role-physical limitations compared to controls. Poor-sleepers survivors reported worse mental ($t(79)=-2.8$, $p< 0.001$) and emotional health ($t(78)=-2.5$, $p< 0.001$). No sleep profile evidenced Survivor vs Control differences for depression or anxiety symptoms.
Conclusion: Distinctive sleep health profiles were found in pediatric Hodgkin lymphoma survivors and community controls. Survivors reported more pain, poorer general health, and more physical and role-physical limitations, while poor-sleepers exhibited worse mental and emotional health compared to controls. We highlight the importance of understanding the dimensions of sleep health to inform targeted interventions focused on improving overall well-being in pediatric cancer survivors.

EFFECTS OF LATE MEAL TIMING ON HUNGER, APPETITE, AND DIETARY BEHAVIORS OF ADULTS WITH OVERWEIGHT/OBESITY: A RANDOMIZED, CROSS-OVER, CONTROLLED TRIAL

Arman Arab[1], Nina Vujovic[2], Frank Scheer[3]

[1] Harvard Medical School, [2] Brigham and Women's Hospital, [3] Brigham and Women's Hospital

Introduction: Late eating has been linked with obesity and unhealthy food choices. However, no randomized clinical trial investigated causality between food timing and eating behaviors. Therefore, we conducted a randomized, cross-over, controlled trial to assess the effects of late vs early eating on hunger, appetite, and dietary behaviors of adults with overweight/obesity.
Methods: Sixteen participants (age:37.25±2.85y; 31% female; BMI:28.66±0.59 kg/m2) complete two 9-day in-laboratory protocols, one with early eating (isocaloric meals 1h0m, 5h10m, and 9h20m after wake) and the other including late eating (5h10 m, 9h20 m, and 13h30 m). The order of early and late protocols was randomized. Each protocol included a 6-d regular sleep/wake schedule followed by a 40-h Constant Routine [continuous wakefulness, semi-recumbent position, dim light (~4lux)] on days 7 and 8, a recovery night, and discharge on day 9. Throughout the Constant Routine, hunger/appetite and craving were assessed hourly. After controlled dietary schedules, participants' ad-libitum, self-selected dietary intake was assessed four times, including dinner and post-dinner snacks on day eight and breakfast and post-breakfast snacks on day nine, for each protocol. Moreover, participants' dietary intake was assessed by a photo-food diary for one week after each discharge.
Results: There was no significant difference in the area under the curve (AUC) in late vs early protocols (AUC mean difference ± SE) for hunger (-82.85±93.48, p=0.389), desire-to-eat (-158.48±104, p=0.148), fullness (13.58±79.95, p=0.867), thirstiness (-35.86±81.83, p=0.667), overall craving (-806.28±167.76, p=0.614), or craving for dairy (-150.42±84.90, p=0.096), meat (-119.61±103.97, p=0.268), vegetables (-139.95±120.41, p=0.263), fruit (-154.23±88.09, p=0.10), salty foods (-175.33±112.84, p=0.141), sweets (-139.11±188.56, p=0.472), and starchy foods (-117.34±86.19, p=0.193) during the Constant Routine. Late eating decreased participants' subsequent ad libitum dinner % of total energy fat intake (-4.98±1.98, p=0.024) and increased breakfast dietary glycemic index (3.06±0.97, p=0.007). During the 1-week post-discharge, late versus early eating decreased total energy intake (-169±65.60, p=0.049) and increased the dietary inflammatory index (0.19±0.06, p=0.034).
Conclusion: These findings suggest that late eating causes unhealthy dietary patterns characterized by a higher dietary glycemic index (in-patient phase) and dietary inflammatory index (out-patient phase). Future studies are needed to assess the long-term effects of meal timing on individuals' dietary behaviors.

FATIGUE IN TEAMS: COULD TEAMING BE AN EFFECTIVE FATIGUE RISK MANAGEMENT COUNTERMEASURE?

Crystal Yates[1], Chantal Mais[2], Mikaela Owen[1], Linda Grosser[1], Ellyse Greer[1], James Baumeister[1], Cedric Buche[3], Siobhan Banks[1]
[1] University of South Australia, [2] Naval Group, [3] Naval Group Pacific

Introduction: When working face-to-face, teams rely on nuanced behaviours to ensure effective team performance. In the operational environment teams are increasingly distributed across multiple locations and must work together effectively despite removing the beneficial visual aid of face-to-face interactions. This study examined the impact of forced disaggregation during sustained operations on alertness and self-reported sleepiness.
Methods: In this study 24 participants in six, 4-person teams (aged 25±7y, 13F/11M, BMI 23.8±4.5kg/m2) completed a 31.5h sustained operations protocol during which they completed one of three team tasks every 2h. The team tasks included Captain Sonar (co-located, cooperative team task), Dungeon game (co-located, collaborative team task) and COHESION (distributed, collaborative team task). Before and after completing each team task participants completed a Karolinska Sleepiness Scale (KSS; sleepiness scale) and Psychomotor vigilance task (PVT; response time task to measure alertness). For KSS and PVT, multiple linear mixed-effects models, with fixed effects of Time Awake, Task (COHESION, Dungeon and Captain Sonar), Pre/Post (before task and after task), and their interaction (Task*Pre/Post) were run.
Results: There was a significant main effect of Time Awake, such that with increasing time awake sleepiness increased ($p < .001$), PVT response time slowed ($p < .001$) and PVT lapses (missed responses) increased ($p < .001$). There was also a significant Task*PrePost interaction for sleepiness, such that following 24h of time awake (07:00), individuals reported significantly increased sleepiness following the distributed team task (COHESION) while participants reported to be less sleepy following Captain Sonar (co-located, co-operative task). Further, participants performance improved at night ($p < 0.01$), with faster response times, following the co-located team tasks (Dungeon and Captain Sonar). Additionally, teams completing co-located tasks maintained overall team performance across the protocol, unlike distributed team tasks with worsened team performance.
Conclusion: This study is the first to look at the impact of team performance during sustained operations in both co-located and distributed locations. These findings highlight the benefits of face-to-face interactions within the context of teaming. Typically fatigue research highlights the impact of fatigue on the individual. This study suggests working within a co-located team environment improves alertness, minimising the detrimental effects of sustained operations.

SLEEP OF ATHLETES WITHIN PROFESSIONAL RUGBY CLUB: FROM PREVENTION AND COACHING TO PERFORMANCE OPTIMIZATION

Alexandre Aranda[1], Laure Aranda[2], Arnaud Lamonzie[3], Philippe Izard[3]
[1] Ramsay Sante Clinique de l'union, [2] Toulouse, [3] Stade Toulousain

Introduction: Elite Athletes are susceptible to sleep inadequacies especially poor sleep quality and short sleep habits. Poor sleep and sleep habit are associated with decreased athletes' performance, increased injuries and less teams' success. Expert consensus and clubs' medical staff are searching for awareness program, medical assessment and more research in this field. We assessed a 360° sleep program (SoSleep) on club's request in prospective follow-up upon volunteer athletes to raise awareness, evaluate and coach with personnalized sleep goals to improve player's sleep for recovery and performance optimization upon elite rugby teams.
Methods: 72 rugbymen athletes from professional teams were proposed for educational and voluntary sleep program (SoSleep) over last 2 seasons in prospective study. The program was consisting in 360° sleep's evaluation directly at club's training field area with education briefing, sensibilization programs, on-line questionnaires, individual sleep assessment, in-board nap room, wearable polysomnography (EEG head band), medical sleep clinic evaluation with full home polysomnography test on medical staff's requirements.
Results: We had 45 awareness program forms, 36 players with several medical interviews, 106 questionnaire sets, 29 head band nights, 2 medical assessment pathways. Awareness program results showed that 52% were exposed to bad sleep prior to program then 89% to individual sleep better knowledge and 98% better sleep management intention after completion. Wearable polysomnography results (n=29) showed 7h52 mean sleep time (49% light-sleep, 17% deep-sleep, 26% REM-sleep, 8% WASO). Average players' satisfaction program level was 4,53/5.
Conclusion: Sleep education program with specific follow-up and polysomnographic evaluation at training field bedside and our results seem of great interest and very promising. Results deserve to be discussed and confirmed subsequently, notably the low polysomnography deep sleep proportion. Up to date main explanation would be that evaluations were made during the regular or final phase season when physical training is adjusted, likely different from pre-season trainings with modified sleep needs. Associated with last rugby team's results with double national and continental victories in major league (French TOP14, European Champions cup), sleep optimization within professional clubs seems to be a required and promising implementation both for the player's individual recovery and performance and for the team's collective performance.

SLEEP BEHAVIORS ARE ASSOCIATED WITH CHRONIC DISEASES IN PUBLIC SECTOR HEALTHCARE WORKERS

Yuan Zhang[1], Alicia Kurowski[1], Rebecca Gore[1], Laura Punnett[1]
[1] University of Massachusetts Lowell

Introduction: Healthcare workers work long or irregular shifts and report high occupational stress, resulting in short and poor sleep. Previous research demonstrated the effect of sleep duration/quality on overall physical and mental health of the general population. The association between sleep behaviors and the incidence of specific chronic diseases has not been well studied in healthcare workers.
Methods: A cross-sectional survey measured sociodemographics, work schedules, sleep, and chronic diseases (diabetes, hypertension,

high cholesterol, low back diseases and others) in healthcare workers at five public sector facilities in the northeast U.S.
Results: Among 1,553 healthcare workers (mean age 46.4 years, 61.5% female), 29% reported sleep disturbances, 51% reported short sleep duration (≤ 5 hours/day), and 20% reported two or more episodes of sleep per day. In total, 42% of the participants reported at least one chronic disease, including 15% diabetes, 28% hypertension, 22% high cholesterol, 14% low back disorders, and 18% others. Hypertension was associated with each of sleep disturbances, short sleep duration and ≥ 2 episodes; low back disorders were associated with sleep disturbances and short sleep duration; and high cholesterol was associated with sleep disturbances. Adverse sleep behaviors (sleep disturbances or short duration or ≥ 2 episodes, score range 0-3) were associated with a crude linear increase in the prevalence of chronic diseases (Chi-square=31, p< 0.001). The risk of any chronic disease was significantly elevated with two or more adverse sleep behaviors after adjusting for sociodemographics (Prevalence Ratio=1.3, 95% Confidence Interval=1.2-1.6).
Conclusion: Healthcare workers' adverse sleep behaviors were associated with an increased prevalence of chronic diseases. Cross-sectional design of the study limited the ability to examine causal relationships, therefore adverse sleep behaviors could be contributors or outcomes of chronic diseases. Evidence-based workplace interventions are needed to improve healthcare workers' sleep behaviors in order to reduce chronic diseases and improve overall health of this occupational group.

SLEEP, LIFESTYLE BEHAVIORS, AND SLEEP-RELATED DAYTIME IMPAIRMENTS IN U.S. NAVY SHIPBOARD ENVIRONMENTS

Josue Uriarte[1], Alice LaGoy[1], Jason Jameson[1], Peter Roma[1], Andrew Kubala[1], Sean Deering[1], Joseph Cuellar[1], Dale Russell[2], Rachel Markwald[3]

[1] Naval Health Research Center, [2] US Air Force, [3] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA

Introduction: The U.S. Navy shipboard setting is associated with high stress and negative health outcomes due in part to constraints limiting opportunities to engage in healthy lifestyle behaviors. Improving our understanding of the relationship between sleep and lifestyle behaviors in this setting may help identify interventions to improve health outcomes. We examined service members' sleep in the shipboard operational setting and investigated the relationships among lifestyle behaviors, sleep, and sleep-related daytime impairments.
Methods: Service members (n = 758, 30 ± 8 years [mean ± SD], 24% female) wore a commercial sleep-tracking device (Oura™ Ring, Generation 2 or 3) to measure total sleep time (TST) while in port and while underway. Participants slept either at home or on ship, depending on their mission and schedule. Participants also completed surveys assessing sleep-related impairment (PROMIS-SRI short form) and multiple lifestyle behaviors, including sun exposure, diet, typical daily exercise, and caffeine/nicotine intake. Relationships between lifestyle behaviors, TST, and sleep-related daytime impairments were examined using linear mixed models, with command included as a random effect.
Results: Service members slept 6.3 ± 1.1 hours/day and reported moderate levels of sleep-related impairments (55.2 ± 9). TST was related to ship schedule (6.2 ± 1.1 underway, 6.8 ± 0.9 in port) but not lifestyle behaviors (all behaviors, p >.05). For sleep-related impairment, shorter TST (B = -1.45, SE = 0.31, p <.001) and poor diet (B = -2.22, SE = 0.33, p <.001) were related to higher impairment. Less physical activity approached statistical significance (B = -3.26, SE = 1.69, p =.053).
Conclusion: Even under the many constraints of shipboard settings and the potential variation due to person-specific characteristics (e.g., department, rank, service years), daytime impairments were related to sleep and lifestyle behaviors, suggesting persistent synergistic connections among them. Therefore, targeting sleep as well as certain lifestyle factors (i.e., diet and exercise) when developing health-related interventions for the U.S Navy personnel serving on warships should be considered.

ARE CANADIAN VARSITY ATHLETES SLEEPING WELL? INSIGHTS ON ADHERENCE TO OPTIMAL SLEEP RECOMMENDATIONS

Félix-Gabriel Duval[1], Jean-François Caron[2], Joshua Fournier[2], Geneviève Forest[1]

[1] Université du Québec en Outaouais, [2] UQO

Introduction: In 2021, Walsh and colleagues highlighted the importance of sleep education for athletes and proposed a series of tips to educate athletes. These tips can be summarized as follow: (1) get more sleep than the standard recommendations; (2) nap to supplement insufficient nocturnal sleep; (3) maintain a good sleep hygiene; (4) having a training schedule in-line with their chronotype. The aim of this study was to explore the proportion of Canadian varsity students who follow these recommendations.
Methods: A total of 173 Canadian varsity athletes (M=20.8 ±2 years 66.5% females) completed an anonymous online survey of about 20 minutes during the academic year. The survey included questions about sleep habits, sleep hygiene, sleep environment, training schedule and lifestyle habits.
Results: Data showed that 65.8% of athletes do not get 8 hours of sleep during weekdays and 29% during weekends. Moreover, 31.5% of athletes do not even get 7 hours of sleep on average during weekdays and 11% during weekends. In addition, before a game, 58,4% rarely or do not nap, while 41,1% occasionally or always nap. On the other hand, during regular weekdays, 66.9% will nap at least once, while 33,1% never nap. Regarding training, 58.3% report training at a time that is not in-lined with their chronotypes. Data on sleep hygiene show that 65% of the athletes use their cellphone within one hour of going to bed, seven days a week, and 33.3% do not turn their notifications off during the night. Finally, 21.4% report that their sleep is disturbed by roommates, 41% report that ambient temperature is interfering with their sleep, 30.1% that ambient light affects their sleep, and 32.9% of them report environmental noise disturbing their sleep.
Conclusion: These results highlight that Canadian varsity athletes seem to be far from sleeping in line with the recommendations set by Walsh et al (2021). Most of Canadians varsity athletes do not

get enough sleep. Our results also seem to indicate that Canadian varsity athletes may not be sleeping in an environment conducive to optimal sleep. Further studies are needed to investigate the factors that may prevent athletes from achieving optimal sleep.

WORLD BELIEFS, NOT RECOVERY EXPERIENCES, PREDICT SUBJECTIVE SLEEP QUALITY

Noah Love[1], Philip Gehrman[1]
[1] University of Pennsylvania

Introduction: Our beliefs about the situations in which we find ourselves influence how we think and behave in those situations. Recent research on primal world beliefs, beliefs about the nature of the world as one big situation, has shown strong relationships between "primals" and important waking psychological variables such as depression, political affiliation, and well-being. These beliefs, which are present in all situations, likely also impact sleeping experiences. The current study explores the relationships between four core primals and subjective sleep quality, in conjunction with measures of waking recovery experiences, which have been shown to be positively related to sleep quality.
Methods: Undergraduate students completed a survey with measures of subjective sleep quality, primal world beliefs, recovery experiences, and demographics. Subjective sleep quality was assessed with the Sleep Quality Scale (SQS). The Good, Safe, Alive, and Enticing primals were measured using the Primals Inventory-18 (PI-18), and recovery experiences were measured using the Recovery Experiences Questionnaire (REQ).
Results: A total of N = 281 students completed the survey, with sample characteristics 72.6 % female, 49.9% White or Caucasian, and average age 20.0 (SD = 1.67). Of the primals measured, Good (r = -.244, p <.001), Safe (r = -.132, p =.029), and Enticing (r = -.251, p <.001) significantly correlated with subjective sleep quality, such that more positive primals (e.g., stronger belief that the world is good) were associated with better subjective sleep quality. The relationship between Alive and sleep quality was not significant (r = -.117, p =.053). The REQ did not significantly correlate with subjective sleep quality (r = -.110, p =.070), nor did the detachment subscale (r =.043, p =.476), which has previously shown a strong relationship with sleep quality.
Conclusion: Preliminary findings indicate that beliefs about whether the world is a good, safe, or enticing place positively predict subjective sleep quality. Further, these beliefs seem to be more strongly related to sleep quality than are recovery experiences. Future research should explore the relationship between worldview and sleep health in more detail by examining the relationships between primals and thorough, objective measures of sleep quality.

POOR SLEEP QUALITY AND EXCESSIVE DAYTIME SLEEPINESS AMONG CANADIAN UNIVERSITY STUDENTS: A COMPARISON A VARSITY ATHLETES AND SEDENTARY STUDENTS

Jean-François Caron[1], Félix-Gabriel Duval[1], Joshua Fournier[2], Geneviève Forest[1]
[1] Université du Québec en Outaouais, [2] UQO

Introduction: Studies have shown that professional athletes and American varsity athletes experience sleep disturbances and short sleep duration, which lead to impaired daytime functioning. Nevertheless, very little is known about Canadian varsity athletes. The objective of this study is to compare the sleep of Canadian varsity athletes and sedentary university students.
Methods: A total of 676 Canadian university students (166 varsity athletes and 510 sedentary students; M= 21.73 ±3.00; 73.4% females) completed an anonymous online survey which included the Pittsburgh Sleep Quality Index (PSQI), the Epworth Sleepiness Scale (ESS), and the Insomnia Severity Index (ISI). Mantel-Haenszel chi-square analyses were used to determine differences in the rates of sleep quality, excessive daytime sleepiness, and insomnia symptoms between varsity athletes and sedentary students, controlling for gender. The Mantel-Haenszel analysis was also employed to compare the proportion of varsity athletes and sedentary students who met the recommended minimum daily sleep duration of 7 hours.
Results: Results showed no group difference on the PSQI, $\chi 2$ (1) = 1.15, p=.284, and ESS scores, $\chi 2$ (1) = 1.46, p=.228. Data showed that 81.3% of varsity athletes and 86.7% of sedentary students scored > 5 on the PSQI. Also, 60.2% of varsity athletes and 53.6% of sedentary students scored > 10 on the ESS. Results showed that varsity students had significantly fewer insomnia symptoms than sedentary students, $\chi 2$ (1) = 11.43, p <.001. Furthermore, data revealed that 27.0% of sedentary students had clinical insomnia, whereas 7.8% of varsity athletes did. Also, 32.1% of varsity athletes and 42.3% of sedentary students slept less than 7 hours per night on weekdays, whereas it was 10.4% and 14.3%, respectively, on weekends.
Conclusion: These results suggest that the sleep of varsity students doesn't seem to be very different from that of sedentary students. Yet, both populations show significant sleep problems, including short sleep duration and sleep disturbances that may affect daytime functioning. Given the importance of sleep for mental health, recovery and athletic performance, this study highlights the urgent need for concrete strategies to target university students, whether they are an athlete or not.

SLEEP'S IMPACT ON PRODUCTIVITY FOR BLACK AND HISPANIC ADULTS: POPULATION DATA FROM NATIONAL SLEEP FOUNDATION

Alysa Miller[1], Spencer Nielson[1], John Lopos[1], Joseph Dzierzewski[1]
[1] National Sleep Foundation

Introduction: Sleep research has had disproportionately little focused on communities of color. Similarly, less research has examined the benefits of healthy sleep as compared to the deficits of poor sleep. Home and work productivity are important components of flourishing and represent relatively novel endpoints in sleep research. Therefore, we sought to document the perceived benefits of sleep health on both work and home productivity and responsibilities in Black and Hispanic adults.
Methods: An online, national survey was administered to a probability-based, random sample of 608 Black and Hispanic U.S. adults during Fall 2024. The survey was administered in English or Spanish, included demographic questions, and asked about the impact of getting enough quality sleep on home and work productivity, as well as ability to perform specific tasks. Descriptive statistics were used to analyze rates of experiencing

positive productivity benefits due to good sleep health within both Black and Hispanic adults.
Results: The vast majority of Black and Hispanic adults reported experiencing positive impacts of getting enough sleep on home (87%) and workplace (90%) productivity. People also reported productivity benefits of good quality sleep at both home (87%) and work (91%). In terms of specific productivity-related behaviors and benefits, Black and Hispanic adults indicated that a good night's sleep had a positive impact on their ability to work the required number of hours (81%), get going at the beginning of the day (85%), stay on task (82%), think clearly (86%), handle the workload (83%), and do their work without making mistakes (82%).
Conclusion: The benefits to productivity, both at home and work, of good sleep health were widely experienced and reported by Black and Hispanic adults. Public health and other awareness campaigns in communities of color can emphasize the positive effects of healthy sleep for productivity-related endpoints and help reframe the narrative on why to prioritize sleep health.

POPULATION DIFFERENCES IN AVOIDING AND PREVENTING DROWSY AND DRUNK DRIVING: A NATIONAL SLEEP FOUNDATION STUDY

Spencer Nielson[1], Joseph Dzierzewski[2], Alysa Miller[2], John Lopos[2]
[1] Virginia Commonwealth University, [2] National Sleep Foundation

Introduction: Drowsy driving is impaired driving, just like drunk, drugged, and distracted causes of crashes. Drowsy driving is a significant public health and safety concern. There are several actionable steps individuals can take to avoid and prevent impaired driving, including changing plans, finding alternative transportation (e.g., taxi or rideshare), and urging others not to drive impaired. This study sought to identify and highlight differences in the likelihood that people would take action to avoid and prevent drowsy driving and drunk driving.
Methods: National Sleep Foundation (NSF) conducted a random, representative national survey of 1,372 US adults, oversampled for Black and Hispanic adults. The survey asked how likely people were to (1) change plans, (2) find alternative transportation, or (3) drive anyway if they had (a) only gotten 3-4 hours of sleep or (b) had several alcoholic drinks. Descriptive statistics were used to summarize rates of likelihood to take steps to avoid and prevent impaired driving, while chi-square tests were used to explore differences based on sleep health.
Results: More U.S. adult drivers stated they would change plans if they had several drinks (81%), compared to if they got insufficient sleep (52%). Nearly 7 in 10 adult drivers (69%) were likely to find alternative transportation to avoid drunk driving compared to only 40% who would do the same to avoid drowsy driving. Strikingly, 50% of U.S. drivers reported being likely to keep their plans and drive despite only sleeping 3-4 hours, while only 11% reported being likely to drive despite having several drinks. Finally, drivers who were likely to avoid drowsy driving had longer average weekly sleep durations and better sleep quality.
Conclusion: Being awake and alert behind the wheel is as important as not being under the influence. Unfortunately, adult drivers reported being nearly five times more likely to keep their plans and drive while drowsy than if they had been drinking. Notably, those with better sleep health were more likely to take steps to avoid drowsy driving. It appears established attitudes and behaviors to prevent drunk driving have not generalized to drowsy driving, another high-risk form of impaired driving.

SLEEP AND EMPLOYEE FUNCTIONING: A NATIONAL SLEEP FOUNDATION STUDY OF THE CONSEQUENCES OF NOT GETTING HEALTHY SLEEP

John Lopos[1], Alysa Miller[1], Spencer Nielson[1], Steve Lerman[1], Joseph Dzierzewski[1]
[1] National Sleep Foundation

Introduction: Much research and public education have documented the numerous negative consequences of poor sleep health, with the bulk of this research focusing on the personal consequences of poor sleep health including mood changes, cognitive difficulties, numerous physical health concerns, and social problems. Less is known about the potential negative effects of not getting healthy sleep in the workplace and employee functioning, which includes general productivity, thinking clearly, working carefully, and avoiding mistakes—among others. This study aimed to document the workplace and employee experiences with the myriad negative effects of not getting healthy sleep.
Methods: Data were drawn from an online, national survey utilizing a probability-based, random sample of 1,372 U.S. adults, oversampled for both Black and Hispanic individuals. The survey was administered in English or Spanish, and included demographic information and questions probing about the employee-reported negative impacts of not getting healthy sleep. Measures of central tendency were used to characterize rates of reported negative consequences of poor sleep in the workplace.
Results: The majority of adults in the US reported negative impacts of not getting enough sleep (58%) and not getting quality sleep (66%) on their general levels of work productivity. In terms of specific workplace and employee-related consequences of not getting healthy sleep, large proportions of adults indicated that poor sleep had a negative impact on their ability to work the required number of hours (54%), get going at the beginning of the day (71%), think clearly (67%), do work carefully (57%), interact with people in person, in meetings, or on the phone (45%), control their temper in front of people (45%), handle the workload (58%), and do work without making mistakes (58%).
Conclusion: Not getting healthy sleep has a real, meaningful, negative impact on the workplace and employees. Over 50% of people indicated poor sleep has a negative impact on their general work productivity, including working required hours, not making mistakes at work, and being able to interact appropriately with others at work. Such negative consequences can have large ramifications on business performance, economics, public health and safety. Employers should invest in the sleep health of their workforce.

ASSOCIATION BETWEEN SLEEP INERTIA AND COGNITIVE PERFORMANCE IN THE WISCONSIN SLEEP COHORT STUDY

Jessica Love[1], Paul Peppard[2], Laurel Ravelo[3], Mari Palta[3], Jesse Cook[4], Erika Hagen[3], David Plante[5]

[1] University of Wisconsin-Madison, Department of Psychology, [2] University of Wisconsin-Madison, [3] University of Wisconsin-Madison, Department of Population Health Sciences, [4] University of Wisconsin-Madison, School of Medicine and Public Health, Department of Psychiatry, [5] University of Wisconsin–Madison

Introduction: Sleep inertia is a transitional state between wake and sleep, resulting in disorientation or grogginess upon waking. Frequent symptoms of sleep inertia are reduced alertness and impaired performance. Although sleep inertia is common, its relationship with objective neurocognitive assessment is understudied and unclear. Thus, this investigation examined the association between subjective, typical sleep inertia severity and a standardized afternoon-assessed objective cognitive testing battery in a population sample of middle-aged and older adults.
Methods: Wisconsin Sleep Cohort participants (N = 462; average age = 74 ± 6.7 years) completed the validated Sleep Inertia Questionnaire (SIQ) and six cognitive tasks: Grooved Pegboard (PEGSUM), Symbol Digits Modalities Test (SDMT), Auditory Verbal Learning Test (AVLT), Oral Word Frequency (OWFRAW), Digit Cancellation Test (Digitcan), and Trail Making Test Part B (TMT-B). All tests were administered and coded by a trained technician following standardized protocols. Associations between total and subscale (physiological, responses to sleep inertia, emotional, and cognitive) SIQ scores with performance on the cognitive tasks (outcome) were assessed using linear regression modeling. All models were adjusted for age, sex, body mass index, education, caffeine use, apnea-hypopnea index, smoking, alcohol, and circadian preference (morning/evening).
Results: Mean SIQ score was 10.74 (SD: 9.54, range: 0 - 63). With every 1 unit increase in the SIQ score, there was an average 1.52-second increase in the time to complete PEGSUM ($p < 0.0001$), a reduction in the average number of matches on SDMT by 0.11 ($p = 0.011$), and an increase of an average of 1.08 seconds to complete TMT-B ($p < 0.0001$). SIQ subscale analysis demonstrated that performance on these tasks was associated with physiological, emotional, and cognitive SIQ subscale scores, but not responses to sleep inertia subscale score. Sensitivity analysis considering apolipoprotein E4 status (N = 391) did not substantially alter results.
Conclusion: These findings suggest sleep inertia may be an important consideration when objectively assessing neurocognitive performance. Future research that examines neurocognitive function among patients with excessive sleep inertia, and probes cause-effect relationships between sleep inertia and cognitive performance are indicated.

CHRONIC VARIABLE SLEEP DEFICIENCY IMPAIRS DECLARATIVE MEMORY IN WOMEN BASED ON MENSTRUAL CYCLE PHASE

Shauni Omond[1], Leilah Grant[2], Kritika Vashishtha[2], Joon Chung[3], Aissata Cisse[4], Steven Lockley[2], Melissa St. Hilaire[5], Shadab Rahman[6]

[1] Brigham and Women's Hospital / Harvard Medical School, [2] Brigham and Women's Hospital, [3] University of Miami, [4] Brigham and Women's Hospital, [5] Merrimack College, [6] Harvard Medical School

Introduction: Chronic variable sleep deficiency (CVSD) is a pattern of insufficient sleep commonly illustrated by sleep loss on weekdays to accommodate social and occupational demands and "catch-up" recovery sleep on weekends. Women are more vulnerable to acute overnight sleep loss during the follicular phase compared to the luteal phase of the menstrual cycle. We therefore examined the impact of chronic sleep loss on declarative learning and memory by menstrual cycle phase using a CVSD paradigm.
Methods: Data from 12 healthy naturally-cycling pre-menopausal women (mean±SEM: 29.95±1.46 years) who completed an ongoing 11-day inpatient study of the neurobehavioral impacts of CVSD were analyzed. Participants were randomized to begin the CVSD protocol at either the follicular (n=8) or luteal phase (n=4) and underwent three cycles of a 10-hour sleep opportunity followed by two consecutive nights of 3 hours sleep, aligned by wake time with a 12-hour recovery sleep before discharge. On the morning after the first 10-hour sleep, participants were trained on a paired-associates task in which they were presented and repeatedly tested on a list of 36 unrelated word-pairs until they achieved a 50%-learning criterion. Participants were asked to recall the same word-pairs the next morning after a 3-hour sleep opportunity. Different sets of word-pairs were used in the first and third CVSD cycles.
Results: Women learned a similar number of word-pairs in the follicular and luteal phases in CVSD-cycle 1 (28.87±1.83 vs. 28.00±2.79, $p=0.79$, respectively) and CVSD-cycle 3 (31.37±0.99 vs. 31.00±2.27, $p=0.86$, respectively). Women recalled significantly fewer words in CVSD-cycle 3 compared to CVSD-cycle 1 (i.e., 5 nights vs. 1 night of sleep loss, respectively) (85.35% ± 3.14 vs. 95.65% ± 3.19, $p=0.04$, respectively) during the follicular phase, but had no difference in word-pair recall between CVSD-cycle 3 and CVSD-cycle 1 during the luteal phase (93.02% ± 3.07 vs. 79.62%±11.41, $p=0.06$, respectively).
Conclusion: These results suggest that CVSD differentially impaired declarative memory in the follicular phase compared to the luteal phase. Additional work with a larger sample size is needed to confirm these preliminary findings and examine the impact of CVSD by menstrual cycle phase on other neurobehavioral outcomes.

RELATIONSHIP BETWEEN SLEEP, PHYSICAL ACTIVITY, AND COGNITIVE FUNCTION IN COMMUNITY-DWELLING OLDER ADULTS

Ikuha Fukamachi[1], Mana Furuta[2], Kyuto Yamazaki[1], Akiko Noda[2]

[1] Chubu University College of Life and Health Sciences, [2] Chubu University Graduate School of Life and Health Sciences

Introduction: Poor sleep quality is a common problem in older adults, with an estimated prevalence rate of 12%–40%. The European Guideline for the Diagnosis and Treatment of Insomnia states that exercise may be effective for insomnia management, suggesting that physical activity could improve sleep quality in older adults. Physical activity may attenuate some of the negative impact that poor sleep has on cognition, and sleep is important through which physical activity improves cognitive abilities. In Japan, where the population is aging, improving the health of elderly individuals in the community is a critical issue. The purpose of this study was to examine the relationship

between sleep, physical activity, and cognitive function in community-dwelling older adults.
Methods: Fourteen consecutive volunteers aged ≥ 60 years were included in this study. After approval by the Chubu University Ethics Review Committee, all participants were informed about the study and its methods, and written consent was obtained from each participant. Actigraphy, sleep diaries, and pedometry were conducted over a period of two weeks. Sleep was analyzed based on data obtained from the actigraphy and sleep diary, while physical activity was assessed with pedometer data. Cognitive function was evaluated using the Trail Making Test Part B (TMT-B) and the Mini-Mental State Examination (MMSE). Participants were classified into two groups: those with a sleep efficiency of 90% or greater and those with a sleep efficiency of less than 90%. The relationship between sleep efficiency and each of these measures was then examined.
Results: TMT-B completion time was significantly longer in the group with sleep efficiency < 90% than group with sleep efficiency ≥90%. Physical amount, number of steps, and total distance was significantly greater in the group with sleep efficiency ≥90% than group with sleep efficiency < 90%. There was no significant difference in MMSE score between the two groups. TMT-B completion time was significantly correlated with the sleep efficiency (r=-0.49, p=0.024)
Conclusion: Sleep quality was associated with both physical activity and cognitive function. Our findings suggest that daily exercise along with sleep guidance may be important.

NEUROTICISM TRAITS PREDICT RESILIENCE TO EXECUTIVE FUNCTION DECLINE DURING SLEEP DEPRIVATION

Jason Katz[1], Kymberly Henderson-Arredondo[1], Allie Jepson[2], Catherine Seader[1], A'mour Canty[1], Salma Patel[2], Michael Grandner[3], Sarah Green[1], David Negelspach[2], Sofia Fluke[4], Brieann Satterfield[4], Alisa Huskey[2], William Killgore[2]
[1] University of Arizona, [2] The University of Arizona, [3] University of Arizona College of Medicine, [4] Washington State University

Introduction: Sleep deprivation (SD) impairs a range of cognitive abilities. There are also consistent inter-individual differences in resilience to these effects. Prior work suggests that personality traits such neuroticism, trait-anger, and introversion are associated with resilience during psychomotor vigilance performance. Here, we extended this line of research to determine the role of neuroticism in sustaining resilience to the degrading effects of SD on a Go/No-Go (GNG) inhibitory task that included a cognitive reversal of the contingencies half-way through. We used metrics of neuroticism, particularly anger hostility (AH) to predict inhibitory resilience during sleep deprivation.
Methods: Participants (n=20; 9 female; age=23.6, SD=4.7 years) completed a 39-hour in-lab sleep deprivation period. One week before arriving at the lab, participants completed the NEO-PI, a personality test of the Big 5 traits, including Neuroticism and its facets. During the in-lab sleep deprivation period, participants awakened at 0700 and completed the GNG task a total of three times: once after waking up on the first day, one at hour thirteen, and one at hour thirty-six of continuous wakefulness. The change from the second to the third GNG score was used as the dependent variable in a multiple linear regression with the Neuroticism facets as predictors.
Results: Simultaneous entry of all 6 facets of Neuroticism yielded a significant model predicting total GNG scores (R=0.783, P=0.03). Of these, anxiety (β=1.073, p=.029), AH (0.757, p=.003), and vulnerability (-0.831, p=.045) had the greatest contributions to the model. We then ran a stepwise model to determine whether other facets predicted above and beyond the effect of AH. The stepwise model only retained AH as accounting for significant variance (R=.523; p=0.18).
Conclusion: The three strongest traits contributing to inhibitory resilience during sleep deprivation were greater anxiety and angry hostility, and lower vulnerability. However, anger/hostility was the strongest predictor when subjected to stepwise entry/deletion. These findings are consistent with prior work showing that trait-anger facilitates resilience to sleep deprivation, presumably through increased tonic arousal that sustains cognitive performance in the face of building homeostatic sleep pressure. These findings also extend this resilience phenomenon to cognitive flexibility and inhibitory capacity.

WAKE TIMING AND SLEEP MAINTENANCE EFFICIENCY ARE ASSOCIATED WITH EATING IN THE ABSENCE OF HUNGER IN PREADOLESCENTS

Emily Hohman[1], Jennifer Savage[1], Orfeu Buxton[2]
[1] Pennsylvania State University, [2] Penn State

Introduction: Poor sleep health is associated with childhood obesity, but the mechanisms underlying this association remain unclear. This study aimed to determine if sleep health variables are related to daily frequency of eating in the absence of hunger (EAH), an obesogenic eating behavior, in preadolescents. We hypothesized that children would be more likely to engage EAH following nights of shorter, later, or less efficient sleep compared to their usual sleep.
Methods: Children 8-12 years of age (n=51) completed wrist actigraphy and smartphone-based ecological momentary assessment to capture eating occasions for 2 weeks during the school year. Prior to each eating occasion, children rated their hunger on a 100-point visual analogue scale. Eating in the absence of hunger (EAH) was defined as pre-meal hunger < 35. Separate multilevel models examined the effect of the previous night's total sleep time, sleep maintenance efficiency, and sleep timing (onset, offset, midpoint) on the percentage of eating events classified as EAH (%EAH). Sleep variables were person-mean centered to disaggregate within- and between-person effects. Covariates included child age, sex, pubertal status, BMI z-score, race/ethnicity, type of day (weekend vs. weekday) and eating occasion reports (number/day), and total sleep time for models examining sleep timing and efficiency.
Results: Participants were 10.5 ± 1.5 years old, 52% female, 85% non-Hispanic white, and 56% with overweight or obesity. The mean daily %EAH was 16.4 ± 17.6%, meaning that on average, about 1 in 6 eating events occurred when the child was not hungry. Children slept 8.3 ± 0.6 hours per day and the mean sleep onset time was 10:16 PM ± 85 minutes. There were no significant effects of within-person sleep variables on %EAH. At the between-person level, children with later mean sleep offset (B= 7.62, p=0.03) and higher mean sleep efficiency (B=-1.57, p=0.03) had a lower %EAH.

Conclusion: Contrary to our hypothesis, night-to-night variation in sleep health is not related the frequency of EAH the following day; however, less efficient sleep and early waking on average may be a risk factor for more frequent EAH, which may in turn increase risk for excess energy intake and obesity.

ASSOCIATION BETWEEN DEPRESSIVE SYMPTOMS AND VIGILANT ATTENTION IN HIGH SCHOOL STUDENTS

Yuito Ueda[1], Hiroo Wada[1], Qinye Zhu[1], Yoshihito Kameda[1], Michiko Minami[1], Takeshi Tanigawa[1]

[1] Department of Public Health, Juntendo University Graduate School of Medicine

Introduction: Depressive symptoms during adolescence may impair vigilant attention, yet the association has not been fully explored. This study aimed to investigate the relationship between depressive symptoms and vigilant attention in Japanese high school students.
Methods: We recruited a total of 426 high school students (ages 15–17) from two high schools in Japan. Each participant completed the Center for Epidemiologic Studies Depression Scale (CES-D) and underwent the Brief Psychomotor Vigilance Test (PVT-B) to measure vigilant attention. Two primary indicators were derived from the PVT-B: response speed (reciprocal reaction time) and lapse (number of reaction times ≥355 ms). For the analysis, the worst 20% of students on each PVT-B metrics (response speed and lapse) were defined as having impaired vigilant attention. Gender-stratified analyses were conducted to examine potential differences between male and female students. Logistic regression was used to compare students with CES-D ≥20 to those with CES-D < 20, adjusting for age, BMI, sleep duration, caffeine intake, and time from awakening to conducting PVT.
Results: In the total participants, depressive symptoms (CES-D ≥20) were associated with slower response speed (adjusted odds ratio [OR] = 1.61, 95% confidence interval [CI]: 0.97–2.67) with marginal statistical significance (p=0.08). Lapse was significantly associated with depressive symptoms (OR = 1.95, 95% CI: 1.16–3.28, p=0.01), suggesting that students experiencing depressive symptoms showed reduced vigilant attention on the PVT-B. Gender-stratified analyses revealed no significant associations between response speed and lapse among male students. However, depressive symptoms were significantly associated with slower response speed (OR = 2.27, 95% CI: 1.14–4.52, p=0.02) and higher lapse (OR = 2.72, 95% CI: 1.34–5.55, p=0.01) among female students.
Conclusion: The present study showed that depressive symptoms are associated with impaired vigilant attention in female high school students, but not in male one.

THE ROLE OF CO-RUMINATION AND BELONGINGNESS IN PREDICTING INSOMNIA AMONG COLLEGE STUDENTS

Kearney Smith[1], John Richmond Sy[1], Ruth Brombach[1], Mariana Monroy Gonzalez[1], Jessica Dietch[1]

[1] Oregon State University

Introduction: Co-rumination, the excessive discussion of problems in dyadic pairs with an emphasis on negative feelings, is associated with internalizing depressive symptoms and sleep problems. Limited research has examined co-rumination's effect on sleep problems, specifically insomnia. A general sense of belongingness, associated with relationship satisfaction and quality, may moderate the negative impact of co-rumination. The primary hypotheses were that co-rumination and belongingness would both be significantly related to insomnia symptoms. The exploratory hypothesis was that the relationship between co-rumination and insomnia would be moderated by belongingness.
Methods: Participants (N=189) were college students (Mage = 22.8, SD = 6.98, 71% Female) from Oregon State University recruited from the online subject pool system who answered an online survey including the Insomnia Severity Index, the General Belongingness Scale, and the Co-Rumination Questionnaire–Abbreviated. Multiple regression analysis in SPSS examined whether a general sense of belonging moderated the relationship between the independent variable, co-rumination, and the dependent variable, insomnia.
Results: Multiple regression analysis showed that the overall model was significant (F[3, 185] = [8.63], p < 0.001) accounting for 12.27% of the variance in insomnia symptoms. Co-rumination significantly predicted greater insomnia symptoms (b= 0.13, p=0.02). Belongingness was a significant independent predictor of insomnia (b= -0.19, p < 0.001) with greater belongingness associated with lower insomnia symptoms. The interaction term between co-rumination and belongingness was not significant (b = -0.05, p = 0.31) indicating that belongingness did not moderate the relationship between co-rumination and insomnia.
Conclusion: This study is the first to identify an association between co-rumination and insomnia. Higher co-rumination was associated with greater insomnia, suggesting that co-rumination may be one mechanism of insomnia in college students. This relationship could be in part due to co-rumination's association with internalizing negative symptoms, particularly depression, giving rise to potential sleep disturbances. Belongingness independently predicted better insomnia outcomes, supporting prior research linking social connection to better sleep outcomes, however, it did not moderate the relationship between co-rumination and insomnia as hypothesized. Future research should aim to further investigate the mechanisms through which co-rumination affects insomnia and different sleep health variables.

QUANTITY, QUALITY, OR PERCEPTION: FACTORS CONTRIBUTING TO ADOLESCENT EXECUTIVE FUNCTION

Jamon Jex[1], Nicholas York[1], Eliza Young[1], Kara Duraccio[1], Daniel Kay[1]

[1] Brigham Young University

Introduction: Sleep duration is frequently related to executive function (EF) in adolescents, though the relationship between EF and other aspects of adolescent sleep health remains unclear. This secondary analysis aimed to examine how EF is related to multiple domains of sleep health in adolescents, specifically sleep quality, daytime sleepiness, and chronotype.
Methods: We used two adolescent datasets that assessed for self-reported sleep health and executive functioning (N = 83, Ages

14-18). All participants completed the Morning-Eveningness Questionnaire (MEQ) to measure chronotype, the Epworth Sleepiness Scale (ESS) to measure daytime sleepiness, the Pittsburgh Sleep Quality Index (PSQI) to measure sleep quality, and the Behavior Rating Inventory of Executive Function (BRIEF) to measure EF; the BRIEF parent report was used in one study (N=31) and the self-report for another (N=52); we used standardized t-scores of the global executive composite (GEC) scale to allow for comparison across studies. A multiple linear regression was performed to examine the predictive effect of adolescent sleep quality, daytime sleepiness, and chronotype on EF. A multiple linear regression was performed to evaluate how adolescent sleep quality, daytime sleepiness, and chronotype predict EF.
Results: Sleep quality (PSQI) was found to be a significant predictor of adolescent EF ($p < 0.001$; adjusted R-squared =.19), with worse sleep quality predicting greater EF impairment. ESS and MEQ were not found to be significant predictors of adolescent EF (p's >.05).
Conclusion: Adolescents with poorer self-reported sleep quality demonstrated greater EF impairment, suggesting that other aspects of sleep health (beyond sleep duration) may play a critical role in EF abilities. However, chronotype and daytime sleepiness did not significantly influence EF, suggesting that perceived sleep quality (above perceived daytime impairment and/or optimal sleep timing) may serve as a more useful predictor when understanding adolescent EF.

THE THEORY OF PLANNED BEHAVIOR AND HEALTHY SLEEP DURATION BEHAVIOR AMONG UNDERGRADUATE COLLEGE STUDENTS

Octavia Goodman[1], Mariana Szklo-Coxe[1]
[1] Old Dominion University

Introduction: Ajzen's Theory of Planned Behavior (TPB) (1991) has been usefully applied as a framework in studies examining the sleep intentions and behaviors of college students. However, existing research remains limited, with considerable variation in methodologies—i.e., differing definitions of sleep duration, settings, and timeframes assessed (past 24 hours, 7 days, 30 days) — leading to inconsistent results across studies. The present study applied the TPB to sleep duration (SD) behavior in college students, examining whether 1) favorable attitudes, favorable subjective norms, and strong perceived behavioral control towards SD predicted intentions to healthy SD behavior; 2) strong perceived behavioral control and intention were directly associated with healthy SD.
Methods: 507 Old Dominion University undergraduates aged 18-24 completed an online Qualtrics questionnaire between April-May 2023 or April-May 2024 with sleep quality, socio-demographic, and TPB construct questions. Using the Target, Action, Context, and Time principle, SD behavior was categorized from the PSQI item as healthy (7-< 9 hours) vs. unhealthy (< 7 or ≥9 hours); and healthy (vs. unhealthy) SD attitudes, norms, control, and intentions based on questions regarding 7-8 hours SD in the past 30 days. Adjusted odds ratios (OR) were estimated from logistic regression models.
Results: After adjusting for race/ethnicity, class, age, enrollment status, and gender, favorable attitudes (OR=3.63, 95% CI, 2.07-6.38), favorable subjective norms (OR=2.74, 95% CI, 1.62-4.63), and strong perceived behavioral control (OR=6.48, 95% CI, 4.31-9.75) were significantly associated with healthy SD intentions. Students reporting healthy (vs. unhealthy) SD behavior had significantly higher odds of strong perceived behavioral control (OR=5.73, 95% CI, 3.57-9.19) and behavioral intention (OR= 4.27, 95% CI, 2.67-6.84) after adjustments.
Conclusion: Favorable attitudes, favorable subjective norms, and strong perceived behavioral control towards SD behavior predicted students' intentions to engage in healthy SD behaviors even after adjustments for socio-demographic factors. Strong perceived behavioral control and behavioral intention predicted self-reported healthy SD, highlighting their critical role in promoting healthy sleep behavior among college students. Findings suggest TPB constructs were predictive of SD intentions and behavior and may help inform interventions targeting behavioral antecedents including perceived behavioral control, intentions, attitudes, and subjective norms to promote healthy sleep practices and overall health among college students.

LONELINESS AND ANXIETY SHOW INDEPENDENT ASSOCIATIONS WITH INSOMNIA SEVERITY AMONG SOUTH FLORIDA HISPANIC ADULTS

Joshua Fouladian[1], Joon Chung[2], Ziyi Ding[1], Dunia Mejia[3], Jasmine Rubio[1], Camila Pow-Sang[1], Stacyca Dimanche[1], Mary Carrasco[4], Laurent Garchitorena[1], Carolina Scaramutti[2], April Rogers[5], Ferdinand Zizi[1], Alberto Ramos[2], Girardin Jean-Louis[6], Azizi Seixas[6]
[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Miami, [3] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [4] Lincoln Memorial University Debusk College of Osteopathic Medicine, [5] St. John's University, [6] University of Miami Miller School of Medicine

Introduction: Meta-analyses suggest that there is a gap in the literature on potential mediators of the known relationship between loneliness and sleep. This study aims to assess the relationship among loneliness, anxiety, and insomnia severity among a cohort of rural and urban Latinos living in South Florida.
Methods: This sample included 608 individuals who participated in the Determinants, Outcomes, Responses, and Mechanisms of Insufficient Sleep in Rural-Urban Settings (DORMIR) study, which investigates the connection between sleep health and cardiometabolic health in South Floridian Hispanic population. Our primary outcome was the Insomnia Severity Index (ISI), a validated, 7-item questionnaire with higher scores suggesting more severe symptoms. We operationalized anxiety by the PROMIS Emotional Distress - Anxiety (Short Form 8a) and loneliness by an item from the Social Needs Screening Tool – "How often do you feel lonely or isolated from those around you?": rarely, sometimes, often/always. All linear regression models were adjusted for age (non-linear), sex, race/ethnicity, Hispanic origin, marital status, education, employment, income, and Body Mass Index. Model 1: loneliness and the ISI. Model 2: anxiety and ISI. Model 3 loneliness and anxiety and ISI scores.
Results: Model 1 showed significant associations between experience of loneliness (rarely, sometimes, often/always) and ISI scores: "rarely" b [95% Confidence Interval(CI)] = 2.60 [1.40, 3.77], p<

0.001; "sometimes" b [95% CI] = 3.45 [2.25, 4.65], p< 0.001; and "often/always" b [95% CI] = 5.03 [3.38, 6.68], p< 0.001. Model 2 showed a significant association between anxiety and ISI scores: b [95% CI] = 0.38 [0.32, 0.43], p< 0.001. Model 3, simultaneous modeling of loneliness and anxiety, showed reduced associations for both loneliness and anxiety: "rarely lonely" b [95% CI] = 1.39 [0.28, 2.5], p=0.014; "sometimes lonely" = 1.37 [-0.06, 2.33], p=0.063; "often/always lonely" = 1.37 [-0.31, 3.05], p = 0.110; anxiety score = 0.34 [0.28, 0.41], p< 0.001.

Conclusion: Loneliness and anxiety are independently correlated with insomnia symptoms. Future research should explore the chronological relationship between anxiety and loneliness, particularly how anxiety may mediate the relationship between loneliness and insomnia, in Hispanics.

BIDIRECTIONAL ASSOCIATIONS BETWEEN SLEEP HEALTH AND CHRONIC PAIN INTERFERENCE IN MIDDLE-AGE AND OLDER ADULTS

Kristin Calfee[1], Soomi Lee[1]

[1] The Pennsylvania State University

Introduction: In 2021, almost 52 million adults in the U.S. reporting having chronic pain, 17 million of whom also reported that their pain significantly interfered with their daily lives. While poor sleep is recognized as a risk factor for chronic pain and vice versa, less is known about the temporal relationship between characteristics of pain (such as interference and location) and multiple dimensions of sleep health.

Methods: The current study investigated longitudinal bidirectional relationships between aspects of chronic pain and a multidimensional measure of sleep health incorporating sleep regularity, satisfaction, alertness, timing, efficiency, and duration in three ways: presence of chronic pain, interference of pain with daily life (such as activities and social relationships), and number of pain locations. The components of the sleep health composite score were measured using a combination of Actigraphy and self-report from a daily sleep diary over 7 consecutive days. The analytical sample consisted of 154 middle-age and older adults from the Midlife in the United States (MIDUS) longitudinal study who responded to questions about chronic pain and provided Actigraphy and sleep diary data.

Results: Bidirectional associations between pain interference and sleep health were found in a subsample of participants (N = 107) who responded to questions about how much their pain interfered with their daily life. These associations indicate that an increase in sleep health problems from timepoint 1 (T1) to timepoint 2 (T2) approximately 9 years later was associated with an increase in pain interference (B =.31, SE =.14, p =.03), and that an increase in pain interference from T1 to T2 was associated with more sleep problems at T2 (B =.16, SE =.07, p =.03) even after controlling for sociodemographic and health covariates as well as baseline sleep health and baseline pain interference.

Conclusion: These findings may have implications for behavioral changes that can be made to reduce pain interference and can provide a foundation for investigating possible mechanisms of the relationship between sleep and pain such as inflammation.

A LATENT CLASS ANALYSIS IN ULTRA-LONG RANGE COMMERCIAL AVIATION OPERATIONS

Ian Rasmussen[1], Amanda Lamp[2]

[1] Washington State University, Spokane, [2] Washington State University

Introduction: Fatigue Risk Management System (FRMS) aviation studies are a data-driven alternative method of compliance to the Federal Aviation Administration regulations. FRMS allows for continuous monitoring and management of safety risks associated with fatigue-related errors, using well-defined and validated measures associated with alertness, fatigue and cognitive performance. This study, which was a sub-analysis of a larger FRMS study, took a novel approach towards identifying underlying factors of behavior, performance, and fatigue in aviation, via a latent class analysis (LCA). Specifically, LCA was used to identify subpopulations of aviation pilots within ultra-long range commercial aviation operations under FRMS.

Methods: Data from 251 Captains and 821 First Officers flying across 24 long-range and ultra-long range routes was collected via pre-study questionnaires, sleep/work logbooks, wrist-worn actigraphy, and the psychomotor vigilance task (PVT). Data collection occurred in real time over the course of a pilot's trip, including 3 pre- and 3-5 post-trip days. Variables included self-reported fatigue, sleepiness, sleep quality, fatigue mitigation strategies, flight information, flying experience, and demographics (e.g., gender, age, BMI). Objective sleep duration was collected with actigraphy and objective cognitive performance was collected with the 5-minute PVT.

Results: This is the first study to use a LCA to identify latent subpopulations within commercial aviation pilot data from real-time, long-range and ultra-long range commercial aviation operations.

Conclusion: Identification of latent subpopulations can support targeted implementation of fatigue prevention strategies and real-time fatigue countermeasures to inform Fatigue Risk Management Systems in the aviation industry, especially relating to improved flight-crew member alertness and cognitive performance.

WHERE DOES SLEEP VALUE FIT IN OUR OVERALL VALUE SYSTEM?

Dustin Sherriff[1], Daniel Kay[1]

[1] Brigham Young University

Introduction: Sleep value reflects the relative importance individuals place on sleep. The Sleep Valuation Item Bank (SVIB) assesses five well-validated dimensions of sleep value: wanting, appreciating, prioritizing, preferring, and not devaluing sleep. Previous research identified five distinct sleep value profiles: Concerned, Appreciative, Devaluing, Ambivalent, and Unconcerned. This study explored the relationships between these sleep value dimensions and profiles with participants' overall value systems, measured through commonly held terminal values (e.g., health, social status).

Methods: Participants aged 18–85 (M = 45) completed an online survey including demographics, the SVIB, and a novel Values Inventory adapted from Milton Rokeach's survey of 38 terminal values. The factor structure of the Values Inventory was determined using exploratory factor mixture modeling and confirmatory factor analysis (CFA). Correlations examined associations between SVIB factors and Values Inventory factors. MANOVA compared sleep value profiles across terminal value factors.
Results: CFA revealed five factors of terminal values (CFI =.951, TLI =.941, RMSEA =.052): Health/Wellbeing (e.g., "mental health"), Fundamental Human Values (e.g., "happiness"), Social Status (e.g., "public image"), Personal Accomplishment/Global Advancement (e.g., "gaining knowledge"), and Community/Belonging (e.g., "belonging"). Valuing health/wellbeing was associated with older age, higher income, and fewer dependents ($p < .01$ for all). It correlated with higher appreciation of sleep, lower prioritizing, and lower devaluing of sleep ($p < .001$). The Appreciative sleep value profile demonstrated the highest levels of valuing health/wellbeing, significantly greater than the Devaluing profile. In contrast, individuals with Ambivalent sleep values tended to prioritize social status and community/belonging.
Conclusion: These findings provide context for interpreting sleep value dimensions and profiles. Specifically, individuals who highly value health/wellbeing are more likely to appreciate sleep, while those ambivalent about sleep's value tend to prioritize social and community-oriented aspects of life. Understanding these associations can inform interventions that align sleep-related messaging with individuals' broader value systems.

YAWN AND ON: IMPACTS OF SLEEP VARIANCE AND REGULARITY ON ADOLESCENT EXECUTIVE FUNCTION

Jamon Jex[1], Isabella Wright[1], Caroline Simmons[1], Kara Duraccio[1], Daniel Kay[1]
[1] Brigham Young University

Introduction: Executive function (EF; higher order cognitive processes including cognitive flexibility and inhibitory control supports)is crucial for adolescent success. Short sleep, common during adolescence, can negatively affect EF, though less is known about how other domains of sleep health relate to EF. Therefore, we aimed to evaluate how both sleep variance (SV; variance in sleep onset) and sleep regularity (SR; variance in sleep midpoint) relate to EF in adolescents. Specifically, we hypothesized that adolescents with greater sleep regularity and lower sleep variability would have greater levels of executive functioning, in comparison with adolescents with less sleep regularity and greater sleep variability.
Methods: Adolescents (ages 14-18; N = 84) who participated in two separate research studies provided 7-10 days of actigraphy where sleep was monitored via an ActiWatch 2; from this data, we computed SV (standard deviation of sleep onsets) and SR (standard deviation of sleep midpoints) across the observational period. The Behavior Rating Inventory of Executive Functioning (BRIEF) was administered to teens or parents across the studies; standardized T-scores in the Global Executive Composite (GEC) score were used as the dependent variable. Regression analyses were conducted to evaluate whether SV or sleep regularity SR predicted scores on the GEC.
Results: Due to high collinearity between SV and SR, we ran two separate regression analyses to determine whether SV and SR predict GEC for adolescents. SV approached significance in predicting GEC ($F(1, 62))=3.58$, $p=0.063$; $R^2=0.055$). SR significantly predicted GEC ($F(1, 62)=4.15$, $p=0.046$; $R^2 = 0.063$). In both cases, greater variability and greater regularity predicted higher GEC scores, reflecting greater EF impairment.
Conclusion: We found the predictive effect of SV to be near-significant and SR to be significant with regards to adolescent GEC, suggesting that SV and SR have a small negative impact on executive functioning. The findings suggest that interventions to improve consistency in sleep timing (and thereby improving SV and SR) could be beneficial for enhancing EF skills in adolescents, particularly if the intervention encourages sleep timing to promote adequate sleep duration, given previous research showing a strong relationship between sleep duration and EF.

BP1.15205, A NOVEL OREXIN-2 RECEPTOR AGONIST, DEMONSTRATES PHARMACOLOGICAL EFFECTS IN A MOUSE MODEL OF NARCOLEPSY

Olivier Finance[1], Xavier Ligneau[1], Shiori Kometani[2], Yuki Umemori[2], Satsuki Chikura[2], Kazuhisa Okada[2], George Nomikos[3], Kumar Budur[3]
[1] Bioprojet, [2] Teijin Pharma Limited, [3] Harmony Biosciences Holdings, Inc.

Introduction: Narcolepsy is a chronic sleep disorder often caused by selective deficiencies in orexin, a brain neurotransmitter that regulates wakefulness. BP1.15205 is a novel, highly potent, and orally bioavailable orexin-2 receptor (OX2R) agonist investigated for its biological effects in a mouse model of type 1 narcolepsy. Present results show BP1.15205 has a favorable pharmacokinetic (PK) profile, robust wake-promoting effects, and no safety signals in rodents.
Methods: Human receptor in vitro studies were performed using a FLIPR calcium assay. For in vivo pharmacology studies, both male wild-type (WT; C57BL/6J) and orexin/ataxin-3 transgenic (TG) mice were used. Male Sprague-Dawley rats (aged 8 weeks) were used for non-GLP toxicity studies. Vehicle or BP1.15205 were administered as suspension or solution via oral gavage. Results from studies in mice were analyzed by the two-tailed Shirley-Williams test with a $p \leq 0.05$ considered statistically significant.
Results: Human receptor in vitro studies demonstrated BP1.15205 is highly potent (EC50 = 0.015 nM at OX2R) with >600-fold selectivity over orexin-1 receptor. PK results support once-a-day dosing, and pharmacodynamic correlations were observed in both WT and TG mice following a single oral administration of BP1.15205. Wake promoting effects were more pronounced in the TG mice as compared to WT at same exposure. Single dose administration in TG mice at beginning of the 12-hour dark phase of a 24-hour light/dark cycle produced significant and dose-dependent increases in total wakefulness time and prolongation of sleep latency, starting at the 0.1 mg/kg dose as compared to vehicle-treated animals. Significant and dose-dependent decreases in the total number and duration of cataplexy-like episodes were also observed in the TG mice in response to BP1.15205 compared to vehicle. In the toxicity study, rats were dosed by oral gavage once daily for 2 weeks (increasing dose levels; one dose/ per group) to identify the No Observed Adverse Effect Level. No changes in body weight, food

consumption, hematology, organ weights, or histopathology were noted at any dose level of BP1.15205.
Conclusion: BP1.15205 is a novel, highly potent OX2R agonist with potential for once-daily dosing that produces significant wake-promoting and cataplexy-suppressing effects in a dose-dependent manner.

BEDTIME PROCRASTINATION EXPERIENCES IN UNIVERSITY STUDENTS: A QUALITATIVE STUDY

Jia Yin RUAN[1], Wing Fai Yeung[1]
[1] The Hong Kong Polytechnic University

Introduction: Bedtime procrastination, a common phenomenon among university students, has been quantitatively shown to be linked to both sleep health and mental well-being. Gaining insight into university students' experiences with bedtime procrastination can provide valuable guidance for designing targeted interventions to reduce this behavior in the future.
Methods: A descriptive qualitative study was utilized. From September to November 2024, we conducted semi-structured individual interviews—either face-to-face or online—with university students recruited through social media advertisements and campus posters at five universities in Hong Kong. The interviews were audio-recorded, transcribed word-for-word, and analyzed using conventional content analysis.
Results: Seventeen university students (6 male and 11 female), aged 18 to 24 and from various majors, participated in the study. Eighteen subthemes across six main themes were identified. Theme 1: being master of myself before bedtime at night (e.g., archiving more me-time); Theme 2: bedtime procrastination being a reward and celebration (e.g., bedtime procrastination as a form of self-reward for the school day); Theme 3: bedtime procrastination becoming a habit (e.g., phone scrolling becoming a pre-bedtime habit); Theme 4: mindless bedtime procrastination (e.g., immersed in negative emotions); Theme 5: productivity, body image, and emotions influenced by bedtime procrastination (e.g., bedtime procrastination influencing body image); Theme 6: modifying bedtime procrastination being not an easy thing (e.g., deficiency of targeted bedtime procrastination reduction interventions).
Conclusion: The findings suggest that bedtime procrastination among university students in Hong Kong is a multidimensional construct, involving both reflective and automatic cognitive processes. Future interventions could be improved by adopting a dual-process approach, along with additional strategies such as integrating knowledge of bedtime procrastination, educating on sleep hygiene, and addressing the impact of negative peer influence to reduce bedtime procrastination.

EFFECTS OF CAFFEINATED COFFEE ON MOOD AND SLEEPINESS UNDER SLEEP RESTRICTION CONDITIONS

Eva-Maria Elmenhorst[1], Eva Hennecke[1], Denise Lange[1], Diego Baur[2], Anna Linea Foerges[3], Andreas Bauer[3], Hans-Peter Landolt[2], David Elmenhorst[4], Daniel Aeschbach[1]
[1] German Aerospace Center, Institute of Aerospace Medicine, [2] University of Zurich, Institute of Pharmacology & Toxicology, [3] Forschungszentrum Jülich, Institute of Neuroscience and Medicine (INM-2), [4] Forschungszentrum Jülich GmbH

Introduction: It has been shown that mood is disturbed by sleep restriction (SR). We examined how mood and sleepiness after SR are impacted by the use of caffeinated coffee.
Methods: Data from 72 volunteers were assessed during 3 baseline and 5 experimental (E1 to E5) days. The control group (n=15, 66.7% male, mean age ± SD 28.0 ± 5.7) had 8 h time in bed (TIB) throughout the study. The sleep restriction group (n=21, 57.1% male, 26.4 ± 3.7), the decaffeinated coffee group (DECAFF, n=17, 58.8% male, 27.9 ± 5.3) and the caffeinated coffee group (CAFF, n=19, 57.9% male, 29.9 ± 5.0) had 8 h TIB at baseline and 5 h TIB during the experimental nights. Both coffee groups consumed standardized 600 ml (E1 to E4) or 400 ml (E5) coffee. Only in the CAFF group, the coffee contained caffeine (200 ml coffee: 100 mg caffeine). Positive (PA) and negative (NA) affect (PANAS) and KSS sleepiness were rated 4 times during scheduled wakefulness. We report here results of mixed ANOVAs and Dunnett-adjusted comparisons of daytime averages during SR.
Results: At baseline, PA, NA, and sleepiness were not different between groups. Compared to baseline, PA deteriorated in the sleep restriction group on E1 through E5 (all $p < 0.001$), in the DECAFF group on E2 through E5 (all $p < 0.001$), and in the CAFF group on E3 through E5 (all $p < 0.001$). Compared to the control group, PA was worse in the sleep restriction group (E2 and E3, both $p < 0.035$), and in the DECAFF group (E1 through E5, all $p < 0.03$), but not in the CAFF group (all $p > 0.2$). NA remained unchanged (group x condition: $p > 0.2$). Compared to baseline, sleepiness increased in the sleep restriction, DECAFF, and CAFF groups on E2 through E5 (all $p < 0.045$). The DECAFF and CAFF groups (but not the sleep restriction group) were sleepier than the control group on E2 through E5 (all $p < 0.035$).
Conclusion: PA and sleepiness, but not NA, were negatively affected by SR. The use of caffeinated coffee under chronic sleep loss may be more effective in improving mood than in counteracting sleepiness.

ELUCIDATING ASSOCIATIONS OF COMBINED ALCOHOL AND CAFFEINE CONSUMPTION WITH SLEEP AMONG BLACK ADULTS

Clarence Locklear[1], Matthew Coppello[2], Nina L'Houtellier[1], Michelle Thompson[3], Sadeaqua Scott[1], Velarie Ansu Baidoo[3], Carolina Scaramutti[1], Denise Vidot[4], April Rogers[5], Judite Blanc[2], Debbie Chung[2], Alberto Ramos[1], Azizi Seixas[1], Girardin Jean-Louis[3]

[1] University of Miami, [2] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [3] University of Miami Miller School of Medicine, [4] School of Nursing and Health Studies, University of Miami, [5] St. John's University

Introduction: Alcohol and caffeine are widely consumed psychoactive substances commonly known to disrupt sleep. The Sleep Foundation recently reported that nearly 2/3 of U.S. adults drink caffeine daily. Furthermore, alcohol and caffeine are often imbibed together in cocktails such as espresso martinis and Jägerbombs. Per the CDC, individuals who mix alcohol and caffeine are more likely to report binge drinking and high blood pressure. Increases in the prevalence of alcohol abuse, combined with known health and sleep disparities experienced among Black Americans emphasizes a necessity to further examine how these substances can negatively impact sleep in tandem. Objectives: This study explored the associations between alcohol, caffeine, and sleep architecture among Black adults residing in New York City and South Florida.
Methods: Participant data was leveraged from two larger studies: ESSENTIAL and MOSAIC (n=381, mean age=51 years, 67% female). Alcohol and caffeine ingestion were obtained from participant self-report. Sleep architecture and related variables (e.g., REM, awakenings, light sleep, time spent in bed, time awake/asleep) were recorded at-home for seven days via SleepImage Ring, Fitbit, and ActiGraph devices. Multiple linear regression, adjusting for age and caffeine/alcohol source, assessed the associations between alcohol and caffeine consumption on sleep.
Results: Analyses indicated that participants who reported having one or more alcoholic drink(s) per week spent less time asleep and had increased number of awakenings, time spent in bed, and light sleep ($p<.01$). Participants who reported drinking beer weekly had lower sleep quality indices and REM sleep ($p<.05$). Furthermore, participants who had both at least one alcoholic drink per week and one cup of coffee per day spent more time awake ($p<.05$). Participants who drank 16 ounces or more of non-diet soda daily had reduced sleep efficiency and REM sleep, as well as more time awake and in bed ($p<.05$). Participants who reported drinking both soda daily and wine weekly had more awakenings ($p<.05$).
Conclusion: These preliminary results indicate that alcohol and caffeine consumption are significantly associated with sleep architecture, especially when consumed together. Future studies aim to increase sample size and sleep metrics to further elucidate negative health consequences.

BIDIRECTIONAL RELATIONSHIPS BETWEEN SLEEP AND CAFFEINE CONSUMPTION

Emma Tussey[1], Kallie Roseborough[1], Maria Wong[1]
[1] Idaho State University

Introduction: Caffeine is the most widely used drug in the world and its negative impact on sleep is well documented. However, most studies examining the impact of caffeine on sleep have been experimental or cross-sectional. Individuals can develop tolerance to caffeine, and real-world caffeine use may not have the same impact on sleep as in experimental settings. Further, individuals may use caffeine because they already have poor sleep. The present study used intensive longitudinal methods to evaluate bidirectional relationships between caffeine intake and sleep. We hypothesized that greater daily caffeine intake would predict greater same-night sleep disturbance, and that greater daily sleep disturbance would predict greater next-day caffeine intake.
Methods: 57 college students (72% female, mean age 24) participated in a two-week study assessing their daily sleep and caffeine intake patterns. Participants wore the Phillips Actiwatch Spectrum and completed daily diaries capturing self-reported sleep quality (1 to 5), morning alertness (1 to 5), and caffeine intake. Linear multi-level models assessed whether daily caffeine intake predicted changes in sleep that night. Linear multi-level models assessed whether the previous night's sleep predicted the next day's caffeine intake. Race, age, sex, and day type (weekday or weekend) were controlled in the analyses. Non-significant covariates were dropped from the final models.
Results: Greater daily caffeine intake predicted lower self-reported sleep quality the night of intake ($B = -0.05$, $SE = 0.025$, $p < 0.05$), and lower morning alertness the next day ($B = -0.061$, $SE = 0.028$, $p < 0.05$). Daily caffeine intake did not predict any objective sleep measures (measured by actigraphy) the night of caffeine intake. Greater daily sleep onset latency (measured by actigraphy) predicted higher next-day caffeine intake ($B = 0.003$, $SE = 0.001$, $p < 0.05$). No other daily sleep variables predicted next-day caffeine intake.
Conclusion: These findings suggest a dynamic, bidirectional relationship between sleep and caffeine intake. Higher daily caffeine was associated with poorer self-reported sleep quality and alertness, although it did not predict objective sleep measures. Additionally, individuals who struggle to fall asleep may compensate by consuming more caffeine the next day.

CANNABIS USE AS A MODERATOR BETWEEN SLEEP AND ACADEMIC PERFORMANCE IN CANADIAN UNIVERSITY STUDENTS

Chloé Turpin[1], Jean-François Caron[1], Félix-Gabriel Duval[1], Vincent Bourgon[1], Geneviève Forest[1]
[1] Université du Québec en Outaouais

Introduction: Good sleep quality plays a crucial role in optimal cognitive functioning and well-being, making it a key factor in academic performance. However, university students are particularly vulnerable to sleep disturbances that may be influenced by lifestyle factors such as substance use. Cannabis, a commonly used substance among young adults, is known to disturb sleep and impair cognitive performance. Hence, we investigated the moderating effect of cannabis use on the relationship between sleep disturbances and academic performance of Canadian university students.
Methods: A total of 778 Canadian university students (M=22.5 ±4.6 years; 71.4% females) participated in a 20-minutes anonymous online survey. The survey included, among others, the Pittsburgh Sleep Quality Index (PSQI) and a homemade lifestyle habits questionnaire. A moderation analysis was performed using PROCESS 4.2 to examine the moderating effect of cannabis use (average weekly usage) on the relationship between sleep disturbances (subscale #5 of the PSQI) and academic performance (self-reported satisfaction with school performance).

Results: The moderation model was significant (F[3,774] = 4.32, p =.005), explaining 1.7% of the variance. Cannabis use had a significant main effect on school performance (b = -0.04, p =.015), and the interaction was significant (b = -0.07, p =.005). Sleep disturbances were associated with school performance when cannabis use was at one SD below the mean (b = -0.15, p =.027) but not at the mean (b = -0.09, p =.118) or above the mean (b = 0.04, p =.537). A simple slope analysis showed that among students with minimal or no cannabis use, fewer sleep disturbances was associated with better academic performance, while more sleep disturbances predicted poorer performance. However, for students with moderate or high cannabis use, fewer sleep disturbances were not associated with better academic performance.
Conclusion: This study highlights how cannabis use may mitigate the beneficial effect of undisturbed sleep on academic performance. Given the modest explained variance, it is essential to consider additional factors. Further research on the influence of lifestyle habits on the relationship between sleep and academic performance among Canadian university students is needed to help students achieve their full academic potential.

TIME-OF-DAY EFFECTS ON EATING BEHAVIOR: EXAMINING CIRCADIAN TIMING AND CALORIC INTAKE PATTERNS

Carson Hernandez[1], Steven Carlson[1], Bradley Appelhans[2], Helen Burgess[3], Lauretta Quinn[4], Chelsea Allen[1], Kelly Baron[1]
[1] University of Utah, [2] Rush University, [3] University of Michigan, [4] University of Illinois Chicago

Introduction: Studies have demonstrated increased impulsivity, poorer health behaviors, and greater risk for type 2 diabetes among individuals with evening chronotype. However, few studies have evaluated these effects relative to circadian biomarkers. Additionally, time of day may impact how chronotype affects behaviors.
Methods: Participants completed an eating in the absence of hunger task during randomly assigned morning and evening sessions, separated by at least 10 days. In each session, participants consumed a preloading portion of unflavored oatmeal until comfortably full, then given free access to various snack foods. Calories consumed from bland, salty, and sweet snacks served as the primary outcomes. For the morning test, participants fasted for at least 8 hours and completed the task around 9 AM. For the evening test, participants fasted for 3 hours and completed the task at 9 PM. Circadian timing was measured as dim light melatonin onset (DLMO) on the day following the morning taste test. Mixed models evaluated differences in caloric intake across food types and sessions, adjusting for order of administration, age, sex, and race. In separate models, caloric intake was regressed onto DLMO and administration order for both morning and evening tests.
Results: A total of 113 participants completed the protocol (57 female; age: M = 35.6, SD = 9.87). Significant time-of-day effects were observed, with lower intake of neutral (B = -5.67, p < 0.001) and salty foods (B = -15.53, p = 0.015) in the evening. Significant order effects showed greater intake during the second administration for total calories and all food categories (ps < 0.01). These findings persisted after adjusting for covariates. No significant associations were found between DLMO and caloric intake in either session.
Conclusion: Time of day influenced specific aspects of eating behavior, with reduced evening intake of neutral and salty foods. The absence of significant associations between DLMO and food intake highlights the complexity of circadian influences on eating.

DAYLIGHT EXPOSURE DRIVES CAUSAL IMPROVEMENTS IN DEEP SLEEP AND NEXT-DAY ALERTNESS

Renske Lok[1], Minqi Yang[2], Roelof Hut[3]
[1] Stanford University, [2] Zhengzhou University, [3] University of Groningen

Introduction: Light serves as the most potent zeitgeber for synchronizing circadian rhythms and shaping sleep-wake cycles. While prior studies have highlighted associations between daytime daylight exposure and sleep quality, the direct causal effects of outdoor light exposure on sleep remain largely unexplored in real-world settings. This study aimed to bridge this gap by investigating the impact of an afternoon stroll under high-intensity light (HIL) or attenuated light (AL) conditions on self-reported and objective sleep quality and alertness.
Methods: Ten healthy participants (4 males and 6 females, aged 19–28 years) participated in a within-subject field study. Each participant completed a three-hour afternoon walk, scheduled during the circadian dead zone, under one of two conditions: high-intensity light (HIL, goggles without neutral density filters) or attenuated light (AL, goggles with neutral density filters reducing light intensity to ~10 photopic lux). The conditions were randomized and spaced across two weeks. Salivary Dim Light Melatonin Onset (DLMO) was assessed at baseline and after each walk to determine the circadian phase and adjust walk timing accordingly. Sleep was subsequently monitored using at-home polysomnography (PSG), while subjective alertness and self-reported sleep quality were evaluated with the Karolinska Sleepiness Scale (KSS) and Groningen Sleep Quality Scale (GSQS), respectively. Data were analyzed using linear mixed models to examine changes across conditions.
Results: There were no significant differences between interventions in the subsequent phase angle of entrainment, confirming that the walk was appropriately centered around the circadian dead zone (p>0.05). No significant differences were observed between the HIL and AL conditions in terms of sleep duration or subjective sleep quality ratings (p>0.05). However, nighttime delta power accumulation was significantly higher following HIL exposure, along with an increased number of epochs scored as deep sleep at the expense of wakefulness after sleep onset (p's< 0.01). Morning alertness following HIL exposure was significantly higher compared to AL exposure (p< 0.05).
Conclusion: This study indicates that daytime exposure to high-intensity natural daylight promotes deeper sleep and reduces next-day sleep inertia. These findings underscore the importance of daylight exposure for optimizing nighttime sleep and next-day alertness, with potential applications for mitigating sleep inertia complaints.

EFFECTS OF BLUE-ENRICHED WHITE LIGHT AND AN AFTERNOON NAP ON ALERTNESS AND MOOD DURING A SIMULATED LONG-HAUL FLIGHT

Joshua Gooley[1], Rachel Charoenthammanon[1], Merlyn Tan[1], Yichen Zhu[1], Venetia Kok[1], Patrick Chia[2]

[1] Duke-NUS Medical School, [2] National University of Singapore

Introduction: Cognitive functioning and mood are important determinants of a passenger's flight experience. We hypothesized that ocular exposure to blue-enriched white light (BEWL) would improve cognition and mood in partially sleep-deprived passengers during a simulated long-haul business class flight. Daytime functioning was measured before and after an afternoon nap to test for effects of BEWL under high and low levels of homeostatic sleep pressure.

Methods: In a within-participant study, 51 adults (30 women; median age=23y) underwent 2 simulated long-haul flights (10:00-19:00) in a physical business class cabin simulator after a night of short sleep (5h). Participants were exposed to typical white light (control) or BEWL (intervention) matched for photopic illuminance for 2h before and after a scheduled nap in darkness (14:30-16:30). The melanopic equivalent daylight illuminance was 2-fold higher in the intervention versus the control at a given seat location (range=42-100lx versus 18-45lx). Self-rated alertness, reaction times, and positive affect were measured during baseline, pre-nap, and post-nap sessions. Two-way repeated measures ANOVA was used to test for effects of study visit (control, intervention) and session (baseline, pre-nap, post-nap) on behavioral outcomes.

Results: Effects of BEWL on alertness, reaction times, and positive affect did not differ relative to the control (interaction effect, P>0.11; main effect of study visit, P>0.41 for each comparison). However, there was a strong main effect of session (P≤0.001 for each comparison) where daytime functioning was better after the nap compared with either the baseline or pre-nap sessions. Pairwise comparisons showed that BEWL was associated with negligible effects relative to typical white light (Cohen's d, range=0.00-0.20, P>0.16), whereas large effect sizes were observed for post-nap versus pre-nap behavior (Cohen's d, range=0.70-2.14, P< 0.001).

Conclusion: BEWL did not boost daytime performance or mood using light levels that are typical of an airline cabin environment. By comparison, there were marked improvements in alertness, reaction times, and positive affect after an afternoon nap. These results suggest that sleep is more effective than BEWL at preventing deterioration in cognition and mood in partially sleep deprived passengers.

EFFECT OF A LIGHT INTERVENTION ON MORNING SLEEP INERTIA SYMPTOMS

Cassie Hilditch[1], Ava Dixon[1], Erin Flynn-Evans[2]

[1] San Jose State University, [2] NASA Ames Research Center

Introduction: Sleep inertia — sleepiness and performance impairment experienced upon waking —improves with light exposure following nocturnal awakenings both in the laboratory and real-world environments. However, light exposure at habitual waketime appears to be less effective. This study investigated the effects of light exposure on sleep inertia at habitual morning waketime in a real-world environment.

Methods: Twenty-nine healthy adults (16 female; mean age 27.1 ± 5.1 y), kept habitual sleep patterns at-home monitored by actigraphy for a week. Following experimental night 7 (monitored by electroencephalography, EEG), participants were woken at their habitual morning waketime via a phone call. Participants were randomized by sex and night-order to either wear light-emitting glasses with the light on (intervention) or off (control) during a test battery that included a 5-minute visual Psychomotor Vigilance Task (PVT; NASA PVT+ App), the Karolinska Sleepiness Scale (KSS), mood and alertness visual analog scales (VAS), and a 3-minute auditory Descending Subtraction Task (DST). Testing occurred at 2, 12, 22, and 32 minutes after waking. Testing sessions were monitored remotely via web-based cameras. Data were analyzed using mixed-effect models with fixed effects of test bout, condition, and their interaction, and a random effect of participant. Baseline performance, duration of ambient light exposure > 10 lux during the testing period (Actiwatch Spectrum PRO), total sleep duration from the prior night (EEG), sex, and randomization order were included as covariates.

Results: There was a significant main effect of condition for PVT speed with those in the light condition performing worse than the control condition (p =.049). There was a significant main effect of test bout for PVT lapses (p =.028), DST total responses (p =.023), DST correct responses (p =.001), VAS-alert (p <.001), with impairment dissipating across time since waking. There were no other significant main or interaction effects (p >.05).

Conclusion: These findings align with previous studies suggesting that light exposure has limited effectiveness after waking in the morning. Worse performance on the PVT may be due to glare from the light glasses interfering with screen visibility. Further exploration of delivery methods for light exposure is needed.

HORMONAL CONTRACEPTIVES IMPAIR PSYCHOMOTOR VIGILANCE TASK PERFORMANCE UNDER SLEEP DEPRIVATION WITH STRESS INDUCTION

Kathryn Kennedy[1], David Negelspach[1], Alisa Huskey[1], Jungwon Cha[1], William Killgore[1]

[1] The University of Arizona

Introduction: Hormonal contraceptives (HC) have been shown to impact cognitive performance in different ways depending on the domain being measured, but limited research has assessed the influence of HC on cognitive performance during sleep deprivation. In line with prior research demonstrating greater fatigue among individuals using HC, we hypothesized that psychomotor vigilance task (PVT) performance would be worse among HC females than naturally cycling (NC) females across a period of sleep deprivation, as compared to males.

Methods: Forty-eight participants (18-30 years; 23 females) were sleep deprived for 32 hours and completed 4 Maastrict Acute Stress Tasks between approximately 7pm and 7am. A PVT was

administered every 2 hours between 12pm on Day 1 and 2pm on Day 2. Several metrics were log-transformed before mixed effects models were created with PVT score (Lapses, Speed, Reaction Time, and False Starts) as the outcome, group (males, NC females, HC females) and time as fixed effects, and participant as a random effect.
Results: A significant group effect was identified for PVT Lapses ($F(2,45) = 3.75$; $p = 0.031$) and Bonferroni-corrected pairwise comparisons revealed that HC females, but not NC females, had significantly more lapses than males at timepoints 9 (4am), 11 (8am), 12 (10am), and 13 (12pm) (Cohen's d range = 0.47-0.64; $p < 0.03$). A significant group effect was also identified for PVT Speed ($F(2,45) = 3.43$; $p = 0.04$), with HC females, but not NC females, taking significantly longer than males at timepoints 9-14 (4am-2pm) (Cohen's d range = 0.47-0.60; $p < 0.03$). There were no significant effects of group on PVT Reaction Time or False Starts.
Conclusion: HC females, but not NC females, performed significantly worse than males in terms of PVT lapses and speed during the second half of a 32-hour sleep deprivation protocol. Further work is needed to comprehensively evaluate the effects of HC on cognitive performance in a larger sample of real-world sleep deprivation scenarios and understand potential underlying mechanisms that drive these effects.

INVESTIGATING THE EFFECTS OF REPEATED TASK EXPOSURE ON CONTROL AND SLEEP DEPRIVED PERFORMANCE IN A SERIAL NOVEL OBJECT RECOGNITION TASK IN RATS

Sofia Fluke[1], Christopher Davis[1], Brieann Satterfield[1]
[1] Washington State University

Introduction: Novel Object Recognition (NOR), a common rodent behavioral task that probes short-term recall via exploration time of a novel versus familiar object, is impaired by sleep deprivation (SD). However, habituation dynamics in repeated testing, along with effects of test order and time of day are often overlooked. These factors may affect learning/performance of tasks with repeated exposures and post-SD recovery performance. Building off our previous work, we present a unique serial NOR paradigm that investigates repeated-exposure habituation, combined with SD, recovery, and test order/Zeitgeber-time (ZT) effects.
Methods: Male Sprague Dawley rats (N=32), housed on ZT0-ZT12 light cycle, underwent ZT12 baseline NOR testing. Tests included three phases: acclimation (no objects), familiarization (identical objects), and recognition (novel/identical objects). Rats were then randomly assigned to 12hr-SD during light cycle or undisturbed controls. A second test followed 12SD/0SD at ZT12, after which rats returned to cages for recovery time of 2-, 4- or 24-hrs. A third test followed at either ZT14 or ZT16 the same day, or ZT12 the next day, matching recovery time. We analyzed object discrimination ratio (DR) and total exploration time at recognition phase using mixed-effects ANOVA, with fixed-effects of test (baseline, treatment, recovery), condition (0SD/12SD), and their interaction. Planned comparisons were made between conditions and testing.
Results: There was a significant difference in DR between conditions at the treatment test ($p < 0.001$). Control rats improved from baseline to treatment, then worsened slightly at 2hr/4hr recovery ($p < 0.08$), but became significantly worse at 24-hr recovery ($p < 0.001$). Performance in the SD condition declined after baseline, but did not vary significantly between treatment and recovery testing ($p>0.39$). Total exploration was not significantly different by group or test.
Conclusion: The serial NOR reliably shows a decline in control performance at third test sessions. This decline is worse at ZT12 than ZT14/16 recovery testing, indicating habituation may be occurring from multiple test sessions at the same ZT. SD continues to inhibit short-term recall. Further investigation is needed to elucidate habituation, as control exploration time remained stable while DR declined, and whether changes in test order/ZT can reduce these effects.

ASSOCIATIONS BETWEEN SLEEP WITH BODY WEIGHT AND ENERGY BALANCE FOLLOWING BARIATRIC SURGERY IN ADULT FEMALES

Hannah Koch[1], Jessica McNeil[1]
[1] University of North Carolina at Greensboro

Introduction: Bariatric surgery is the most effective treatment for obesity, yet many individuals experience substantial weight regain following surgery. Body weight is influenced by sustained changes in energy balance, which include energy intake (EI) and energy expenditure (EE). Short sleep and poor sleep quality are risk factors for primary weight gain, yet its impact on body weight, EI and EE after bariatric surgery remains largely unknown. The purpose of this cross-sectional analysis is to examine associations between sleep (duration, efficiency, and architecture) with body weight, body composition, EI and EE adult females who have undergone bariatric surgery.
Methods: Eighteen female adults (age: 54.3±9.7 years; body mass index (BMI): 34.8±9.0 kg/m2; body fat: 43.9±9.3%) who underwent bariatric surgery >1 year ago completed a 7-day study protocol. Actigraphy-derived sleep efficiency and duration were calculated using the Cole-Kripke algorithm. On one night, sleep was captured via in-home polysomnography and analyzed for duration, efficiency, and architecture (i.e., stage N2, N3, rapid eye movement (REM) sleep). Participants self-reported date of surgery. Current body weight and body composition were measured via Bod Pod. EI was self-reported via 3-day food logs. Total daily EE was calculated as the sum of resting metabolic rate (via indirect calorimetry), physical activity EE (via actigraphy), and the thermic effect of food (estimated 10% of daily EE). Spearman partial correlations assessed relationships between actigraphy- and polysomnography-derived sleep with body weight, body composition, and components of energy balance, with time since surgery (months) as a covariate.
Results: Actigraphy-measured sleep duration and sleep efficiency were inversely associated with total daily EE (rho=-0.73, $p< 0.01$; rho=-0.62, $p=0.01$, respectively) and body fat percentage (rho= -0.50, $p= 0.04$; rho= -0.52, $p= 0.03$, respectively). Stage N3 duration was inversely associated with current body weight (rho= -0.51, $p= 0.04$). REM sleep duration was also inversely associated with body fat percentage (rho= -0.57, $p= 0.02$). There were no associations between sleep with EI.
Conclusion: Results from these pilot findings suggest that greater total sleep duration, characterized by higher stage N3 and REM sleep duration, and greater sleep efficiency may have beneficial impacts on body weight and body composition following bariatric surgery.

SLEEP PATTERNS OF RECREATIONALLY ACTIVE ADULTS THROUGHOUT A THREE-WEEK HIGH-INTENSITY OVERREACHING TRAINING PROTOCOL

thomas Gooding[1], Ian Rasmussen[2], Amanda Lamp[1], Hans Haverkamp[1]

[1] Washington State University, [2] Washington State University, Spokane

Introduction: Sleep disturbances are often reported in athletes classified as overtrained; however, it is unclear whether poor sleep contributes to the progression of overtraining or is merely a symptom. Few studies have objectively measured sleep during periods of intensified training. The purpose of this study was to investigate how chronic, high-intensity exercise affects sleep characteristics–including sleep regularity–in healthy, moderately active adults.
Methods: Twenty healthy, recreationally-active adults were randomized into training (TR, n=11) or control (CON, n=9) groups. TR participants underwent a three-week training protocol designed to induce short-term overtraining (overreach, OR) under laboratory conditions, followed by a three-week recovery phase. Sleep was measured daily using actigraphy and paired sleep surveys. Exercise performance was measured weekly (graded exercise test, cycle ergometer). Illness symptoms were assessed using the Wisconsin Upper Respiratory Illness questionnaire.
Results: Across all visits, total sleep time (TST) was similar between CON and TR groups (7.01 ± 1.11 versus 6.68 ± 1.21 hours·night-1, respectively); however, the TR group exhibited higher TST variability (59 ± 11 vs. 77 ± 23 minutes·night-1, respectively; p=0.04) and were more likely to accumulate sleep debt ($p< 0.05$). Compared to the CON group, the TR group exhibited later sleep onset times during the training phase (22:50 ± 1:22 vs. 23:17 ± 1:35, respectively; p=0.010). After training, three TR participants were classified as OR (-10.3% ± 5.4% decrease in exercise performance); TR participants without performance decrements were considered adapted (AD, n=8). Across all visits, the OR group exhibited progressive increases in self-reported sleepiness and fatigue at sleep and wake times, compared to CON and AD groups ($p< 0.05$). No sleep differences were detected between AD and OR groups; however, illness symptoms increased during both the training and recovery phases in the OR group but remained unchanged in CON and AD groups ($p< 0.05$).
Conclusion: High-intensity exercise may impact TST regularity and sleep onset, thereby promoting the accumulation of sleep debt. Significant increases in illness symptoms in OR participants in the absence of sleep differences between AD and OR groups suggests that immune system function plays a role in the pathological progression of overtraining.

THE EFFECTS AND ASSOCIATIONS OF PHYSICAL EXERCISE IN LUTEAL PHASE ON HEAT DISSIPATION, SLEEP STRUCTURE, AND SUBJECTIVE EVALUATION

Momo Fushimi[1], Ryusei Iijima[2], Shiori Noguchi[3], Sayaka Aritake-Okada[1]

[1] Saitama Prefectural University, Graduate School of Health Sciences and Social Work, [2] Saitama Prefectural University, [3] Waseda University, Graduate School of Sport Sciences

Introduction: The menstrual cycle and body temperature significantly influence sleep in women. This study focused on enhancing heat dissipation through physical exercise, examining the effects of resistance training (RT) on pre-bedtime and nighttime heat dissipation, as well as its impact on objective and subjective sleep evaluation during the follicular phase (FP) and luteal phase (LP).
Methods: The experiment involved 12 young women over four days, under the following four conditions: FP Non-Exercise Condition, FP Exercise Condition, LP Non-Exercise Condition, LP Exercise Condition. Participants engaged in 40 minutes of moderate-intensity RT during the day. Sleep EEG and skin temperature were recorded at home overnight, and participants completed a Visual Analogue Scale (VAS) assessment before and after sleep. The distal-proximal temperature gradient (DPG), a key marker of heat dissipation and sleep onset, was calculated from distal and proximal skin temperature differences. The study received approval from Saitama Prefectural University ethics committee.
Results: In the LP Exercise Condition, RT enhanced DPG both pre-bedtime and nighttime, accompanied by an increase in Stage N3 (p=0.028). Notably, Stage N3 sleep was sustained during the latter half of sleep, with concurrent increases in delta-power (p=0.043) and DPG (p=0.046). Subjectively, participants reported significant improvements in difficulty organizing thoughts and eye fatigue compared to the LP Non-Exercise Condition (p=0.039, p=0.041). Additionally, in the LP Exercise Condition, stronger heat dissipation before sleep correlated positively with feeling refreshed(r=0.829, p=0.042) and mood improvement (r=0.812, p=0.049), while showing a negative correlation with physical fatigue (r=-0.883, p=0.020). Furthermore, in the LP exercise condition, the higher the appearance rate of Stage N3, the more it showed a positive correlation with alertness (r=0.829, p=0.021), and a negative correlation with sleepiness (r=0.852, p=0.015) and difficulty organizing thoughts (r=0.802, p=0.030).
Conclusion: The findings suggest that daytime physical exercise during the luteal phase enhances heat dissipation before sleep and promotes deeper sleep, particularly SWS. These changes contribute to improved subjective evaluations upon waking, including reduced fatigue and improved mood. Thus, incorporating physical exercise during the luteal phase may serve as an effective strategy for improving sleep quality and post-sleep well-being in women.

A RANDOMISED PILOT TRIAL FOR BEDTIME PROCRASTINATION: EXAMINING THE EFFICACY & FEASIBILITY OF THE REDUCING EVENING SCREEN TIME ONLINE INTERVENTION

Vanessa Hill[1], Sally Ferguson[1], Amanda Rebar[2], Hailey Meaklim[3], Grace Vincent[1]

[1] Central Queensland University, [2] Arnold School of Public Health, University of South Carolina, [3] University of Melbourne

Introduction: Bedtime procrastination is associated with inadequate sleep and is a novel intervention target to improve sleep health. Formative work indicates that pre-sleep electronic device use, a ubiquitous bedtime procrastination behaviour, may be targeted using a behaviour change approach. This pilot study aimed to examine (1) the acceptability and feasibility of the Reducing

Evening Screen Time online program (REST-O) in new career starters, and (2) the preliminary effect of the program on daily pre-sleep electronic device use and sleep duration, as well as weekly measures of bedtime procrastination, excessive device use, and sleep quality and duration.
Methods: Participants (N = 55) were randomised into three arms; an active Control (n = 19), Prevent (n = 18) and Substitute (n = 18), who used behavioural substitution at different times of day. Daily assessments were conducted for two weeks, and weekly measures at baseline, pre-intervention, post-intervention, and follow-up (end of Week Three).
Results: All groups experienced a reduction in daily pre-sleep device use (M = 23.4 mins per day) and an increase in daily sleep duration (M = 12.7 mins per day) post-intervention. Continued reductions in bedtime procrastination, excessive device use, and improvements in sleep quality and duration were observed at follow-up.
Conclusion: The program appears feasible and acceptable to participants with a high daily completion rate (M = 84.7%). Reductions in habit strength and hedonic motivation suggest potential mechanisms of change. Findings provide preliminary evidence for behaviour change interventions in targeting pre-sleep electronic device use and bedtime procrastination, with broader implications for sleep health.

NEUROBEHAVIORAL OUTCOMES IMMEDIATELY FOLLOWING A DAYTIME SLEEP OPPORTUNITY WITH PINK NOISE

Cassie Hilditch[1], Rachel Jansen[2], Sean Pradhan[3], Nicholas Bathurst[2], Zachary Glaros[2], Lucia Arsintescu[1], Crystal Kirkley[2], Erin Flynn-Evans[2]
[1] San Jose State University, [2] NASA Ames Research Center, [3] Menlo College

Introduction: Pink noise is purported to enhance slow wave activity during sleep. Increased slow wave activity during a sleep episode has been associated with greater sleep inertia symptoms after waking. We investigated whether a pink noise intervention during a 4-hour daytime nap affected neurobehavioral outcomes immediately after the sleep opportunity.
Methods: Fourteen participants (7 female, 7 male; mean age = 24.86 y, SD = 5.20) spent two 26-hour periods in the sleep laboratory, both preceded by a week at home of 8.5 hours' time-in-bed (verified by actigraphy). Both lab visits included a 4-hour nap opportunity ending 10 hours after habitual waketime on the first day (i.e., during the circadian day). In a randomized, crossover design, the nap either involved pink noise (50 dB) played through headband speakers (intervention), or a headband with no sound playing (control). A test battery including the Karolinska Sleepiness Scale (KSS) and a 5-minute psychomotor vigilance task (PVT; NASA PVT+ App) was administered before lights out and again at 2, 12, 22, and 32 minutes after lights on. Participants were seated at a desk adjacent to their bed during testing. Mixed effects models were used to investigate the difference between the two conditions and across test bouts. Sex and baseline measures were included as covariates.
Results: There was no difference in sleep inertia outcomes between conditions. There was a significant effect of test bout for KSS with the greatest sleepiness experienced 2 minutes after the end of the nap opportunity (p =.004). There were no other significant main or interaction effects for KSS, PVT speed, or PVT lapses (all p >.05).
Conclusion: These preliminary findings suggest that there was no difference in subjective alertness nor objective vigilant attention in the 40 minutes following a daytime nap opportunity with pink noise compared to a no-noise control. Future analyses are needed to investigate how sleep metrics may have influenced these results.

VIGILANCE AND REACTION TIME VARIABILITY AFTER SLEEP RESTRICTION IN ADOLESCENTS: THE INFLUENCE OF ADHD AND MENTAL HEALTH SYMPTOMS

Jessica Smith[1], Gina Mason[2], Grace Kupka[3], Claire Mayew Sherman[3], Sinead Moyles[3], Victoria Dionisos[3], Taylor Christiansen[4], David Barker[2], Daniel Dickstein[5], Mary Carskadon[2], Jared Saletin[2]
[1] Florida International University; The Warren Alpert Medical School of Brown University, [2] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University, [3] E.P. Bradley Hospital Sleep Research Laboratory, [4] The University of Iowa, [5] Department of Psychiatry, Harvard Medical School

Introduction: Sleep restriction compromises vigilance. While adolescents commonly experience sleep loss, attention-deficit/hyperactivity disorder (ADHD) may expose vulnerability. Reaction time variability (RTV) is a cardinal deficit of ADHD, yet it is relatively understudied as a sleep loss phenotype compared to lapses. As vigilance may further contribute to mental health in ADHD, we investigated how ADHD and mental health symptoms interact with the effect of sleep restriction on vigilance and response time variability in youth.
Methods: Fifty-five adolescents in R01HD103665 (29F; ages: 12.3±1.2yrs, range: 10-15yrs) completed two crossover conditions: sleep optimization (5 nights of 10h time-in-bed (TIB) anchored to optimal risetimes) and sleep restriction (5 nights at 7.5h TIB; equally delaying bedtime and advancing risetime). After each condition, participants completed a 10-minute psychomotor vigilance task (PVT) yielding lapse (RTs>500ms) and reciprocal reaction time (1/RT [RRT]) variables. We then separated gaussian and exponential components of the RT distribution and estimated RTV via sigma (gaussian variability) together with mu and tau (means of gaussian and exponential components). Conners-3 parent t-scores indexed ADHD symptoms in inattention (58.0±14.0; range: 40-90) and hyperactivity/impulsivity (60.6±16.4; range: 41-90) domains. Mental health symptoms were measured on PROMIS scales for child-reported anxiety (47.8±9.0; range: 35.6-66.2) and anger (45.1±8.9; range: 31.5-61.6) and psychological stress (parent-report 47.8±14.9; range: 4-71.1; child-report: 50.1±8.1; range: 39.5-68.8). Separate linear mixed models examined how sleep condition (restriction vs. optimization) and each symptom interact in explaining PVT performance.
Results: Sleep restriction moderated the effect of inattention on RTV (b=0.51, SE=0.24, p=.042). Higher inattention was associated with more variable RTs (sigma) only in sleep restriction. For lapses, we identified a main-effect of condition (b=12.68, SE=4.74, p=.010) and an interaction with psychological stress

(b=-0.21, SE=0.095, p=.032); worse psychological stress was associated with fewer lapses after sleep restriction. No other analyses were statistically significant.
Conclusion: These data indicate that ADHD and mental health symptoms may differentiate vigilance and response time variability after sleep restriction. The well-established association between ADHD symptoms and response time variability was only observed in sleep restriction; optimizing sleep schedules may mask ADHD sequelae. We will continue to probe the origin and consequence of these inter-individual differences.

GAME-CHANGING SLEEP: A BRIEF AND PERSONALIZED INTERVENTION APPROACH FOR ATHLETIC PERFORMANCE

Isabella Wright[1], Anna Wheeler[1], Eliza Brooks[1], Gracie Crandall[1], Brett Mortensen[1], Coleby Clawson[1], Michael Larson[1], Daniel Kay[1], Kara Duraccio[1]
[1] Brigham Young University

Introduction: Sleep is increasingly recognized as a critical factor influencing athletic performance in college athletes. While cognitive-behavioral therapy for insomnia (CBT-I) is the gold-standard treatment for sleep disturbances, it can be time-consuming and overly comprehensive for athletes seeking targeted sleep optimization. This study aimed to evaluate the effectiveness of a personalized, brief behavioral sleep intervention for Division 1 college football players.
Methods: A pilot study was conducted with 27 Division 1 football athletes. Two weeks prior to their first appointment, athletes received a Polar Grit X Pro device to monitor baseline sleep. Baseline sleep assessments included the Athlete Sleep Screening Questionnaire (a measure of athlete sleep disturbance), RU-SATED (a measure of sleep health), the Ford Insomnia Response to Stress (a measure of reactivity to new sleep environments), STOP-BANG (a measure of sleep apnea risk), the Depression Anxiety and Stress Scale and constructed measures of sleep resilience, vulnerability, self-efficacy, and valuation. At the first appointment, a doctoral-level interventionist conducted a sleep assessment and provided motivational interviewing, psychoeducation, and 1 to 3 individualized, evidence-based strategies to improve sleep health. Athletes implemented these strategies for two weeks, maintaining daily electronic sleep diaries and wearing the Polar Grit X Pro for continuous monitoring. A follow-up appointment included repeated assessments, progress reviews, problem-solving, and treatment maintenance guidance.
Results: Paired-sample t-tests revealed significant improvements in sleep disturbance (ASSQ scores; $p = 0.02$, $g = 0.45$) and sleep self-efficacy ($p = 0.01$, $g = 0.64$) from pre- to post-intervention. Depression, anxiety, and stress total scores showed a trend toward improvement ($p = 0.06$), while other measures remained unchanged.
Conclusion: A brief, targeted behavioral sleep intervention effectively improved sleep disturbance and self-efficacy in Division 1 football athletes, providing a practical alternative to traditional CBT-I. These findings suggest that such personalized interventions can enhance sleep health and accessibility in athlete populations. Although improvements in mood measures approached significance, the small sample size and short intervention period may have limited broader effects.

SELF-RATED PERFORMANCE IMMEDIATELY FOLLOWING A 1-HOUR NIGHTTIME NAP

Cassie Hilditch[1], Rachel Jansen[2], Erin Flynn-Evans[2]
[1] San Jose State University, [2] NASA Ames Research Center

Introduction: Sleep inertia is the temporary impairment of performance and alertness experienced after waking. Subjective perceptions of performance during this period may not match actual performance, which is problematic in occupational settings where fitness for duty is self-assessed. We investigated self-rated performance predictions following a 1-hour nighttime nap with blue-enriched light compared to a no-nap dim light condition.
Methods: Following a week at home of 8.5 hours' time-in-bed (verified by actigraphy), n = 15 participants (7 female; mean age = 25.86 y, SD = 6.35) spent two 26-hour periods in the sleep laboratory. In a within-subjects, randomized, cross-over design, one visit included a 1-hour nap opportunity ending 21 hours after habitual waketime (i.e., during the circadian low), followed by exposure to blue-enriched light (250 lux; nap + light). The other visit involved a 1-hour rest period without sleep in a semi-recumbent position in dim light (< 10 lux), followed by exposure to 150 lux (no-nap + dim). A test battery including a 5-minute psychomotor vigilance task (PVT, NASA PVT+) was administered before lights out and again at 2, 12, 22, and 32 minutes after lights on. Participants estimated their performance prior to each PVT on a 100 mm visual analog scale. Linear mixed-effects models were run separately for each condition (nap + light; no-nap + dim) to evaluate the association between subjective performance estimates and actual PVT performance (speed, 1000/reaction time) and test bout, with participant as a random effect.
Results: Subjective performance was significantly associated with PVT speed ($p = .02$) in the nap + light condition but there was no effect of test bout. In the no-nap + dim condition, subjective performance was not related to PVT speed but there was a significant effect of test bout ($p < .001$).
Conclusion: These preliminary findings suggest that participants were more able to predict their performance while exposed to blue-enriched light following a nap and less able when kept awake at night in dim light. Future analyses will investigate the influence of sleep metrics and different interventions on these results.

PERCEIVED ALERTNESS MODERATES THE RELATIONSHIP BETWEEN ACTUAL AND PERCEIVED PERFORMANCE

Rachel Jansen[1], Cassie Hilditch[2], Erin Flynn-Evans[1]
[1] NASA Ames Research Center, [2] San Jose State University

Introduction: Previous work has shown that performance degrades following sleep loss as does the ability to self-assess one's performance. In this study, we investigate the extent to which humans are aware of their own ability to perform and what other factors may contribute to their judgments of their own ability.
Methods: Following a week of 8.5 h time-in-bed (verified by actigraphy), n = 15 participants (7 female; mean age = 25.86

y, SD = 6.35) spent two 26-hour periods in the sleep laboratory. Participants completed a test battery including a 5-minute psychomotor vigilance task (PVT, NASA PVT+ App) 4.5 hours after habitual wake and then 16 times throughout the evening and night after a four-hour daytime nap opportunity. Immediately before each PVT, participants were asked to indicate how well they expected to perform on their upcoming PVT (VASperformance). During each battery, participants also rated their own sleepiness on a 100 mm visual analog scale (VASsleepiness) We ran a linear mixed-effects model predicting estimated performance (VASperformance) to actual performance (PVT speed), with participant as a random effect (baseline model). The same model was repeated with perceived sleepiness (VASsleepiness) as another independent variable to evaluate the strengths of the relationships between these constructs.

Results: In the baseline model, better PVT speed was associated with significantly higher performance estimates (beta = 18.0, p <.001) indicating individual awareness of their ability to perform. The model that included sleepiness ratings revealed a reduced coefficient between speed and perceived performance (beta = 9.0, p <.001) and a significant main effect of subjective sleepiness (beta = -0.3, p <.001).

Conclusion: These results suggest that during a single overnight study in a controlled laboratory setting, participants have some sense of their own ability to perform, though their perceived sleepiness attenuates this effect and affects how participants rate their ability. Future work will investigate the role that acute sleep loss and circadian misalignment play in the accuracy of perceived judgments of ability.

QUANTIFYING SCRATCH DURING SLEEP IN ATOPIC DERMATITIS PATIENTS WITH THERMAL CAMERA TECHNOLOGY

Matthew Patterson[1], Sylvain Zorman[2], Ali Neishabouri[2], Christine Guo[2]

[1] ActiGraph L.L.C., [2] ActiGraph LLC

Introduction: Scratching during the sleep period in atopic dermatitis patients results in inflammation or a lesion on the affected area and further perpetuates the itch-scratch cycle. Night scratching disrupts patients sleep and negatively affects overall quality of life. The purpose of this work is to quantify amount of nocturnal scratching in atopic dermatitis patients and to compare scratching on the dominant and non-dominant hand.

Methods: A FLIR a400 thermal camera was set up in a sleep laboratory to record atopic dermatitis patients sleeping over night. The thermal video was annotated for scratch by trained annotators. Right and left hand scratches were annotated separately and hand dominance from each patient was recorded. Twelve nights were recorded from seven patients, five patients had two nights recording and three patients had one night of observation. Data from patients with two nights of data were averaged. The SCORAD clinical rating scale was used to quantify the severity of each patients atopic dermatitis.

Results: On average, all patients scratched for 15.1 minutes (14.1 minutes std) over each night. The dominant hand did most of the scratching (9.6 minutes, 11.1 minutes std). The non-dominant hand did on average 5.4 minutes (3.2 minutes std) of scratching per night. Each scratch event is called a bout, there were on average 109.5 bouts (59.6 std) per night. There were more dominant hand scratching bouts per night (63.1 bouts, 41.1 std) than non-dominant hand bouts (46.4 bouts, 20.7 std). The Pearson Product Correlation between the SCORAD clinical rating and time scratching per night was 0.451.

Conclusion: There is a large variation in how much atopic dermatitis patients scratch per night. A patient with a severe SCORAD score scratched less than a patient with a moderate SCORAD score. The low correlation between SCORAD and time spent scratching overnight indicates the importance of quantifying nocturnal scratching in atopic dermatitis patients. The atopic dermatitis patients in this study scratched more often with their dominant hand, compared to their non-dominant hand.

CHRONOTYPE AND DISORDERED EATING BEHAVIOR: A SYSTEMATIC REVIEW AND META-ANALYSIS

Arman Arab[1], Elham Karimi[2], Marta Garaulet[3], Frank Scheer[4]

[1] Harvard Medical School, [2] Arash Women's Hospital, [3] University of Murcia, [4] Brigham and Women's Hospital

Introduction: Chronotype refers to an individual's typical or preferred timing of behaviors throughout the day. A later chronotype has been associated with emotional dysregulation, psychological disturbances, and unhealthy foods, although these findings are still controversial and inconclusive. Therefore, we conducted this systematic review and meta-analysis to investigate the association between chronotype and disordered eating behaviors among the general population.

Methods: Online databases, including PubMed, Scopus, and ISI Web of Science, were searched. We used the PECOS framework as follows: Population (general population), Exposure (individuals with later chronotype), Comparison (individuals with earlier chronotype), Outcome (disordered eating behaviors), and Study design (observational studies). We enrolled 36 studies comprising 28,352 participants with a mean age and BMI ranging from 14.1-52.6 years and 19.83-34.54 kg/m2, respectively.

Results: Later chronotype (i.e., a lower MEQ score) was associated with a higher binge-eating behavior score (Correlation coefficient [r]: -0.39; 95% CI, -0.43, -0.35; P < 0.001; I2 = 94.38 %), higher disordered eating attitude score (r: -0.17; 95% CI, -0.20, -0.13; P < 0.001; I2 = 95.45 %), higher emotional eating score (r: -0.06; 95% CI, -0.11, -0.02; P = 0.010; I2 = 56.97 %), higher uncontrolled eating score (r: -0.14; 95% CI, -0.22, -0.06; P < 0.001; I2 = 77.01 %), higher food addiction score (r: -0.17; 95% CI, -0.23, -0.11; P < 0.001; I2 = 80.19 %), higher food craving score (r: -0.09; 95% CI, -0.12, -0.06; P < 0.001; I2 = 69.97 %), higher food-related disinhibition score (r: -0.11; 95% CI, -0.14, -0.08; P < 0.001; I2 = 76.85 %), and higher night-eating syndrome score (r: -0.19; 95% CI, -0.28, -0.10; P < 0.001; I2 = 80.26 %); as well as a lower restrained eating score (r: 0.11; 95% CI, 0.06, 0.15; P < 0.001; I2 = 7.01 %).

Conclusion: Our findings highlight an association between late chronotype and increased disordered eating behaviors; however, we need more longitudinal and intervention studies to test causality and underlying mechanisms.

TOTAL SLEEP DEPRIVATION IMPAIRS DECISION MAKING MORE IN HEALTHY SLEEPERS THAN IN INDIVIDUALS WITH CHRONIC INSOMNIA

Gisella Logioia[1], Courtney Kurinec[2], Devon Hansen[2]
[1] Washington State University Elson S. Floyd College of Medicine,
[2] Washington State University

Introduction: Work in healthcare routinely involves night and rotating shifts, early morning starts, and variable call schedules, resulting in short and/or disrupted sleep. We conducted a laboratory-based experiment in both normal sleepers and those with chronic insomnia to better understand implications of total sleep deprivation (TSD) on decision making using a reversal learning task (i.e., go/no go; GNG) with unannounced reversal contingences.
Methods: 28 individuals completed the sleep study, 15 with sleep-onset insomnia (ages 22-40, 11 females), of whom 7 underwent TSD, and 13 normal sleeper controls (ages 22-40, females), of whom 7 underwent TSD. The insomnia group met International Classification of Sleep Disorders (3rd edition; ICSD-3) criteria for chronic insomnia with no other clinically relevant condition contributing to their sleep disturbance. Subjects were in the laboratory for 5 days/4 nights. The first 2 days and nights were baseline days, each with a 10h opportunity for sleep (22:00—08:00). This was followed by 38h of TSD or another nighttime sleep opportunity for the control group. The last day was a recovery day, with a 10h sleep opportunity for all participants. Unique versions of a GNG task were administered in random, counterbalanced order at baseline and 24h later during TSD (or 2h awake in the control group).
Results: There was a significant main effect of day ($F_{1,69}$= 10.37, P=0.002), condition ($F_{3,69}$ = 5.94, P = 0.001), phase ($F_{1,69}$ = 10.03, P = 0.002), and day by condition by phase interaction ($F_{10,69}$ = 4.73, P < 0.001). In general, participants performed better before TSD and pre-reversal. While both TSD groups showed poorer performance post-reversal during TSD, only the TSD insomnia group showed relatively intact performance pre-reversal.
Conclusion: TSD led to significant impairment on a reversal learning task for both normal sleepers and those with chronic sleep-onset insomnia. This has important implications for healthcare workers who are routinely exposed to disrupted sleep which may leave them more susceptible to making potentially life-threatening errors. Hyperarousal, the widely accepted underlying mechanism perpetuating insomnia, may provide those chronically exposed to sleep loss some level of protection on decision making tasks compared to normal healthy sleepers during TSD.

COGNITIVE AND CORTISOL MEASURES DURING SLEEP DEPRIVATION AND PSYCHOLOGICAL STRESS INFLUENCE RECOVERY SLEEP METRICS

Namni Goel[1], Lauren Pasetes[1]
[1] Rush University Medical Center

Introduction: Little is known about the factors during total sleep deprivation (TSD) and psychological stress that affect recovery sleep. We determined the relative contributions of cognitive and cortisol measures, which represent distinct domains, as predictors of recovery sleep timing and duration.
Methods: We conducted a five-day experiment under highly controlled conditions in 32 healthy adults (ages 27-53; 14 females). Salivary cortisol samples were collected during 1) TSD morning (TSD AM; after 25h of TSD) and 2) TSD evening following a modified Trier Social Stress Test, which induced psychological stress (TSD PM; after 34h of TSD). Digit Span Test (DS), Digit Symbol Substitution Test (DSST), and Psychomotor Vigilance Test (PVT) performance data were collected at 0400h, 1130h, and 1730h during TSD and averaged. Wrist actigraphy assessed sleep indices during the first recovery night following TSD (10h time in bed). Multiple linear regression models determined the impact of TSD cognitive and cortisol measures as predictors of recovery sleep timing and duration. The models and independent variables were all significant ($p < 0.05$).
Results: Sleep Onset. Each 1-point DS total # correct increase predicted a 0.042h later sleep onset and each 1 µg/dL AM cortisol increase predicted a 0.958h later sleep onset. Sleep Offset. In addition, each 1 PVT lapse increase predicted a 0.031h later sleep offset and each 1 µg/dL PM cortisol increase predicted a 1.205h earlier sleep offset. Sleep Duration. Each 1 PVT lapse increase predicted a 2.153 minute sleep duration increase, and each 1 µg/dL AM cortisol increase predicted an 87.367 minute sleep duration decrease. In addition, each 1-point DSST # correct increase predicted a 1.657 minute sleep duration decrease and each 1 µg/dL PM cortisol increase predicted a 100.535 minute sleep duration decrease. Across models, 35.8%-40.6% of the sleep timing and duration variance was explained, with r ranges between 0.598-0.637.
Conclusion: Our results elucidate the important roles of cognitive performance and cortisol metrics obtained during sleep loss in influencing recovery sleep timing and duration, suggesting the possibility of intervening on these measures to modify subsequent sleep. Our findings highlight hypothalamic-pituitary-adrenal axis and cognitive measures as biomarkers for recovery sleep health.

SLEEP INTERRUPTED: EXPLORING THE EFFECTS OF TOTAL SLEEP DEPRIVATION ON CHRONIC INSOMNIA THROUGH POLYSOMNOGRAPHY

Delaney Miller[1], Lillian Skeiky[2], Myles Finlay[3], Devon Hansen[3]
[1] Washington State University Elson S. Floyd College of Medicine,
[2] Uniformed Services University, [3] Washington State University

Introduction: Conventional sleep staging is the standard for diagnosing most sleep disorders but has little diagnostic yield for chronic insomnia. Despite this, there has been a large effort to identify unique polysomnographic (PSG) patterns in chronic insomnia. Current consensus of PSG markers of chronic insomnia includes increased sleep onset latency (SOL) and wake time after sleep onset (WASO) and decreased total sleep time (TST) and sleep efficiency (SE). Less is known about how acute total sleep deprivation (TSD) may impact these same sleep markers. We investigated PSG patterns at baseline and after TSD in individuals with chronic sleep-onset insomnia as compared to healthy sleeper controls.

Methods: 11 individuals with chronic insomnia and 11 healthy controls (ages 22-40y, 14 females) completed a 5-day laboratory study with an adaptation night, baseline night, assignment to 38h TSD (n=6 insomnia, n=5 control) or equivalent non-TSD control (n=5 insomnia, n=6 control), and recovery night. Sleep periods were 10h (22:00-08:00) and measured with PSG. Data were analyzed using mixed effects ANOVA with fixed effects of condition (TSD or control) and night (baseline and recovery) and their interaction, with a random effect over subjects on the intercept.
Results: There was a significant interaction of condition by night with increases in TST ($F_{3,18}=5.61$, $P< 0.01$), SE ($F_{3,18}=5.53$, $P< 0.01$), and total N3 ($F_{3,18}=12.76$, $P< 0.001$), and a decrease in SOL ($F_{3,18}=3.91$, $P=0.026$), N1 ($F_{3,18}=3.82$, $P=0.028$), and WASO ($F_{3,18}=4.32$, $P=0.018$) in both the insomnia and healthy controls following TSD. No significant difference between conditions were observed in any measured sleep metric at baseline (all $P>0.13$).
Conclusion: After TSD, both groups demonstrated the expected increased SE and total N3 alongside decreases in WASO and SOL and were not significantly different from each other. These findings suggest that conventional sleep staging lacks the sensitivity to identify distinct features of insomnia, both with and without TSD. This underscores the need for alternative methods of measurement such as spectral analysis, the results of which are forthcoming. Additionally, these findings highlight the importance of incorporating subjective sleep assessments in studies of insomnia as objective metrics may not always align with subjective reports of poor sleep.

BIDIRECTIONAL PREDICTORS BETWEEN CATECHOLAMINES DURING SLEEP DEPRIVATION AND STRESS AND BASELINE AND RECOVERY SLEEP

Lauren Pasetes[1], Namni Goel[1]
[1] Rush University Medical Center

Introduction: We examined whether baseline sleep measures the night before total sleep deprivation (TSD) predicted concentrations of two catecholamines, epinephrine (adrenaline) and norepinephrine (noradenaline), during TSD and psychological stress. We also assessed whether these markers predicted subsequent recovery sleep measures.
Methods: During a controlled five-day experiment, epinephrine and norepinephrine via blood samples were collected in 8 healthy adults (ages 28-42): 1) after two baseline 8h time in bed (TIB) nights (B1, B2); 2) during TSD morning (TSD AM; after 25h of TSD); 3) during TSD evening following a modified Trier Social Stress Test, which induced psychological stress (TSD PM; after 34h of TSD); and 4) after two recovery nights of 8-10h TIB (R1, R2). Wrist actigraphy assessed sleep indices during the B2 and R1 nights. Simple linear regression determined predictive relationships between B2 and R1 sleep metrics and TSD AM and TSD PM epinephrine and norepinephrine metrics ($p< 0.05$ was significant).
Results: Longer B2 sleep duration significantly predicted greater TSD AM and PM epinephrine (r: 0.722-0.725; β: 0.955-0.964), while longer B2 sleep onset latency significantly predicted lower TSD AM and PM epinephrine levels (r: −0.937-−0.864; β: −3.893-−3.638). Later B2 sleep onset significantly predicted lower TSD PM epinephrine levels ($r=-0.702$; $\beta=-55.717$). Greater B2 wake after sleep onset (WASO) significantly predicted higher TSD AM norepinephrine levels ($r=0.790$; $\beta=4.092$), while higher B2 percent sleep showed the opposite relationship ($r=-0.777$; $\beta=-20.457$). B2 sleep measures predicted 49.3%-87.9% of the TSD epinephrine and norepinephrine variance. Higher TSD AM and PM norepinephrine significantly predicted shorter R1 sleep duration (r: −0.933-−0.775; β: −0.218-−0.206), and higher TSD AM norepinephrine significantly predicted greater R1 WASO, and lower sleep efficiency and percent sleep (r: −0.954-0.925; β: −0.036-0.133). TSD AM and PM norepinephrine predicted 60.0%-91.0% of the variance in R1 sleep measures. TSD epinephrine concentrations, however, did not significantly predict R1 sleep measures.
Conclusion: Baseline sleep measures uniquely predicted a remarkably high percentage of epinephrine and norepinephrine variance during TSD and psychological stress. Similarly, norepinephrine levels predicted a notably high percentage of the variance in recovery sleep metrics. Our novel findings highlight important biomarkers and mechanisms between catecholamine regulation and sleep health.

IMPACT OF SLEEP DEPRIVATION ON SYNAPTIC DENSITY IN HUMAN BRAINS

David Elmenhorst[1], Anna L. Foerges[2], Ali Gordji-Nejad[2], Eva-Maria Elmenhorst[3], Tina Kroll[2], Andreas Matusch[2], Bernd Neumaier[2], Philipp Krapf[2], Christoph Lerche[2], Alexander Drzezga[2], Andreas Bauer[2]
[1] Forschungszentrum Jülich GmbH, [2] Forschungzentrum Jülich, [3] German Aerospace Center, Institute of Aerospace Medicine

Introduction: According to the synaptic homeostasis hypothesis, wakefulness will lead to an increase in synaptic strength. Several lines of evidence indicate in animals that markers of synaptic strength increase during wake and decline during sleep. Examples of proxies of synaptic strength are the amount of AMPA receptors, the cortical spine density, the number and size of synapses and the local field potential rising. Nevertheless, some in-vitro and in-vivo studies of synaptic strength in animals reveal opposite results which may be due to differences in examined brain regions, cortical layers or housing of animals. Thus far, changes in EEG following transcranial magnetic or direct current stimulation have been an indirect marker of altered plasticity in humans. Results from these studies point to an increase of synaptic strength. Synaptic vesicle protein 2A (SV2A) is an established marker of synaptic density and can be quantified by F-18 SynVesT 1 positron emission tomography (PET). Here we report a cohort (n=40, f/m 14/26) which was randomized to either a normal sleep (n=20) or an acute total sleep deprivation group.
Methods: F-18 SynVesT-1 PET and MRI data were collected twice in the morning on consecutive days in healthy volunteers (age: 27.5± 6.5 years) using a MR/BrainPET system. The control group slept for 7.8 hours (scheduled 23 to 7 or 0 to 8:00 h) in-between. At the start of the second scan the sleep deprivation group had been awake for an average of 28.5 ± 2.0 hours. SV2A was quantified by using the simplified reference tissue model 2 with centrum semiovale as reference region.

Results: We found a significant increase in synaptic density after sleep deprivation in most of the investigated brain regions, e.g. Thalamus +4.6±7.3% (p=0.005); Hippocampus +5.6±8.2% (p=0.013); Parietal cortex +3.2±5.1% (p=0.014)).
Conclusion: Our results suggest - for the first time in humans - that there is a global increase in synaptic density after sleep deprivation.

SLEEP MODERATES THE RELATIONSHIP BETWEEN BODY FAT PERCENTAGE AND APPETITE

Vincent Bourgon[1], Jessica McNeil[2], Jean-François Brunet[1], Éric Doucet[3], Geneviève Forest[1]
[1] Université du Québec en outaouais, [2] University of North Carolina at Greensboro, [3] University of Ottawa

Introduction: Body fat percentage is a known predictor of appetite measures, such as hunger, fullness, desire to eat, and prospective food consumption (PFC). Sleep deprivation has also been associated with changes in these appetite measures. This study examined whether sleep deprivation moderates the relationship between body fat percentage (BF%) and appetite responses (feelings of hunger, fullness, desire to eat, and PFC) following an ad libitum lunch.
Methods: Eighteen participants (6 females; 23.2±3.8 years; body fat (BF%)=18.8±9.9%) underwent 3 sleep conditions following a randomized crossover design: one habitual sleep night (control), and two sleep deprivation conditions where sleep was shortened during the second half of the night (early wake) or the first half of the night (late bedtime). The next day, measures of appetite were captured via four visual analog scales (immediately following an ad libitum lunch. BF% was measured with Dual-Energy X-Ray Absorptiometry (DEXA) at baseline. Four moderation analyses were conducted, with BF% as the predictor, sleep condition (Control, Early wake or Late Bedtime) as a categorical moderator, and post-lunch hunger, fullness, desire to eat, and PFC as dependent variables.
Results: With desire to eat as the outcome, the model was significant (F[5,48]=3.83, p=.005, R2=.29) with a significant interaction term (b=.51, t(48)=3.33, p=.002). Specifically, there was no relationship between BF% and Desire to eat in the control condition (b=-.18, t(48)=-1.67, p=.10), but the relationship was positive and significant in both the early wake (b=.27, t(48)=2.52, p=.02) and late bedtime (b=.33, t(48)=3.04, p=.004) sleep deprivation conditions. The models for hunger (F[5,48]=.90, p=.49), fullness (F[5,48]=.16, p=.98), and PFC (F[5,48]=.47, p=.80) were not significant.
Conclusion: These results suggest that post-meal desire to eat is increased in individuals with higher BF% following sleep deprivation, but not following habitual sleep duration. These findings suggest that sleep deprivation may amplify a person's desire to eat, and that individuals with larger BF% may be at a greater risk. These findings provide further evidence on the role of sleep deprivation in modulating appetite and may, consequently, be a risk factor for greater energy intake in individuals with higher BF% or at greater risk for obesity.

ALCOHOL AND CANNABIS AFFECT NEUROBEHAVIORAL IMPAIRMENT FROM ACUTE TOTAL SLEEP DEPRIVATION

Jazira Ssetuba[1], Hans Van Dongen[2], Matthew Layton[3], Claire Bryant[4], Daniel Mollicone[5], Devon Hansen[2]
[1] University of Surrey, [2] Washington State University, [3] Elson S. Floyd College of Medicine, Washington State University, Spokane, Washington, USA, [4] National Safety Council, [5] Pulsar Informatics, LLC

Introduction: Acute total sleep deprivation (TSD) is common due to extended work hours or other time demands. In controlled laboratory settings, individuals exposed to TSD display highly reproduceable profiles of neurobehavioral impairment. In real-world settings, however, TSD is often combined with substance intake, including alcohol and cannabis. In this pilot study, we investigated the effect of substance intake on the neurobehavioral response to TSD.
Methods: Six healthy individuals (ages 23-37y, all male) completed two 24h in-laboratory study visits separated by ≥1 week. During each visit, they were kept awake from 15:00 until 06:00 the next day, and they completed a 10min PVT every 2-3h. This was followed by an 8h recovery sleep opportunity. For the second visit, participants were randomized – three per group – to receive oral administration of cannabis at 22:30 (10mg) or alcohol at 23:30 (peak blood alcohol concentration of 0.043±0.006% at 00:13, decaying to 0.005±0.007% by 03:55). PVT mean RT, number of lapses (RT>500ms) and false starts were analyzed using mixed-effects regression.
Results: As expected, PVT performance deteriorated through the second half of the extended waking period (after midnight), with slower mean RT, more lapses, and more false starts (F>3.6, P< 0.002). Alcohol increased mean RT (F=4.9, P=0.002) and lapses (F=7.7, P< 0.001), but did not significantly affect false starts (F=1.0, P=0.41). Cannabis did not significantly affect mean RT (F=0.9, P=0.46), lapses (F=1.1, P=0.37), or false starts (F=0.8, P=0.56) during TSD.
Conclusion: Alcohol exacerbated neurobehavioral impairment during TSD, even at blood alcohol levels below the legal limit of most countries and states, reaching statistical significance despite our small sample size. Cannabis at the dose provided did not significantly further degrade PVT performance during TSD. Importantly, no attempt was made to make the alcohol and cannabis doses equipotent; therefore, these results should not be interpreted as evidence of their relative effect sizes or safety profiles. Yet, our findings provide preliminary evidence suggesting that commonly used drugs such as alcohol may amplify neurobehavioral impairment from sleep loss, which may have critical implications for automobile driving and other safety-sensitive activities.

MAPPING THE BRAIN AROUND THE CLOCK: SPONTANEOUS NEURAL ACTIVITY IS INFLUENCED BY TIME AWAKE AND TIME OF DAY

William Killgore[1], Kymberly Henderson-Arredondo[1], Jason Katz[1], Catherine Seader[1], Allie Jepson[2], A'mour Canty[1], Kathryn Kennedy[2], Salma Patel[2], Sarah Green[1], Alisa Huskey[2], Jungwon Cha[2], David Negelspach[2]

[1] University of Arizona, [2] The University of Arizona

Introduction: The timing and depth of sleep and wakefulness are influenced by a homeostatic process that reflects accumulating sleep pressure over time (Process S) and a circadian process (Process C) that produces an oscillating diurnal rhythm of alertness. Together, these two processes influence an individual's propensity toward sleep or alertness throughout the day, but their neurobiological mechanisms remain to be fully elucidated. Here, we obtained repeated resting state fMRI scans every 6 hours during 39 hours of continuous sleep deprivation and mapped the changes in cerebral Amplitude of Low Frequency Fluctuations (ALFF), a measure of spontaneous neural activity.
Methods: Twenty healthy adults (9 female; age=23.6, SD=4.7 years) underwent a night of normal sleep in the lab followed by a 39-hour period of continuous wakefulness. Beginning at 0900, rsFMRI scans were collected at 3T every 6-hours. Data were preprocessed and analyzed using standard pipelines using CONN v22.v2407. Spontaneous neural activity was identified using ALFF at each timepoint. Two GLMs were calculated: 1) the linear change in ALFF across sessions, controlling for the circadian rhythm (based on a cosine function model), and 2) the circadian rhythm, controlling for the linear effects of time awake.
Results: There was a significant ($p<.05$, FDR corrected) linear effect of sleep deprivation (Process S), showing increasing ALFF within primary sensory and motor regions (e.g., precentral/postcentral gyri; superior temporal gyrus, occipital cortex) and thalamus, basal ganglia, amygdala, and medial orbitofrontal cortex). After removing the effect of sleep deprivation, ALFF showed significant ($p<.05$, FDR corrected) circadian modulation (Process C) primarily within higher order cortex including dorsolateral prefrontal, ventromedial prefrontal, lateral orbitofrontal, inferior parietal cortices, and the temporal poles.
Conclusion: This is the first study to demonstrate changes in spontaneous neural activity over the course of sleep deprivation. There was a linear increase in ALFF within frequently used regions of the sensorimotor cortex, consistent with the tenets of the synaptic homeostasis hypothesis (SHY), which posits a buildup of synaptic potentiation with increasing time awake. Higher order regions involved in executive functioning showed a circadian pattern of spontaneous neural activity. These findings provide a neurobiological basis for models of cognitive fatigue during sleep loss.

SOCIAL BEDTIME PROCRASTINATION ASSOCIATES WITH GREATER NEED TO BELONG

Venetia Kok[1], Joshua Gooley[1]

[1] Duke-NUS Medical School

Introduction: Bedtime procrastination involves choosing to go to bed later despite being aware of its potential negative consequences. In this study, we investigated how socializing for leisure contributes to bedtime procrastination in a residential college. We hypothesized that social bedtime procrastination on school nights would be associated with shorter nocturnal sleep, and membership and ties within the bedtime procrastination social network would be predicted by a greater need to belong.
Methods: University students in a residential college (n=104, 59 women) wore actigraphy watches and proximity beacon watches for 2 weeks during the school semester to track their nocturnal sleep and the times they were in close proximity to one another. Daily diaries recorded instances of in-person social bedtime procrastination and the person(s) who were involved in delaying bedtime. The Need to Belong Scale assessed individual differences in the desire for acceptance and belonging. Linear mixed models tested associations between social bedtime procrastination and sleep, while exponential random graph models predicted tie formation in the bedtime procrastination social network.
Results: Sleep duration was about an hour shorter on school nights when students procrastinated their bedtime for in-person social leisure activities (β=-0.97 h, 95% CI=-1.34 to -0.59 h). On these nights, students' bedtime was strongly correlated with the timing of their last objectively measured proximity to the person who delayed their bedtime ($r=0.81$, $P< 0.001$). Students within the bedtime procrastination social network scored higher on need to belong compared with students outside the network (Cohen's $d=0.63$, 95% CI=0.21 to 1.03). Furthermore, need to belong predicted tie formation within the bedtime procrastination social network (log odds ratio=0.97, 95% CI=0.49 to 1.45).
Conclusion: Social bedtime procrastination may be an important factor contributing to late bedtimes and short sleep among students living in residential colleges or dormitories. Individuals with a stronger need to belong may be more inclined to delay their bedtime to partake in social activities. These insights could inform interventions aimed at promoting healthier sleep habits within social contexts.

SLEEP RESTRICTION INCREASES EXPERIENCES OF BOREDOM AND INHIBITS INTEREST

Cara Palmer[1], Patrick Alexander[1], Giovanni Alvarado[1]

[1] Montana State University

Introduction: Studies on sleep and emotional experiences suggest robust effects of sleep loss on blunted experiences of positive affect. However, research has largely relied on broad experiences of positive or negative mood, and few studies have examined the impact of sleep loss on experiences of specific types of emotions. The current study examined how sleep restriction may alter experiences of interest and boredom.
Methods: Healthy participants (N = 16; 85% female, ages 18-25 years) completed an intake assessment followed by two weeks of at home sleep monitoring using actigraphy. On nights 7 and 14, participants completed a night of sleep restriction (4h sleep opportunity) or control sleep (9h sleep opportunity) using a randomized crossover design. Following each sleep manipulation, participants returned to the lab to complete several behavioral

tasks. Specifically, participants completed a boredom/interest task where they were presented with a variety of randomized, counterbalanced stimuli (i.e., abstract art, summaries of science discoveries, and philosophy quotes) and were asked to rate how interested and bored they were in response to each stimuli. Participants also completed a Thought Action Repertoire task where they were asked to list all of the things they would be interested in doing at that moment.
Results: After sleep restriction, participants reported less interest in response to all stimuli. Specifically, after sleep restriction, participants reported less interest in response to abstract art (p =.018, d =.67), science discoveries (p =.04, d =.56), and philosophy (p =.04, d =.56). Participants also reported more boredom in response to abstract art (p =.019, d = -.66). After sleep restriction, participants reported that they would be interested in pursuing fewer activities (t(14) = 2.18, p =.04, d =.56) compared to after a night of control sleep. Differences in the types of activities listed also emerged.
Conclusion: This study is one of the first to examine the effects of sleep loss on experiences of interest and boredom. Implications for the role of sleep in the development of depression and anhedonia (i.e., loss of interest and engagement in activities) will be discussed.

THE SWEET SPOT OF WEEKEND CATCH-UP SLEEP: A PROTECTIVE FACTOR AGAINST DEPRESSIVE SYMPTOMS?

Sojeong Kim[1], Jason Carbone[2], Melynda Casement[1]
[1] University of Oregon, [2] Wayne State University

Introduction: Chronic sleep deprivation is common and often linked to increased internalizing symptoms. Weekend catch-up sleep (WCS) or extending sleep duration on weekends to compensate for weekday deficits, has shown mixed effects on mental health across age groups. This study examines the association between WCS duration and internalizing symptoms in adolescents.
Methods: Data were drawn from year four of the Adolescent Brain Cognitive Development (ABCD) Study (n = 1,877; mean age = 13.5 years). Sleep duration was objectively measured using Fitbit devices, while internalizing symptoms were assessed using the Brief Problem Monitor-Youth (BPM-Y). Three independent variables captured weekend catch-up sleep (WCS): (1) WCS duration, calculated as the difference between weekend and weekday sleep duration; (2) WCS classification, a binary variable indicating whether WCS duration was greater than 0 hours or not; and (3) WCS groups, categorized as WCS duration < 0 hours, 0 to < 2 hours, and ≥ 2 hours. The dependent variable was internalizing symptoms, measured as a continuous factor score derived from the BPM-Y. Linear regression analyses were conducted to examine the associations between WCS and internalizing symptoms.
Results: No significant association was observed between WCS classification (WCS > 0 hours or not) and internalizing symptoms (t = 0.68, p = 0.498). However, adolescents with 0–2 hours of WCS exhibited fewer internalizing symptoms compared to those with no WCS (β = -0.139, p = 0.048). In contrast, longer WCS durations (continuous variable) were associated with a slight increase in internalizing symptoms at year four follow-up (β = 0.008, p = 0.029).
Conclusion: Moderate WCS (0–2 hours) may protect against internalizing symptoms in adolescents, while excessive WCS appears to have the opposite effect. These findings highlight the importance of understanding optimal sleep balance during adolescence, though further research is needed to clarify the directionality of these relationships.

THE IMPACT OF REPORTED SLEEP DURATION AND SUBJECTIVE SLEEP SUFFICIENCY ON ANXIETY, DEPRESSION, AND FATIGUE

Sang Min Paik[1], Hyo-Jin Park[1], Sun-Ku Han[1], Jae Rim Kim[1], Woo-Jin Lee[1], Daeyoung Kim[2], Kwang Ik Yang[3], Min Kyung Chu[4], Chang-Ho Yun[5]
[1] Department of Neurology, Seoul National University Bundang Hospital, [2] Department of Neurology, Chungnam National University Hospital, Chungnam National University School of Medicine, [3] Sleep Disorders Center, Department of Neurology, Soonchunhyang University Cheonan Hospital, Soonchunhyang University College of Medicine, [4] Department of Neurology, Severance Hospital, Yonsei University College of Medicine, [5] Department of Neurology, Seoul National University Bundang Hospital, Seoul National University College of Medicine

Introduction: Short sleep duration is linked to increased psychiatric risks, yet the protective role of subjective sleep sufficiency in short sleepers remains unclear. This study examines how reported sleep duration and subjective sleep sufficiency influence anxiety, depression, and fatigue in a Korean adult population.
Methods: Data from 2,492 participants in the Korean Sleep Headache Study were analyzed (age range: 19-92, mean 47.9 ± 16.4yrs, 49.6% male). Reported sleep duration was classified as inadequate (< 7 hours) or adequate (≥7 hours) based on weighted weekly averages from the Korean Munich Chronotype Questionnaire. Subjective sleep sufficiency was assessed via the question, "Do you think you are getting enough sleep at night?" with responses categorized as "sufficient" or "insufficient." Anxiety, depression, and fatigue were defined using Generalized Anxiety Disorder-7 (≥10), Patient Health Questionnaire (≥10), and Fatigue Severity Scale (≥36), respectively. Logistic regression analyses, adjusting for sociodemographic, lifestyle, and sleep quality covariates, were performed to evaluate the associations between reported sleep duration and sufficiency on anxiety, depression, and fatigue.
Results: Participants reported inadequate sleep in 42.87% and insufficient sleep in 56.11%. Inadequate sleep duration was significantly associated with higher odds of anxiety and fatigue (OR [95% CI], 4.13 [1.75-11.41], p=0.003, and 1.33 [1.12-1.61], p= 0.002, respectively), while insufficient sleep was significantly associated only with fatigue (1.43 [1.18-1.72], p< 0.001). Depression was not significantly associated with either. Participants were categorized into sufficient adequate sleep (26.67%), insufficient adequate sleep (30.46%), sufficient inadequate sleep (17.22%), and insufficient inadequate sleep (25.65%). Notably, insufficient inadequate sleepers had the highest odds of anxiety (3.92 [1.24-17.42], p=0.036) and fatigue (1.89 [1.46-2.45], p< 0.001) compared to sufficient adequate sleepers, followed by insufficient adequate sleepers (1.48 [1.16-1.89], p=0.002) and

sufficient inadequate sleepers (1.40 [1.06-1.86], p=0.018) for fatigue. For depression, insufficient inadequate sleepers showed slightly higher odds (1.22 [0.80-1.85], p=0.354), though this was not statistically significant.
Conclusion: Inadequate sleep duration and insufficient subjective sleep may exacerbate on daytime symptoms such as anxiety and fatigue. While sufficient subjective sleep may mitigate the impact of short sleep, particularly on fatigue, securing adequate sleep remains essential for managing mood and fatigue.

SLEEP DIFFICULTIES, ANXIETY, AND DEPRESSION AMONG CANNABIS CONSUMERS AND NON-CONSUMERS IN THE HERBAL HEART STUDY

Ranya Marrakchi El Fellah[1], Amrit Baral[2], Bria-Necole Diggs[2], Kylee Krivijanski[1], Carolina Scaramutti[3], Girardin Jean-Louis[2], Denise Vidot[1]

[1] School of Nursing and Health Studies, University of Miami, [2] University of Miami Miller School of Medicine, [3] University of Miami

Introduction: Research indicates that individuals with sleep disturbances report higher rates of anxiety and depression. Cannabis is used to self-manage sleep disturbances; however, little is known about differences between anxiety and depression by sleep difficulties and use. This study examined these relationships in the Herbal Heart Study, a cohort of 18-to-35-year-olds.
Methods: Cannabis (CB+) was self-reported and confirmed by urine. Anxiety and depression were evaluated via Beck Anxiety Inventory (BAI) and Beck Depression Inventory (BDI). Difficulty falling and/or staying asleep was self-reported via the Medical History Questionnaire. A binary variable, "poor sleep", represented those with >1 type of sleep difficulty. Mann-Whitney U tests compared median BAI/BDI scores by sleep and cannabis use.
Results: Majority (63.0%) of the sample (N=200; mean age: 25.2 years, SD = 4.8; 65.0% female; 54.5% Hispanic/Latino) were CB+. Sleep difficulties were reported by 23.0% (difficulty falling asleep; DFA), 16.5% (difficulty staying asleep; DSA), and 29.0% (poor sleep) of the sample. CB+ with sleep difficulties had higher median BAI scores: DFA (15.0 vs 7.0, p< 0.0001), DSA (17.0 vs 7.0, p< 0.0001), and poor sleep (17.0 vs 7.0, p< 0.0001). Median BDI scores were also higher: DFA (17.0 vs 7.0, p< 0.0001), DSA (20.5 vs 7.0, p< 0.0001), and poor sleep (20.5 vs 7.0, p< 0.0001). Non-consumers with sleep difficulties had higher median BAI scores: DFA (13.0 vs 5.0, p< 0.001), DSA (15.0 vs 6.0, p < 0.001), and poor sleep (14.0 vs 4.5, p< 0.01). Median BDI scores showed the same pattern: DFA (15.0 vs 5.0, p< 0.001), DSA (20.0 vs 5.0, p< 0.001), and poor sleep (15.5 vs 5.0, p< 0.0001).
Conclusion: Those with sleep difficulties had elevated anxiety and depression scores, attenuated by CB+. Further investigation is needed to explore the complex relationship between cannabis, mental health, and sleep to inform public health interventions.

SLEEP RESTRICTION, ACADEMIC-ORIENTED PERFORMANCE, AND ADHD SEVERITY IN ADOLESCENTS

Claire Mayew Sherman[1], Gina Mason[2], Sinead Moyles[1], Victoria Dionisos[1], Taylor Christiansen[1], David Barker[2], Daniel Dickstein[3], Mary Carskadon[2], Jared Saletin[2]

[1] E.P. Bradley Hospital Sleep Research Laboratory, [2] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University, [3] Department of Psychiatry, Harvard Medical School

Introduction: Adolescents experience insufficient sleep that may impact academic performance. Youth with attention-deficit/hyperactivity-disorder (ADHD) may be particularly vulnerable to the effects of sleep loss. By leveraging ecologically relevant tests of math and language arts, we investigated how sleep restriction affects academic performance in children differing in ADHD symptoms.
Methods: Fifty-seven adolescents from R01HD103665 provided usable data (27M; age: 11.6±1.04yrs, range: 10-15yrs) and were grouped by ADHD symptoms on the Conners-3-Parent ADHD Index Probability score as high (ADHDy; ≥50%ile; n=25) or low (ADHDn; < 50%ile; n=32). All completed online quizzes featuring standardized-test math and language questions (prior grade-level) during two counterbalanced conditions: 5 nights of sleep optimization (10h TIB) and 5 nights of sleep restriction (7.5h TIB, equally delaying bedtime and advancing risetime). Quizzes were given in the afternoon after 1, 3, and 5 nights of each condition graded from 0-8 correct answers. We examined performance on days 1 and 5 and the change from day 1 to 5. All analyses used 2x2 ANOVAs modeling effects of group (ADHDy vs. ADHDn) and condition (restriction vs. optimization).
Results: For performance on Days 1 and 5, we found no significant main effects or interactions (all p's>=.09, ηp^2's=<.07), and a trending main-effect of group at Day 1. With respect to change in performance (Day 5 - Day 1), we found a significant main-effect of condition (F(1,41)=4.30, p=.04, ηp^2=.09), such change in performance during the restriction condition (0.68±0.24 points) was higher overall than during the optimization condition (-0.03±0.3 points), and a trending main-effect of group (F(1,41)=3.73, p=.06, ηp^2=.08), but no condition-x-group interaction (F(1,41)=0.01; p=.92; ηp^2=.00). Post-hoc tests indicated performance in the ADHDy group increased from Day 1 to 5 during sleep restriction (1.10±1.58 points; t(20)=-3.18; p=.01; d=1.58) but not during sleep optimization (.09±2.24 points; t(22)=-0.19; p=.85; d=-.039). ADHDn group performance did not change across either condition (p's >.23).
Conclusion: These analyses examine whether ADHD symptoms moderate the impact of 5-nights of insufficient sleep on academic performance. We identify paradoxical improvements across sleep restriction but only in youth with high ADHD symptoms. We will next examine how compensatory factors such as hypervigilance may explain these results.

SUBSTANCE USE AND SLEEP ISSUES: FINDINGS FROM AN INTERNET GAMING ADDICTION STUDY ON JAMAICAN ADOLESCENTS

Jasmine Davis[1], Anuradha Ramdas[1], Josef Thomas[2], Gerren Austin[2], Avril Dailey[2], Ken-Garfield Douglas[2], Janelle Greene[2], Marvin Reid[2], Winston De La Haye[2], Denise Vidot[1]

[1] University of Miami, [2] University of the West Indies

Introduction: Addiction and sleep disorders are a problem due to its impact on sleep physiology. We evaluated substance use, gaming addiction, and sleep issues among adolescents.
Methods: Data are from a 3-stage stratified cluster-sample of Jamaican students (N=358; 14.8y (2.2), 54.2% female, 45.8% male) in one highschool. Measures included Patient Health Questionnaire-9, Car, Relax, Alone, Forget, Friends, Trouble Screening Tool, Gaming Addictions Scale for Adolescents, and demographics. STATA 18 analyzed data via Chi-square and logistic regression.
Results: Sleep was associated with "who you live with" (p=0.010), parental marital status (p=0.046), and substance use (p< 0.001). Of the 14.5% of substance consumers, moderate users (59.6%) reported sleep issues more frequently than severe users (23.1%, p=0.010). There was a significant association between sleep, substance use, and internet gaming addiction (p=0.0002). Moderate substance users had a 3.13 higher odds of sleep issues than non-users (95% CI=1.39, 7.07). Severe substance users had 9.42 higher odds of reporting sleep issues than non-users (95% CI=1.21, 73.59). Odds of sleep issues in students with internet-gaming-addiction was 1.62 higher than those without internet-gaming-addiction (p=0.048).
Conclusion: Findings suggest that substance use and internet gaming addiction are potential risk factors for sleep issues among adolescents. Further studies should focus on parental marital status, substance use, who you live with, and internet gaming addiction in adolescents who exhibit sleep related issues.

NOCTURNAL LONELINESS: EXPLORING A UNIQUE SYMPTOM OF INSOMNIA AND ITS LINK TO SUICIDAL IDEATION FREQUENCY

Dustin Sherriff[1], Daniel Kay[1]

[1] Brigham Young University

Introduction: Nocturnal loneliness—feeling disconnected and isolated when awake at night—is a commonly overlooked symptom of insomnia with potential implications for its course, prognosis, and treatment. Both loneliness and insomnia are associated with suicidality, and prior research has found a strong link between being awake at night and increased suicidality. This study aimed to validate a novel Nocturnal Loneliness Scale (NLS) and examine whether nocturnal loneliness uniquely mediates the relationship between insomnia severity and suicidal ideation.
Methods: A total of 442 participants (ages 18–80, M = 46) completed an online survey via Qualtrics. Measures included demographics, NLS, the 20-item UCLA Loneliness Scale (general loneliness), the Insomnia Severity Index, the Frequency of Suicidal Ideation Index (past year), and the Patient-Reported Outcomes Measurement Information System (PROMIS) Depression Short Form. The NLS factor structure was examined using exploratory and confirmatory factor analyses. Structural equation modeling tested whether nocturnal loneliness mediates the relationship between insomnia severity and suicidal ideation frequency while accounting for general loneliness, depression, and demographic variables.
Results: The NLS demonstrated a single-factor structure with excellent reliability (Omega =.97). Insomnia severity was significantly associated with suicidal ideation frequency (p <.001). Both nocturnal and general loneliness significantly mediated this relationship (p <.01 for both). However, when depression was included as a mediator, it fully accounted for these relationships (p <.001).
Conclusion: Our findings replicate the established association between insomnia severity and suicidal ideation frequency. Nocturnal loneliness, while distinct from general loneliness, was not uniquely associated with suicidality beyond the influence of depression. Depression emerged as the strongest mediator, suggesting that insomnia's impact on suicidal ideation is primarily explained through depressive symptoms, and not through loneliness. Although nocturnal loneliness warrants further exploration as a unique symptom of insomnia, its role in frequency of suicidal ideation appears secondary to depression.

THALAMO-TEMPORAL FUNCTIONAL CORRELATES OF THE SLEEP-SUICIDAL IDEATION ASSOCIATION

Jolynn Jones[1], Daniel Kay[2]

[1] University of Rochester Medical Center, [2] Brigham Young University

Introduction: Suicide claims nearly 800,000 lives annually, profoundly impacting millions worldwide. Addressing suicide risk requires identifying mechanisms of modifiable factors, such as sleep disturbances including insomnia and nightmares, which are both common and strongly linked to suicidality. We hypothesize that sleep disturbances increase neural activity during sleep, disrupting its restorative processes and leading to brain region-specific impairments in daytime functioning. This pilot study investigated functional brain differences across wake and sleep in relation to sleep disturbances and suicidality.
Methods: Participants included individuals with recent suicidal ideation (SI; n=10) and those with no history of suicidal ideation (NSI; n=13). All participants completed 10+ days of sleep diaries, sleep and mood questionnaires, overnight ambulatory polysomnography, and wake and sleep electroencephalography-functional magnetic resonance imaging (EEG-fMRI). Ten minutes of wake in the morning scan and ten minutes of sleep following self-reported sleep onset from the evening scan were used in the analysis. Key measures included the Insomnia Severity Index (ISI), Disturbing Dream and Nightmare Severity Index (DDNSI), Patient Health Questionnaire (PHQ-9), and Frequency of Suicidal Ideation Inventory (FSII). Functional connectivity changes from wake to sleep were analyzed using seed-to-voxel analyses in the CONN Toolbox, with regions of interest including the anterior cingulate (caudal and rostral), insula, middle frontal

gyrus, posterior cingulate, thalamus, amygdala, and orbitofrontal cortex.
Results: The SI group exhibited smaller functional connectivity changes from wake to sleep, that was specific to the right thalamus to the left (t = 6.1, p-FDR < 0.001) and right superior/middle temporal regions (t = 5.37, p-FDR < 0.001).
Conclusion: Reduced functional connectivity changes in the thalamo-temporal regions among the SI group support the local sleep deprivation hypothesis, suggesting that deficits in auditory processing may be diminished during wakefulness and/or hypervigilant during sleep. These findings underscore the role of thalamic dysfunction during sleep as a potential mechanism through which sleep disturbances are associated with suicide risk, highlighting the importance of targeting specific brain mechanisms during sleep in suicide prevention efforts.

EXAMINING THE RELATIONSHIP BETWEEN DEFENSE STYLES AND RISK-TAKING PROPENSITY AMONG SLEEP-DEPRIVED SUBJECTS

Natisha Charoenmins[1], Alisa Huskey[1], Kathryn Kennedy[1], Sarah Green[2], William Killgore[1]
[1] The University of Arizona, [2] University of Arizona

Introduction: There is considerable inter-individual variability in risk-taking propensity during sleep deprivation. We hypothesized that Defense Styles – an individual's response to perceived stressors, which have the function of alleviating discomfort or distress – assessed prior to sleep deprivation would predict risk-taking propensity when it was presented.
Methods: Thirty-three healthy participants completed the Defense Styles Questionnaire-40 (DSQ-40) prior to 32 hours of total sleep deprivation. The DSQ-40 measures 20 different defenses. The Balloon Analogue Risk Task (BART) was administered at two time-points: 14:15 on Day 1 (after a normal night of sleep), and 14:15 on Day 2 (after 32 hours of sleep deprivation). Participants experienced either neutral (n=15) or negative (n=18) mood inductions between the two BART administrations. Adjusted average number of pumps was used as a measure of risk-taking propensity. A stepwise regression was used to determine whether specific defenses predicted risk-taking propensity.
Results: There was a significant association between Splitting and risk-taking propensity ($F(1,31)=8.80$, $R2=.22$, $p=.006$). Additionally, a combination of five defenses predicted risk-taking propensity during sleep deprivation, but only within the negative mood-induction condition (Suppression, Rationalization, Passive Aggression, Idealization, and Splitting: $F(5,12)=22.62$, $R2=.90$, $p<.001$). Greater Suppression ($\beta=.53$, $t(17)=4.21$, $p=.001$), lower Rationalization ($\beta=-.53$, $t(17)=-4.83$, $p<.001$), lower Passive Aggression ($\beta=-.48$, $t(17)=-4.48$, $p<.001$), lower Idealization ($\beta=-.50$, $t(17)=-4.84$, $p<.001$), and greater Splitting ($\beta=.28$, $t(17)=3.07$, $p=.010$) predicted increased risk-taking following sleep deprivation.
Conclusion: Splitting predicted increased risk-taking propensity when the sample was examined as a whole. Greater suppression, lower rationalization, lower passive aggression, lower idealization, and greater splitting were predictors of increased risk-taking propensity among those in the negative mood-induction condition. When under the stress of sleep deprivation, those who make efforts to avoid confronting negative emotions and adopt polarizing views tend to take greater risks when sleep-deprived. However, those who justify their past behaviors, indirectly express negative emotions, and view others in an excessively positive way tend to take lower risks when sleep-deprived. These findings suggest that individual emotional coping strategies are associated with risk-taking behavior during sleep deprivation.

BIDIRECTIONAL PREDICTORS BETWEEN BASELINE AND RECOVERY SLEEP AND CORTISOL AND C-REACTIVE PROTEIN DURING SLEEP LOSS

Lauren Pasetes[1], Namni Goel[1]
[1] Rush University Medical Center

Introduction: We determined whether baseline sleep measures obtained the night before total sleep deprivation (TSD) predicted two common biological metabolites, cortisol and high-sensitivity C-reactive protein (CRP), during TSD and psychological stress. We also assessed whether these markers predicted subsequent sleep measures during recovery.
Methods: We conducted a five-day experiment under highly controlled conditions in 32 healthy adults (ages 27-53; 14 females). Cortisol via saliva samples and CRP via blood samples were collected: 1) after two baseline 8h time in bed (TIB) nights (B1, B2); 2) during TSD morning (TSD AM; after 25h of TSD); 3) during TSD evening following a modified Trier Social Stress Test, which induced psychological stress (TSD PM; after 34h of TSD); and 4) after two recovery nights of 8-10h TIB (R1, R2). For CRP, undetectable samples were assigned half of the minimum detectable value. Wrist actigraphy assessed sleep indices during the B2 and R1 nights. Simple linear regression assessed predictive relationships between B2 and R1 sleep metrics and TSD AM and TSD PM cortisol and CRP metrics ($p< 0.05$ was significant).
Results: Greater B2 sleep efficiency significantly predicted both lower TSD AM ($r=-0.399$; $\beta=-0.159$) and PM ($r=-0.391$; $\beta=-0.172$) CRP levels, explaining 15.3%-16.0% of the CRP variance. Notably, B2 sleep measures did not significantly predict TSD cortisol concentrations. Greater TSD AM cortisol levels significantly predicted longer R1 sleep onset latency ($r=0.388$; $\beta=6.390$) and later R1 sleep onset ($r=0.517$; $\beta=1.021$), while greater TSD PM cortisol concentrations significantly predicted earlier R1 sleep offset ($r=-0.469$; $\beta=-1.573$). In addition, both greater TSD AM ($r=-0.532$; $\beta=-106.927$) and PM ($r=-0.486$; $\beta=-121.308$) cortisol levels significantly predicted shorter R1 sleep duration. Overall, TSD AM and PM cortisol levels predicted 15.1%-28.3% of the variance in R1 sleep measures. By contrast, TSD CRP concentrations did not significantly predict R1 sleep measures.
Conclusion: Our novel results demonstrate that baseline sleep measures uniquely predicted CRP, but not cortisol levels during TSD and psychological stress. By contrast, cortisol, but not CRP levels during TSD and psychological stress predicted recovery sleep metrics. Thus, our results underscore crucial relationships, mechanisms and biomarkers between sleep health, inflammatory, and hypothalamic-pituitary-adrenal axis indicators.

THREE DAYS OF SLEEP RESTRICTION INCREASES 24-HOUR GLUCOSE LEVELS IN HEALTHY YOUNG ADULTS AS MEASURED BY CONTINUOUS GLUCOSE MONITORING

Robin Yuan[1], Kirsi-Marja Zitting[1], Wei Wang[1], Frank Scheer[2], Jonathan Williams[1], Jeanne Duffy[3], Charles Czeisler[4]

[1] Brigham and Women's Hospital, [2] Brigham and Women's Hospital, [3] Brigham & Women's Hospital, Harvard Medical School, [4] Harvard Medical School

Introduction: The adverse effect of sleep restriction on glucose metabolism is now well-established. Most prior reports used measures of insulin sensitivity or glucose tolerance at a specific time point following sleep restriction; for example, by conducting a euglycemic-hyperinsulinemic clamp or oral/intravenous glucose tolerance test after exposure to sleep restriction. With the advent of continuous glucose monitoring (CGM), it is now possible to obtain a highly granular assessment of the glucose response to sleep loss across longer periods of time. Thus far, few studies have used CGM to examine glucose responses following sleep loss.
Methods: 10 healthy young adults (30.5±4.7y, 4F) participated in an inpatient study of sleep restriction. CGM was recorded during three baseline days (10h overnight sleep opportunity) and three days of sleep restriction (10h overnight time-in-bed, 5h sleep opportunity, centered). Interstitial glucose measurements were taken every 15 min over the course of each day. All participants lived in the laboratory for at least four days prior to the baseline measurement. Macronutrient content and clock timing of meals were matched between baseline and sleep restriction. Mixed models were used to analyze the outcomes.
Results: We found a significant ~5.0% increase in 24-hour glucose area-under-the-curve (AUC) during three days of sleep restriction compared to three days of baseline (p=0.0028). We also examined 10h overnight glucose AUC and 14h daytime glucose AUC separately and found that both were significantly higher during sleep restriction compared to baseline (+5.8% overnight, p=0.0203 and +4.6% daytime, p=0.0031).
Conclusion: Sleep restriction significantly increased 24-hour, overnight, and daytime glucose AUC in healthy young adults. Given the widespread prevalence of sleep insufficiency, even short durations of insufficient sleep may contribute to the development of metabolic disorders such as type 2 diabetes.

PERCEIVED SLEEPINESS AND OBESITY RISK: EFFECT OF EXCESSIVE DAYTIME SLEEPINESS ON ADOLESCENTS' FOOD CHOICES AND SEDENTARY ACTIVITY

Afton Beard[1], Zack Crane[1], Alec Harlow[1], Jamon Jex[1], Daniel Kay[1], Kara Duraccio[1]

[1] Brigham Young University

Introduction: Adolescence is a critical period of development with increased risk for disrupted sleep and obesity. Current research suggests insufficient sleep duration and quality are associated with obesogenic behaviors such as increased intake of calories, carbohydrates, and added sugar and sedentary activity. However, research on the relationship between excessive daytime sleepiness (EDS) and obesogenic behaviors is limited. We hypothesize that higher EDS will be positively associated with carbohydrate intake, added sugar intake, and sedentary activity and negatively associated with physical activity in adolescents.
Methods: Data was collected across three separate studies. Ninety-nine adolescents (ages 14-18; 86.8% European American; 50.5% female) wore Actiwatch 2 wrist accelerometers (for sleep measurement) and an ActiGraph GT3x+ (for sedentary/physical activity measurement) across a 7-10 day monitoring period; during this monitoring period, they also completed 2-3 dietary recalls (the Automated Self-Administered 24-hour Dietary Assessment Tool) and completed the Epworth Sleepiness Scale (ESS). Partial correlation analyses were run to examine associations between daytime sleepiness and dietary intake and physical activity while controlling for sleep duration (measured by accelerometry) and sleep quality (measured by the Pittsburgh Sleep Quality Index). An independent sample t-test was run to examine differences between EDS groups (high sleepiness: ESS≥10; low sleepiness: ESS< 10) and dietary intake and physical activity.
Results: While controlling for sleep duration and quality, there was no association between ESS scores and total kilocalories (p=.607), grams of carbohydrates (p=.805), and added sugars (p=.108) or minutes spent in sedentary (p=.835), light (p=.399), or moderate-vigorous physical activity (p=.533). There was no difference between those with higher EDS (ESS≥10) and those with lower EDS in total kilocalories (p=.706), grams of carbohydrates (p=.807), and added sugar consumption (p=.487) or minutes spent in sedentary (p=.904), light (p=.729), or moderate-vigorous physical activity (p=.477).
Conclusion: Excessive daytime sleepiness is not associated with macronutrient intake and physical activity when controlling for sleep duration and sleep quality, suggesting that feeling sleepy may not be the driving mechanism linking poor sleep with increased obesogenic behaviors.

PHYSICAL ACTIVITY AND DIETARY QUALITY ARE ASSOCIATED WITH SLEEP-RELATED IMPAIRMENT AMONG RURAL AND URBAN LATINOS

Ziyi Ding[1], Joon Chung[2], Dunia Mejia[3], Jasmine Rubio[1], Camila Pow-Sang[1], Stacyca Dimanche[1], Mary Carrasco[4], Laurent Garchitorena[1], Carolina Scaramutti[2], April Rogers[5], Ricardo M. Osorio[6], Ferdinand Zizi[1], Alberto Ramos[2], Girardin Jean-Louis[7], Azizi Seixas[7]

[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Miami, [3] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [4] Lincoln Memorial University Debusk College of Osteopathic Medicine, [5] St. John's University, [6] NYU Langone Health, [7] University of Miami Miller School of Medicine

Introduction: Despite the increasing use of lifestyle interventions to improve sleep and related outcomes, gaps remain regarding the associations between lifestyle factors, such as physical activity and dietary quality, and sleep-related functioning or impairment in specific populations. This study examines associations

between physical activity and dietary habits on Sleep-Related Impairment (SRI) among rural and urban Latinos.
Methods: 613 participants from rural and urban areas of Florida in the Determinants, Outcomes, Responses, and Markers of Insufficient Sleep in Rural-Urban settings study (DORMIR). Physical activity was measured using the Leisure Score Index (LSI) from the Godin-Shephard Leisure-Time Physical Activity Questionnaire; higher scores indicate greater physical activity. Dietary quality was assessed using the Rapid Eating Assessment for Participants-Shortened Version (REAP-S); higher scores indicate higher dietary quality. SRI was assessed using the PROMIS Sleep-Related Impairment Short Form 4a; higher scores reflect more impairment. Both LSI and REAP-S scores were standardized to compare effect sizes. SRI scores were regressed on LSI and REAP-S scores in a linear regression, adjusting for covariates including age, gender, education, race, Hispanic ethnicity, marital status, employment, income, and language.
Results: After adjusting for covariates, a standard deviation increase in LSI (mean = 5.61, SD = 4.87, range = 0–21), reflecting greater physical activity, was significantly associated with a 0.09-unit decrease in SRI (β = -0.09; 95% Confidence Interval [CI]: -0.15 to -0.02; P = 0.008). Similarly, a standard deviation increase in REAP-S score (mean = 27.03, SD = 3.84, range = 14–36), indicating better dietary quality, was significantly associated with a 0.11-unit decrease in SRI (β = -0.11; 95% CI: -0.20 to -0.03; P = 0.007).
Conclusion: Greater physical activity and higher dietary quality are significantly associated with reduced SRI among rural and urban Latinos, with a slightly stronger association for dietary quality. While the effect sizes are modest, they suggest that lifestyle interventions focused on improving diet and physical activity could effectively address SRI. Further studies are needed to explore additional lifestyle factors and their potential to improve sleep and related outcomes.

ASSOCIATION FOUND BETWEEN DIET AND SLEEP QUALITY: INSIGHTS FROM REAP SCORES AND INSOMNIA SEVERITY IN A LATINO POPULATION IN FLORIDA

Jasmine Rubio[1], Joon Chung[2], Ziyi Ding[1], Dunia Mejia[3], Camila Pow-Sang[1], Stacyca Dimanche[1], Laurent Garchitorena[1], Mary Carrasco[4], Carolina Scaramutti[2], Alberto Ramos[2], April Rogers[5], Sujata Thawani[6], Ferdinand Zizi[1], Girardin Jean-Louis[7], Azizi Seixas[7]

[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Miami, [3] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [4] Lincoln Memorial University Debusk College of Osteopathic Medicine, [5] St. John's University, [6] NYU Langone Health, [7] University of Miami Miller School of Medicine

Introduction: While substantial evidence links healthy dietary patterns to reduced insomnia symptom prevalence, the specific impact of diet on insomnia severity within the Latino/a population remains underexplored. This study seeks to address this gap by examining the relationship between dietary habits, assessed through the Rapid Eating Assessment for Participants (REAP) score, and insomnia severity, measured by the Insomnia Severity Index (ISI).
Methods: This work utilized data from the NIH-funded DORMIR study, investigating determinants of sleep and heart health outcomes among urban and rural Latinos/as living in Florida. A sample of 603 participants completed the Rapid Eating Assessment for Participants (REAP-S) and Insomnia Severity Index (ISI) capturing their diet and sleep quality measures. The respondents had a mean age of 41.6 years (±16.6), with 399 females and 204 males. A linear regression analysis was performed to determine if the quality of a participant's diet is associated with insomnia severity. Models were adjusted for age, sex, race/ethnicity, Hispanic origin, education, income, employment, Body Mass Index, and whether participants responded in English or Spanish.
Results: A one-unit increase in REAP diet scores was associated with a -0.24 decrease in ISI scores, after adjustment (β [95% Confidence Interval] (95% CI) = -0.24 [-0.37, -0.12], p< 0.001). Notably, those responding in Spanish independently had higher ISI scores (β [95% CI] = 1.59 [0.58, 2.61], p =0.002).
Conclusion: The results indicate that a healthier diet is significantly associated with lower ISI scores among a diverse group of Hispanic adults in South Florida. These results underscore the importance of culturally and linguistically tailored public health strategies to address insomnia across diverse populations.

RELATIONSHIP BETWEEN RELIGIOUS FREQUENCY AND SLEEP LATENCY AMONG BLACK ADULTS

April Rogers[1], Elizabeth Mirabal[2], Nina L'Houtellier[3], Aisha Severe[2], Matthew Coppello[2], Sadeaqua Scott[3], Guithele Ruiz-Nicolas[2], Azizi Seixas[4], Girardin Jean-Louis[4]

[1] St. John's University, [2] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [3] University of Miami, [4] University of Miami Miller School of Medicine

Introduction: Religion has influenced society for centuries and research suggests it may also impact sleep health through various pathways. These pathways include religious coping strategies, such as prayer and meditation, which promote relaxation and reduce stress, as well as religious involvement that fosters social support and mental well-being, improving sleep. Additionally, religious involvement often fosters social support and enhances mental well-being, both of which contribute to improved sleep. However, research on minoritized groups is limited, highlighting a gap in understanding sleep health disparities. This study aims to explore the impact of religious frequency on sleep health among Black adults, using sleep latency as a key indicator of sleep quality and overall well-being.
Methods: The data was collected in collaboration with two NIH-funded observational studies, investigating sleep and health disparities among Black and African American individuals (N=318, 62.4% females, aged 51.5±33.5 years) in South

Florida. Over a 7-day period, sleep metrics were collected using a wearable device known as the Sleep Image Ring. The device provided data used to access sleep latency, alongside subjective baseline questionnaire data. The baseline questionnaire gathered demographic information, including religion practiced, place of worship attendance, and frequency of religious participation. A linear regression analysis was conducted to analyze the relationship between sleep latency and religious frequency, controlling age and gender. All analysis was performed using RStudio 4.3 3.
Results: The regression analysis revealed a significant association between religious frequency and sleep latency (r2 =.01, 95% CI: [63.86, 892.29]). These findings suggest that individuals who attended a place of worship experienced longer sleep onset times compared to those who did not attend. This finding suggests that religious involvement may impact sleep patterns, particularly sleep onset, though the small R-squared value indicates other unaccounted factors may also influence this relationship.
Conclusion: Results indicate that Black adults who attended a place of worship more frequently take longer to fall asleep. These findings provide an insight into how religious practices may influence sleep patterns. Further research is needed to explore the underlying factors contributing to this association and to determine its practical significance in relation to sleep quality.

SLEEP DURATION, EFFICIENCY, AND NOCTURNAL BLOOD PRESSURE AMONG A SAMPLE OF PARTICIPANTS WITH SHORT SLEEP DURATION AND ELEVATED BLOOD PRESSURE

Joshua Landvatter[1], Adam Bress[1], Jennifer Duffecy[2], Molly Conroy[1], Sara Simonsen[1], Chelsea Allen[1], Tom Greene[1], Christopher Sparks[1], Kelly Baron[1]
[1] University of Utah, [2] UIC Resliency Center

Introduction: Multiple aspects of sleep, including duration and efficiency, are important for blood pressure (BP) regulation and cardiovascular health. While prior research links sleep efficiency (SE) and total sleep time (TST) to BP outcomes, less is known about these associations among populations with chronic short sleep duration. This study examined associations between SE, TST, and 24-hour ambulatory BP in individuals with elevated BP and sleep duration < 7 hours per night.
Methods: Participants were screened for a randomized sleep extension intervention among individuals with elevated BP (□120 mmHg systolic and/or 80 mmHg diastolic) and habitual short sleep. SE and TST were measured via 7-day wrist actigraphy. Participants completed 24-hour ambulatory BP monitoring, with variables including average awake and asleep SBP/DBP and dipping ratios (asleep BP/awake BP, classified as non-dipping if ≥0.9). Associations between sleep and BP outcomes were analyzed using linear regression for continuous outcomes (e.g., SBP, DBP, dipping ratios) and Poisson regression with a log-link for binary outcomes (e.g., Asleep Hypertension, Non-Dipping SBP, Non-Dipping DBP). Two models were tested: Model 1 (unadjusted) and Model 2 (adjusted for age, sex, and race).
Results: The study included 114 participants (mean age: 42 years, SD: 11; 40% female). Longer TST was significantly associated with more favorable nocturnal BP measures. For every 10-minute increase in TST, the odds of Asleep Hypertension decreased by 6.3% (OR = 0.937, 95% CI [0.896, 0.980], p = 0.009), and the odds of Non-Dipping DBP decreased by 8.7% (OR = 0.913, 95% CI [0.844, 0.990], p = 0.031). SE was significantly associated with DBP Dipping Ratio in unadjusted models (b = 0.0035, 95% CI [0.0001, 0.0068], p = 0.040) but was marginal after adjustment (b = 0.0033, p = 0.059). Neither TST nor SE were associated with awake BP measures.
Conclusion: Longer TST was consistently associated with better nocturnal BP, including lower odds of asleep hypertension and non-dipping DBP. The relationship with SE and BP values diminished significance after adjustment, suggesting confounding. Results align with prior literature, highlighting the importance of promoting adequate sleep duration to mitigate cardiovascular risks in populations with short sleep and elevated BP.

ASSOCIATIONS OF OBJECTIVELY MEASURED SLEEP RESTRICTION-REBOUND PATTERNS WITH ALL-CAUSE MORTALITY

Xiaoyu Li[1], Manrui Zhang[1], Zhenyu Li[1], Shengkui Zhang[1]
[1] Department of Sociology, Tsinghua University

Introduction: Clinical guidelines recommend 7–9 hours of regular sleep and weekend catch-up sleep following weekday sleep deficits for optimal health. However, real-world sleep patterns are more complex than laboratory-studied models or simple weekday-weekend cycles. The associations of day-to-day sleep restriction-rebound patterns with mortality remain poorly understood.
Methods: In this prospective cohort study of 85,881 UK Biobank participants, we analyzed accelerometer-derived objective sleep data and identified five sleep restriction-rebound patterns: regular sleep, mild sleep restriction (SR) without rebound, mild SR with rebound, SR without rebound, and SR with rebound. Using Cox proportional hazards regression models, we examined their associations with all-cause mortality across short, medium, and long baseline sleep durations.
Results: The mean (SD) age was 61.8 (7.9) years; 56.4% were female. Compared to regular sleep, SR without rebound was significantly associated with increased mortality risk across all groups (adjusted HR for short sleepers = 1.43, 95% CI = 1.22-1.68; for medium sleepers = 1.49, 95% CI = 1.08-2.04; for long sleepers = 1.72, 95% CI = 1.20-2.47). Mild SR without rebound was associated with mortality only in short sleepers (HR = 1.22, 95% CI = 1.05-1.42). The presence of sleep rebound mitigated these risks. Among long sleepers, the associations were stronger in men than in women.
Conclusion: Our findings suggest that short-term sleep restriction might be detrimental, particularly for short sleepers, and highlight sleep rebound as a potential strategy to reduce mortality risk in vulnerable groups.

IMPACT OF INSUFFICIENT SLEEP ON RESPIRATORY QUOTIENT AND SUBSTRATE UTILIZATION

Luisa Marot[1], Dana Withrow[2], Christopher M. Depner[3], Edward Melanson[4], Janine Higgins[4], Kenneth Wright[2]
[1] Sleep and Chronobiology Laboratory, Departament of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado,

USA, [2] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA, [3] University of Utah, [4] University of Colorado Anschutz Medical Campus

Introduction: Overeating and insufficient sleep have been reported to increase total daily carbohydrate utilization. Here we evaluated substrate utilization over 24h and specifically during nighttime hours under insufficient sleep conditions.
Methods: Thirty-six healthy participants (18 women/18 men) aged 25.5±4.7y (mean±SD), with normal body mass index (BMI) 22.4±1.7kg/m2 completed a 13-16 day in-laboratory study. Participants were randomly assigned to one of three groups with different sleep opportunities simulating two work weeks (WW1 and WW2) and one weekend between them. After three baseline (BL) laboratory days of 9h sleep opportunity per night, participants in the control group (n=8) were scheduled to 10 days of 9h sleep opportunity; the sleep restriction (SR) group (n=14) were scheduled to 10 days of 5h sleep opportunity, and the weekend recovery (WR) group (n=14) were scheduled to five days of 5h sleep opportunity (WW1) followed by two days of ad libitum weekend recovery sleep, followed by three days of 5h sleep opportunity (WW2). Participants were provided an energy balanced diet for three days prior to laboratory admission and continued for the three BL days. Food intake was ad libitum during WW1 and WW2. Whole room indirect calorimetry assessed hourly substrate utilization on days 3 (BL), 5 (WW1) and 11 (WW2). Respiratory quotient (RQ), fat and carbohydrate utilization were assessed by oxygen consumption and carbon dioxide production. Differences in RQ and substrate utilization throughout the 24h were analyzed within groups across BL, WW1 and WW2.
Results: Sleep restriction significantly ($p < 0.05$) increased carbohydrate utilization, especially during the 4h prior to bedtime, during WW1 (SR: 0.28g.min-1±0.02 and WR: 0.31g.min-1±0.02) and WW2 (SR: 0.30g.min-1±0.02 and WR: 0.31g.min-1±0.02)compared to baseline (SR: 0.15 g.min-1±0.02 and WR: 0.14g.min-1±0.02) for SR and WR groups. Additionally, the 24h RQ and 24h carbohydrate utilization were higher for the WR group in WW2 compared to BL ($p < 0.05$).
Conclusion: Insufficient sleep under conditions of ad libitum food intake appears to increase nighttime carbohydrate utilization prior to bedtime. These findings contribute to our understanding of how insufficient sleep alters energy metabolism in humans.

SUBCORTICAL DYNAMICS DURING FAILURES IN MAINTAINING ALERTNESS AFTER SLEEP RESTRICTION IN THE HUMAN BRAIN

Ewa Beldzik[1], Daniel Gomez[2], Nicholas Cicero[1], Zinong Yang[1], Juan Iglesias[1], Brian Edlow[2], Laura Lewis[1]
[1] Massachusetts Institute of Technology, [2] Massachusetts General Hospital

Introduction: Sleep restriction significantly impairs our ability to maintain alertness during tasks, leading to delayed responses, omissions, and even microsleeps. However, the neural mechanisms underlying these periods of extreme drowsiness and the subsequent recovery of alertness remain poorly understood. While previous fMRI studies have focused primarily on cortical and thalamic regions, these areas may reflect the downstream consequences of dysregulated arousal mechanisms originating in the brainstem and hypothalamus, as highlighted by extensive animal research. Due to their small size and deep location, high-resolution imaging of these critical brain structures in humans has been challenging.
Methods: This study aimed to address these challenges by using ultra-high-field (7T) fMRI to assess activity in brain regions essential for sleep-wake regulation during a simple attention task (psychomotor vigilance task) in sleep-restricted individuals (n=25). Advanced subcortical segmentation techniques were employed to analyze hemodynamic activity linked to the first omission trial (a marker of drowsiness onset) and the first alert trial following an omission (a marker of regaining alertness), across all nuclei of the ascending arousal network (AAN).
Results: Our findings revealed a significant reduction in activity across all AAN regions during the transition into drowsiness, with the exception of the tuberomammillary nucleus of the hypothalamus, which showed increased activity. Upon regaining alertness, a marked increase in fMRI signal was observed across all AAN regions, except in the hypothalamic preoptic area, where activity decreased in line with its role in promoting wakefulness. Notably, the brain activity during these transitions was modulated by the duration of the drowsiness period. Additionally, we observed distinct temporal characteristics of hemodynamic activity across AAN regions, such as variations in the number of peaks and troughs, their latency, and width, suggesting local neuromodulatory influences on fMRI signals.
Conclusion: These results offer valuable insights into the complex interactions between cortical and subcortical circuits that regulate attentional lapses following sleep restriction. This research represents a crucial step toward understanding the neural circuit dynamics underlying sleep disorders such as hypersomnolence and insomnia, and provides a scientific foundation for future clinical studies exploring diagnostics, disease mechanisms, and therapeutic targets.

TRAIT EXTRAVERSION PREDICTS PSYCHOMOTOR VIGILANCE PERFORMANCE AND CHANGES IN FUNCTIONAL CONNECTIVITY DURING SLEEP DEPRIVATION

Allie Jepson[1], David Negelspach[1], Alisa Huskey[1], Jason Katz[2], Salma Patel[1], William Killgore[1]
[1] The University of Arizona, [2] University of Arizona

Introduction: Individual differences in resilience to sleep deprivation may be influenced by personality type. Previous research indicates a relationship between the NEO Personality Inventory's (NEO-PI) Extraversion measure and decline in Psychomotor Vigilance Test (PVT) performance over a period of sleep deprivation. Here, we examined the association between resilience to sleep deprivation, as measured by PVT performance, and Extraversion subscores on the NEO-PI. We further examined their relationship to the underlying functional connectivity within the brain to elucidate neural components of resilience.
Methods: Healthy participants (n=20; Age=23.1, SD=3.7) underwent a 39-hour sleep deprivation period in which PVT,

and functional magnetic resonance imaging (fMRI) scans were conducted every 6 hours to measure alertness and functional connectivity, respectively. A week prior to the in-lab visit, the NEO-PI was administered as a baseline personality inventory. To determine how Extraversion personality traits relate to sleep deprivation task performance, we calculated the difference in mean PVT reaction time from baseline to the most sleep deprived states and correlated this with individual Warmth scores. A covariate of interest analysis correlated fMRI connectivity with each participant's PVT difference scores. The medial prefrontal cortex (mPFC) was chosen as the primary seed region based on its role in personality traits such as Extraversion.

Results: We found a significant positive correlation between Warmth personality scores and change in mean PVT response time ($P = 0.049$, $R = 0.38$). Functional connectivity analysis showed the personality trait of Warmth was associated with reduced functional connectivity between mPFC and anterior cingulate cortex (ACC) when comparing baseline fMRI scans to scans at the end of the sleep deprivation period.

Conclusion: Consistent with prior research, individuals with higher scores on the Warmth component of Extraversion were less resilient to sleep loss, as evident by their slowing of PVT reaction time. This change was also associated with decreased functional connectivity between mPFC and ACC. Given the mPFC's role in emotional regulation and the ACC's role in error monitoring and decision making, these results suggest that future research explores emotional resilience to sleep loss, connecting both top-down cognitive functioning and behavior adjustment.

NEURAL CORRELATES OF PUTAMEN CONNECTIVITY AND ITS ASSOCIATION WITH COGNITIVE OUTCOMES FOLLOWING SLEEP DEPRIVATION

Jungwon Cha[1], Alisa Huskey[1], David Negelspach[1], Kathryn Kennedy[1], William Killgore[1]

[1] The University of Arizona

Introduction: Sleep deprivation (SD) is known to impair cognitive functions, particularly attention and vigilance, but these effects often vary widely across individuals and the neurobiological substrates underlying these individual differences remain to be elucidated. The psychomotor vigilance test (PVT) is commonly used to measure lapses in attention, which are often reflected in reaction time. The putamen, a key region in motor control and attention, is hypothesized to play an important role in cognitive fatigue during SD. This study examines the relationship between resting-state functional connectivity (RSFC) of the putamen and attentional lapses following SD.

Methods: Forty-four participants (22 males, 22 females; ages 21–43, mean = 25.1, SD = 5.6) underwent a 24-hour period of SD. Attentional lapses were assessed using the PVT, administered hourly for a total of 17 sessions. The total number of lapses across all 17 sessions was calculated for each participant, and the square root of this value (Sqrt_Lapse) was used as a single measure of cognitive decline during SD. Resting-state fMRI scans were conducted at baseline to analyze RSFC using the putamen as the seed region. Correlations between RSFC and Sqrt_Lapse were explored. Structural analyses were performed using Freesurfer to assess the volume and surface area of relevant regions.

Results: Sqrt_Lapse was positively correlated with RSFC between the putamen and lateral orbitofrontal cortex (OFC; voxel-wise threshold $p < .001$, cluster-wise corrected $p < .03$). This suggests that higher connectivity in this network was linked to increased attentional lapses. Structural analysis showed no significant correlation between putamen volume and Sqrt_Lapse ($p = 0.867$), but there was a significant negative correlation between lateral OFC surface area and Sqrt_Lapse ($p = 0.001$), indicating that individuals with a smaller lateral OFC surface area exhibited more cognitive lapses.

Conclusion: These findings suggest that increased putamen-lateral OFC connectivity may indicate a compensatory or inefficient response to SD, while reduced lateral OFC surface area represents a structural vulnerability to vigilance declines during acute sleep deprivation. These results highlight the importance of fronto-striatal networks in understanding individual differences in cognitive resilience during SD.

STRUCTURAL CHANGES IN VISUAL CORTEX AND COGNITIVE DECLINE DURING SLEEP DEPRIVATION

Jungwon Cha[1], David Negelspach[1], Alisa Huskey[1], Kathryn Kennedy[1], Jason Katz[2], Kymberly Henderson-Arredondo[2], A'mour Canty[2], Catherine Seader[2], Allie Jepson[1], Elizabeth Le[2], William Killgore[1]

[1] The University of Arizona, [2] University of Arizona

Introduction: Sleep deprivation (SD) significantly impairs visual processing and attention. While these declines in function are often attributed to changes in brain activity measured by functional-neuroimaging or electroencephalography. Whether there are morphological changes in the cortex that correspond to these impairments remains relatively unexplored. Visual cortices, critical for interpreting and processing visual stimuli, may exhibit structural changes under SD conditions, reflecting decreased neural efficiency. This study examined the relationship between sleep deprivation, surface area changes in the visual cortices, and their implications for visual cognitive performance.

Methods: Structural T1-weighted-MPRAGE images were collected from 12 subjects, each undergoing seven MRI scans over time during a 39-hour sleep deprivation protocol. Freesurfer was used to calculate surface area metrics for the cuneus and occipital regions from each scan. For each time point, Freesurfer-derived structural values and attentional lapse values, measured via the psychomotor vigilance task (PVT), were averaged across all subjects and normalized. Correlation analyses were performed to examine the relationship between structural metrics and attentional lapses across time points.

Results: A significant negative correlation was observed between changes in cuneus surface area and increased attentional-lapses ($r=-0.88$, $p=0.009$). Similarly, surface area in the occipital region showed a significant negative correlation with lapses ($r=-0.864$, $p=0.012$). These findings suggest that structural changes in visual cortices are closely associated with cognitive decline in attention and visual task performance during sleep deprivation.

Conclusion: Acute sleep deprivation induced significant structural changes in the visual cortex, with reductions in the surface area of the cuneus and occipital regions strongly associated with declines in attention and visual task performance. The observed

changes suggest that prolonged wakefulness may disrupt the brain's normal functioning, potentially reflecting both short-term adjustments and long-term negative effects in the cortex. The mechanisms potentially underlying these changes remain to be elucidated, but likely candidates include neuroinflammatory responses, synaptic pruning, or altered glymphatic clearance. Future studies should examine the reversibility of these structural alterations with recovery sleep and investigate their broader implications for chronic sleep deprivation and associated neurocognitive deficits, potentially identifying novel targets for therapeutic interventions and preventive strategies.

TRANSCRANIAL DIRECT CURRENT BRAIN STIMULATION IS WELL TOLERATED DURING SLEEP DEPRIVATION

Tracy Jill Doty[1], Sidney Allotey-Addo[1], Chloe Fong[1], Isabelle Kennealy[1], Kajsa Carlsson[1], Lonique Moore[1], Samantha Riedy[1], Thomas Balkin[1], Tad Brunye[2], John Hughes[1]

[1] Walter Reed Army Institute of Research, [2] U.S. Army DEVCOM Soldier Center

Introduction: Transcranial direct current stimulation (tDCS) applied to the prefrontal cortex (PFC) improves performance in well-rested individuals. We assessed the tolerability of this technology during sleep loss, associated with a reduced pain threshold, to ensure its usefulness during extended periods of wakefulness.

Methods: During a four-night stay healthy participants were given a two hour sleep opportunity at 2300 the first night followed by 46 hours of sleep deprivation (SD). There were a total of four stimulations for 10 min during the SD period (1.5, 2.75, 25.25, and 26.5 hours into SD). The tDCS group received 9 min of sustained 2mA stimulation following a 30 sec ramp up and ending with a 30 sec ramp down, and the sham group received only the 30 sec ramp up and down at beginning and end of the stimulation period. Participants rated the sensation of stimulation (from 0-9) on the Thermal Sensation Scale (TSS) at 30 sec into stimulation and after stimulation termination. Stimulation was immediately stopped if a rating was seven or higher.

Results: Analysis of 17 healthy individuals (nine in the tDCS group, eight in the sham group) revealed that stimulation was well tolerated across all four stimulation sessions for both groups (average TSS score during stimulation = 3.00 ± 1.60, after stimulation = 1.72 ± 1.34). TSS scores during stimulation increased with repeated stimulation sessions and longer extended wakefulness (main effect of session $p=0.02$), but consistently remained well below the cutoff for stimulation termination within each session (average TSS score during stimulation for 3rd and 4th sessions = 3.06 ± 1.48 and 3.82 ± 1.38, respectively). TSS scores did not differ between groups (effect of group during stimulation $p=0.07$ and after stimulation $p=0.72$).

Conclusion: These findings indicate that PFC tDCS during SD is well tolerated by healthy individuals. Although TSS scores increased with sleep loss, these ratings remained low and comparable for the tDCS and sham groups (suggesting that participants remained blinded during the study). These findings demonstrate that PFC tDCS can be administered safely and comfortably during sleep loss.

THE EFFECT OF CHRONIC TRAZODONE ADMINISTRATION ON SLEEP IN THE APPNL-F MOUSE MODEL OF ALZHEIMER'S DISEASE

Emad Shams[1], Mayuko Arai[2], Cody Stevens[2], Jefferey Yue[3], Artemis Kohanfekr[2], Daniela Purvica[2], Hillary Han[2], Brianne A. Kent[2]

[1] Simon Fraser University - Translational Neuroscience Lab, [2] Simon Fraser University, [3] Simon Fraser University - Department of Molecular Biology and Biochemistry

Introduction: Sleep disturbances are prevalent among individuals diagnosed with Alzheimer's disease (AD), typically manifested as low levels of slow-wave sleep (SWS; N3 stage). Restoring SWS has been suggested as an intervention to slow AD progression. Trazodone is a licensed antidepressant also commonly prescribed to manage sleep disturbances due to its hypnotic effects, safety, and tolerability. However, there is limited preclinical research on the effects of trazodone beyond the antidepressant effects. We investigated the effect of voluntary oral trazodone administration at doses 0mg, 10mg, 40mg, and 60 mg/kg on sleep in C57BL/6J mice (n=15; age 10-13 months). We found that a single dose of trazodone hydrochloride (HCL) has a dose-dependent effect on the duration of non-rapid eye movement (NREM) and delta power; 60 mg/kg caused an increase in NREM compared to the baseline (mean increase = 1.54 h ± 0.40 SEM; mixed-design ANOVA dose x vigilance state $F(6, 36) = 17.89$, $p < 0.0001$).

Methods: We then investigated the effect of chronic trazodone administration on sleep in a mouse model of AD (APP NL-F) in a younger (n=16, 9 months-old) and older (n=18, 14 months-old) cohort. Trazodone was administered orally at 60mg/kg through voluntary intake for 60 days. Mice were implanted with EEG/EMG headmounts and were recorded for 7 sessions, each lasting 48 h over the 60-day treatment period. Our results show that the mice reliably consumed trazodone throughout the treatment period, with n=30/34 mice fully consuming the trazodone on all 60 days. The EEG/EMG data were manually scored for wake, NREM, and rapid eye movement (REM).

Results: Preliminary analysis for 9 months-old cohort showed a significant effect of treatment on NREM sleep (repeated measures ANOVA, $F(4, 12) = 21.433$, $p < 0.001$). Post hoc analysis confirmed increased NREM sleep after 60 days, compared to the baseline ($p = 0.0205$).

Conclusion: Together, these studies demonstrate for the first time that trazodone dose-dependently increases SWS in mice and that trazodone can enhance NREM sleep in a mouse model of AD, even after 60 days of treatment.

ALTERATIONS IN SLEEP ARCHITECTURE FOLLOWING DUAL GABAERGIC NEURONAL ABLATION IN THE PARAFACIAL ZONE AND PREOPTIC AREA

Myrto Stylianou[1], Yoan Cherasse[2], Michael Lazarus[2], Henrik Bringmann[3]

[1] TU-Dresden Biotec, [2] University of Tsukuba, [3] TU-Dresden

Introduction: GABAergic neurotransmission plays a pivotal role in sleep regulation. Key sleep-promoting centers in the mammalian brain, such as the medullary parafacial zone (PZ) and the hypothalamic preoptic area (POA), rely on GABA to mediate their function. Both regions have sleep active GABAergic neurons and modulation of their activity can affect sleep patterns. This study investigates the combined effect of GABAergic neuronal ablation in these two regions on sleep architecture.
Methods: To selectively ablate GABAergic neurons, Vgat-Cre mice were injected bilaterally with an adeno-associated virus (AAV) expressing diphtheria toxin A (DTA) in the POA and/or the PZ. Control mice received AAV-GFP injections, resulting in green fluorescent protein (GFP) expression. Electroencephalography (EEG) screws were implanted in the frontal and parietal cortices, along with an electromyography (EMG) pad. Baseline EEG/EMG activity was recorded continuously for 48 hours, two weeks post-ablation. To evaluate homeostatic regulation, mice underwent behavioral sleep deprivation followed by two days of recovery sleep monitoring.
Results: Preliminary findings indicate that mice with dual GABAergic ablation in the PZ and POA spent less time in rapid eye movement (REM) and non-REM (NREM) sleep compared to control mice and single-region ablation groups. Dual-region ablated mice also exhibited shorter sleep episodes compared to control mice and a blunted sleep rebound response following sleep deprivation.
Conclusion: Initial results indicate that dual GABAergic neuronal ablation in the POA and PZ disrupts sleep architecture by reducing NREM and REM sleep time, increasing sleep fragmentation, and potentially impairing homeostatic regulation. Further investigation is needed to confirm these findings, elucidate underlying mechanisms and uncover the potential involvement of other sleep and/or wake-promoting regions.

THE CORTEX AND PARAFACIAL ZONE OF INFANT RATS EXHIBIT PARALLEL HOMEOSTATIC RESPONSES TO SLEEP DEPRIVATION

Midha Ahmad[1], Greta Sokoloff[2], Mark Blumberg[2]
[1] University of Iowa, [2] The University of Iowa

Introduction: Beginning around postnatal day 12 (P12) in rats, quiet sleep (QS, or NREM sleep) increases at the expense of active sleep (AS, or REM sleep). The developmental increase in QS is accompanied by the sudden emergence of cortical delta (0.5-4 Hz). We recently discovered a novel delta rhythm in a medullary structure, the parafacial zone (PZ), a region implicated in regulating QS in adults. At P12, PZ delta was generated locally and was highly coherent with cortical delta. We hypothesized that if PZ delta is a homolog of cortical delta, then the two rhythms should exhibit parallel homeostatic responses to sleep deprivation.
Methods: P12 rats (n=8) were deprived of sleep for 30 minutes while recording from the PZ and frontal cortex. Cold stimuli were applied to the snout to induce arousal whenever cortical delta was observed. After deprivation, pups were allowed to sleep undisturbed for an additional 60 minutes for recovery. Control pups (n = 8) were matched for sex and age and were left undisturbed for 90 min. PZ and cortical LFP, PZ unit activity, respiration, and behavioral measures (EMG, video) were obtained for each pup.
Results: Sleep deprivation produced intense sleep pressure, as operationalized by the need to increase the rate of arousing stimulations over the 30-minute deprivation period. Over the recovery period, PZ and cortical delta showed parallel homeostatic responses consisting of initially increased delta power that decreased in lock-step toward baseline over time. The durations of QS and AS showed a similar pattern. Brief arousals (< 10 s) occurred more often during the recovery period; these arousals elicited simultaneous decreases in delta power in PZ and cortex. Surprisingly, pups breathed more deeply at the start of the recovery period, providing additional evidence of a link between respiration and delta power at this age.
Conclusion: These results support the notion that PZ and cortical delta are closely linked components within the sleep-regulatory system. Also, the findings suggest intimate connections between delta- and respiration-generating structures in the brainstem, a possibility that is currently being investigated.

WAKEFULNESS BY OPTOSTIMULATION OF BASAL FOREBRAIN VGLUT2+ NEURONS TRIGGER DIFFERENT PATTERNS OF BRAIN ACTIVITY AND RECOVERY SLEEP FROM GENTLE HANDLING

Radhika Basheer[1], Chun Yang[2], David Uygun[3], Victoria Lombardi[4], Ritchie Brown[5], James McKenna[6]
[1] Harvard Medical School-VA BHS- Boston VA Res Inst., [2] Boston VA Research Institute- VA Medical Center, [3] VABHS Harvard Medical School Dept of Psychiatry, [4] VA Boston Healthcare System-Boston VA Res Inst., [5] VA Boston Healthcare System, [6] Harvard Medical School

Introduction: Prolonged wakefulness induces a homeostatic sleep response (HSR) with increases in non-REM sleep time and delta power. The quality of wakefulness impacts the magnitude and form of the HSR but little is known about the neural mechanisms. Opto-stimulation of basal forebrain (BF) glutamatergic neurons (stim) leads to arousal and avoidance behavior. Here we compared the HSR following 4 hr of prolonged wakefulness induced by opto-stimulation of BF glutamate neurons and compared to sleep deprivation (SD) induced by gentle handling (GH). Finally, we compared the c-Fos activation pattern of the whole brain after 4hr of opto-stimulation compared to 4hr SD induced by GH.
Methods: Mice (vGlut2-Cre or C57BL6) were implanted with microdialysis/optodialysis probes targeting the BF and EEG/EMG electrodes. Unilateral opto-stimulations of BF vGluT2 (20Hz, 5s On-55s Off) neurons and SD were performed during ZT3-ZT7 with or without the administration of ionotropic glutamate receptor antagonists (DNQX + D-AP5) and allowed 3h of recovery sleep. For cFos mapping whole brains were collected after 4hr of stim or SD with time-matched undisturbed controls, and analyzed for activated cFos (Lifecanvas, Inc).
Results: BF vGluT2 stimulation caused rapid arousal and, compared to baseline day, mice stayed awake (93.3 ±1.2%. N=10) during the 4 h of stimulation, comparable to that noted for SD (~95%) by GH. Stim conditions showed a significant hourly decrease in wakefulness from 2-4h which was further decreased by optodialysis of the ionotropic glutamate receptors antagonists, effects not seen in SD condition. Unlike SD group, the recovery NREM sleep remained unaltered following BF vGluT2

stim. SD increased NREM delta (0.5-4Hz) but the stim group showed a selective increase in 2.5-3.5Hz range. The whole brain c-Fos mapping revealed different activation patterns between stimulation and SD groups for multiple brain regions including the habenula and hypothalamus.
Conclusion: Our data suggests a differential pattern of arousal and HSR following BF vGluT2 stimulation, and resulting activation of aversive brain circuits, when compared to that of GH-induced SD.

CEREBLON DEFICIENCY INCREASES AMP-ACTIVATED KINASE AND HOMEOSTATIC SLEEP RESPONSE MICE

Jinhong Kim[1], Junhyung Jung[1], Uroos Akber[1], Nayoung Lee[1], Jeongwon Baek[1], Jieun Jung[1], Mincheol Park[1], Jiseung Kang[1], Seungje Jeon[1], Chulseung Park[1], Tae Kim[1]
[1] Gwangju Institute of Science and Technology

Introduction: Energy homeostasis and sleep have a bidirectional relationship. Cereblon (CRBN), a substrate receptor of the CRL4 E3 ubiquitin ligase complex, regulates energy levels by ubiquitinating AMP-activated protein kinase (AMPK), a master energy sensor. While CRBN's role in energy regulation is established, its involvement in sleep remains unclear. Thalidomide, a pharmacological modulator of CRBN, has shown to improve sleep quality, particularly by increasing slow-wave sleep (SWS) and overall sleep efficiency. This study explores the impact of CRBN deletion on sleep-wake patterns and examines parallels to thalidomide's effects.
Methods: Sleep-wake patterns were analyzed in Crbn+/+ and Crbn-/- mice under three conditions: 24-hour baseline, 6-hour sleep deprivation (SD), and 6-hour recovery sleep (RS). EEG/EMG recordings quantified sleep architecture, with a focus on slow-wave activity as an indicator of homeostatic sleep drive. Stress-associated proteins, including phospho-Tau, phospho-α-Synuclein, DNAJA1 (DJ2), DNAJB1 (DJ1), and Heat Shock Protein 70 (HSP70), were measured via immunoblotting.
Results: At baseline, sleep architecture was similar between Crbn+/+ and Crbn-/- mice. Sleep deprivation reduced CRBN expression in Crbn+/+ mice and elevated stress markers such as phospho-Tau, phospho-α-Synuclein, DJ2, and DJ1 in both genotypes. Crbn-/- mice showed a blunted increase in phospho-Tau and phospho-α-Synuclein but higher levels of HSP70, DJ2, and DJ1. During recovery sleep, Crbn-/- mice exhibited significantly increased slow-wave activity, suggesting heightened homeostatic sleep pressure, likely due to AMPK hyperactivation in the absence of CRBN.
Conclusion: CRBN plays a critical role in regulating sleep homeostasis and recovery sleep, likely through its modulation of AMPK activity and stress protein responses. Interestingly, thalidomide, a CRBN modulator, has been shown to enhance slow-wave sleep and overall sleep quality in clinical studies. This improvement in slow-wave activity parallels the increased SWA observed in Crbn-/- mice during recovery sleep. However, while thalidomide's effects appear beneficial, the heightened sleep drive in CRBN-deficient mice likely reflects underlying AMPK hyperactivation. This highlights a dual role for CRBN in both promoting energy balance and regulating sleep architecture. Thalidomide or related CRBN modulators could offer therapeutic benefits for improving sleep quality and mitigating neurodegeneration associated with disrupted sleep, while careful attention is needed to avoid unintended effects related to CRBN deficiency.

A HIGH-FAT DIET INCREASES NEURODEGENERATION IN THE LOCUS COERULEUS AND WORSENS SLEEP DISTURBANCES INDUCED BY CHRONIC SLEEP RESTRICTION IN RATS

Mikhail Guzeev[1], Ksenia Lapshina[1], Maria Pazi[1], Kira Derkach[1], Irina Ekimova[1]
[1] Sechenov Institute of Evolutionary Physiology and Biochemistry Russian Academy of Sciences

Introduction: Chronic sleep restriction (CSR) and overeating are factors that affect human health and are primarily related to lifestyle. Both these factors are widespread in modern society. It can also mutually reinforce each other's negative health effects. Just as sleep restriction can lead to metabolic disorders and obesity, obesity can also cause sleep disorders. We studied the effects of a high-fat diet (HFD) on sleep and neurodegenerative changes in the locus coeruleus after CSR in rats.
Methods: Wistar rats were kept on a HFD from two months of age. For CSR, 7-8-month-old rats underwent cycles of 3 h of sleep deprivation using an orbital shaker and 1 h of sleep opportunity (SO) continuously for 5 days. Control rats were maintained in standard dry rat chow. Sleep was recorded before, during CSR, after two days, and two weeks. Neurodegeneration in the locus coeruleus was assessed by Nissl staining.
Results: Rats fed HFD had a 30% greater body weight than control rats before the start of CSR. There were no differences in sleep between the HFD and control groups before CSR. During CSR, slow-wave sleep (SWS) and REMS were reduced by 60% and 55%, respectively, in both groups. SWS EEG delta power during the SO period decreased gradually from the first to the fifth CSR day for both groups, but the last dark time of day that decline was greater in HFD rats. We observed the same decrease in EEG delta power of the SWS during the light (inactive) time of day in both groups during two days after CSR. After two weeks, EEG delta power returned to baseline in the control group, whereas it remained suppressed in HFD rats. We also found that CSR-induced neurodegeneration of monoaminergic neurons in the locus coeruleus was greater in HFD rats than in control rats.
Conclusion: We consider HFD to be a factor leading to longer lasting suppression of homeostatic mechanisms of sleep regulation caused by CSR. The greater dysfunction of the noradrenergic pathways of the locus coeruleus in HFD may make some contribution to these mechanisms.

INCREASED AB DEPOSITION FOLLOWING CHRONIC SLEEP DISRUPTION CORRELATES WITH ALTERED GLIOSIS AND AQP4 IN 5XFAD MICE

Samantha Keil[1], Taylor Pedersen[2], Ron Vered[3], Mathew Sevao[4], Sanjana Agarwal[5], Molly Braun[6], Abigail G. Schindler[7], Jeffrey J. Iliff[4]

[1] Weill Cornell Medicine, [2] Washington University in St. Louis, [3] National Institute of Health, [4] VISN [20] Mental Illness Research, Education, and Clinical Center, [5] John Hopkins Medicine, [6] Medical College of Georgia, [7] University of Washington

Introduction: Chronically dysregulated sleep is increasingly recognized as a risk factor in the development and progression of neurodegenerative disease states, including Alzheimer's disease (AD). Despite this known association, the mechanism connecting dysregulated sleep, particularly over chronic timescales, and downstream AD pathology remains unclear. This study investigates the impact of chronic sleep disruption on amyloid beta (A□) accumulation, glymphatic aquaporin 4 (AQP4) alteration, and gliosis in a 5xFAD mouse model. We hypothesized that chronic sleep disruption leads to an increased A□□burden, and that this increase would be correlate with markers of glymphatic function and inflammation.

Methods: Female and male 5xFAD+ and wildtype (WT) littermate controls underwent chronic sleep disruption using Lafayette sleep fragmentation cages from 10 to 18 weeks of age (n = 9-12 in each group). Glymphatic clearance was assessed via regional distribution of fluorescent CSF tracer into brain tissue after cisternal magna injection in WT mice, while amyloid deposition (NAB228) was evaluated in 5xFAD+ animals. Subsequently, regional immunofluorescent evaluations of AQP4, GFAP, and Iba1 expression and localization were performed. Correlation analyses were conducted to assess relationships between glymphatic clearance markers and measures of AQP4 and gliosis.

Results: Chronic sleep disruption significantly increased A□burden, altered changes in AQP4 expression and localization, and increased gliosis. Notably, the strongest correlations were observed between measures of tracer distribution and amyloid deposition with both gliosis and AQP4 were in the sleep disrupted mice. Together, these findings underscore the role chronic sleep disruption plays in pro-inflammatory glial activation and glymphatic impairment.

Conclusion: Our study demonstrates that chronic sleep disruption exacerbates amyloid pathology, alters AQP4 expression, and increases pro-inflammatory glial response in the 5xFAD mouse model. Additionally, the correlations observed between markers of glymphatic clearance, gliosis, and AQP4 expression are stronger in the chronically sleep disrupted mice compared to sham controls. These findings emphasize the critical role sleep health plays in neurodegenerative disease and suggest that preserving glymphatic function and mitigating proinflammatory glial responses could be important therapeutic targets in AD progression. Future research should explore interventions aimed at restoring sleep health to enhance glymphatic efficiency and reduce neuroinflammatory activation.

POORER ACTIGRAPHIC SLEEP HEALTH IN ADOLESCENCE PREDICTS LOWER CARDIOVASCULAR HEALTH SCORE IN YOUNG ADULTHOOD

Gina Mathew[1], David Reichenberger[2], Orfeu Buxton[3], Anne-Marie Chang[4], Norrina Allen[5], Noreen Goldman[6], Donald Lloyd-Jones[5], Daniel Notterman[6], Lauren Hale[1]

[1] Stony Brook Medicine, [2] Oregon Health & Science University, [3] Penn State, [4] The Pennsylvania State University, [5] Northwestern University Feinberg School of Medicine, [6] Princeton University

Introduction: Short sleep duration among middle-aged and older adults predicts worse cardiovascular health (CVH) later in life. It is unclear whether adolescent sleep health predicts young adult CVH, particularly using objective sleep measures. We examined whether several dimensions of actigraphic adolescent sleep health predicted young adult CVH among a diverse, longitudinal sample from 20 U.S. cities.
Methods: Data were derived from sub-studies of the Future of Families and Child Wellbeing Study (FFCWS; n=307; 57%F), a diverse birth cohort. At age 15y, adolescents wore wrist-actigraphy for ~1 week (6.8±1.9 nights). At age 22y, CVH was assessed from the FFCWS Cardiovascular Health Among Young Adults sub-study using the seven non-sleep factors from the American Heart Association's Life's Essential 8—diet, physical activity, nicotine exposure, body mass index (BMI), blood lipids, blood glucose, and blood pressure—that were averaged into a composite score (0, poor–100, ideal). Separate linear regression models assessed whether age 15 average actigraphic total sleep time (TST; linear and quadratic), sleep timing, sleep maintenance efficiency, and variability (SD) of these measures predicted age 22 CVH composite score, adjusting for age 22 sociodemographic characteristics and age 15 self-reported BMI, diet, and physical activity.
Results: Earlier age 15 average sleep onset (b=−1.11, p=.023, β=−.12) and offset (b=−1.08 p=.015, β=−.12) and higher sleep maintenance efficiency (b=+0.66, p=.008, β=+.14) predicted higher (i.e., better) age 22 CVH score. Lower variability in TST (b=−1.97, p=.042, β=−.11) and in sleep onset (b=−1.93, p=.035, β=−.11) predicted higher age 22 CVH score. Lower age 15 variability in sleep maintenance efficiency marginally predicted higher age 22 CVH score (b=−1.19, p=.057, β=−.10). Age 15 average TST (linear and quadratic) and variability in sleep offset did not significantly predict age 22 CVH score (p≥.10).
Conclusion: Adolescent TST did not significantly predict young adult CVH in the present study. Instead, earlier, more efficient, and less variable adolescent sleep predicted higher young adult CVH scores, even after adjusting for adolescent lifestyle factors and other confounders. Interventions aiming to protect future CVH should consider improving adolescent sleep health across multiple dimensions.

MATURATIONAL TRAJECTORIES OF SLOW WAVE ACTIVITY ARE ASSOCIATED WITH EXTERNALIZING PSYCHOPATHOLOGY

Julio Fernandez-Mendoza[1], Christina Stetter[1], Anthony Rahawi[1], Susan Calhoun[1], Alexandros Vgontzas[2], Duanping Liao[1], Edward Bixler[1], Lan Kong[3], Jidong Fang[1]

[1] Penn State College of Medicine, [2] Sleep Research and Treatment Center, Penn State College of Medicine, [3] Department of Public Health Sciences, Penn State College of Medicine

Introduction: Declines in non-rapid eye movement (NREM) sleep slow wave activity (SWA) in the transition to adolescence are indicative of maturational brain structural and functional changes. However, whether abnormal maturational trajectories of SWA are associated with psychopathology have lacked replication in population-based studies with multiple time points across the lifespan.
Methods: A total of 673 participants from the Penn State Child Cohort, a randomly-selected population-based sample, underwent 9-hour in-lab polysomnography studies in childhood (median age 9y), adolescence (median age 16y), and young adulthood (median age 25y) with a median time-to-follow-up of 16y. We extracted SWA power during NREM sleep using sleep FFT software and log-transformed it. First, growth mixture models for clustering of longitudinal data series were used to identify latent classes of log-SWA, while adjusting for sex. Next, mixed-effects models were fitted to test the association of log-SWA classes with externalizing behaviors, as measured by Achenbach System of Empirically Based Assessment, and working memory, as measured by Wechsler Intelligence Scale's Digit Span Backward Test, while adjusting for sex, race/ethnicity, insomnia symptoms, and body mass, apnea/hypopnea, and periodic limb movements indices.
Results: SWA showed three maturational trajectories, of which two were cubic and one was linear. There were significant associations between SWA trajectories and rate of change in externalizing behaviors (p=0.052) and working memory (p=0.028). Compared to the shallowest SWA cubic trajectory (n=342, Group 3), the SWA trajectory with the greatest cubic slope (n=114, Group 2) experienced faster worsening in externalizing behaviors (p=0.056) and slower improvement in working memory (p=0.067), while the linear SWA trajectory (n=217, Group 1) experienced slower improvement in working memory over the 16y follow-up (p=0.017).
Conclusion: Our data provide evidence linking developmental trajectories of SWA with externalizing psychopathology. Youth with abnormal developmental declines in SWA are associated with worse externalizing behaviors and underlying working memory deficits.

CHILDHOOD SLEEP SPINDLE DENSITY AND FREQUENCY ARE ASSOCIATED WITH ADOLESCENT WORKING MEMORY AND NONVERBAL ABILITY

Melany Morales-Ghinaglia[1], Fan He[2], Susan Calhoun[2], Jidong Fang[2], Alexandros Vgontzas[3], Duanping Liao[2], Edward Bixler[2], Magdy Younes[4], Anna Ricci[5], Julio Fernandez-Mendoza[2]

[1] Northwestern University, [2] Penn State College of Medicine, [3] Sleep Research and Treatment Center, Penn State College of Medicine, [4] University of Manitoba, [5] University of Vermont

Introduction: Sleep spindles are an underlying mechanism of cognition. Prior research was primarily cross-sectional or conducted in experimental studies of highly selective samples of

youth. We aimed to clarify the longitudinal relationship between sleep spindles and cognition in the transition from childhood to adolescence in both typically developing (TD) and unmedicated youth diagnosed with psychiatric/learning disorders.
Methods: We leveraged 836 sleep EEGs from 9-hour in-lab polysomnography recordings of the Penn State Child Cohort, a longitudinal population-based sample (N=418). We analyzed 261 TD youth who were 5-12y (median 8y) at baseline and 12-23y at follow-up (median 16y) as well as 88 unmedicated youth with psychiatric/learning disorders, including attention deficit/hyperactivity disorder comorbid with learning disorders (ADHD/LD), of the same baseline and follow-up ages. Medicated youth were excluded (n=69). We calculated sleep spindle density (SSD; number of spindles/minute) and peak spindle frequency (PSF; 10-16 Hz range) at central derivations during stage N2 using MSS software. Wechsler intelligence testing assessed working memory (WM), verbal and non-verbal (NVIQ) IQ. Linear regression models examined the longitudinal association of SSD and PSF with cognitive outcomes, while adjusting for age, sex, race/ethnicity, PSG system, insomnia symptoms, body mass and apnea/hypopnea indices.
Results: In TD youth, higher childhood SSD (B=0.937, SE=0.443, p=0.036) and a smaller change in PSF from childhood to adolescence (B=-3.561, SE=1.732, p=0.041) were longitudinally associated with better NVIQ; neither childhood SSD (B=0.157, SE=0.139, p=0.261) nor change in SSD (B=0.171, SE=0.127, p=0.179) were longitudinally associated with WM in TD adolescents. In youth diagnosed with ADHD/LD, lower childhood PSF (B=-2.621, SE=1.005, p=0.012) and a smaller change in PSF from childhood to adolescence (B=-2.188, SE=0.750, p=0.005) were longitudinally associated with better WM; neither childhood SSD (B=-0.263, SE=0.279, p=0.350) nor change in SSD (B=0.033, SE=0.245, p=0.893) were associated with WM (or NVIQ, p=0.070) in unmedicated adolescents.
Conclusion: Sleep spindles may serve as a biomarker for neural and cognitive maturation in TD adolescents, with higher childhood density and lower frequency supporting NVIQ. While this relationship is altered in youth with unmedicated psychiatric/behavioral disorders, low-frequency spindles may serve as a protective mechanism supporting WM in adolescents with ADHD/LD.

SLEEP-STAGE MODULATION OF TWITCHES AND SLEEP SPINDLES IN INFANTS AT 6 MONTHS OF AGE

Taylor Christiansen[1], Hailey Long[1], Olivia Kopp[1], Lydia Karr[1], Greta Sokoloff[1], Mark Blumberg[1]
[1] The University of Iowa

Introduction: Twitches are discrete movements that contribute to the self-organization of the sensorimotor system. At 3 months of age, infants begin to twitch during both NREM and REM sleep, and twitches during NREM occur in synchrony with sleep spindles. In the present study, we examine in 6-month-olds how the specific stage of NREM sleep (i.e., N2 vs. N3) modulates the characteristics of twitches and their coupling with spindles.
Methods: EEG and video were recorded during daytime naps in 21 infants (7F, 6.19 ± 0.10 months). Twitches of the arms, legs, and face, and rapid eye movements, were visually identified by two independent raters. EEG was scored in 30-s epochs using AASM scoring criteria. Spindles were identified in the C3 electrode during artifact-free periods using an automated detection algorithm. Differences in twitch rate (twitches/min) between sleep stages (i.e., REM vs. NREM) and substages (i.e., N2 vs N3) were analyzed. Paired t tests were used to assess differences in spindle rate (spindles/min) and twitch-spindle co-occurrences between NREM substages.
Results: The rate of twitching in NREM was not significantly different from that during REM (NREM: 9.13 ± 1.16, REM: 13.70 ± 2.68; N = 18 infants; Z = -1.24). During NREM, infants twitched significantly more in N2 than in N3 (N2: 13.45 ± 1.95; N3: 5.68 ± 0.77; N = 20 infants; Z = - 3.21, p = 0.001), but the spindle rate was the same across the substages (N2: 3.28 ± 0.27; N3: 3.03 ± 0.33; N=20 infants; t(19)=.904). Regardless of substage, there was a high probability that a spindle occurred at the onset of a twitch. Moreover, the proportion of twitches with co-occurring spindles was not different between substages (N2: 0.26 ± 0.03; N3: 0.24 ± 0.03; N=17 infants; t(16) = 0.80).
Conclusion: These results indicate that 6-month-old infants twitch more during N2 than N3, but exhibit similar rates of spindle production. Regardless of NREM substage twitches are equally likely to co-occur with spindles. Thus, it may be that it is the presence of slow waves during N3 that is incompatible with the production of twitches. This possibility is currently being examined.

FRONTAL AND CENTRAL SPINDLE DENSITY AND DEVELOPMENTAL OUTCOMES IN INFANCY

Melissa Horger[1], Allison Swift[1], Rebecca Spencer[1]
[1] University of Massachusetts, Amherst

Introduction: Spindle density, frequency, and topography change from infancy through adolescence as spindles bifurcate into subtypes: fast in the central regions and slow in the frontal regions. Changes in spindle characteristics may reflect underlying cortical maturation and neural plasticity. Spindles are related to behavioral outcomes across multiple domains, including fine and gross motor ability, working memory, and perceptual reasoning. The present research aimed to examine emerging longitudinal relationships between frontal and central spindles and motor, language, and cognitive development.
Methods: Thirteen infants participated in a cross-lagged longitudinal design. Two timepoints were separated by 3 months and infants began participating when they were 9- or 12- months old. At each timepoint, they took a morning and afternoon nap. Trained sleep technicians identified sleep stages and sleep spindles across channels. Spindle density was calculated as the number of spindles out of N2/N3 sleep and averaged by region and across the two naps. A series of linear mixed effects models tested the impact of time, starting age, and change in frontal and central spindle density (Time 2 – Time 1) on scaled Bayley scores (Fine/Gross Motor, Expressive/Receptive Language, Cognition).
Results: Fine Motor scores were not significantly predicted by the model. Gross Motor (β=7.61, p<.01), Expressive Language (β=8.09, p<.01), Receptive Language (β=5.94, p<.01), and Cognitive (β=4.26, p<.05) scores were all significantly predicted by change in central spindle density. The regression model on cognitive scores also had significant interactions between starting

age and both central (β=1.84, p<.05) and frontal (β=2.34, p<.01) change in density.
Conclusion: We found change in central spindle density had a consistent main effect on all but one developmental domain. Increased central spindle density from infants' first to second timepoint was related to better Gross Motor, Expressive Language, Receptive Language, and Cognitive scores, independent of age at start. Changes in frontal spindle density were only significant as an interaction in predicting Cognitive scores, though the direction of the effect was the same. Our results add to literature reporting unique roles of frontal and central spindles and earlier maturation of central vs. frontal spindles.

ACTIGRAPHY-ESTIMATED REST-ACTIVITY RHYTHM CHARACTERISTICS OF ADOLESCENTS BY SOCIO-DEMOGRAPHIC FACTORS

Misol Kwon[1], Pin-Wei Chen[2], Jessica Decker[2], Philip Gehrman[1], Babette Zemel[2], Jonathan Mitchell[2]
[1] University of Pennsylvania, [2] The Children's Hospital of Philadelphia

Introduction: Characterizing 24-hour rest-activity rhythm (RAR) patterns in adolescents is critical, as this developmental period is marked by developmental and social changes that may impact circadian regulation. This study aimed to characterized 24-hour RAR patterns among adolescents transitioning from middle to high school, with a focus on variations across socio-demographic factors, pubertal status, and season of measurement.
Methods: Baseline and follow-up data in the Sleep and Growth Study were analyzed (N=107; 45.8% female; Mage 13.9 years [baseline] and 14.9 years [follow-up]). Wrist actigraphy (ranging from 3-14 days) was used to collect movement profiles (Philips Actiwatch 2) and proprietary count data were further processed using ActCR and GGIR (g.getM5L5) packages to derive RAR parameters. Non-parametric (i.e., interdaily stability [IS], intradaily variability [IV], relative amplitude [RA], most active 10-hour midpoint [M10], least active 5-hour midpoint [L5]), and parametric (i.e., mesor, amplitude, acrophase) RAR metrics were estimated. Data on socio-demographic factors (sex, race, parental education level, household income), and pubertal status were obtained through self/parental-report; and season of measurement was based on measurement (Nov-Apr, May-Oct). Linear mixed effect modeling was used to examine the impacts of grade, socio-demographic factors, and season.
Results: Compared to 8th grade, adolescents in 9th grade exhibited less stable RAR (IS: β=-0.03, p=0.001) and more fragmented patterns (IV: β=0.07, p=0.000). Male sex, compared to female, was associated with lower amplitude (β =-30.37, p=0.013) and earlier acrophase (β=-0.36, p=0.025). Adolescents in lowest household income category, compared to those in the highest, had earlier midpoint for the least active 5-hour period (L5 midpoint: β=-1.12, p=0.004). Post-pubertal, compared to pre-pubertal adolescents, exhibited lower IS (β=-0.03, p=0.024), lower amplitude (β=-40.89, p=0.000), lower mesor (β=-18.25, p=0.006), earlier acrophase (β=-0.36, p=0.025), and delayed daily activity midpoint (M10 midpoint: β=0.41, p=0.018). No associations were observed between any RAR metrics and sex, household income, parental education level, or season of measurement.
Conclusion: Advancing grade level, male, lower socioeconomic factors, and pubertal maturation were associated with less stable, more fragmented, reduced amplitude and mesor, and shifts in activity timing. These findings underscore the developmental and socio-demographic influences on circadian rhythms during adolescence.

ASSOCIATIONS BETWEEN SLEEP, MENSTRUAL PROBLEMS, AND AFFECTIVE, SOCIAL, AND COGNITIVE FUNCTIONING IN ADOLESCENT GIRLS

Evelyn Perez-Amparan[1], Ruby Fan[1], Hannah Giarrusso[2], Nicole Arra[1], Marie Gombert[1], Eva Muller Oehring[1], Fiona Baker[1], Orsolya Kiss[1]
[1] SRI International, [2] Center for Health Sciences, SRI International, Menlo Park, CA, USA

Introduction: Menstrual pain and premenstrual symptoms are known to influence affective, social, and cognitive functioning in adult women. However, these associations are less studied in adolescence—a sensitive developmental period when sleep is undergoing key changes and menstrual-related disorders emerge. This study examined the effects of sleep and menstrual problems, as well as their interaction, on daily psychosocial functioning in adolescent girls.
Methods: Data from 2,131 post-menarcheal girls (Mean age=13.09 years, range=12–15 years) in the ongoing Adolescent Brain and Cognitive Development (ABCD) Study® were analyzed. Sleep behavior was assessed with the Munich Chronotype Questionnaire (youth self-report), and menstrual problems were evaluated through self-reported menstrual cycle characteristics. Affective, social, and cognitive functioning outcomes were measured using the Child Behavior Checklist (caregiver-report). Linear mixed effect models examined associations between sleep, menstrual problems, and functioning outcomes, with age, time since menarche, BMI, hormonal contraceptive use, and socio-demographic factors as covariates.
Results: More severe premenstrual symptoms were associated with higher levels of anxiety and depressive symptoms (p<.01), stress (p<.01), somatic symptoms (p<.01), social problems (p<.01), sluggish cognitive tempo (p=.001) and attention problems (p=.002). Menstrual pain and its impact on daily life were positively associated with anxiety and depressive symptoms (p<.01 and p<.01, respectively), stress (p<.01 and p<.01), somatic symptoms (p<.01 and p<.01), and social problems (p=.042 and p=.003), but not with cognitive outcomes. Sleep behavior moderated multiple associations. Adolescents with later bedtimes and more pain impact had higher anxiety and depressive symptoms (p=.033) and more social problems (p=.007). Later bedtimes combined with greater pain intensity or higher impact of premenstrual symptoms on daily life had more social problems (p=.005 and p=.008). Those with shorter sleep duration and high pain impact or severe premenstrual symptoms had higher sluggish cognitive tempo scores (p=.021 and p=.019). Additionally, later bedtimes were associated with more attention problems in those experiencing greater pain intensity (p=.031).
Conclusion: Menstrual pain and premenstrual symptoms are associated with poorer affective, social, and cognitive functioning in adolescent girls, and sleep behavior moderates these associations. Addressing both sleep and menstrual health could

enhance our understanding of female adolescent well-being during this critical developmental stage.

SLEEP TIMING AND SOCIAL JET LAG ARE ASSOCIATED WITH CIRCADIAN GENE EXPRESSION: A CROSS-SECTIONAL STUDY IN MEXICO CITY ADOLESCENTS

Donghan Su[1], Jaclyn Goodrich[1], Jennifer Lee[1], Dana Dolinoy[1], Karen Peterson[1], Ronald Chervin[2], Helen Burgess[1], Martha Maria Tellez-Rojo[3], Alejandra Cantoral[4], Libni Torres-Olascoaga[3], Peter Song[1], Louise O'Brien[1], Erica Jansen[5]

[1] University of Michigan, [2] Sleep Disorders Center and Department of Neurology, University of Michigan, [3] Instituto Nacional de Salud Publica, [4] Iberoamerican University, [5] University of Michigan School of Public Health

Introduction: Circadian disruption has been linked to adverse metabolic health, potentially mediated through altered expression of circadian genes. Adolescents are particularly susceptible to circadian disruptors, such as delayed sleep onset and social jetlag. This study of adolescents during peri-puberty investigated associations between circadian disruption and circadian gene expression, independent of sleep duration, and potential sex differences in the associations.
Methods: The analytic sample included 203 adolescents (96 boys, 107 girls) from the ELEMENT longitudinal cohort in Mexico City. Sleep was assessed via 7-day wrist actigraphy, and a fasted blood sample was collected during a study visit between 8:00 AM and 12:00 PM. Sleep midpoint was calculated as the midpoint between bed and wake times, and social jetlag as the difference in sleep midpoint on weekends versus weekdays. RNA was isolated from blood leukocytes, and RNA sequencing was performed to determine the relative expression of genes. We conducted differential gene expression analysis, in relation to weekday sleep midpoint and social jetlag, for 12 core clock genes using the DESeq2 package (R), adjusting for sleep duration and other potential confounders. A Bonferroni-corrected statistical significance (0.05/12 genes) was considered.
Results: Participants had a median age of 14 years (interquartile range: 12–16). Later sleep midpoint (per 1-hour increase) was associated with reduced mid-morning expression of four circadian genes: RORA (log2 fold change [LFC]: -0.190; P value: 0.001), RORC (LFC: -0.147; P value: 0.039), CLOCK (LFC: -0.141; P value: 0.019), and NR1D2 (LFC: -0.093; P value: 0.029). In sex-stratified analysis, later sleep midpoint was significantly associated with lower RORA expression in girls only (LFC: -0.255; P value: 0.002). Greater social jetlag was linked to increased expression of PER1 (LFC: 0.275; P value: 0.017) in girls, but no associations were found in boys or the combined sample. The associations with RORA met a more stringent Bonferroni-corrected statistical significance (P< 0.004).
Conclusion: Later weekday sleep midpoint and greater social jetlag were associated with altered expression of some core clock genes collected in mid-morning, particularly among adolescent females. Future studies are needed to evaluate the potential impact of differential clock gene expression, especially for RORA, on cardiometabolic health.

ABERRANT MELATONIN SECRETION PATTERN IN SMITH-MAGENIS SYNDROME - AND ITS IMPLICATION ON SLEEP

Christos Polymeropoulos[1], Sandra Smieszek[1], Naoise Synnott[1], Changfu Xiao[1], Gunther Birznieks[1], Mihael Polymeropoulos[1]

[1] Vanda Pharmaceuticals Inc.

Introduction: Smith-Magenis Syndrome (SMS OMIM 182290) is a rare developmental disorder that results from an interstitial deletion of human chromosome 17p11.2, and in rare cases from a point mutation in the RAI1 gene. Majority of the SMS patients harbor a recurrent 3.7 Mb microdeletion of 17p11.2, yet some cases harbor point mutations in the retinoic acid-induced gene 1 (RAI1). Haploinsufficiency of RAI1 is considered the cause of SMS.
Methods: It has been documented that the vast majority of SMS patients have an aberrant diurnal melatonin secretion pattern although a small minority have demonstrated normal or near to normal patterns. The functional mechanisms of this phenomenon are yet to be delineated. In this observational study, eight patients with genetically confirmed diagnosis of SMS had their sleep behaviors characterized through surveys and actigraphy as outpatients. In addition, the patients were admitted to clinic on three separate occasions and had hourly serum melatonin levels sampled for 36 hours.
Results: In this study, 6 of the patients resembled abnormal melatonin pattern whereas 2 of these patients exhibited closer to normal melatonin secretion pattern. Behavioral analysis revealed that these two patients initiated sleep more quickly (as determined by actigraphy and questionnaire) than the remaining six. Time-frequency analysis of the melatonin time series revealed a relationship between sleep onset and the timing/frequency range of the melatonin peak. Melatonin circadian rhythm was shifted to an abnormal phase with peak secretion occurring during the daytime. This analysis suggests that the frequency as defined by the shape of the melatonin rise affects sleep in addition to phase in the SMS patients. These individuals with SMS have normal cortisol rhythms but abnormal daytime production of melatonin.
Conclusion: Therapies that target circadian disruptions in melatonin production are beneficial for the treatment of sleep disruptions in individuals with RAI1 haploinsufficiency.

EXPLORING THE RELATIONSHIP BETWEEN CHRONOTYPE AND HEALTH CONDITIONS IN BLACK ADULTS LIVING IN THE U.S

Gabrielle Belony[1], Matthew Coppello[1], Clarence Locklear[2], Sadeaqua Scott[2], Azizi Seixas[3], Girardin Jean-Louis[3]

[1] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [2] University of Miami, [3] University of Miami Miller School of Medicine

Introduction: Chronotype, an individual's preference for morning (morningness) or evening (eveningness) activity, may influence the likelihood of developing certain diseases. Previous studies have suggested that chronotype could contribute to

disease susceptibility, but few have examined chronotype as a potential risk factor, especially in Black American populations. This study explores the relationship between chronotype and the prevalence of diseases including hypertension, diabetes, sleep apnea, anxiety, dyslipidemia, and depression in Black Americans living in New York City (NYC) and South Florida (Miami-Dade County, Broward County, and Palm Beach County).
Methods: Data were collected from 599 Black American participants (385 females, 214 males; mean age = 44.2 ± 15.3 years) enrolled in the NIH sleep studies ESSENTIAL and MOSAIC. Participants, residing in NYC or South Florida, were analyzed to examine the association between chronotype and specific health conditions, including hypertension, diabetes, sleep apnea, anxiety, dyslipidemia, and depression. Chronotype was assessed using the validated Munich Chronotype Questionnaire (μMCTQ) or the Morningness Eveningness Questionnaire (MEQ), categorizing participants as morning (0), intermediate (1), or evening (2) based on sleep and wake preferences. The health conditions were designated as binary variables (0 = no, 1 = yes). A one-way ANOVA was performed to compare the intermediate chronotype to both morningness and eveningness.
Results: One-way ANOVA results indicated that participants' chronotype was associated with significant differences in prevalence of hypertension, diabetes, sleep apnea, and anxiety ($p< 0.05$). Tukey's HSD post-hoc analysis showed that morningness had higher prevalence of disease compared to the evening and intermediate chronotypes ($p< 0.05$).
Conclusion: This study suggests that morning chronotype may be associated with a higher prevalence of hypertension, diabetes, anxiety, and sleep apnea, compared to intermediate chronotype, in Black Americans living in NYC and South Florida. These findings highlight the complex role of chronotype in disease risk among Black adults. Further research is needed to clarify causal pathways, explore mechanisms linking chronotype to health conditions, and develop prevention and management strategies tailored to Black American communities.

HOUSEHOLD CHAOS IN DIVERSE FAMILIES: DOES IT INFLUENCE FAMILY SLEEP OR CIRCADIAN ALIGNMENT?

Amy Janis[1], Itzel Sotamba[2], Kameron Moding[1], Sarah Honaker[3], A.J. Schwichtenberg[1]
[1] Purdue University, [2] Indiana University Indianapolis, [3] Indiana University School of Medicine

Introduction: A series of studies document associations between high levels of household chaos and less optimal sleep for infants and parents; although most of these studies have included well-resourced, predominantly white samples. An objective of the Sleep and Health in the Home (SHH) study is to examine associations between household chaos and family circadian/sleep patterns in Latine and Black families.
Methods: Thirty-seven mothers and their infants, M(SD) = 4.90(.70) months of age, were enrolled in an observational study focused on sleep and health in the home. All enrolled mothers self-identified as Black, Latine, or both (n = 17, 19, 1, respectively). Mothers completed the Confusion, Hubbub and Order Scale (CHAOS) and a 24-hour recall diary for seven days. Sleep estimates for child and mother bedtime, morning rise time, nighttime sleep duration, and night wakings were estimated from averaging diary data across 7 nights. Additionally, alignment between infant-parent bedtime and morning risetime were calculated to explore family circadian alignment. Considered covariates included breastfeeding status, sleep location, and maternal race/ethnicity.
Results: Household chaos was not significantly associated with parent or infant sleep (all $p >.05$), nor with alignment between infant and maternal bed or morning rise times. However, mother bedtimes, $r(34) =-.73$, $p <.001$, and child bedtimes, $r(34) = -.44$, $p =.005$, were correlates of sleep duration; wherein, earlier bedtimes for mothers and infants were associated with more sleep for mothers. Additionally, mothers who were more closely aligned with their infant's bedtime, $r(34) = -.70$, $p <.001$, and morning rise times, $r(34) =.38$, $p =.01$, reported more sleep.
Conclusion: Unlike previous studies in minimally diverse samples, household chaos was ultimately not associated with maternal or infant sleep. Rather, earlier bedtimes and more tightly aligned maternal-infant circadian patterns were associated with greater sleep duration for mothers. Study findings highlight the role of early and aligned sleep schedules and can inform future interventions aimed at promoting infant and maternal sleep in Black and Latine families.

EVALUATING SLEEP QUALITY AND CIRCADIAN RHYTHMS IN YOUNG AUTISTIC CHILDREN USING ACTIGRAPHY: A FEASIBILITY STUDY

Clara Rapp[1], Mikhaïl Kissine[1], Lotte Van Esch[2], Ellen Demurie[3], Marielle Weyland[1], Ilse Noens[4], Herbert Roeyers[3], BeLAS Consortium[5], Gaétane Deliens[1]
[1] ACTE, Autism in Context: Theory and Experiment (Université libre de Bruxelles)., [2] Parenting and Special Education Research Unit, Leuven Autism Research (LAuRes), [3] RIDDL (Research in Developmental Diversity Lab), University of Gent, [4] Parenting and Special Education Research Unit, Leuven Autism Research (LAuRes), University of Leuven, [5] ULB, KUL and UGent

Introduction: Sleep problems affect up to 81% of autistic children. Studies suggest a link between sleep quality, sleep-wake rhythms, and language development in early childhood, highlighting the need for objective sleep measures. However, obtaining which measures is challenging in young autistic children, particularly due to their sensory sensitivities. Actigraphy, a less invasive tool, shows promise for autism. However, autism is a highly heterogenous condition, and to date, no study has explored which individual characteristics predict effective actigraphic monitoring. The present study assesses the feasibility of actigraphy in autistic children and identifies profiles that support long-term monitoring.
Methods: Data were collected for the multi-site BeLAS (Belgian 'Language in Autism' Study) project (Université Libre de Bruxelles, KU-Leuven, Ghent University). A cohort of 214 autistic children (2-6 years, 155 boys, mean age = 53.35 months) were instructed to wear an actigraph wGT3X-BT for 14 days. Parents completed a sleep diary and the Children's Sleep Habits Questionnaire (CSHQ). Valid recordings required at least 5 days for sleep quality or 7 consecutive for circadian rhythm analysis, along with correct diary completion (with a ≤ 30 min discrepancy

between diary and actimetric sleep start and end times). Logistic regression was used to predict actimetry wearability with age, IQ, total-CSHQ and ADOS-2 (Autism Diagnostic Observation Scale) comparison scores as predictors. Odds ratios (OR) and their 95% confidence intervals (CI) were calculated.
Results: Actigraphy was completed by 54% of participants. Data loss occurred due to intolerance (42%), technical issues (2%), and lost devices (2%). Logistic regression identified higher non-verbal IQ (OR=1.03, CI [1.01; 1.06]), lower ADOS comparison scores (OR=0.80, CI [0.63; 0.99]), and fewer sleep issues (as indicated by the total-CSHQ) (OR= 0.95, CI [0.90; 0.99]) as significant predictors of successful actigraphy recordings, with no age or site effect. Among participants who wore the actimeter, 85% provided usable data for sleep quality, and 71% for circadian rhythms analysis.
Conclusion: Continuous actigraphy is feasible in preschool-aged autistic children, despite a significant data loss rate (46%). Successful actigraphy recordings were predicted by higher non-verbal intelligence, fewer sleep issues and less autistic characteristics.

SEX DIFFERENCES IN SLEEP MEASURED IN YOUNG ADULTS WITH POLYSOMNOGRAPHY AND WEARABLE DEVICES

Marie Gombert[1], Evelyn Perez-Amparan[1], Orsolya Kiss[1], Elisabet Alzueta[1], Ruby Fan[1], Nicole Arra[1], Allison Morehouse[2], Alessandra Shuster[2], Andres Pena[2], Katharine Simon[2], Sara Mednick[2], Fiona Baker[1]
[1] SRI International, [2] University of California, Irvine

Introduction: Sleep patterns and their variability across time are influenced by biological and behavioral factors. Sex differences in sleep, including variability potentially influenced by hormonal fluctuations during the menstrual cycle in females, remain poorly understood. This study compared sleep and its monthly variability between females with ovulatory menstrual cycles and males, using polysomnography (PSG) and wearables.
Methods: We compared 14 males and 14 females (age range:18-32 Years). Ovulation was confirmed with urine. Data included four in-lab PSG recordings, scheduled for males at 1-week intervals and for females specifically targeting 4 menstrual windows:1) menses, 2) ovulation, 3) mid-luteal, 4) late-luteal. Oura ring gen2 data were collected through the study. The means and monthly variability of each sleep variable (monthly ranges for PSG data and standard deviations for wearable data) were calculated within each participant. These individual averages and variability measures were compared by sex were performed using Wilcoxon tests, and results are presented as the median ± half the interquartile range.
Results: In PSG measures, sleep latency to stage N2 was longer in females (2.44 ± 1.06 min) compared to males (1.33 ± 0.46 min, $p = 0.045$). Fewer awakenings were observed in females (20.5 ± 2.83) than in males (23.5 ± 3.00, $p = 0.042$). In wearable measures, the time awake at night was shorter in females (63.55 ± 12.00 min) than in males (83.00 ± 7.64 min, $p < 0.01$). Wearable-derived sleep efficiency was higher in females (87.79 ± 2.66%) compared to males (82.70 ± 1.56%, $p < 0.01$). Wearable-detected deep sleep was also higher in females (136.14 ± 18.66 min) than in males (89.89 ± 15.15 min, $p < 0.01$). No sex differences were found in the monthly variability for any of the PSG and wearable sleep measures.
Conclusion: Using multiple nights of PSG data and a continuous month of wearable data, we found sex differences in sleep measure levels, with indications of more objective sleep disturbances in males than in females. However, no sex-differences in monthly variability was observed. These findings highlight the importance of considering sex-specific factors when assessing and interpreting sleep patterns and variability.

AGE & SEX TRAJECTORIES IN HEART RATE & VARIABILITY: LINKS TO SLEEP & ACTIVITY FROM LARGE-SCALE WEARABLE DATA

Iman Alikhani[1], Mari Karsikas[1], Massimiliano de Zambotti[2]
[1] Oura Health Oy, [2] Ouraring Inc.

Introduction: Heart rate variability (HRV), once confined to research settings, is now widely accessible through wearable technology, offering unprecedented insights into autonomic nervous system function and overall health. This study leverages wearable-derived data to explore sleep-related HR and HRV trajectories across age and sex, while examining the influence of sleep duration and physical activity on these key health metrics.
Methods: The sample comprised 25,759 Oura Ring users, evenly distributed by age (20–85 years in 5-year increments) and sex (1:1 ratio). One month of de-identified sleep HR and HRV data (i.e., the root-mean-square of successive differences between heartbeats, reflecting parasympathetic autonomic activity) were analyzed using generalized linear model (GLM) regression, with age, sex, sleep duration, physical activity, and their interactions as categorical factors.
Results: Women exhibit higher HR than men across the lifespan, averaging 7.5 bpm more, with HR peaking at 65.2 bpm in women aged 50–54 and slightly declining to 62.8 bpm by 80–85 ($p<.001$). Men's HR peaks later, at 62.0 bpm in the 55–59 age group, with a greater variability range (56.6–62.0 bpm) compared to women (62.8–65.2 bpm) ($p<.001$), across the lifespan. HRV shows an asymmetric U-shaped pattern, declining from early life to mid-adulthood and slightly increasing in older age, with women showing lower HRV in early to mid-adulthood (20–44 years) ($p<.001$). Sleep duration and physical activity strongly influence HR and HRV: shorter sleep (< 6 hours) and low activity levels (< 5000 steps/day) are linked to higher HR and lower HRV, while longer sleep duration and higher activity level (>12,500 steps/day) have the opposite effect ($p<.001$). These dose-dependent patterns are significant and consistent across age and sex.
Conclusion: Scientific knowledge of HR and HRV reference values across the lifespan is limited. These findings enhance our understanding of sleep-related HR and HRV dynamics by age, sex, sleep duration, and physical activity. Future research should explore temporal relationships to uncover causal pathways.

ACTIGRAPHY-DETERMINED CHRONOTYPE IS MORE SIMILAR BETWEEN CLOSE FRIENDS

Venetia Kok[1], Joshua Gooley[1]
[1] Duke-NUS Medical School

Introduction: Friends often show similarities in health-related behaviours, which may contribute to the spread or reinforcement of poor sleep health within social networks. Here, we investigated the relationship between friendship and sleep behaviour in university students. We hypothesized that closer friendships would be associated with greater similarity in sleep timing (i.e., chronotype) and duration.
Methods: Friend pairs of undergraduate students (n=300, 150 pairs) simultaneously wore actigraphy watches and completed daily sleep diaries for 2 weeks during the school semester. Friendships were classified as either close (78 pairs) or casual (72 pairs) based on independent survey responses from each friend. Absolute differences in actigraphy-derived sleep variables (onset, offset, midpoint, and duration) were calculated each day for a given friend pair. Linear mixed models were used to test for associations between closeness of the friendship (close versus casual) with friend-pair differences in sleep outcomes, adjusting for covariates.
Results: On non-school nights, friend-pair differences in sleep onset, sleep offset, and sleep midpoint were about 30 minutes smaller for close friends, reflecting more similar sleep timing compared to casual friends (onset: β=-0.48 h, 95% CI=-0.86 to -0.11 h, P=0.016; midpoint: β=-0.54 h, 95% CI=-0.94 to -0.15 h, P=0.011; offset: β=-0.50 h, 95% CI=-0.95 to -0.05, P=0.039). Friend-pair differences in sleep duration did not reach statistical significance (β=-0.20 h, 95% CI=-0.45 to 0.06 h, P=0.145). On school nights, friend-pair differences in sleep behaviour were primarily determined by whether they had similar class start times, rather than closeness of the friendship (P>0.05 for all comparisons).
Conclusion: Closer friends exhibited more similar sleep timing (i.e., chronotype) when their sleep behaviour was not constrained by school start times. The relationship between friendship and chronotype could be attributed to homophily or peer influence. Our findings highlight the need to consider both the strength of social ties and the impact of social schedules (e.g., school or work start times) when assessing the role of social networks in sleep health.

EVENING SUNGLASSES PROTECT DAYTIME ATTENTION IN SLEEP RESTRICTED ADOLESCENTS

Connor Lafeber[1], Allison Monterastelli[1], Ieva Misiunaite[1], Charmane Eastman[1], Stephanie Crowley[1]
[1] Rush University Medical Center

Introduction: Staying awake late and rising early for school produces partial sleep deprivation and circadian misalignment in adolescents. We tested whether wearing sunglasses when staying up later than usual can help with daytime performance on reaction time tests that measure attention.
Methods: Adolescents (n=74, 36F; 14.1-18.0 years-old) completed a 14-day protocol. On days 1-7 (baseline), participants slept at home on individualized 10-h sleep/dark schedules. On days 8-14, they lived in the laboratory. Sleep opportunity remained at 10h (n=11) or was restricted to 8.5h (n=19), 7h (n=23), or 5.5h (n=21) by delaying bedtime 1.5h, 3.0h, or 4.5h, respectively on days 9 and 10. Thirty-three participants wore amber-lensed glasses (transmit ~14% visible light) during the extra 1.5-4.5h time awake before bed; 41 remained in room light without glasses. Participants completed simple reaction time tests on day 5 (baseline) and on day 11 after the two sleep restriction nights. Daily difference-from-baseline scores for lapses (≥ 500 msec), median reaction time, and mean response rate were calculated. Two (glasses vs no glasses) by four (sleep opportunity groups) analyses of variance were completed for each outcome; post hoc t-tests compared outcomes between glasses groups within each sleep opportunity.
Results: For all reaction time measures, attention deficits increased as sleep opportunity shortened [sleep opportunity main effect: p's< 0.01]; however, when participants wore the amber-lensed glasses these deficits were no longer observed and remained close to baseline levels [glasses main effect: p's< 0.001]. With 8.5-h, 7-h and 5.5-h sleep opportunities and amber-lensed glasses, adolescents showed fewer lapses, faster reaction times and greater throughput (mean response rate) compared to no glasses (p values ranged from 0.001 to 0.009).
Conclusion: Reducing the intensity of evening light when staying up later by wearing amber-lensed glasses protected against daytime attention deficits in adolescents. Evening light has a delaying effect on the circadian clock. Reducing the intensity of this light may reduce phase delays and, in turn, circadian misalignment. Therefore, this simple intervention has potential to improve academic performance and enhance safety during the school commute. Whether these improvements are maintained after more than two nights of sleep restriction is to be determined.

ASSOCIATIONS BETWEEN ACTIGRAPH-DERIVED SLEEP MEASURES AND PSYCHOSIS-RISK SYMPTOMS IN 22Q11.2 DELETION SYNDROME

Jennifer Xu[1], Kathleen O'Hora[2], Hoki Fung[3], Charles Schleifer[3], Leila Kushan-Wells[3], Rune Bøen[2], Elizabeth Bondy[3], Natasha Reddivalam[3], Jared Saletin[4], Carrie Bearden[2]
[1] Department of Psychiatry and Biobehavioral Sciences, Semel Institute for Neuroscience and Human Behavior, University of California, Los Angeles, CA, USA, [2] University of California, Los Angeles, [3] Department of Psychiatry and Biobehavioral Sciences, Semel Institute for Neuroscience and Human Behavior, University of California, Los Angeles, [4] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: 22q11.2 Deletion Syndrome (22q11DS) is a recurrent copy number variant with a wide range of impacts on neurodevelopment. Sleep disturbances are common among 22q11DS, a population at greatly elevated risk for psychosis. Prior studies in 22q11DS report a positive association between psychosis-risk symptoms and sleep disturbances. However, these findings are limited by the use of a single sleep rating from a structured clinical interview. Here, we use an objective sleep measure, wrist actigraphy, to examine whether psychosis-risk symptoms are related to sleep duration and wake after sleep onset (WASO) in 22q11DS.
Methods: 22q11DS participants (n=25 [10 male], Mage=17.1±7.3 years) and typically developing (TD) controls (n= 26 [12 male], Mage=18.3±5.4 years) completed approximately one week of

actigraphy (Axivity AX6). Average sleep duration and WASO were derived from accelerometer data processed using the van-Hees 2018 algorithm implemented using the GGIR R package. A clinical assessment of psychosis-risk symptoms (Structured Interview of Psychosis-Risk Syndromes; SIPS) gave indices of positive, negative, and disorganized symptom severity. Using linear regression, we tested a group-by-sleep interaction to determine if the relationship between symptoms and sleep differed between groups. If there was no significant interaction, we reported the effect of sleep on symptoms across groups. Age and sex were included as covariates in all models.
Results: 22q11DS participants exhibited increased sleep duration (m±sd: 7.6±1.0 hours) compared to TD participants (m±sd: 6.9±0.9 hours; b=-0.70, p=0.011). They demonstrated more severe negative symptoms compared to controls (b=-0.77, p=0.006), but there was no significant difference between groups in positive (b=-0.33, p=0.228) and disorganized symptoms (b=-0.51, p=0.057). Across groups, increased sleep duration was associated with increased positive (b=0.31, p=0.049) and disorganized symptoms (b=0.34, p=0.028). Group did not moderate the association between sleep duration and positive or disorganized symptoms. There were no other significant relationships between sleep and psychosis-risk symptoms (all p's>0.083).
Conclusion: 22q11DS participants exhibited increased sleep duration and negative symptoms. Our findings support prior research reporting associations between sleep and psychosis-risk symptoms. Future research utilizing measures of sleep neurophysiology is required to further understand the mechanistic relationship between sleep and psychosis-risk.

NEIGHBORHOOD PERCEPTIONS AND SLEEP HEALTH IN PREGNANT AFRICAN AMERICAN WOMEN OF LOW SOCIOECONOMIC STATUS

Sarah Farabi[1], W. Todd Cade[2], Rosemary Bass[3], Rick Stein[3], Candice Woolfolk[3], Cindy Schwarz[4], Rachel Tabak[4], Sam Klein[3], Debra Haire-Joshu[4], Cahill Alison[5]
[1] Barnes Jewish College Goldfarb School of Nursing, [2] Duke University, [3] Washington University School of Medicine in St. Louis, [4] Washington University in St. Louis, [5] University of Texas at Austin

Introduction: Poor sleep health is associated with pregnancy complications. Perceptions of neighborhood likely affect sleep in pregnant women. African American women of low socioeconomic status (SES) often live in neighborhoods with disproportionally high crime and traffic. The aim of this study was to evaluate the relationship between perceptions of neighborhood environment and sleep health in pregnant women of African American race and low SES. We hypothesized that higher crime and traffic would be associated with poorer sleep health.
Methods: Baseline data obtained from pregnant women of African American race and low SES (assessed by Medicaid status) who were participants in one site of The Lifestyle Interventions for Expectant Moms Consortium were analyzed. Perceptions of neighborhood crime and traffic were determined by questions from the Physical Activity Neighborhood Environment survey. Components of sleep health measured included self-reported sleep duration, latency, and wake after sleep onset (WASO) and objective sleep duration assessed by 7-day wrist actigraphy (Actigraph GT3X+). Participants were divided into four groups based on their perception of neighborhood crime and traffic (dichotomized as "strongly agree/agree" versus "disagree/strongly disagree" that neighborhood crime rate makes it unsafe and traffic makes it difficult to walk). Sleep characteristics in each group were compared by Kruskal-Wallis tests.
Results: Two hundred and sixty two women (BMI 32.3±5.1kg/m2 [mean±SD]; age 25.8±5 years; gestational age 14.0±1.8 weeks) completed baseline assessments, 169 women had at least 5 nights of actigraphy data. Self-reported sleep duration was shorter in those who perceived high level of neighborhood traffic (7.2±1.6 vs. 7.9±2.0 hours/night, p=0.03). Self-reported sleep latency was longer and WASO was higher in those who perceived a high level of neighborhood crime (32.1±37.8 vs. 24.8±28.9min, p=0.03; 38.7±48.9 vs. 21.5±29.2min, p< 0.01 respectively). Objective sleep duration tended to be shorter in those who perceived high crime in their neighborhoods (7.8±0.9 vs. 8.1±1.0 hours/night, p=0.06).
Conclusion: Perceptions of neighborhood crime and traffic are related to shorter sleep and higher WASO in pregnant African American women of low SES. Larger studies with more robust measures of neighborhood and sleep are needed to better understand the impact of neighborhood environment on sleep health.

PARENTAL CHILDHOOD EXPERIENCES AS A SOCIAL DETERMINANT OF SLEEP HEALTH IN OFFSPRING

Lauren Bailes[1], Maristella Lucchini[2], Natalie Barnett[2]
[1] Oklahoma State University, [2] Nanit Lab

Introduction: The Social Determinants of Health theory posits that social and community context, or the social environment of an individual, including their developmental history, contribute to individual health outcomes. Recent literature has highlighted the intergenerational transmission of social determinants, such that parental experiences can undermine (or support) health outcomes in offspring. During infancy, sleep is critical in promoting health, including brain connectivity and immune health. Identifying correlates of parental social determinants and infant sleep is critical to better understand and support infant sleep health during this critical time. The current study aimed to examine the associations between parental early adversity and positive experiences from childhood in relation to infant sleep.
Methods: Participants (N=262) of 4- to 12-month-old infants were recruited from the Nanit Lab userbase. Participants completed questionnaires on their adverse (Adverse Childhood Experiences Scale; ACEs) and positive childhood experiences (Protective and Compensatory Experiences Scale; PACEs) and provided up to 2 weeks of objective sleep metrics from the autovideosomnography algorithms. Using multi-level modeling to account for the nested nature of the data, we tested the association between infant age (in days), ACEs, and PACEs, and the two- and three-way interactions on total sleep (TST), number of wakings (NW), and parent visits to crib (PV).
Results: Using hierarchical MLM, we found a significant interaction between infant age and PACEs (β=.18, SE=.09, p=.036). Simple slope analyses at one standard deviation above and below the mean suggested that caregivers who reported higher PACEs had a stronger

positive slope between infant age and TST (β=.47, SE=.09, p<.001), suggesting that parents who had more supportive experiences from childhood have infants who increase in TST faster compared to parents who do not have as many supportive experiences. Additionally, ACEs were positively associated with NW (β=.19, SE=.09, p=.001), indicating that infant sleep was more frequently disrupted.
Conclusion: Findings from the current study highlight the importance of understanding the intergenerational effects of social determinants of health and the critical need to identify mechanisms by which parental childhood experiences impact infant sleep.

SEX-SPECIFIC CHANGES IN CARDIOPULMONARY COUPLING CALCULATED SLEEP QUALITY IN ADULTS

Solveig Magnusdottir[1], Hugi Hilmisson[1], Robert Thomas[2]
[1] MyCardio LLC, [2] Beth Israel Deaconess Medical Center

Introduction: Many physiological functions change with age and show sex differences. Women report less sleep quality and greater frequency of sleep disturbances while having better polysomnography (PSG) defined sleep quality than men. The aim of this analysis was to better understand sex-specific changes in objective sleep quality across the adult human life span based on cardiopulmonary-coupling (CPC) sleep quality index (SQI); metric heavily weight by stable-sleep (high-frequency-coupling).
Methods: De-identified data derived from the SleepImage-system (MyCardio LLC, Denver, CO, USA) was analyzed. The system analyses changes in signals (heart rate variability and breathing) modulated by the autonomic nervous system using CPC to derive sleep stages and states, andcalculate proprietary SQI. One-million nights of sleep recording of >6-hours in duration and >4-hours of total sleep time, with good signal quality (>80%) from individuals >18-years of age were included in the analysis. Average nights of recordings/person were 2-nights.
Results: Age groups were defined as 18-30-years (46%-women), 31-40-years (42%-women), 41-50-years (43%-women), 51-60-years (47%-women), 61-70-years (49%-women) and >71-years (47%-women). In all age groups, women had on average higher SQI compared to men (average[standard deviation], 58.9[19.4] vs. 58.3[19.2] p< 0.003; 53.2[19.1] vs. 52.8[19.2,] p< 0.06; 47.5[18.3] vs. 45.8[18.3],p< 0.001; 43.2[17.4] vs. 39.1[16.8], p< 0.001; 39.2[16.8] vs. 34.1[15.2], p< 0,001; 37.9[16.3] vs. 33.3[16.3], p< 0.001 but lower sleep efficiency (SE), 84.3[10.1] vs. 84.5[10.6], p< 0.001; 84.6[10.6] vs. 85.9, p< 0.001; 84.8[10.8] vs. 86.7[10.6], p< 0.001; 83.7[12.1] vs. 85.2[11.4], p< 0.001; 80.7[13.4] vs. 81.8[12.5], p< 0.001 respectively. The apnea hypopnea index (AHI3%) was lower in women that men in all age groups, 7.8[9.3] vs.11.4[12.5], 10.6[12.0] vs.16.9[16.6],13.5[14.1] vs.21.4[18.4], 17.8[15.7] vs. 23.2[18.4], 19.6[15.7] vs. 22.6[17.8] and 20.9[16.7] vs. 22.0[16.5]. Regression analysis demonstrated that SQI was negatively correlated with AHI, with a higher correlation coefficient in men comapred to women 0.33 vs. 0.29; 0.33 vs. 0.21; 0.34 vs. 0.16; 0.30 vs. 0.17; 0.22 vs. 0.15; 0.20 vs. 0.14, and gradually decreasing after 40-years in women and 50-years in men.
Conclusion: In adults, with increasing age, both SQI and SE gradually decline and AHI increases. Sleep quality evaluated with CPC is higher in women than men in all age-groups, similar to that reported with PSG.

INFANT SIBLING DEVELOPMENTAL MONITORING: EARLY SLEEP AND LANGUAGE ASSOCIATIONS

Moon West[1], A.J. Schwichtenberg[1]
[1] Purdue University

Introduction: Toddler sleep is linked with early word learning and some aspects of early language. Findings vary by sample/population (e.g., typically developing, neurodevelopmental disabilities, low sociodemographic resources) but elements of sleep duration, variability, and timing are noted as influential. Within this study, toddlers (infant siblings) at low and high likelihood for language delays (based on a family history of autism) are prospectively followed from 18 to 30 months of age with assessments of language and sleep to assess their associations across early development.
Methods: One hundred and one toddlers contributed data to this study with assessments at 18, 24, and/or 30 months of age. Toddler data were excluded if they received an autism or another major neurodevelopmental disorder diagnosis (e.g., global developmental delay). Expressive and Receptive language skills were assessed using the Mullen Scales of Early Learning. Actigraphy sleep estimates included nighttime, daytime, and 24-hour sleep durations, sleep variability, and bedtime. All analyses included adjustments for child sex and maternal education.
Results: As expected, receptive and expressive language were consistent across early development; wherein, toddlers with higher language scores at 18 months continued to have higher language scores at 24 and 30 months (all p <.01). Nighttime sleep duration followed a similar pattern – toddlers who slept more at night at 18 months continued to sleep more at night at 24 and 30 months (all p ≤.05). Associations between sleep parameters and language were sporadic with no robust patterns emerging although all significant findings were in the expected directions. For example, at 30 months of age, more daytime sleep was associated with higher expressive language scores, r(22) =.37, p <.05.
Conclusion: A wide variety of factors influence child language development with notable differences based on infant sex, maternal education, and previously mastered skills. Although sleep is important for several developmentally consequential skills, its associations with language development appear nuanced and not as robust as other factors (as noted above). Within this study, the unique nature of our sample could contribute to this – as their language-related risks likely include a genetic loading.

PREDICTORS OF SLEEP SATISFACTION IN FIRST YEAR UNIVERSITY STUDENTS

Corinne Fitzsimmons[1], Michael Scullin[1]
[1] Baylor University

Introduction: Sleep satisfaction is a component of sleep health that is not well-captured by objective measures. To advance understanding of sleep satisfaction in student groups, we examined its correlates with habitual sleep behaviors, modifiable habits, environmental factors, mental health, and educational experiences.

Methods: First-year undergraduate students (N=488, 72.1% female, 46.3% white) completed questionnaires pertaining to sleep behaviors, modifiable habits, mental health, and educational experiences. Sleep satisfaction was measured from 1-4 (very good to very bad) with the single question "During the past month, how would you rate your sleep quality overall?" Following preliminary and conceptual analysis, we examined sleep satisfaction in relation to five composite scores: sleep habits (sleep onset latency, prior night sleep duration, weekday sleep duration and bedtime, and morningness-eveningness score), modifiable behaviors (TV use in and out of bed, social media use in bed, time management, efficiency, and procrastination), environmental factors (trouble sleeping due to noise and light), mental health (life satisfaction, mental well-being, resilience, perceived stress, trait anxiety, and depression), and educational experiences (discrimination experiences, imposter syndrome, and other negative experiences).
Results: 26% of first year students indicated fairly bad or very bad sleep satisfaction. The composite scores explained 27.3% of the variance in sleep satisfaction $F(5,374)=28.36$, $p<.001$. Sleep habits explained the largest variance, $\beta=.302$, $p<.001$, followed by mental health, $\beta=.270$, $p<.001$, and environment factors, $\beta=.171$, $p<.001$. Modifiable behaviors and educational experiences did not explain unique variance (ps>.10). Further analysis indicated that the composite effects were driven by difficulties with sleep onset latency $\beta=.149$, $p<.001$, short prior night sleep duration $\beta=-.100$, $p=.046$, short weekday sleep duration $\beta=-.318$, $p<.001$, evening circadian preferences, $\beta=-.102$, $p=.043$, exposure to disruptive noises $\beta=.249$, $p<.001$, and depression symptoms, $\beta=.283$, $p<.001$.
Conclusion: Sleep dissatisfaction is common amongst university students. Improving sleep satisfaction may require multifactorial approaches that address environmental and mental health contributors alongside sleep restriction behaviors.

PARENTAL BEHAVIORS AND CHILD'S CARDIAC VAGAL FLEXIBILITY PREDICT INFANT' SLEEP QUALITY

Nila Shakiba[1], Cathi Propper[2]
[1] Auburn University, [2] University of North Carolina at Chapel Hill

Introduction: Biological and environmental factors shape and impact infant's sleep development from the first months of life (Sadeh et al., 2010). In a sample of African American infants (Mage = 6.53 months, 45% female) and their caregivers (n = 86), the current study examined the links between parental behaviors (sensitive and harsh parenting behaviors), child's parasympathetic functioning to stress, and sleep quality. Cardiac vagal flexibility is a physiological index of social-emotional sensitivity in young children (Miller et al., 2013; Shakiba et al., 2023), with children with greater vagal flexibility tend to be responsive and influenced by their familial environmental cues, either positive or negative cues (Muhtadie et al., 2015). The study further explored whether the effects of parenting behaviors on a child's sleep quality may vary, in part, depending on the child's physiological responsiveness and regulation in response to stressors.
Methods: Mothers and their 6-month-olds were observed during a free-play task at the home visit. The parent-child interaction was coded based on various subscales assessing caregiving sensitivity and harshness. Children's parasympathetic functioning, indexed by the respiratory sinus arrhythmia (RSA), was assessed during the Face-to-Face Still Face Paradigm (FFSFP; Tronick et al., 1978). Child's vagal flexibility (Miller et al., 2013) represents the non-linear and dynamic patterns of RSA change over the course of the task and was modeled by using the latent basis growth curve modeling approach. Infant's sleep was objectively measured using videosomnography and actigraphy. Structural equation modeling approach was performed to test the study's questions.
Results: We found that the effects of parenting on children's sleep efficiency, defined as the ratio of sleep interval to rest interval, differed across children and depended upon their levels of vagal flexibility to stress. High-sensitive caregiving predicted greater sleep efficiency only in infants who exhibited high vagal flexibility or adaptive patterns of parasympathetic regulation across the FFSFP. Similarly, for infants with high (but not low) vagal flexibility, high levels of harsh parenting predicted lower sleep efficiency.
Conclusion: The findings highlight the importance of considering the interplay between biological and environmental factors to better understand individual differences in infants' sleep development and patterns.

ASSOCIATIONS BETWEEN PARENTAL BEDTIME BEHAVIORS AND SLEEP QUALITY IN TODDLERS

Jennifer Holmes[1], Rebecca Spencer[1]
[1] University of Massachusetts, Amherst

Introduction: In early childhood, helping children develop healthy sleep habits is paramount. Much attention is placed on ensuring children develop good sleep hygiene practices, largely through encouraging consistent bedtime routines. There is, however, a lack of consensus on what bedtime behavior strategies are best to encourage optimal child sleep. Thus, we aimed to explore how parental bedtime behaviors relate to sleep quality in toddlerhood. We hypothesized that greater use of interactive bedtime behaviors (e.g., cuddling, feeding, reading before bed) would relate to poorer quality sleep in toddlers, as evidenced by longer sleep latency, shorter nighttime sleep, and less consistent sleep timing. Conversely, more frequent parental encouragement to self-soothe to sleep would relate to better sleep quality.
Methods: Toddlers (n=53, M age=22.7 mos) wore actigraph watches on their ankle for up to 14 nights. Primary caregivers (98% mothers) completed sleep diaries as well as the Parental Interactive Bedtime Behavior Scale (PIBBS). The PIBBS allowed us to determine the frequency with which caregivers employ common bedtime behavior strategies, including Active Comfort, Passive Comfort, Movement, or Encouraging Autonomy. Actigraph data was scored according to accepted standards and averaged across all nights of wear (M=9.3 nights).
Results: Partial Pearson's correlations were used to determine relations between parental bedtime behaviors and toddler's objective sleep measures. We controlled for SES as it was significantly associated with most bedtime behaviors. Nighttime sleep duration was negatively associated with Active Comfort ($r=-.478$, $p<.001$), Passive Comfort ($r=-.359$, $p=.01$), and Movement ($r=-.323$, $p=.02$) strategies, while it was marginally positively

associated with Encouraging Autonomy (r=.266, p=.06). Sleep midpoint was positively associated with parental use of Active Comfort (r=.415, p=.003). Lastly, variability in sleep midpoint was negatively associated with Encouraging Autonomy (r=-.516, p<.001). Sleep latency was not related to any bedtime behaviors.
Conclusion: Overall, greater parental tendency to encourage autonomy as part of their toddler's bedtime routine was associated with longer sleep duration and more consistent sleep timing. When parents used more interactive strategies such as Active Comfort, toddlers tended to have shorter overnight sleep and later sleep timing. Future analyses will explore to what extent parent bedtime behavior strategies relate to pre-existing child sleep problems.

DAY-TO-NIGHT SLEEP RATIOS AND GUT MICROBIOME COMPOSITION IN INFANCY: A LONGITUDINAL ANALYSIS

Megan Petrov[1], Sterling Wright[2], Corrie Whisner[2]
[1] Edson College of Nursing and Health Innovation, Arizona State University, [2] Arizona State University

Introduction: Infancy is a critical period for neurodevelopment and long-term health. Emerging evidence suggests that sleep-wake circadian rhythms and the gut microbiome (GM) are interlinked and influence these outcomes, yet this relationship remains underexplored. This study examines whether day-to-night sleep duration ratios in infancy are associated with GM community structure and species abundance during the first year of life.
Methods: A subset of mother-infant dyads from the Snuggle Bug / Acurrucadito cohort was analyzed. In total, 80 full-term infants provided 24-hr actigraphic sleep recordings and fecal samples at six time points (3 and 8 weeks, 3, 6, 9, and 12 months). The primary sleep variable included in the gut microbiome analysis was the average proportion of nocturnal total sleep (NTST) relative to 24hr TST (24TST). Fecal microbial DNA was extracted using DNeasy Pro kits and analyzed via PacBio's full-length16S rRNA gene sequencing, processed with the HiFi-16S Nextflow pipeline to generate high-quality amplicon sequence variants (ASV). Beta diversity, based on Aitchison distance, was assessed using ADONIS in QIIME2 while adjusting for individual and age effects. A linear mixed-effect model with Maaslin2 (q-value≤0.25) was employed to identify differentially abundant species.
Results: From 80 participants, 196 valid actigraphy and fecal samples were provided. The NTST/24TST significantly increased with age (β±SE=0.02±0.01, p=0.033, range: 0.57-0.99). NTST/24TST was significantly associated with gut microbial community structure after adjusting for time and individual effects (R2=0.014, p=0.016). While the interaction between the age of the infant and NTST/24TST was not significant (p=0.07), the effect size was notable (R2=0.22). Four species were differentially abundant: Anaeroglobus massiliensis (β=-0.05, p=0.0002, q=0.08), Enterobacter cloacae (β=-0.23, p=0.002, q=0.20), and Haemophilus D. sp. 001915335 (β=-0.034, p=0.002, q=0.20) were associated with lower NTST/24TST, with the latter species being an opportunistic pathogen. Conversely, Mediterraneeibacter faecis (β=0.62, p=0.002; q=0.20), a short-chain fatty acid producer, was associated with higher NTST/24TST.
Conclusion: Day-to-night sleep duration ratio differentiated gut community structures in infancy. Although these findings are preliminary, lower NTST/24TST may reflect a microbiome profile with reduced beneficial microbe abundances. Together, these findings highlight the need for further investigation into the connection between sleep-wake rhythms and gut microbiome composition.

MEASUREMENT CONSISTENCY OF HABITUAL SLEEP PATTERNS OF CHILDREN AND ADOLESCENTS IN THE MOTRPAC STUDY

Ariel Neikrug[1], Shlomit Radom-Aizik[1], Ivy Chen[1], Annamarie Stehli[1], Henry Lin[1], Dylan Barry[1], Greyson Hanson[1], Bryce Mander[1], Ruth Benca[2]
[1] University of California, Irvine, [2] Wake Forest University

Introduction: Characterizing habitual sleep patterns in children and adolescents is challenging due to the well-documented variability inherent in standard assessment methods, which often yield poor to moderate internal consistency. This quality control study aimed to evaluate the internal consistency of habitual sleep assessment methods (questionnaire, sleep diary, and accelerometry) using data from the Interacting Mechanisms of SLeep and Endurance Exercise in Pediatrics (iSLEEP) study, an ancillary project of the UCI pediatric Molecular Transducers of Physical Activity Consortium (MoTrPAC). Additionally, it examined whether incorporating sleep/wake pattern parameters into sleep continuity measures improve internal consistency.
Methods: Seventy-seven healthy children and adolescents (Mage=15.0±2.3 years, 62.3%f) completed the iSLEEP MoTrPAC ancillary study including questionnaire [School Sleep Habit Survey (SSHS)] and 7-14 days of accelerometry (Actiwatch) with daily sleep diaries. Sleep continuity variables [i.e., sleep onset/offset times, midsleep time, total sleep time (TST), and sleep efficiency (SE)], were derived from SSHS, diary, and accelerometry (using standardized scoring approaches that include the diary). Behavioral sleep/wake patterns were estimated using UP/DOWN times/slopes, deriving from Shape Language Modeling (SLM) using minute-by-minute activity counts. Internal consistency (Cronbach's alpha) and reliability coefficients were computed. Factor analyses identified latent structures which were correlated between measurement approaches, and the contribution of sleep/wake pattern correlation metrics to traditional sleep continuity measures from accelerometry was evaluated.
Results: Sleep continuity measures from diaries (α=0.63) and accelerometry (α=0.65) demonstrated similar moderate internal consistency, while questionnaire showed expected poor consistency (α=0.21). Behavioral sleep/wake pattern variables (UP/DOWN times/slopes) showed good and acceptable internal consistency (α=0.78). Factor analyses identified two key components solutions for sleep continuity measures in diaries and accelerometry: Factor 1: sleep timing (onset, offset, midsleep; p's< 0.001) and Factor 2: TST and SE (p's< 0.001). Factors were significantly correlated between the measurement approaches (timing factor, r=0.87; TST/SE factor, r=0.50, p's< 0.001). Integrating behavioral sleep/wake pattern variables with the traditional accelerometry-derived sleep continuity measures resulted in strong internal consistency (α=0.83).

Conclusion: Diary and accelerometry exhibited comparable internal structure and validity of habitual sleep pattern characterization in children and adolescents. Incorporating behavioral sleep/wake activity patterns alongside traditional sleep continuity measures enhances validity measures.

LONGITUDINAL STUDY OF SLEEP DURATION AND VARIABILITY ACROSS EARLY CHILDHOOD

Allison Swift[1], Melissa Horger[1], Jennifer Holmes[1], Tracy Riggins[2], Rebecca Spencer[1]
[1] University of Massachusetts, Amherst, [2] University of Maryland

Introduction: Sleep is critical to early physical, cognitive, and psychomotor growth. Sleep patterns, including duration, timing, and quality, change drastically across early childhood. Most previous work has relied on caregiver-reported sleep times, who typically overestimate their child's sleep duration, and data is often cross-sectional. Here we used a staggered longitudinal design to examine objectively-measured changes in sleep across early childhood.
Methods: 65 infants and toddlers (36 females; 9-31 months) wore actigraph watches for up to 16 days. Infants < 26 months wore the actigraph on their left ankle, while older toddlers wore the actigraph on their left wrist. Caregivers completed a sleep diary detailing sleep onset and offset times for all sleep bouts. Actigraphy was scored in Philips Actiware by trained scorers. Children were assessed at 9, 12, 15, 16, 21, and/or 26 months. Data include children with data at 1-3 ages.
Results: Not surprisingly, total 24-hour sleep duration decreased with age ($F(6,58)=4.581$, $p< 0.0001$). Tukey posthoc tests identified significant differences between 12 and 21 months ($p< 0.05$), and 12 and 26 months ($p< 0.05$). While the impact of age on overnight sleep duration was not significant ($F(6,58)=2.009$, $p=0.0789$), we found a significant effect of age on nap duration ($F(6,58)=3.776$, $p< 0.005$) with significant differences between 12 to 26 month groups ($p< 0.05$) and 15 to 26 month groups ($p< 0.05$). There was also a significant effect of age on nap efficiency ($F(6,58)=2.437$, $p< 0.05$), but not night sleep efficiency. We found no significant effect of age on overnight sleep midpoint variability ($F(6,58)=0.442$, $p=0.848$).
Conclusion: We will provide a rare view of sleep changes in this critical window when sleep is thought to change drastically in duration and consolidation. These data are useful for identifying critical points of sleep changes which is essential for considering interventions on sleep for children at-risk. Moreover, these transition points will also be useful for further research seeking to identify underlying mechanisms for changes in sleep.

DOES SLEEP PHYSIOLOGY PREDICT LANGUAGE AND LITERACY DEVELOPMENT IN EARLY CHILDHOOD?

Lena Gaudette[1], Lindsey Mooney[2], Melissa Horger[2], Tracy Riggins[3], Rebecca Spencer[2]
[1] University of Massachusetts Amherst, [2] University of Massachusetts, Amherst, [3] University of Maryland

Introduction: Sleep is essential for cognitive and emotional development, influencing key processes such as memory consolidation and emotional regulation. This exploratory research investigates the relationship between sleep parameters and literacy engagement behaviors, including children reading independently, being read to, and family participation in reading and writing tasks. We hypothesized that greater engagement in these activities would be associated with greater N3 sleep due to literacy-related learning and plasticity.
Methods: Participants were 15 3-5-year-old children (8 female). Parents completed a questionnaire probing home, language, and literacy activities. Polysomnography was recorded for both nap and overnight sleep either in-lab or in-home. Sleep parameters included percentage of time spent in each sleep stage (%N1, %N2, %N3, and %REM) as well as total sleep time (TST).
Results: Positive associations were observed between the frequency of children engaging with books at home (e.g., looking at books, asking to be read to) and %N3 during overnight sleep ($r(13)=0.53$, $p=0.04$), but not time spent in other sleep stages or TST. There was no significant relationship between language acquisition measures and other sleep stages, nor nap sleep physiology.
Conclusion: These findings suggest that N3 may play a role in processing home-based literacy-related learning in children. The strength of this relation relative to other literacy behaviors may be related to in-home literacy activities occurring close to bedtime. These results are consistent with other literature on sleep's role in language acquisition and may point to learning experiences prior to bedtime being prioritized in sleep, a focus for future research.

Introduction: Screen time is linked to sleep problems in young children, but few studies have examined this in infants using actigraphy. We aimed to assess infant screen time in association with actigraphy-assessed sleep patterns at six months of age among an active, ongoing cohort.
Methods: Fifty-six, full-term (≥37wk), singleton infants with normal weight (2.5-4kg) and without major medical problems were recruited from Phoenix, Arizona. At 6 months, infants wore an actigraph to capture five 24hr sleep periods (i.e., 24hr total sleep time [TST, hh:mm], nocturnal TST [hh:mm], bedtime [AM/PM], sleep onset latency [min], number of long wakes [>5min], nocturnal longest sleep bout [min], nocturnal time-in-bed [hh:mm]). Mothers reported on typical daily infant attentive screen time, and the time spent watching or in the presence of screens in the hour before bedtime. Infant weight was collected via digital scale and weight-for-age z-score (WAZ) by sex was computed. Multivariate ANOVA models for all sleep variables by daily infant screen time (median split: < 10 vs. ≥10min) and by infant screen exposure before bedtime (median split: < 20 vs. ≥20min) adjusted for infant sex and WAZ were conducted.

Results: At six months, infant's mean 24hrTST, nocturnal TST, bedtime, sleep onset latency, long wakes, nocturnal longest sleep bout, and nocturnal time-in-bed were 11:47±1:15, 9:33±0:58, 20:20±1:14 PM, 19.6±14.6min, 3.2±1.6 wakes, 2:50±1:07, and 10:51±1:00, respectively. Daily screen time ≥10min, relative to < 10min, was significantly associated with less 24hrTST (M±SE: 11:17±0:16 vs. 12:13±0:15, F[1,37]=6.00, p=0.019), less nocturnal TST (M±SE: 9:16±0:11 vs. 9:50± 0:12, F[1,51]=4.3, p=0.04), later bedtime (M±SE: 20:47±0:14 vs. 19:52± 0:15 PM, F[1,51]=7.2, p=0.01), and less nocturnal time-in-bed (M±SE: 10:34±0:12 vs. 11:10±0:12, F[1,51]=4.3, p=0.04). There were no differences in any sleep quality measures. In models of infant screen exposure before bedtime, ≥20min was trending toward longer sleep onset latency (M±SE: 23.6±2.8 vs. 16.0±2.7min, F[1,51]=3.8, p=0.056, ηp2=0.07). There were no other significant or trending differences in sleep outcomes.
Conclusion: Greater daily attentive infant screen time at six months of life was associated with compromised sleep opportunity, quantity, and later bedtimes but not sleep quality. Screen exposure before bedtime may be related to potential delays in sleep onset.

THE OVERLAP OF SLEEP AND SCREEN USE: PATTERNS OF SMARTPHONE USE BEFORE AND AFTER SLEEP ONSET IN ADOLESCENTS

Orsolya Kiss[1], Ruby Fan[1], Evelyn Perez-Amparan[1], Hannah Giarrusso[2], Nicole Arra[1], Marie Gombert[1], Janosch Linkersdörfer[3], Eva M Müller-Oehring[4], Jason M. Nagata[5], Fiona Baker[1]

[1] SRI International, [2] Center for Health Sciences, SRI International, Menlo Park, CA, USA, [3] Department of Psychiatry, University of California, [4] Department of Neurology and Neurological Sciences, Stanford University School of Medicine, [5] Division of Adolescent and Young Adult Medicine, Department of Pediatrics, University of California San Francisco

Introduction: Sleep is important for emotional, behavioral, and cognitive development in adolescents. Prior research shows that smartphone use, particularly around bedtime and during the night, can interfere with sleep, however, findings mostly rely on self-reported measures. Here, we address this gap by combining objective smartphone usage and sleep measures to examine smartphone use around sleep onset and during the sleep period.
Methods: Participants included 653 adolescents (Mean age=14.09 years) from the Adolescent Brain Cognitive Development (ABCD) Study. Smartphone use was recorded over three weeks using the Effortless Assessment Research System (EARS) app, which logged the last engagement in multiple app categories. Sleep onset and sleep period were measured with Fitbit Charge 2 wearables. Screen use events were categorized as daytime usage; usage near sleep onset: for one hour before and one hour after sleep onset, nighttime usage (overlapping sleep); and after-sleep morning usage.
Results: Screen activity within one hour before sleep onset occurred in 91.0% of participants, with 81.8% showing this pattern on more than half the days. Usage in the hour after sleep onset was observed in 45.7% (20.1% on more than half the days), while 56.0% had nighttime screen activity (29.9% on more than half the days). Significant weekday vs. weekend differences emerged in daytime usage categories. Daytime usage within one hour before sleep onset was higher on weekdays (6.8%) than on weekends (6.1%, t=2.54, p=0.011), as was overall daytime usage (66.4% vs. 61.0%, t=4.59, p<.001). Nighttime usage showed no significant weekday-weekend differences. Social networking apps were most frequently used across all categories. Significant correlations were observed between daytime usage within one hour before sleep onset and nighttime usage one hour after sleep onset (r=0.48, p<.001) and between daytime usage and nighttime usage (r=0.35, p< 0.001).
Conclusion: Screen use around sleep onset and during the night is highly prevalent among adolescents, with social media app usage dominating at all times of the day. Associations between daytime and nighttime proximity to sleep onset usage suggest persistent screen habits, highlighting the need for interventions promoting healthier use patterns, especially near sleep onset.

BODY COMPOSITION AND DIETARY INTAKE ASSOCIATES WITH SLEEP MACRO-ARCHITECTURE IN YOUNG ADULTS

Daphne Valencia[1], Caroline Chovanes[2], Sue Shapses[2], Andrea Spaeth[2]

[1] Rutgers University, New Brunswick, [2] Rutgers University

Introduction: Insufficient sleep is associated with excess body fat and daytime sleepiness in adults. Prior work has also shown that body fat percentage associates with increased rapid-eye movement sleep (REM) and that fiber intake associates with increased slow wave sleep (SWS). Here we aimed to examine relationships between body composition and sleep macro-architecture in young adults, who are at increased risk for insufficient sleep.
Methods: Participants were 55 students enrolled at a large public university (20.3±1.68y, 35 female) who completed the Epworth Sleepiness Scale (ESS) and dietary screening questionnaire (DSQ), wore an actigraph on their non-dominant wrist 24/7 for 14 days and completed at-home polysomnography on a night where they were instructed to remain in bed for 9h. Body composition and bone metrics were measured by dual X-ray absorptiometry. Pearson's and Spearman's correlations analyzed relationships between body composition and sleep variables.
Results: Higher BMI associated with poorer actigraphy-measured sleep efficiency (ρ = -0.425, p < 0.01) and greater wake after sleep onset (ρ=0.34, p< 0.01). Greater fat mass associated with less total sleep time (actigraphy: r=-0.32, p< 0.05; PSG: r=-0.27, p< 0.05), poorer sleep efficiency (PSG: r=-0.28, p< 0.05) and greater daytime sleepiness (r=0.29, p< 0.05). Greater bone mineral content (BMC) was associated poorer sleep efficiency SE (r=-0.26, p< 0.05). In n=25 with completed DSQ, calcium (ρ=-0.45, p< 0.05) and dairy (ρ=-0.401, p< 0.05) intake also associated with poorer sleep efficiency.
Conclusion: Findings contribute to growing evidence demonstrating bidirectional relationships between sleep health and body composition, particularly fat mass.

STOP MAKING TEENS GO TO BED BEFORE THEIR DLMO! IT'S HURTING THEIR FEELINGS!

Allison Monterastelli[1], Nina Blaise[1], Ieva Misiunaite[1], Charmane Eastman[1], Stephanie Crowley[1]

[1] Rush University Medical Center

Introduction: Most adolescents experience chronic sleep restriction and circadian misalignment due to delayed sleep propensity combined with early school start times. The present analysis aims to examine adolescent mood under conditions of sleep restriction and circadian misalignment.

Methods: 74 (37 female) adolescents (14.1-18.0 years) completed a 15-day study. Participants spent days 1-7 (baseline) at home following individualized 10-h sleep schedules. Participants lived in the laboratory on days 8-14. On days 9-13, sleep was restricted by delaying bedtime 1.5h (n=20), 3h (n=23), or 4.5h (n=20). Between baseline bedtime and delayed bedtime, 34 participants wore amber-lensed glasses (16±2 lux), and 29 participants remained in room light without glasses (104±11 lux). Eleven participants continued the 10-h sleep opportunity followed during baseline. On day 11, sleep/dark shifted 1.5h earlier. On days 12-13, sleep/dark shifted 1h earlier each day. All participants received 1.5h of bright light (8595±834 lux) within 5 minutes of waking on days 12-14. Circadian phase (dim light melatonin onset (DLMO)) was measured on days 8 and 14. The protocol produced a wide distribution of day 14 DLMOs (17:30–4:10). Throughout the study, participants completed visual analog scales before bed to assess mood. An individual's mood on day 13 (after 2.5-h sleep/dark advance) was subtracted from their baseline week average. Mood change scores were compared between participants with day 14 DLMOs before (n=43; "aligned") or after (n=31; "misaligned") day 13 scheduled bedtime. Day 14 DLMOs ranged from 4.5h before to 3.3h after day 13 bedtime.

Results: Misaligned teens reported feeling more tense (p=0.02), less energetic (p=0.02), and less calm (p=0.03) than aligned teens. The use of amber-lensed glasses only impacted feelings of calmness; participants wearing glasses were calmer than individuals without (p=0.05). Sleep duration only impacted feelings of sleepiness; the 10-h group felt less sleepy than the 8.5-h (p=0.05), 7-h (p=0.08), and 5.5-h (p=0.02) groups. Changes in happiness, temper, irritability, and concentration did not differ in any analyses.

Conclusion: These results indicate that circadian misalignment plays a role in adolescent mood. Subsequent analyses will expand the current focus beyond the evening by evaluating mood at different times of day.

LIGHT AFTER LUNCH: AFTERNOON BRIGHT LIGHT IS NOT EFFECTIVE FOR ADVANCING CIRCADIAN PHASE OF ADOLESCENTS

Elaine Poole[1], Allison Monterastelli[1], Charmane Eastman[1], Stephanie Crowley[1]

[1] Rush University Medical Center

Introduction: Morning bright light is most effective in shifting circadian phase earlier; however, our adolescent PRC to bright light unexpectedly showed phase advances in response to bright light timed in the afternoon (Crowley & Eastman, JBR 2017 32(4):334-344). The current ongoing study is examining phase shifts in response to three bright light schedules: morning bright light (MBL), afternoon bright light (ABL), and a combination of morning and afternoon bright light (MBL+ABL) compared to a room light (RL) control.

Methods: So far, 51 adolescents (27F) aged 18.3-20.9 years completed a two-week study. During the first week, participants followed a rigid individualized 9-hour sleep schedule at home. On days 8-13, participants lived in the lab. On day 8, participants completed initial phase assessments to determine Dim Light Melatonin Onset (DLMO). On day 9, they followed their baseline sleep schedule. On days 10-12, their sleep (dark) advanced 1-hour earlier each day. DLMO was measured again on day 13. Three groups received bright light from light boxes (8542±820 lux, 45-min exposures totaling 3h/day) on days 10-13 at the following times: all 4 exposures started 5h after wake (ABL; n=18), all 4 exposures started within 5 minutes of wake (MBL; n=7), or 2 exposures started within 5 minutes of wake and 2 exposures started 7 h after wake (MBL+ABL; n=8). A fourth group (RL; n=17) completed the same protocol but remained in room light (45±22 lux).

Results: DLMO advanced in all groups (RL: 0.8±0.5h; ABL: 0.9±0.6h; MBL: 1.9±0.9h; MBL+ABL: 0.9±0.6h). A main effect of group ($F(3,46)=5.86$, $p=.002$) was explained by the MBL group showing larger phase advances compared to all other groups (p's<.02).

Conclusion: Gradually advancing the sleep (dark) schedule by 1h/day for 3 days advanced the circadian clock of adolescents by ~1h. Adding 3h of morning bright light increased the advance to ~2h. Afternoon bright light, even when combined with morning light, did not significantly change the phase advance obtained by advancing sleep (dark) only.

ASSESSMENT OF THE IMPACT OF PUBERTAL DEVELOPMENT AND WORK OR STUDY SHIFTS ON THE SLEEP HABITS OF ADOLESCENTS

Ana Nunes-Oliveira[1], Priscila F Tempaku[2], Sergio Tufik[3], Allan Oliveira[1], Vânia D'Almeida[4]

[1] Universidade Federal de São Paulo, [2] Sleep Institute, Associação Fundo de Incentivo à Pesquisa, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo, [4] UNIFESP - Universidade Federal de São Paulo

Introduction: Puberty involves physiological changes in circadian oscillatory processes that impact circadian preferences and sleep-wake patterns. During this stage, individuals tend to have an eveningness preference and this circadian clock delay peaks at the end of adolescence. However, excessive exposure to light at night and social demands, such as school schedules, can lead to accumulated sleep debt, negatively impacting health and performance

Methods: A cross-sectional study was conducted at the Premature Outpatient Clinic of UNIFESP/EPM, involving 58 preterm children and adolescents aged 10 years and older. School or work shift schedules and pubertal status were self-reported. The Morningness-Eveningness Scale (M/E) and the Munich Chronotype Questionnaire were evaluated. Linear

regression analyses were performed to evaluate the impact of school or work shifts and pubertal development on sleep habits. The significance level adopted was 5%

Results: Our sample consisted of 65.5% females and 34.5% males, with a mean age of 14.3±2.9 years. 44.7% studied or worked in the morning, 23.7% in the afternoon, 7.9% at night; 18.4% in full-time shifts, and 5.3% had undefined schedules. The average score of the M/E questionnaire was 31.4±5.06, indicating a stronger preference for morningness. Participants who work or study in the morning woke up earlier (5:54a.m.±0:30) than the night group (8:48a.m.±2:00) and afternoon group (08:45a.m.±01:32) during weekdays. Those who study or work in the morning slept less (07:44±01:26h) than the night (10:00±2:17h) and afternoon (10:18±1:30h) groups on weekdays. Regarding pubertal development, for each additional point on the pubertal scale, there was a 6-minute reduction in wake-up time and a 9-minute reduction in sleep duration during weekdays

Conclusion: The results indicated that social demands such as study or work shifts greatly impacted sleep habits. Even individuals with more advanced pubertal development, marked by a greater tendency to be an evening person, woke up earlier, had shorter sleep durations on weekdays, and expressed preference for morningness

HOW THE TIMING OF PHYSICAL ACTIVITY IMPACTS SLEEP QUALITY IN ADOLESCENTS

Dustin Sherriff[1], Katie Rugh[1], Justin Ison[1], Clark Wilson[1], Daniel Kay[1], Kara Duraccio[1]

[1] Brigham Young University

Introduction: Moderate-to-vigorous physical activity (MVPA; exercise that elevates heart rate and breathing), generally has positive effects on sleep outcomes, such as improved sleep efficiency, reduced sleep onset latency (SOL), and increased total sleep time (TST). Less is known about the ideal time of day to exercise for benefits towards sleep, though preliminary evidence suggests that late-evening MVPA can worsen sleep efficiency and increase SOL. This study aims to investigate how the timing of physical activity across various times of day influences same-night sleep outcomes in adolescents.

Methods: We analyzed sleep and activity pattern data from adolescents (ages 14–18; N = 100) across three separate studies. Sleep and physical activity were collected across a 7-10 day monitoring period using Actiwatch 2 devices to assess for sleep, and Actigraph GT3x+ devices to assess for physical activity. Daily activity was broken down into three distinct periods of the day: After waking (within 2 hours of waking), during the day (after 2 hours of waking until 2 hours before bedtime), and before sleep (< 2 hours before bedtime). A linear mixed-effects model was performed to analyze how MVPA during these three time periods impact same night sleep, including: wake after sleep onset (WASO), SOL, sleep period length, and sleep efficiency.

Results: We observed that MVPA before sleep predicted increased WASO (p=<.01). In addition, we found that MVPA before sleep predicted decreased SOL (p=<.001). Activity after waking and during the day did not positively or negatively predict any sleep variables, and sleep efficiency was not predicted by any activity timing.

Conclusion: These findings suggest that a more nuanced approach to physical activity recommendations, specifically tailored to specific types of insomnia, may be beneficial. For adolescents with sleep onset insomnia, engaging in physical activity right before bed may help reduce the time it takes to fall asleep, while those with maintenance insomnia may benefit more from morning or daytime activity to improve sleep throughout the night. Future research could explore how physical activity timing impacts adolescents' sleep when misaligned with their chronotype. Additionally, studies could identify which activity types and intensities are most effective for improving sleep outcomes.

SEASONAL AND CONTEXTUAL EFFECTS ON HABITUAL SLEEP PATTERNS IN MOTRPAC'S CHILDREN AND ADOLESCENTS

Ivy Chen[1], Annamarie Stehli[1], Henry Lin[1], Greyson Hanson[1], Dylan Barry[1], Sheldon Watanabe[1], Bryce Mander[1], Ruth Benca[2], Shlomit Radom-Aizik[1], Ariel Neikrug[1]

[1] University of California, Irvine, [2] Wake Forest University

Introduction: Adolescence involves well-known changes in sleep and circadian patterns, further influenced by contextual variations (seasons and school/vacation). Using both subjective (sleep diaries) and objective (accelerometry) data from the Interacting Mechanisms of SLeep and Endurance Exercise in Pediatrics (iSLEEP) study, an ancillary project to the UCI pediatric Molecular Transducers of Physical Activity Consortium (MoTrPAC), this study evaluated contextual factors as a quality control measure. The aim was to assess whether the data reflect expected seasonal and contextual variability, confirming the need for adjustments for these confounding factors to ensure data integrity in future analyses.

Methods: Seventy-seven healthy children and adolescents (Mage=15.0±2.3yrs, 62.3%f) who completed the iSLEEP Pediatric MoTrPAC Ancillary study underwent 7–14 days of accelerometry (Actiwatch) alongside daily sleep diaries. Assessed sleep parameters included sleep onset/offset times, midsleep time, total sleep time (TST), and sleep efficiency (SE). Circadian metrics included UP/DOWN times and slopes, deriving from Shape Language Modeling (SLM) using minute-by-minute activity counts. Non-parametric one-way ANOVAs, adjusted for age and sex, were conducted to assess whether sleep and circadian data showed expected patterns across seasons and school/vacation periods, validating the need for contextual adjustments.

Results: Significant seasonal and contextual variability was observed in sleep offset, midsleep, and UP times, with later timing during summer and no-school periods compared to spring and school periods (p's< 0.05). In contrast, no significant variations were found in sleep onset time, TST, SE, or DOWN time/slope. Consistent findings were observed in subjective and objective methods, enhancing confidence in data integrity.

Conclusion: Consistent with prior research, certain sleep and circadian parameters (sleep offset, midsleep, and UP times) reliably reflect seasonal and school-related variability, highlighting their sensitivity to contextual changes between school and vacation periods that were also reflected in the summer season. In contrast, parameters like sleep onset and TST appear less

responsive. The complementary use of subjective and objective methods enhances methodological rigor and provides insights for optimizing data interpretation. These findings underscore the need for context-specific adjustments in data analyses and emphasize the importance of robust data quality and validity assessment in pediatric sleep research.

THE ASSOCIATION BETWEEN SLEEP ARCHITECTURE AND WHITE MATTER MICROSTRUCTURE DURING EARLY ADOLESCENCE

João Paulo Lima Santos[1], Adriane Soehner[1]
[1] University of Pittsburgh

Introduction: Sleep plays a vital role in brain development during adolescence. However, the relationship between sleep architecture and white matter remains poorly understood. Additionally, little is known about how puberty influences these associations, despite adolescence being a period of significant sleep and white matter changes. We investigated the association between sleep architecture and white matter integrity during early adolescence and examined whether these relationships vary with puberty. The uncinate fasciculus was selected due to its association with sleep and its role in emotion and memory, making it particularly relevant for studying sleep-related effects.
Methods: A total of 455 adolescents (Female=217; Age range=10.75-13.41 years; Mean age[SD]=11.97[0.65]years) from the Adolescent Brain Cognitive Development (ABCD) study with good quality diffusion MRI and Fitbit wrist monitoring were included. Sleep architecture (light, deep, and REM) was estimated from Fitbit data. Neurite Orientation Dispersion and Density Imaging (NODDI) metrics were derived from diffusion MRI: Neurite Density Index (NDI) to measure neurite density and Orientation Dispersion Index (ODI) to assess neurite organization. Linear regressions tested cross-sectional associations between sleep stages and white matter. Pubertal status (136 prepubertal vs. 319 undergoing puberty) was included as an interaction. Age and sex at birth were covariates.
Results: Longer duration of REM sleep was associated with greater uncinate fasciculus NDI (β=0.27,P=.003). Shorter duration of light (β=-0.21,P=.008) and deep (β=-0.14,P=.005) sleep were associated with greater uncinate fasciculus ODI. While the effect of deep sleep was consistent across puberty groups, prepubertal adolescents showed stronger effects of REM sleep on NDI (β=0.24,P=.006) and light sleep on ODI (β=-0.20,P=.017) relative to those already undergoing puberty.
Conclusion: This analysis highlights the role of sleep in white matter development during early adolescence, with stage-specific and puberty-dependent associations between sleep architecture and white matter. REM sleep enhance neurite density (↑NDI), potentially supporting axonal growth. In contrast, light and deep sleep improve white matter organization (↓ODI), crucial for efficient brain network connectivity. These findings provide new insights into sleep's associations with white matter structure and imply differential importance of specific sleep physiological features for white matter development by developmental stage.

RELATIONS BETWEEN SLOW OSCILLATION SPINDLE COUPLING AND HIPPOCAMPAL SUBFIELDS IN DEVELOPMENT

Lindsey Mooney[1], Roger Balcells Sanchez[1], Sanna Lokhandwala[2], Melissa Horger[1], Jade Dunstan[3], Zehua Cui[3], Tracy Riggins[3], Rebecca Spencer[1]
[1] University of Massachusetts, Amherst, [2] Boston Children's Hospital, [3] University of Maryland

Introduction: Non-REM (nREM) sleep features, particularly slow oscillations (SO) and spindle activity, are associated with cognitive development in early childhood. These hallmarks of nREM sleep support memory consolidation, with SO-spindle coupling proposed as a key mechanism. Meanwhile, the developing hippocampus has been shown to support memory abilities in young children. Within the hippocampus, the CA1 subfield plays a unique role in memory processes, particularly replay and the integration of new information. The development of the hippocampus and its subfields coincides with changes in sleep morphology, such as increased spindle density and refinement of SO-spindle coupling, which are predicted to reflect maturing memory systems. Investigating the interplay between these sleep features and the hippocampus during early childhood is essential for understanding how memory is supported during this critical developmental period.
Methods: Preschool-aged children (N = 26; M= 4.26 years, SD=0.65 years, Range=3.43-5.82 years) underwent ambulatory polysomnography during a daytime nap. Expert scorers and a custom MATLAB program (PSGPower) delineated individual sleep states, sleep spindles, and SOs in 30s epochs. A T1-weighted magnetic resonance imaging (MRI) scan was used to delineate hippocampal subfield volumes, quantified by volumetric analysis using Freesurfer 6.0.
Results: When controlling for age and total sleep time, the number of coupled SOs and spindles within the central areas during slow wave sleep as well as between the central and frontal areas correlated with the size of the CA1 (right: r(24)=.41, p=.05; left: r(24)=.34, p=.10), but not the dentate gyrus/CA2-4, or the subiculum.
Conclusion: The relation between CA1 volume and central SO-spindle coupling during slow wave sleep underscores the burgeoning functional specialization of hippocampal subfields during early childhood development, as well as the memory-supporting significance of slow wave sleep. With the CA1 developing earlier than other subfields, it may lead the charge for consolidation of long-term memories. As such, increased coupled SOs and spindles may occur more when the CA1 is further developed. Subsequent analyses will explore phase amplitude coupling specifically in relation to hippocampal subfield volumes, elucidating the importance of both for memory and neuroplasticity.

ASSOCIATION BETWEEN ACTIGRAPHY-ESTIMATED REST ACTIVITY RHYTHMS AND ADIPOSITY OUTCOMES IN ADOLESCENTS

Misol Kwon[1], Pin-Wei Chen[2], Jessica Decker[2], Philip Gehrman[1], Babette Zemel[2], Jonathan Mitchell[2]

[1] University of Pennsylvania, [2] The Children's Hospital of Philadelphia

Introduction: Rest-activity rhythms (RAR), a behavioral manifestation of circadian rhythms, represent the patterns of activity and rest/sleep across a 24-hour period. However, little is known about how changes in RARs during adolescence may influence adiposity outcomes. We examined the associations between RAR and body composition measures in adolescents. We hypothesized that disrupted RAR patterns are associated with adverse adiposity outcomes.
Methods: Baseline and follow-up data were collected from participants in the Sleep and Growth Study. Movement profiles were recorded using wrist-worn actigraphy devices (Philips Actiwatch 2); proprietary count data were analyzed using ActCR and GGIR packages to calculate RAR metrics. These included non-parametric (interdaily stability, intradaily variability, relative amplitude, most active 10-hour midpoint, least active 5-hour midpoint) and parametric (mesor, amplitude, acrophase) metrics. Body composition measures were assessed via dual-energy x-ray absorptiometry (DXA) scans: fat mass index (FMI, kg/m^2, and z-score) and visceral fat area (cm^2). Quantile regression was used to test for associations between RAR and specific percentiles (i.e., 5th, 25th, 50th, 75th, 95th) of the body composition outcomes, that represent the lower, middle and upper ranges of the frequency distributions.
Results: The sample consisted of 107 adolescents (mean age: 13.9 years at baseline and 14.9 years at follow-up), with 54.2% male and predominantly non-Hispanic White participants. Associations between RAR metrics and FMI were first examined. No significant associations were observed between any RAR metric and FMI (kg/m2, and z-score) across the 5th, 25th, 50th, 75th, and 95th percentiles. We then examined the associations between RAR metrics and visceral fat area. Similarly, no significant associations were identified between RAR metrics and visceral fat area across any percentiles.
Conclusion: In this relatively small longitudinal dataset with robust assessments of RAR and body composition, we found no evidence to support associations between RAR metrics and obesity-related outcomes in adolescents. Further research with larger sample sizes and additional cardiovascular data is needed to better understand the potential links between RAR and obesity-related health outcomes.

SOCIAL CONNECTEDNESS AS PREDICTOR OF SLEEP IN ADOLESCENTS: PROSPECTIVE ANALYSIS OF ABCD DATA IN COVID-19 PANDEMIC

Marie Gombert[1], Orsolya Kiss[1], Eva Muller Oehring[1], Lucy Shao[2], Susan Tapert[2], Elizabeth Sowell[3], Deanna Greene[2], Andrew Marshall[4], Holly Shakya[2], Bohan Xu[5], Wes Thompson[5], Chun Chieh Fan[5], Fiona Baker[1]
[1] SRI International, [2] University of California San Diego, [3] Keck School of Medicine of USC, [4] Children's Hospital Los Angeles, [5] Laureate institute of brain research

Introduction: The COVID-19 pandemic disrupted adolescents' social interactions through lockdowns and distancing measures, altering the quality, quantity, and type (in-person vs. online) of social connections. It also affected sleep patterns, providing a unique opportunity to examine the relationship between social connectedness and sleep.
Methods: Data from 4,996 children (8.9–11 years old; 48.42% female; 62.5% white) in the Adolescent Brain Cognitive Development (ABCD) Study who completed at least two COVID-19 surveys (T1 = May and T2 = August 2020) were analyzed. Social connectedness variables at T1 included family conflicts, habits such as eating together, relationships with friends and family, neighborhood activities, and technology-mediated socializing. Sleep duration (from caregiver reports) was measured at T1 and T2. Mixed-effects models examined associations between social connectedness variables and sleep duration, with covariates for sex, age, race, household income, and site as random effect. Clustering analysis explored differences in adequate sleep duration (9–11 hours/night) at T2 rates across groups sharing similar social connectedness characteristics at T1.
Results: Family conflict, household distancing, and technology-mediated connections were predictive of shorter sleep at T1 (all $p< 0.01$) and T2 ($p=0.02$, $p< 0.01$, $p< 0.01$, respectively). Conversely, eating dinner with family (T1 and T2, $p< 0.01$) and participating in neighborhood activities (T1, $p=0.05$; T2 n.s.) predicted longer sleep. Five social connectedness clusters at T1 were identified. The lowest rates of adequate sleep at T2 were in clusters characterized by high technology-mediated relationships (40.39%) or by poor family/friend relationships and little parental engagement (42.07%, $p=0.59$). Clusters characterized by high parental engagement, such as eating together and discussing plans for the following day, had significantly higher rates of adequate sleep (50.85%, $p< 0.01$; 47.57%, $p=0.03$; 47.52%, $p< 0.01$).
Conclusion: Social connectedness significantly predicted adolescent sleep duration during the pandemic, with family conflict and high technology-mediated relationship predictive of shorter sleep, while family meals and parental engagement were associated with longer sleep. Clusters with stronger parental involvement had higher rates of adequate sleep, whereas those with high technology-mediated relationships had the lowest, even lower than those with poor relationships. These findings highlight the importance of supportive family interactions and balanced technology use for healthy adolescent sleep.

INTERACTION BETWEEN SLEEP DISTURBANCE AND INFLAMMATION IN PREDICTING SUBSEQUENT RISK OF FRAILTY AMONG OLDER ADULTS

Muhammad Thalil[1], Soomi Lee[1]
[1] The Pennsylvania State University

Introduction: Sleep disturbances can disrupt various physiological processes, potentially leading to increased vulnerability to frailty. Similarly, chronic low-grade inflammation can negatively impact muscle function, immune response, and tissue repair, all of which are crucial for maintaining physical health and preventing frailty. While sleep disturbances and elevated inflammatory markers have been identified as potential contributors to frailty, the interaction between these factors remains understudied. We examined the associations of sleep disturbances, inflammatory biomarkers and their interactions with physical frailty among older adults.

Methods: We included 3,571 community-dwelling older adults age 65 years and above from the two waves of the National Aging and Health Trends Study (2017-18) who provided blood samples in 2017. We assessed frailty using Fried's phenotype, and the inflammatory biomarkers included C-reactive protein (CRP), interleukin-6 (IL-6), cytomegalovirus (CMV) infection, and hemoglobin A1c. We used multinomial logistic regression models to examine the individual and interactive associations of sleep disturbances and the inflammatory biomarkers with the subsequent risk of pre-frailty and frailty.
Results: After adjusting for baseline frailty, socio-demographics and chronic conditions including hypertension, diabetes, heart attack, heart disease, stroke, lung disease, arthritis, and cancer; older adults with difficulty initiating sleep (RR: 1.71, 95% CI: 1.32, 2.22) and maintaining sleep (RR: 1.41, 95% CI: 1.09, 1.83) had higher risk of developing frailty. Higher levels in inflammatory biomarkers such as CRP (RR: 1.43, 95% CI: 1.22, 1.67), CMV (RR: 1.25, 95% CI: 1.07, 1.47) and hemoglobin A1c (RR: 7.54, 95% CI: 2.16, 26.28) were each associated with increased risk of frailty. Having sleep maintenance difficulties and higher levels of hemoglobin A1c was associated with more pronounced pre-frailty and frailty, with significant interaction effects (p-values: 0.017 and 0.039).
Conclusion: Difficulty with sleep initiation and maintenance, as well as elevated inflammatory markers, increased the risk of frailty. The combination of sleep maintenance difficulties and higher hemoglobin A1c levels, a marker of long-term blood glucose control, further amplified frailty. Improving sleep health and managing inflammation, either through behavioral interventions, or pharmacological treatments, may help reduce the risk of frailty among older adults.

EFFECTS OF TIME-OF-DAY AND CIRCADIAN MISALIGNMENT ON BLOOD-BASED ALZHEIMER'S BIOMARKERS

Kate Timothy[1], Kenneth Wright[2], Edward Melanson[3], Christopher M. Depner[4], Andrew McHill[5]
[1] University of Colorado Boulder, [2] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA, [3] University of Colorado Anschutz Medical Campus, [4] University of Utah, [5] Oregon Institute of Occupational Health Sciences, Oregon Health & Science University, Portland, Oregon, USA

Introduction: The human blood proteome has been found to vary with time-of-day and in response to circadian misalignment (daytime sleep, nighttime wakefulness). Efforts to develop blood-based biomarkers for Alzheimer's disease have largely ignored such factors. We identified plasma candidate biomarkers for Alzheimer's disease by a literature review of current proteomic studies and examined if the biomarkers were influenced by time-of-day and/or circadian misalignment during an in-laboratory study.
Methods: A systematic literature review using keywords including but not limited to, "Alzheimer's", "mild cognitive impairment", "proteomics" and "plasma biomarker" was performed to find relevant studies. Biomarkers were chosen based upon their presence in three or more studies or cohorts. Identified proteins were analyzed using the SomaLogic Inc platform in six healthy men aged 26.2±5.6y (mean±SD) that completed a 6 day in-laboratory simulated night-shift protocol. We compared proteins analyzed every four hours during baseline circadian alignment and circadian misalignment conditions with mixed model ANOVA.
Results: From the literature review, we identified 28 proteins that appeared in three or more studies or cohorts. Of the 28 proteins, 14% varied with time-of-day (main effects of time-of-day, $p < 0.05$; angiopoietin-2, apolipoprotein B, insulin-like growth factor-binding protein 2, myoglobin), and 17% were influenced by circadian misalignment (main effect of study day, $p < 0.05$; beta-2-microglobulin, insulin-like growth factor-binding protein 2, immunoglobulin M, brain natriuretic peptide, vascular cell adhesion molecule-1). Furthermore, 17% showed study day by time-of-day interactions ($p < 0.05$; alpha-1-antitrypsin, apolipoprotein E, beta-2-microglobulin, myoglobin, pancreatic polypeptide) such that the time-of-day variation of these proteins depended on whether the participants were circadian aligned or misaligned.
Conclusion: The current findings suggest that the time-of-day modulates concentrations of some protein biomarkers of Alzheimer's disease, and that circadian misalignment also impacts such biomarkers. These findings have implications for the further development of plasma biomarkers for Alzheimer's disease, Alzheimer's disease risk, the potential implementation of such biomarkers, as well as precision medicine efforts.

CHRONOTYPE, SLEEP TIMING, SLEEP REGULARITY, AND CANCER RISK: A SYSTEMATIC REVIEW

Sidney Donzella[1], Benjamin Bryer[1], Trang VoPham[2], Matthew Weaver[3], Nathaniel Watson[1], Charlie Zhong[4], Alpa Patel[4], Amanda Phipps[1]
[1] University of Washington, [2] Fred Hutchinson Cancer Center, [3] Brigham and Women's Hospital, [4] American Cancer Society

Introduction: Sleep is a multidimensional modifiable lifestyle factor related to cancer risk. Prior research has primarily focused on sleep duration, despite the increasing importance of sleep timing and sleep regularity in the health research field. The objective of this systematic review was to synthesize the existing literature on the relationship of chronotype, sleep timing, and sleep regularity with cancer risk.
Methods: We searched four databases (PubMed, CINAHL, PsychInfo, and Embase) in October 2024. The sleep exposures of interest included sleep timing, sleep regularity, sleep midpoint, social jetlag, chronotype, and weekend catch-up sleep, and the outcome of interest was cancer incidence (overall or site-specific).
Results: A total of 22 studies were included, of which 18 investigated chronotype, two investigated social jetlag, two investigated sleep midpoint, and one investigated weekend catch-up sleep as the sleep exposure. The majority of studies assessed sleep using self-reported questionnaires (95%) and investigated site-specific cancer incidence (91%). We found no consistent evidence linking late chronotype, later sleep midpoint, increased social jetlag, or weekend catch-up sleep to elevated risk of cancer.
Conclusion: This review highlights the heterogeneity in how sleep timing and sleep regularity are assessed. Future research should standardize measures on how to quantify sleep timing and sleep regularity and replication studies in diverse populations are

needed. Current evidence remains inconclusive on the direction of the potential relationship of sleep timing and sleep regularity with cancer risk.

BEYOND SLEEP STAGING: POPULATION-LEVEL SLEEP DYNAMICS THROUGH WEARABLE SENSING ACROSS AGE AND SEX

Iman Alikhani[1], Mari Karsikas[1], Massimiliano de Zambotti[2]
[1] Oura Health Oy, [2] Ouraring Inc.

Introduction: Understanding normative age-related changes is essential for distinguishing normal from abnormal sleep trajectories. This study examines age- and sex-related variations in sleep and circadian patterns using large-scale data from consumer wearables.
Methods: One month of sleep data was evaluated from 25,918 Oura Ring users, equally distributed across age groups (spanning 20y to 85y, in increments of 5y and an equal male-to-female ratio (1:1). Standard sleep parameters (total sleep time, time spent awake, percentage of time in 'light', 'deep', and REM sleep), circadian factors (sleep midpoint, chronotype), and 30-second epoch-to-epoch transition probabilities (a measure of within-night sleep stability) were analyzed via generalized linear model (GLM) regression with age, sex, and age*sex as factors.
Results: Overall, women slept longer than men (+16.2 min; p<.000). Total sleep time peaked in the 20–25-year-old group (441±78 min) and declined to 403±68 min in the 80–85-year-old group (p<.000). Deep sleep percentage halved with age, while REM sleep showed smaller decreases beginning after 35 years (p<.000). Light sleep increased steadily, comprising 70–75% of total sleep in the oldest group (p<.000). The sleep midpoint slightly decreases with age, with chronotype showing advancement as people age. Sleep stability declined with age, with deep-to-deep and REM-to-REM transitions decreasing, particularly from 35 years onward (p<.000). Men experienced earlier stability declines around 40–45 years, while in women, these began around 55–60 years. Deep-to-light transitions rose from 3.4% in young adults to 8.4% in older adults (p<.000), with men showing earlier changes. REM-to-awake transitions increased with age, and REM-to-light transitions accelerated after 35 years, becoming most pronounced after 60 years. Significant differences were also observed in the interaction between age and sex on several other aspects of sleep dynamics.
Conclusion: This study highlights the impact of aging and sex on sleep dynamics, with wearable data offering powerful insights into previously inaccessible patterns. By leveraging these findings, wearables have the potential to transform our understanding of sleep health and its role in disease progression, paving the way for targeted interventions and personalized solutions.

SWEET DREAMS ARE MADE OF EEG: REVISITING THE FIRST NIGHT EFFECT BY EXAMINING DIFFERENCES IN POLYSOMNOGRAPHY AND AN EEG HEADBAND

Anne Chen[1], Brienne Miner[1], Gawon Cho[1], Ian Murphy[1], Jarett Talarcyzk[1]
[1] Yale University

Introduction: Polysomnography (PSG) is the gold standard for objective sleep measurement, but may not represent habitual sleep due to the first-night effect (FNE). This study quantified FNE by comparing total sleep time (TST) and wake after sleep onset (WASO) from one night of home-based PSG to contiguous measures from an electroencephalography (EEG)-measuring headband averaged over multiple nights.
Methods: Sixty-three community-living adults ≥55 years with symptoms of insomnia and/or daytime sleepiness ≥once/week completed an eight-day home-based protocol with one night of PSG (NOX Medical) and seven nights of EEG-headband (Beacon Biosignals). For the current analyses, we excluded 7 participants (6 had TST < 4 hours on PSG; 1 had < 4 nights of headband use). Among 56 participants, objective measures of TST and WASO from PSG were compared to averages from the headband (calculated from all nights of headband use or from nights prior to PSG). Two-sample paired T-tests examined mean differences in TST and WASO between PSG and the headband.
Results: Participants had a mean age of 75.7 (±7) years, 69.6% were women, 27% were minority race/ethnicity, and mean Insomnia Severity Index and Epworth Sleepiness Scale scores were 12.3 (±4) and 7.4 (±5), respectively. Excluding the PSG night, participants wore the headband for 5.5 (±0.7) nights overall and 4.1 (±1.4) nights pre-PSG. TST was significantly longer on PSG nights compared to non-PSG and pre-PSG nights (differences of 28.2 [8.9, 47.5] and 19.9 [1.4, 38.5] minutes, respectively; p values ≤0.04). WASO was significantly longer on PSG nights compared to non-PSG and pre-PSG nights (differences of 34.0 [15.7, 52.3] and 34.9 [16.8, 53.0] minutes, respectively; p values < 0.01).
Conclusion: Contrary to expectations, we found that TST was longer on PSG nights, possibly due to protocol-driven earlier bedtimes. WASO increased by approximately 30 minutes on average on PSG nights. These findings highlight how PSG protocols might alter sleep patterns and suggest we should be cautious when assuming that PSG-measured sleep metrics represent habitual sleep patterns.

OBJECTIVE SLEEP AND MICROVASCULAR ENDOTHELIAL FUNCTION IN POSTMENOPAUSAL FEMALES

Chowdhury Tasnova Tahsin[1], Stephany Nathe[1], Elise Toussaint[1], William Stokes[1], Emma Lee[1], Miguel Anselmo[1], Anne Blaes[1], Snigdha Pusalavidyasagar[2], Manda Keller-Ross[1], Ida Fonkoue[1]
[1] University of Minnesota, [2] University of Minnesota Medical School

Introduction: Menopause, the cessation of sex-hormone production from the ovaries, is associated with an accelerated rate of cardiovascular disease (CVD). Sleep disturbance, a common and debilitating menopausal symptom, can increase CVD risk. Further, low endothelial function is associated with increased CVD risk. However, the link between objective sleep measures and microvascular endothelial function in otherwise healthy postmenopausal females is unclear. The goal of this ongoing study is to test the hypothesis that short sleep duration and low

sleep quality, quantified by actigraphy, would be associated with attenuated microvascular endothelial function.
Methods: Eleven healthy females [menopause completed at 52±2years (mean±SD)] completed two study visits, 7-days apart. Informed consent was obtained at Visit 1 and participants were given the Actiwatch Spectrum Plus to track their sleep-wake cycle for the next 7 days. Prior to Visit 2, participants fasted and abstained from caffeine, alcohol and exercise for 12 hours. During this visit, we assessed endothelial function using endothelial peripheral arterial tonometry (EndoPAT) to quantify reactive hyperemia index (RHI) and its natural log (LnRHI). Resting hemodynamic parameters were also obtained via EndoPAT. Pearson's correlation was used to probe the association of sleep duration and sleep efficiency with RHI and LnRHI. Independent sample t-tests were used to compare mean RHI and LnRHI between short- and long-sleepers. The two "sleepers" groups were determined using a median split of the sleep duration (7.81 hours).
Results: The study participants were 62±3years with a body mass index of 25.5±3.2kg/m2. Average sleep duration was 7.48±0.96hours and mean sleep efficiency was 81.4±6.3%. Average blood pressure was 126±8mmHg and 80±7mmHg for systolic and diastolic, respectively, while mean heart rate was 60±7beats/min. Our preliminary analyses revealed that endothelial function was not associated with sleep duration (RHI: r=0.21, p=0.54; LnRHI: r=0.09, p=0.80) or sleep efficiency (RHI: r=0.10, p=0.76; LnRHI: r=-0.14, p=0.68). No differences were observed in endothelial function between the short- (RHI: 1.79±0.36; LnRHI: 0.63 ±0.13) and long-sleepers (RHI: 2.01±0.54 a.u., p=0.47; LnRHI: 0.67±0.29 a.u., p=0.77).
Conclusion: Albeit a small sample size, preliminary analyses did not reveal an association between objective sleep and endothelial function in healthy postmenopausal females.

SELF-REPORTED MULTIDIMENSIONAL SLEEP HEALTH IS NOT ASSOCIATED WITH COGNITIVE DECLINE AND THE RISK OF DEMENTIA IN TWO POPULATION-BASED COHORT STUDIES

Sanne Hoepel[1], Nina Oryshkewych[2], Lisa Barnes[3], Daniel Buysse[4], Meryl Butters[2], Andrew Lim[5], Kamran Ikram[6], Lan Yu[2], Frank Wolters[6], Meredith Wallace[2], Annemarie Luik[6]
[1] Erasmus Medical Center, Department of Epidemiology, [2] University of Pittsburgh, [3] Rush University Medical Center, [4] University of Pittsburgh School of Medicine, [5] University of Toronto, [6] Erasmus MC, Rotterdam, The Netherlands

Introduction: The links between sleep disturbances, cognitive decline, and dementia are increasingly recognized, but few studies have considered that sleep health is multidimensional. We evaluated how multidimensional sleep health relates to cognitive decline and the risk of dementia in middle-aged and elderly populations.
Methods: Self-reported sleep health indicators (satisfaction, alertness, timing, efficiency, and duration) were measured in 7892 participants in the Rotterdam Study (RS) (median [Q1-Q3] age: 68.5 [61.6-76.1] years, 58.2% female) and 1601 participants in the Rush Memory and Aging Project and Minority Aging Research Project (MAP/MARS) (79.2 [73.8-85.3] years, 77.3% female). A multidimensional sleep health score was calculated as the number of adverse sleep health indicators. Latent class analysis identified three multidimensional sleep health profiles: average sleep, inefficient sleep, and poor sleep. Sleep health scores, profiles, and individual indicators were related to five cognitive tests measured repeatedly over time (linear mixed effects models) and to risk of dementia (Cox proportional hazards models).
Results: In RS, 1148 (14.5%) participants developed dementia during a median of 11 (7.7-14.3) years. In MAP/MARS, 287 (17.9%) participants developed dementia during a median of 5.0 (3.0-8.0) years. Multidimensional sleep health scores and profiles were not associated with accelerated cognitive decline or the risk of dementia in either sample (Hazard Ratios [HRs] between 0.72-1.15). The individual indicators early timing (RS: HR 1.60; 95%CI [1.23-2.09]; MAP/MARS: HR 1.37 [0.95-2.00]) and long sleep duration (RS: HR 1.61, [1.34-1.94]; MAP/MARS: HR 1.23 [0.81-1.88]) were associated with a higher risk of dementia. Long sleep duration was associated with accelerated cognitive decline on word learning, substitution, and category fluency tasks in MAP/MARS.
Conclusion: Self-reported multidimensional sleep health was not associated with cognitive decline and the risk of dementia in two samples of middle-aged and elderly persons. Individual sleep health indicators might be more informative than aggregate measures for predicting cognitive decline and dementia. Future research should consider more complex combinations of self-reported sleep health features and objective measures of sleep.

SEX HORMONES AND SLEEP IN PERIMENOPAUSE: A CROSS-SECTIONAL STUDY

Vibha Gangwar[1], Manish Verma[1], Arvind Singh[2], Neetu Singh[3], Manish Kulshreshtha[4], Sunita Tiwari[4], Rajani Bala Jasrotia[1]
[1] DrRMLIMS, [2] Dr Ram Manohar Lohia Institute of Medical Sciences Lucknow, [3] Dr Ram Manohar Lohia Institute of Medical sceinecs Lucknow, [4] Dr Ram Manohar Lohia Institute of Medical Sciences

Introduction: Perimenopause is a transitional phase marked by significant fluctuations in sex hormones and vasomotor symptoms such as sleep disturbances and night sweats, which may negatively affect cardiovascular health. Understanding the association between sex hormones and sleep disturbances in perimenopausal women is critical for improving their quality of life. This study aimed to evaluate the association of sex hormone levels and sleep disturbances in perimenopausal women with a focus on identifying hormonal patterns associated with sleep disturbances.
Methods: This cross-sectional study involved 200 women, aged between 40-55 years, with perimenopausal symptoms. Data on anthropometric measures, medical history, vasomotor symptoms (sleep disturbances and night sweats), menstrual history, and exercise habits was collected. Blood samples were analysed for level of estrogen, FSH, DHEA-S, SHBG and Testosterone using electrochemiluminescence immunoassay (ECLIA) on

Roche Cobas analysers. Data was analysed using. Association between hormone levels and sleep disturbances were analysed by Pearson correlation test using SPSS 21 IPM software. P< 0.5 was considered as statistically significant.

Results: The mean age of the participants was 43.31± 4.10 years. The mean hormonal levels were: Estradiol (EII) 96.73± 53.15 pg/ml, FSH 40.26 ± 14.57 mIU/ml, testosterone 11.64 ± 3.81 mIU/ml, SHBG 57.74 ± 16.78 nmol/ml and DHEA-S 70.77 ± 21.15 µg/dl. Sleep disturbance was present in 90 (45%) women while night sweats were present in 125 (62.5%) women. Estradiol level was significantly lower in women with both sleep disturbances (P=0.005) night sweats (P=< 0.0001). Testosterone was also lower in women with night sweats (P=0.046). DHEA-S levels were lower in women without night sweats (p=0.037). There were significant negative correlations between estradiol and SHBG levels with frequency and duration of vasomotor symptoms (P< 0.0001, P=0.028 and P 0.032 respectively). No significant correlation was found with FSH, and DHEA-S levels.

Conclusion: Reduced estradiol, testosterone and SHBG levels are significantly associated with sleep disturbances and night sweats in perimenopausal women. These findings suggest that hormonal management strategies could improve sleep related problems in perimenopausal women which may improve their cardiovascular health.

APOE-4 STATUS INDEPENDENTLY AFFECTS SLEEP ARCHITECTURE AND CHOLESTEROL CLEARANCE

Swati Levendovszky[1]

[1] University of Washington

Introduction: Poor sleep can contribute to elevated LDL cholesterol levels, and high cholesterol can exacerbate sleep fragmentation. Individuals carrying the ApoE ε4 allele, a known genetic risk factor for Alzheimer's disease, typically have higher LDL cholesterol levels and fragmented sleep, though the exact relationship between ApoE status and sleep remains unclear. This study addressed two main questions: (1) Is ApoE allele status associated with altered cholesterol levels and sleep architecture? (2) Does altered sleep architecture in ApoE ε4 carriers mediate the relationship between ApoE status and high cholesterol, or is the reverse true?

Methods: Data (N = 997, ages 22-78, 52 male) was obtained through the National Sleep Research Resource, from a study on Sleep Disordered Breathing, ApoE, and Lipid Metabolism at Stanford University. It included polysomnography (PSG) results, demographic information, sleep disorder diagnoses, metabolic panel results, and Epworth Sleepiness Scale scores. Of the 997 individuals, 647 had complete data and were included in the analysis: 409 were homozygous for the ε3 allele, 129 were heterozygous (ε3/ε4), and 13 were homozygous for the ε4 allele, with the remaining carried the ε2 allele. Only untreated patients suspected of sleep-disordered breathing were included; patients using CPAP therapy were excluded. We performed linear regression analysis to examine the association of ApoE status with LDL cholesterol levels and the N3/REM duration ratio. A subsequent mediation analysis assessed whether ApoE status influenced LDL cholesterol via N3/REM duration duration, or if LDL cholesterol influenced sleep architecture.

Results: Regression analysis revealed that both LDL cholesterol levels and the ratio of N3/REM duration increased significantly in a dose-dependent manner with ApoE ε4 status. REM duration remained mostly unchanged, except in homozygous ε4 carriers. Total sleep time also did not differ and increased N3 duration was observed at the expense of reduced N2 duration. No significant mediation effect was detected.

Conclusion: Our findings align with previous research showing higher LDL cholesterol levels in ε4 carriers. Studies have theorized that increased N3 duration in this group is associated with memory complaints likely due to synaptic overpruning. Finally, the ε4 isoform independently affects both sleep architecture and cholesterol levels.

MAPPING THE RELATIONSHIPS BETWEEN STRUCTURAL BRAIN MRI CHARACTERISTICS AND SLEEP EEG PATTERNS

Nataliia Kozhemiako[1]*, Susan Heckbert*[2]*, Cecilia Castro-Diehl*[3]*, Caitlin Ballard Paquet*[4]*, Suzanne Bertisch*[4]*, Mohamad Habes*[5]*, Alison E Fohner*[2]*, R. Nick Bryan*[5]*, Ilya Nasrallah*[5]*, Timothy M. Hughes*[6]*, Susan Redline*[7]*, Shaun Purcell*[4]

[1] Brigham & Women's Hospital, [2] University of Washington, [3] Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Harvard Medical School, [4] Brigham and Women's Hospital, Harvard Medical School, [5] University of Pennsylvania, [6] Wake Forest School of Medicine, [7] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: While brain morphology is well-established as a key factor influencing overall brain function, little is known about how brain structural properties are associated with oscillatory activity, particularly during sleep.

Methods: In this study, we analyzed whole-night sleep EEG and brain structural MRI data from a subset of 621 individuals in the Multi-Ethnic Study of Atherosclerosis to explore the relationship between brain structure and sleep EEG properties. Sleep EEG data were preprocessed and analyzed using the open-source software Luna (https://zzz.bwh.harvard.edu/luna/).

Results: We found that larger total white matter (WM) volume was associated with higher absolute broad-band power, regardless of sleep stage (the strongest effects in the beta band during R, bst = 0.45, p = 3x10-6), likely reflecting WM contribution to enhanced synchronization across cortical regions and reduced activation attenuation via long-range myelinated fibers. Additionally, both WM fractional anisotropy and thalamus volume showed negative association with relative slow power and positive association with delta power during non-rapid eye movement sleep (strongest effect with corpus callosum FA, bst = –0.22, p = 2x10-6 for slow and bst = 0.15, p = 1x10-4 for delta band). This was mirrored in the duration of slow oscillations (SOs), both overall and when divided into slow-switching and fast-switching types, with their ratio additionally linked to total WM volume. Furthermore, we observed strong but largely independent effects of age and sex on sleep EEG and structural MRI metrics, suggesting that sleep EEG captures aging processes and sex-specific features that extend beyond the macro-scale brain morphology changes examined here.

Conclusion: Overall, these findings deepen our understanding of how structural brain properties influence sleep-related oscillatory activity.

CHARACTERIZING HUMAN SLEEP SPINDLE TEMPORAL DYNAMICS ACROSS HEALTH, DISORDERED CONDITIONS, AND AGING

Shuqiang Chen[1], Uri Eden[1], Michael Prerau[2]

[1] Boston University, [2] Brigham and Women's Hospital

Introduction: Sleep spindles, transient brain waveforms of ~12 Hz oscillatory activity that define NREM stage 2 sleep, have been linked to memory consolidation, sleep stability, neurological disorders, and aging. While spindles are known to be influenced by multiple factors including sleep depth, cortical up/down states, breathing, and temporal clustering, most studies examine spindles in isolation without examining how these mechanistic influences interact and contribute to spindle dynamics. Without a systematic characterization of spindle dynamics, our ability to identify biomarkers for aging and disordered conditions remains critically limited.

Methods: We develop a statistical modeling framework based on point process theory to quantify spindle temporal dynamics and mechanistic influences as an integrated system. This framework models the relative impact of multiple factors (e.g., sleep stage/depth, slow oscillation, spindle history, respiration) to the moment-to-moment probability of spindle activity. In doing so, we can quantitatively evaluate the relative contribution of each factor, their interactions, and test mechanistic hypotheses across individuals, healthy and disordered populations, and aging.

Results: We applied this framework to a large cross-sectional dataset from the Cleveland Family Study (CFS, 735 participants, male/female: 329/406, 5 to 95 years) and a clinical database of pediatric Trisomy 21 (T21) patients (100 T21 patients and 100 age- and sex-matched controls, male/female: 54/46, 0 to 31 years). In both datasets, most participants showed a characteristic timing pattern that involves a refractory period followed by an excitatory period. Across the lifespan, older participants exhibited greater variability in spindle timing, suggesting age-related impairment in spindle production. In T21 patients, spindle timing patterns showed a lower excitatory peak compared to controls, indicating less predictable and disrupted spindle generation that may contribute to altered sleep architecture and cognitive deficits. Additionally, we revealed that spindle activity is modulated by normal breathing, with distinct temporal associations between obstructive sleep apnea/hypopnea events and spindles.

Conclusion: Overall, by characterizing spindle temporal dynamics across diverse populations, we provide novel mechanistic insights into aging, neurodevelopmental disruptions in T21 patients, and the effects of sleep-disordered breathing.

CHARACTERIZING BROAD CLASSES OF SPINDLE-LIKE TRANSIENT EVENTS ACROSS THE LIFESPAN

Habiba Noamany[1], Thomas Possidente[2], Mingjian He[3], Sophie Brennan-Saremsky[4], Michael Prerau[4]

[1] Harvard University, [2] Boston University, [3] Massachusetts Institute of Technology, [4] Brigham and Women's Hospital

Introduction: Sleep spindles, transient oscillatory events linked to memory consolidation, vary in neurodegenerative disorders and healthy aging. Understanding spindle activity changes across the lifespan aids in distinguishing healthy from pathological aging, improving diagnosis and tracking of age-related pathologies. While many previous studies analyze spindle features across the lifespan, they typically rely on detection algorithms with ad-hoc frequency and rarity constraints, leading to inconsistent results. Recent work shows that agnostic transient event detection can reveal multiple spindle-like classes without these assumptions. This study characterizes spindle-like activity dynamics across the lifespan, providing an objective lens for viewing brain development and aging, creating a more accurate framework for understanding age-related pathologies.

Methods: We examined tens of thousands of 2-16 Hz spindle-like events from the C3 electroencephalogram (EEG) in each of 712 subjects from the Cleveland Family Study (7-88 years, 55% F) during NREM sleep using the DYNAM-O toolbox. We characterized events as a function of their frequency, sleep depth, and slow oscillation (0.5-1.5Hz) phase, identifying clusters of distinct classes of transient oscillatory activity and their dynamics across the lifespan.

Results: Population analyses identified four distinct classes of transient oscillations, quantifying their multidimensional longitudinal dynamics with age. Beyond confirming previous spindle findings, we provide several novel insights. Specifically, fast spindle range (12-16 Hz) event phase-coupling becomes less frequency-dependent with age. Events in the slow-spindle range (10-12 Hz) tend to appear at ~20 years and move earlier in sleep depth with age. We identified a class of events that rises from 6 Hz to 9 Hz between 7 and 25 years old, serving as a new potential neurodevelopmental biomarker. A class of delta (2-4 Hz) events increases in density with age but decreases in frequency and sleep depth. Additionally, we identified different subgroups of individuals with specific combinations of event classes.

Conclusion: These results reveal the complex multidimensional dynamics of a broad range of spindle-like activity across the lifespan. In doing so, this work enhances our understanding of traditional spindle events and suggests new classes of events that can be leveraged for improved identification of biomarkers of age and disorder in the sleep EEG.

ASSOCIATION BETWEEN SLEEP REGULARITY AND COGNITIVE FUNCTION IN OLDER ADULTS

Meina Zhang[1], Carinda Linkenmeyer[1], Karin Hoth[1], Linlin Ding[1], Chooza Moon[1]

[1] University of Iowa

Introduction: Sleep changes are common as people age, with nearly 50% of older adults experiencing sleep-related difficulties. Poor sleep quality negatively impacts cognition; however, much of the existing research has relied on self-reported sleep questionnaires instead of objectively assessing different sleep characteristics and has utilized only global cognitive screening tools. The primary aim of this study is to investigate the association between sleep regularity (i.e., the consistency of sleep timing across multiple nights) assessed by actigraphy and cognitive function in older adults. The secondary aim is to explore the association between wake after sleep onset (WASO) and cognitive function in this population.
Methods: Fifty-seven older adults with no clinically identified cognitive impairment diagnosis (mean age = 70±7.3 years, 56.3% female, mean years of education = 16.1±3.4) participated in the study. Sleep parameters, including sleep regularity and WASO (mean ± SD = 44.16±24.01 minutes), were objectively measured using actigraphy over a 14-day period. A clinical neuropsychological battery was administered to assess cognitive function across multiple domains, including immediate memory, delayed memory, visual spatial ability, executive function, attention, and processing speed. Multiple regression analyses, adjusted for age, gender, and education, were conducted to examine the association between each sleep parameter and cognitive performance on the six domains.
Results: No significant associations were found between sleep regularity and any cognitive domain. In line with previous research emphasizing sleep quality and continuity, lower WASO was associated with improved immediate memory performance (β = -0.118, p = 0.006).
Conclusion: These findings indicate that sleep regularity was not significantly associated with cognitive functions in older adults. Consistent with previous research, sleep continuity indicators appear to be more closely linked to cognitive functions. These results highlighted the importance of prioritizing interventions that improve sleep quality and continuity over regularity for cognitive benefits in aging populations.

LIFE COURSE SLEEP DURATION TRAJECTORIES AND RISK AND AGE AT ONSET OF PARKINSON'S DISEASE

Yi Fang[1], Rebecca Hardy[2], Kristine Yaffe[3], Simon Little[3], Caroline Tanner[3], Yue Leng[4]

[1] University of California, San Francisco, [2] Loughborough University, [3] UCSF, [4] Department of Psychiatry and Behavioral Sciences, University of California, San Francisco

Introduction: Sleep disturbances may be prodromal signs or risk factors for Parkinson's disease (PD). This study aims at characterizing life course sleep duration trajectories and examining their associations with PD risk and age at onset (AAO).
Methods: Participants in Parkinson's Progression Markers Initiative (PPMI)-Online (started in 2021) and Fox Insight (FI, started in 2018) reported long term sleep duration: ages 18 to 80+ (PPMI-Online), and ages 12 to 66+ (FI). Latent class growth analysis was used to characterize sleep duration trajectories. Associations between sleep duration trajectories and PD diagnosis or AAO were examined using logistic regression and linear regression, respectively.
Results: The 17,834 participants were 54.6% female and aged 67.2 (7.83).The discovery cohort (PPMI-Online) included 5,660 people with PD (PwPD) and 10,245 without PD, and the replication cohort (FI) included 1,929 PwPD. The study sample included 5,660 people with PD (PwPD) and 10,245 without PD. Sleep trajectories from PPMI-Online remained stable during early adulthood (<=6, 6-7, 7-8, >8 hours/day) but showed varying trends (stable, increasing, decreasing) during midlife. After adjusting for demographics, lifestyle, depression, anxiety, and RBD screening, midlife decreases in sleep (from 6-7 hours/day: OR = 1.90, 95% CI 1.61-2.24, P <.001; from 7-8 hours/day: OR = 1.64, 95% CI 1.40-1.91, P <.001) and consistently short sleep (<=6 hours/day throughout adulthood: OR = 1.41, 95% CI 1.19-1.67, P <.001) were linked to increased risk. Low sleep in early adulthood and midlife was also associated with earlier AAO, with the most pronounced effect in those with consistently short sleep across adulthood (β = -2.45 years, 95% CI -3.33 to -1.56, P = <.001). The findings with AAO were validated in FI.
Conclusion: Self-reported shorter sleep in early adulthood and decreasing sleep in midlife are associated with increased PD risk and earlier AAO. Midlife sleep reduction may mark future PD. Further studies should explore their links with RBD. Persons with life-course short sleep may be candidates for preventive intervention.
Support (if any): The PPMI and FI Study is funded by The Michael J. Fox Foundation for Parkinson's Research. We would like to thank Parkinson's community for participation. Funding partners of PPMI are available at https://www.ppmi-info.org/about-ppmi/who-we-are/study-sponsors.

EXPLORING THE SEX-DEPENDENT ASSOCIATION BETWEEN NAPPING AND CARDIOVASCULAR FUNCTION AMONG OLDER ADULTS

Susan Rodriguez[1], Amy Costa[1], Christina McCrae[1], Ashley Curtis[1]

[1] University of South Florida

Introduction: The link between poor nighttime sleep and cardiovascular dysfunction is established, with known sex differences in both factors. The relationship between daytime sleep behaviors like habitual napping and cardiovascular function remains unclear, particularly in aging populations. Given that cardiovascular disease is the leading cause of death, it is crucial to assess how nighttime sleep, napping, and cardiovascular function interact in aging populations most affected by the disease. This study evaluated whether the association between habitual napping and resting autonomic functioning is influenced by sleep efficiency, and whether this relationship is moderated by sex in older adults.

Methods: Older adults (N=66, Mage=68.6±5.4 years, 37 women; NCT04282642, AASM:256-FP-21, PI:Curtis) completed 2-weeks of sleep diaries assessing napping frequency/duration, and sleep efficiency %. Participants also completed an in-lab 5-minute resting echocardiogram (Holter monitor). Multiple linear regressions and simple slope analyses tested if sex, sleep efficiency, napping (frequency and duration), or their interactions were associated with cardiovascular function (heart rate and heart rate variability metric root mean squared of standard deviation of normal-to-normal heartbeats (RMSSD)), controlling for age.
Results: The interaction of sex, sleep efficiency, and napping duration was associated with resting RMSSD (R2-change=.11, p=.01). Specifically, for women, longer nap duration was associated with lower resting RMSSD measures at higher levels of sleep efficiency (~81%; B=-0.30, p=.03). In men, longer nap duration was associated with lower resting RMSSD at moderate sleep efficiency levels (~59%; B=-0.43, p=.02), and this was exacerbated (1.6-fold) at lowest sleep efficiency levels (~40%; B=-0.68, p=.02).
Conclusion: Present findings suggest the relationship between sleep efficiency, daytime napping and cardiovascular functioning in older adults is sex dependent. Consistent results support current recommendations in insomnia behavioral interventions (e.g., cognitive behavioral therapy for insomnia) to avoid napping. This may be particularly important for men with moderate-to low sleep efficiency and women with higher (but sub-optimal) sleep efficiency, to mitigate cardiovascular risks. Findings highlight the importance of investigating whether behavioral sleep treatments that reduce napping duration also reduce CVD risk, especially among older men.
Support (if any): This research was made possible by awards (PI:Curtis) from the American Academy of Sleep Medicine Foundation, a foundation of the American Academy of Sleep Medicine.

THE RELATIONSHIP BETWEEN PHYSIOLOGICAL ARTERIAL FUNCTION AND SLEEP-RELATED FACTORS IN YOUNG ADULT WOMEN AND MENOPAUSAL WOMEN

Mami Yamaji[1], Honoka Oshida[2], An Saotome[3], Momo Fushimi[3], Sayaka Aritake-Okada[3]
[1] Saitama Prefectural University, Graduate School of Health Sciences and Social Work, Koshigaya, Japan, [2] Saitama Prefectural University, Department of Health Sciences, Laboratory Sciences, Koshigaya, Japan, [3] Saitama Prefectural University, Graduate School of Health Sciences and Social Work

Introduction: In menopausal women, ovarian function declines several years before menopause, causing a rapid decrease in the secretion of female hormones and the flexibility of blood vessels. Previous studies have reported that up to 60% of menopausal women complain of sleep problems, and sleep problems have been found to contribute to arteriosclerosis. In the current study, we investigated the relationship between physiological arteriosclerosis indicators and lifestyle habits in young and menopausal women.
Methods: Twenty-three healthy adults (11 young women and 12 menopausal women) participated in the experiment. Mean intima-media thickness (IMT), peak-systolic velocity, end-diastolic velocity, resistance index, and pulsatility index were measured using carotid artery ultrasound. Ankle brachial index, pulse wave velocity (PWV), blood pressure, as well as new indices of arteriosclerosis, arterial velocity pulse index (AVI) and arterial pressure volume index were then measured. Participants completed the PSQI and morningness-eveningness questionnaire, a questionnaire on lifestyle habits, Epworth sleepiness scale(ESS), and Simplified Menopausal Index. This study was approved by the Ethical Committee of Saitama Prefectural University.
Results: Menopausal women had significantly higher blood pressure, AVI, IMT, and PWV compared with young women (all $p < 0.05$). Strong correlations were observed between irregular bedtime and AVI, and between subjective sleep latency and PWV in young women (Rho = 0.742, p = 0.009; Rho = 0.892, $p < 0.001$, respectively). The time spent using a mobile phone and frequency of sleepiness were significantly positive corelated with IMT values (Rho = 0.669, p = 0.024; Rho = 0.626, p = 0.039). In menopausal women, a significant positive correlation was observed between ESS scores and AVI (Rho = 0.680, p = 0.015). Moreover, ankle brachial index in menopausal women was positively correlated with evening-type and frequency of eating out (Rho = 0.669, p = 0.024; Rho = 0.580, p = 0.048, respectively).
Conclusion: In young women, irregular bedtimes, subjective sleep latency, and prolonged use of electronic media is associate with arteriosclerosis. In menopausal women, a nocturnal lifestyle and frequent eating out are associated with arteriosclerosis, and the progression of arteriosclerosis may be related to sleepiness.

JOINT ASSOCIATIONS OF SLEEP DURATION AND QUALITY WITH DAILY RUMINATION AND MEMORY LAPSES: DIFFERENCES BY AGE GROUPS

Kyoungmin Cho[1], Soomi Lee[1]
[1] The Pennsylvania State University

Introduction: The association between sleep and cognitive functioning is well documented. However, less is known about the distinct roles of sleep duration and sleep quality in shaping day-to-day subjective cognitive experiences, such as rumination and memory lapses. Additionally, it remains unclear whether these two sleep dimensions interact—either compensating for one another or amplifying adverse effects. Understanding age-related variations in such interactions warrants attention, given age-linked shifts in sleep patterns and cognitive resilience.
Methods: Data were drawn from 964 adults (Mage=60.59, SDage=9.20) who took part in the MIDUS III main survey and an 8-day diary study. Each day, participants reported the previous night's sleep duration and quality, followed by measures of rumination and memory lapses. Multilevel models examined both between-person (habitual) and within-person (daily fluctuation) effects of sleep duration and quality, as well as their interaction, on next-day cognition, adjusting for socio-demographics, physical health, and daily covariates.
Results: Independent of sleep duration, poorer sleep quality was linked to more frequent rumination, both at the between-person (B=-0.14, SE=0.02, p <.001) and within-person (B=-0.05, SE=0.01, p <.001) levels. In this model, shorter sleep duration predicted greater rumination only at the within-person level (B=-0.01, SE=0.004, p=.045). For memory lapses, poorer sleep quality was associated with more lapses at the between-person level

(B=-0.37, IRR=0.69, SE=0.09, p <.001), while sleep duration had no independent relation. Longer sleep duration attenuated the negative association of poorer sleep quality with rumination both at the between-person (B=0.02, SE=0.01, p=.018) and within-person (B=0.02, SE=0.01, p=.007) levels. No significant interaction emerged for memory lapses. The compensatory effect of sleep duration on the sleep quality—rumination link was evident only among adults aged 60–67, but for adults aged 43-59, or 67-83.
Conclusion: Findings highlight the independent and joint roles of sleep duration and quality in daily subjective cognition. Longer sleep may help offset poor sleep quality's detrimental cognitive effects, particularly in early old adulthood, offering insights for tailored interventions.

AGE-RELATED DIFFERENCES IN THE RELATIONSHIP BETWEEN OBJECTIVE AND SUBJECTIVE MEASURES OF SLEEPINESS

Katie McCullar[1], Lara Keohane[1], Elizabeth Klerman[2]
[1] Mass General, [2] Mass General Brigham

Introduction: Daytime sleepiness may be used to assess the quality and quantity of the previous night's sleep. We investigated whether there were age-related differences between objective and subjective measures of sleepiness during the day, and the previous night's sleep duration. The Multiple Sleep Latency Test (MSLT) is an in-lab test that utilizes polysomnography (PSG) to provide objective measures of sleepiness; the Karolinska Sleepiness Scale (KSS) is a 9-point scale for subjective sleepiness levels.
Methods: 35 Younger (Y) (18-32, 18 F) and 18 Older (O) (60-76, 6 F) healthy participants were studied using PSG in an in-lab protocol. During night 1 (BL), participants were scheduled to sleep at a time and duration based on their sleep schedules. Five sessions of an MSLT were conducted the following day (MSLT1). Participants then had 4-7 consecutive days with 16 hrs (12 hrs at night and 4 hrs nap) sleep opportunities per day, followed by a second MSLT (MSLT2). The sleep episode before MSLT2 was scheduled for 12 hours (Long). Total sleep time (TST) for the nighttime sleep episodes prior to both sets of MSLTs was calculated. The median sleep latency of each MSLT session and the percentage of the time individuals fell asleep within MSLT1 and MSLT2 were calculated. Tobit regression models assessed relationships between KSS scores and sleep latency on the MSLTs.
Results: There was no relationship between sleep latency and KSS score for each MSLT nap. Percent slept for MSLT1 and MSLT2 were positively correlated in Y (Pearson R = 0.49, p=0.002) and O (Pearson R = 0.59, p= 0.009) despite the Y sleeping longer than O on the night before MSLT1 (Yave=7.88 hrs, Oave = 6.58, p< 0.001) and MSLT2 (Yave=8.18 hrs, Oave = 6.06, p< 0.001). MSLT1 correlates with prior sleep only in Y after BL (Pearson R=0.35, p=0.049); MSLT2 is not correlated with prior sleep in either group.
Conclusion: Subjective measures of sleepiness as measured by the KSS are not correlated with objective measures of sleepiness as measured by sleep latency on the MSLT in both age groups. These data suggest that sleep latency may have trait-like, state-dependent, and age-dependent relationships.

OBJECTIVELY-ASSESSED NAPPING BEHAVIORS PREDICT MORTALITY IN MIDDLE-TO-OLDER AGED ADULTS

Chenlu Gao[1], Ruixue Cai[1], Xi Zheng[1], Lei Gao[1], Kun Hu[1], Peng Li[1]
[1] Massachusetts General Hospital/ Harvard Medical school

Introduction: Self-reported daytime napping is associated with various adverse health outcomes. We examined whether actigraphy-measured objective daytime napping behaviors predict all-cause mortality in middle-to-older aged adults in the UK Biobank.
Methods: We studied 86,565 participants (baseline age=63 years, SD=8, range: 43-79; 57% female) in the UK Biobank who did not have shiftwork history, completed a 7-day actigraphy monitoring, and had data linked to mortality registeries. We implemented the Cole-Kripke algorithm to identify daytime sleep episodes from actigraphy and computed the following nap metrics: (1) mean nap duration between 9am-7pm; (2) intra-individual variability across days (individual SD) in nap duration; (3) timing of naps quantified as the percentage of nap duration in each 2-h bin between 9am-7pm (i.e., 9-11am, 11am-1pm, 1-3pm, 3-5pm, 5-7pm). Nap variables were square-root transformed to correct for right skewness and standardized for interpretation. Cox proportional hazards models were performed to test the associations between napping metrics and all-cause mortality, adjusting for demographics, BMI, smoking, alcohol consumption, comorbidities, nighttime sleep duration, and chronotype.
Results: Median nap duration was 0.40 hours/day (IQR=0.19-0.77), and intra-individual variability of nap duration was 0.39 hours (IQR=0.19-0.69). Thirty-four percent (IQR=12%-52%) of the naps were taken between 9-11am, 10% (IQR=0%-17%) between 11am-1pm, 14% (IQR=0%-22%) between 1-3pm, 19% (IQR=1%-29%) between 3-5pm, and 22% (IQR=4%-32%) between 5-7pm. During an up to 8-year follow-up, 2,950 (3.4%) participants died, and among them, the average survival time was 4.19 (range: 0.03-8.15) years after baseline. Longer nap duration (for 1-SD, HR=1.20, 95%CI: 1.16-1.24, p< 0.0001), greater intra-individual variability (for 1-SD, HR=1.14, 95%CI: 1.10-1.18, p< 0.0001), and higher percentage of naps between 11am-1pm and between 1-3pm were associated with mortality (for 1-SD, 11am-1pm: HR=1.07, 95%CI: 1.03-1.11, p=0.0005; 1-3pm: HR=1.07, 95%CI: 1.03-1.12, p=0.0002).
Conclusion: Longer naps, greater intra-individual variability in daytime nap, and higher percentages of naps around noon and in the early afternoon are associated with greater mortality risks. These findings highlight the potential importance of considering napping behaviors in risk stratification of mortality in middle-to-older aged adults. Incorporating actigraphy-based nap assessments into clinical and public health practices may provide novel opportunities for early risk identification and personalized interventions to promote longevity.

BIOLOGICAL VALIDATION OF LIFESPAN MODELING IN DROSOPHILA MELANOGASTER

Jennifer Harrell[1], Gayla Olbricht[1], V. Samaranayake[1], Landon Oelschlaeger[1], Matthew Thimgan[1]

[1] Missouri University of Science and Technology

Introduction: Sleep is an evolutionary conserved function across species, indicating that it is a necessary function for life. Inadequate sleep promotes several disease states across a variety of systems that reduce lifespan, leading us to hypothesize that there must be a general underlying mechanism affected by sleep. To discover this mechanism, our interdisciplinary team has developed unique mathematical models to predict lifespan in chronologically identical Drosophila melanogaster, based on their sleep characteristics. Proteostasis, oxidative stress, and energy homeostasis are all associated with aging and thus make sense to pursue first in lifespan model validation.
Methods: Sleep is monitored for 30-days using the Trikinetics DAM system. Those data are used to make lifespan predictions, and flies are then binned into two groups – predicted long life (PLL) and predicted short life (PSL) for subsequent experimentation. To validate the models, we used a variety of molecular techniques. Overall soluble protein was quantified using a standard Bradford assay protocol. Metabolites were quantified using standard LC-MS/MS methods. MALDI-TOF imaging was used to examine energy metabolism, oxidative stress, and lipids. MALDI-TOF imaging was done using 9-Aminoacridine (9-AA) matrix with a target range between 50 m/z -1000 m/z. All statistical analyses were done using a Student's T-test, with α=0.05.
Results: Our predictions successfully binned the flies into two groups, with 26.7% of PSL flies dying between lifespan prediction and experimentation, compared to only 11.8% of PLL flies. We found evidence of proteome collapse, with overall soluble protein concentration significantly higher in PLL flies than PSL flies ($p< 0.05$). Our PSL flies had a significantly higher GSSG/GSH ratio, indicating oxidative stress ($p< 0.0001$). Furthermore, we found elevated AMP in PSL flies, indicating trouble maintaining the energy required for proteostasis and appropriate oxidative stress response. MALDI imaging showed localization differences of AMP/ATP/ADP and GSSG/GSH in abdomens of PLL and PSL flies ($p< 0.05$). Furthermore, MALDI-TOF imaging found free fatty acids and acylcarnitines to be significantly decreased in PSL flies ($p< 0.05$).
Conclusion: Our models can successfully separate our flies into distinct, biologically different groups, based on sleep characteristics. This allows us to make inferences between sleep and molecular function.

ALTERED GLYMPHATIC ACTIVITY IS ASSOCIATED WITH SLEEP PROBLEMS AND REDUCED COGNITIVE FUNCTION IN MIDDLE-AGED AND OLDER AUTISTIC ADULTS

Annika Linke[1], Stephanie Pedrahita[1], Michaela Cordova[1], Molly Wilkinson[1], Sabrena Tuy[1], Gioia Toro[1], Kale Alemu[1], Jiwandeep Kohli[1], Janice Hau[1], Ralph-Axel Müller[1], Ruth Carper[1]
[1] San Diego State University

Introduction: The glymphatic system is crucial for removing waste products from the brain, particularly during sleep. Atypical glymphatic function, quantified non-invasively from functional magnetic resonance imaging (fMRI) as the coupling between the global gray matter blood-oxygenation level dependent (BOLD) signal and cerebrospinal fluid (CSF) flow has been associated with cognitive decline in neurodegenerative disorders like Alzheimer's and Parkinson's Disease. Reduced BOLD-CSF coupling has also been linked to insomnia in depression. Sleep disturbances are common in autism spectrum disorder (ASD) but it is unclear whether glymphatic function is impacted. Examination of the potential sleep-glymphatic link is especially relevant in aging autistic adults as it might contribute to cognitive decline.
Methods: Resting state fMRI (12 min., TR=800ms) was acquired from 40 neurotypical (NT) and 27 autistic adults (40-70 year-olds). The global BOLD signal was extracted from gray matter masks and the CSF inflow signal derived from the central canal inferior to the cerebellum. The cross-correlation between BOLD and CSF fluctuations at a 2.4s lag quantified BOLD-CSF coupling, as in previous studies. Group differences were tested with a general linear model (GLM) controlling for age, fMRI quality and time of scan. Participants also completed standardized neuropsychological assessments (e.g., the California Verbal Learning Test [CVLT]) and were subtyped by reported sleep problems. Associations between BOLD-CSF coupling, sleep and cognitive function were tested with a GLM and partial correlations.
Results: The ASD and NT groups did not differ on age, gender, or non-verbal IQ. However, autistic adults were more likely to have sleep disturbances (69% vs. 35%; p=.01). BOLD-CSF coupling was significantly reduced in autistic compared to NT adults (p=.03) and, specifically, was lower in autistic adults with sleep problems (p<.001). BOLD-CSF coupling was not associated with executive function in autistic adults, but correlated negatively with short (r=-.49, p=.03) and long delay (r=-.51, p=.02) cued recall on the CVLT.
Conclusion: Our results suggest glymphatic system dysfunction in autistic adults that is associated with frequently co-occurring sleep problems and reduced verbal learning and memory. These findings highlight the importance of future longitudinal studies to better understand the impact of disrupted sleep on aging in autism.

RELATIONSHIP BETWEEN SELF-REPORTED OR OBJECTIVE PHYSICAL ACTIVITY MEASURES AND SLEEP AMONG OLDER PERSONS WITH SLEEP DISTURBANCES

Jarett Talarcyzk[1], Yulu Pan[2], Anne Chen[1], Emily Xu[3], Gawon Cho[1], Brienne Miner[1]
[1] Yale University, [2] University of North Carolina, [3] Yale School of Medicine

Introduction: The relationship between physical activity (PA) and sleep among older persons with sleep disturbances is unclear, possibly due to biases in self-reported measures. We examined the association of physical activity, measured by self-reported or objective measures, with objective measures of sleep among older persons.
Methods: This was a cross-sectional analysis among 64 community-living older persons with symptoms of insomnia and/or daytime sleepiness ≥once/week. Participants completed a medical interview and an 8-day home-based protocol with 7 days and

nights of actigraphy and one night of polysomnography. Self-reported PA measures were assessed over the previous month and included taking a walk for exercise ≥once/week (SRW) or doing vigorous activities that increased the heart rate ≥once/week (SRVA). Objective PA measures were assessed by moderate-to-vigorous activity (MVPA; the proportion of activity counts >1040 over 24 hours) and averaged over 7 days. Measures of sleep were assessed by polysomnography and included total sleep time (TST) and wake-after-sleep onset (WASO). Linear regression analyses examined the association of self-reported (SRW, SRVA) or objective (MVPA) physical activity measures with TST or WASO.

Results: The average age was 63 (10) years; 64% identified as White and 64% were females. Forty-three percent of participants said they performed SRW ≥once/week, while 19% said they did so for SRVA. Average TST and WASO were 370 (93) min and 90 (64) min, respectively. In regression models, increases in self-reported PA were not significantly associated with TST or WASO (p values > 0.05). Among participants with a higher proportion of MVPA, there was a trend for increased TST (p= 0.11), but no significant differences in WASO.

Conclusion: Among older persons with sleep disturbances, increases in self-reported or objective PA were not associated with increases in TST or decreases in WASO. These results need to be confirmed in a larger, longitudinal study but suggest factors other than the method of measurement for PA may explain the relationship between PA and sleep amongst an older population with sleep disturbances.

SEX DIFFERENCES IN THE ASSOCIATION BETWEEN SLEEP AND NEURODEGENERATIVE BIOMARKERS: RESULTS FROM THE EINSTEIN AGING STUDY

Linying ji[1], Yuqi Shen[2], Monique Balthazar[2], Angel Garcia De La Garza[3], Carol Derby[3], Christopher Engeland[2], Orfeu Buxton[4]

[1] Montana State University, [2] Pennsylvania State University, [3] Albert Einstein College of Medicine, [4] Penn State

Introduction: Sleep health is crucial in physiological restoration and has been associated with an increased risk of cognitive decline. The glymphatic system, which removes toxins associated with Alzheimer's disease (AD) pathology during sleep, can be negatively affected by suboptimal sleep. Neurodegenerative biomarkers (NDBMs) in blood plasma are cost-effective indicators of AD risk. We explored associations between objectively measured sleep health characteristics and NDBMs and investigated sex differences in these associations in a diverse sample of older adults.

Methods: Participants without dementia (N=262, Mean age=77 years, 69% women; 46% White, 41% Black, 13% Hispanic/other) were from the Einstein Aging Study. Actigraphy (2 weeks) yielded wake-after-sleep onset (WASO), total night sleep time (TST), and midpoint night sleep. NDBMs included Amyloid-Beta (Aβ42/40 ratio), neurofilament light (NFL), and phosphorylated Tau181 (pTau181, log-transformed). Bayesian variability models evaluated associations of NDBMs with mean and variability of sleep measures, adjusted for sex, age, race, ethnicity, literacy level, hypoxemia, oxygen desaturation index (ODI), and mild cognitive impairment status. Models for pTau181 were additionally adjusted for the estimated glomerular filtration rate. Models were stratified by sex.

Results: Average later nighttime sleep midpoint was associated with higher levels for NFL and pTau181 in the full sample. Sex-stratified analyses showed different associations between NDBMs and sleep variables for men and women, even though men and women did not differ in sleep variables in this sample. Among men, later average sleep timing was associated with higher levels of pTau181 and greater Aβ42/40 ratios. Among women, analysis suggests a possible positive association between average sleep timing and levels of NFL (credible interval: [-0.025,3.981]). Variability of sleep timing was not credibly associated with any NDBMs in this sample. We did not find associations of mean or variability of TST and WASO with NDBMs among men or women.

Conclusion: In stratified analyses, we observed different associations between NDBMs and sleep timing for men and women. This study emphasized the importance of understanding sex differences in studying pathways to AD.

WEAPON-CARRYING IN US HIGH SCHOOLS IS ASSOCIATED WITH INSUFFICIENT SLEEP: 2009-2023

Marie-Rachelle Narcisse[1], David Barker[2], Kiara Medeiros[3], Mary Carskadon[4]

[1] Psychiatry and Human Behavior, Alpert Warren Medical School of Brown University, [2] Rhode Island Hospital / Alpert Warren Medical School of Brown University, [3] BrownHealth, [4] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: Most United States (US) high schools prohibit the possession of weapons on school property and consider weapon-carrying as misconduct. Insufficient sleep is associated with impulsivity, lack of self-control, and other adverse emotional and mental health outcomes, which may contribute to risk-taking behaviors. The role of sleep in influencing risk-taking behaviors, such as weapon carrying, among adolescents has been underexplored. We examined whether insufficient sleep on school days was associated with the risk of teenagers carrying weapons at school. Furthermore, we explored whether race/ethnicity would modify this association.
Methods: The study utilized repeated cross-sectional data from the Youth Risk Behavior Surveillance System Survey (YRBSS, 2009-2023) from nationally representative samples of high school students ages 16-18 (n=88,044). Weighted multivariable logistic regression models assessed the association of self-reported insufficient sleep (< 8 hours/night on school days) with weapon carrying on school properties (the dependent variable), adjusting for survey years and sociodemographic variables (age, biological sex, and race/ethnicity). Race/ethnicity was further explored as an effect modification to identify subgroup differences in this association. Adjusted Wald test was used to assess the statistical significance of effect modification. All descriptive and regression analyses accounted for the YRBSS complex survey design.
Results: An estimated 5% of high school students reported carrying weapons on school property. Seven in ten teenagers (70%) reported sleeping less than eight hours. Insufficient sleep (< 8 hours) was associated with greater odds of carrying weapons on school property (AOR: 1.14; 95% [CI: 1.02; 1.27]). More specifically, reported sleep for 4 hours/night (8.4% of participants) tripled the odds of weapons-carrying (AOR: 3.14; 95% CI: 2.67; 3.70]. Although the odds of weapon-carrying were greater among American-Indian/Alaska Native and Native Hawaiian/other Pacific Islander adolescents (AOR: 1.76; [1.07; 2.91] and 2.04 [1.19; 3.48]) than among their White peers, the association between insufficient sleep (< 8 hours) and weapon-carrying was not modified by race/ethnicity F(6,536) = 0.57; p=0.76).
Conclusion: Findings underscore the potential risks associated with having sleep-deprived students on school property. Policies that promote sufficient sleep during school days (e.g., later school start time) could help mitigate some of the risks of carrying weapons to school.

ADOLESCENT SOCIO-ECOLOGICAL PREDICTORS OF MEETING SLEEP GUIDELINES ON WEEKDAYS IN ADOLESCENCE AND YOUNG ADULTHOOD

Kayla Johnson[1], Rachel Widome[1], Dianne Neumark-Sztainer[1]

[1] University of Minnesota - Twin Cities

Introduction: Introduction: Inadequate and poor-quality sleep are associated with several leading causes of death (e.g. heart disease, accidents, and diabetes) as well as poor mental health. Understanding determinants of poor sleep may highlight avenues for interventions that could prevent the development of sleep problems. We aimed to explore how factors during adolescence, at all levels of the socio-ecological framework, relate to meeting sleep recommendations both concurrently and later in young adulthood.
Methods: Methods: Participants (n=1559) were recruited from Twin Cities, MN schools as part of Project EAT. They completed baseline surveys in 2009-2010 (mage=14.5) and follow-up surveys in 2017-2018 (mage=22.0). Logistic regression was used to examine whether adolescent socio-ecological factors (i.e., depression, screen time, parental connectedness, neighborhood safety, etc.) related to odds of meeting sleep guidelines in adolescence and young adulthood. Models were adjusted for age, sex, socioeconomic status, and race/ethnicity.
Results: Results: Multiple individual-level and interpersonal-level factors were relevant to adolescents' sleep. For instance, for each one-point increase in depression score adolescents' odds of meeting sleep guidelines lowered 8%. Although other individual-level factors in adolescence no longer predicted young adult sleep, adolescent depression remained a predictor of subpar sleep in young adulthood (OR=0.92; CI: 0.88-0.97). At the interpersonal-level, experiencing sexual harassment or harassment based on socioeconomic status, weight, or appearance, during adolescence predicted 25% lower odds of meeting sleep guidelines as adolescents (OR=0.75; CI: 0.60-0.93) and the effect extended into young adulthood (OR=0.70; CI: 0.52-0.94). However, other characteristics of adolescents' families that had concurrently predicted sleep in adolescence (such as family functioning and parental monitoring) did not predict meeting young adult sleep recommendation. At the environmental-level, increased safety in the adolescents' neighborhoods predicted higher odds of adolescents meeting sleep recommendations (OR=1.08; CI: 1.02-1.15) but the safety of one's adolescent neighborhood was not associated with sleep in young adulthood.
Conclusion: Conclusion: Adolescent factors at all levels of the socio-ecological framework related to sleep in adolescence and some effects persisted into young adulthood. There are multiple familial factors that could be enhanced through intervention that may improve sleep; meanwhile societal factors such as adolescent discrimination and harassment can negatively affect sleep and deserve attention.

SCHOOL CONNECTEDNESS AND SLEEP HEALTH DURING ADOLESCENCE

Shameka Rodgers Phillips[1], Teresa Ward[2], Priscilla Carmiol-Rodriguez[1], Tumaini Coker[1], Kristin Carlin[3]

[1] University of Washington, [2] University of Washington, Department of Pediatrics, School of Medicine; Center for Child Health, Behavior, and development, Seattle Children's Research Institute, [3] Seattle Children's Hospital

Introduction: Poor sleep health is prevalent among adolescents. Schools are an important environment where adolescents spend

a considerable amount of time. School connectedness, one's sense of being cared for and closeness to school staff and peers, has been found to be a protective factor for adolescent health. Less is known about school connectedness and sleep, particularly among adolescents experiencing health inequities. This study leveraged the Future of Families and Child Wellbeing Study (FFCWS) to examine the relationship between school connectedness and sleep health and whether race, socioeconomic status (SES), and caregiver education moderated these relationships in adolescents.

Methods: The sample included 690 adolescents with completed surveys and 7 days of actigraphy. Linear regression models were conducted to assess the relationship between school connectedness and sleep (total sleep time [TST], wake after sleep onset [WASO], sleep efficiency [SE], naps, and day-to-day variability in TST, WASO, SE, naps) with race, SES, and caregiver education entered as moderators.

Results: Adolescents had a mean age of 15 years; 53% were female, and 47% were non-Hispanic Black. Significant negative associations were found between school connectedness and nap duration ($r = -0.18$, $p < 0.001$) and variability ($r = -0.15$, $p < 0.001$), even after accounting for covariates ($B = -6.23$, $p = 0.004$; $B = -6.02$, $p = 0.03$), respectively. Among adolescents whose families lived 100 – 199% below the poverty threshold, every unit increase in school connectedness was associated with lower variability in TST ($B = -25.13$, $p = 0.007$) and WASO ($B = -0.83$, $p = 0.017$) compared to those living 0-49% below the poverty level. Among adolescents whose families lived 50-99% and 300% below the poverty threshold, every unit increase in school connectedness was associated with an increase in mean SE ($B = 1.36$, $p = 0.049$) and variability of SE ($B = -0.62$, $p = 0.018$), respectively, compared to those living 0-49% below the poverty level.

Conclusion: Our findings support the importance of school connectedness as a protective factor for good sleep health in adolescents despite their risk of health disparities.

RACIAL/ETHNIC DISPARITIES IN SLEEP VARIABILITY AND IRREGULARITY IN ADOLESCENTS: IMPACT OF SCHOOLING

Natasha Morales-Ghinaglia[1], Susan Calhoun[2], Raegan Atha[2], Jason Liao[2], Alexandros Vgontzas[3], Duanping Liao[2], Edward Bixler[2], Julio Fernandez-Mendoza[2]

[1] Geisinger Commonwealth School of Medicine, [2] Penn State College of Medicine, [3] Sleep Research and Treatment Center, Penn State College of Medicine

Introduction: While prior research has shown sleep health disparities as a function of race/ethnicity, most studies do not account for the impact of entrainment to the academic school schedule. We hypothesize that adolescents who identify as a racial/ethnic minority, compared to non-Hispanic whites, have greater sleep variability (amount) and irregularity (timing) when evaluated while attending school.

Methods: We analyzed 365 adolescents from the Penn State Child Cohort (median 16y; 46% female; 19% racial/ethnic minority, of which 67% were Black/African American and 33% Hispanic) who had at least 3 nights of actigraphy. Sleep midpoint was defined as the intra-individual mean middle point of the sleep period. Sleep irregularity was defined as the intra-individual standard deviation of sleep midpoint. Social jetlag was defined as the absolute difference between sleep midpoint on weekdays vs. weekends. Sleep duration was defined as the intra-individual mean total sleep time. Sleep variability was defined as the intra-individual standard deviation of total sleep time. Self-reported circadian preference was assessed via Morningness-Eveningness Questionnaire. Subjects reported race/ethnicity and were re-categorized into "Black/African American", "Hispanic/Latinx", "non-Hispanic/Latinx white" or "Other" for analytical purposes. ANOVAs were stratified by "in-school" and "on-break" to examine mean differences on each sleep duration and timing metric between non-Hispanic whites and minoritized adolescents.

Results: Adolescents evaluated while having to entrain to the school schedule and who identified as a racial/ethnic minority showed 12 minutes greater sleep variability ($p = 0.042$) and 15 minutes greater sleep irregularity ($p = 0.011$) compared to non-Hispanic/Latinx whites evaluated under the same entrainment conditions. Specifically, Black/African American adolescents showed 17 minutes greater sleep variability ($p = 0.030$) and Hispanic/Latinx adolescents showed 21 minutes greater sleep irregularity ($p = 0.021$) compared to non-Hispanic/Latinx whites. There were no significant racial/ethnic differences in sleep metrics when adolescents were evaluated while on-break.

Conclusion: Racial/ethnic disparities in sleep duration and circadian timing are aggravated by entrainment to the academic school schedule. Studies should identify the upstream determinants of these inconsistencies in the timing and amount of sleep when attending school. Additionally, interventions should target the observed sleep health inequalities in order to reduce their downstream effects in historically minoritized racial/ethnic groups.

LATER AGE OF MENARCHE IS ASSOCIATED WITH BETTER ACTIGRAPHIC SLEEP QUALITY AND FEWER SELF-REPORTED INSOMNIA SYMPTOMS IN ADOLESCENT GIRLS

Saran Ashley Douglas[1], Angel Collie[1], Gina Mathew[2], Lindsay Master[3], Orfeu Buxton[3], Lauren Hale[4], Anne-Marie Chang[5]

[1] Penn State University, [2] Stony Brook Medicine, [3] Penn State, [4] Stony Brook University, [5] The Pennsylvania State University

Introduction: Early age of pubertal onset is associated with increased sleep disturbances in girls; however, little is known about whether age of menarche is associated with sleep health in adolescent girls, particularly using objective sleep measures such as actigraphy. We examined whether age of menarche is associated with both actigraphic and self-reported sleep health among adolescent girls in a large, diverse population. Given the literature showing earlier age of menarche in Black and Hispanic girls, we also examined whether race/ethnicity moderated this relationship.

Methods: Data from 1,558 female participants who had experienced menarche (range: 8-16y) and had self-reported sleep outcomes were obtained from the age 15 wave of the Future

of Families and Child Wellbeing Study. Self-reported sleep outcomes included trouble falling and trouble staying asleep, bedtimes, wake times, and sleep duration on school days and weekends. Actigraphic sleep measures, including sleep onset, sleep duration, sleep maintenance efficiency, and wake after sleep onset (WASO), were collected in a subsample of 403 female adolescents (range: 8-14.7y) who participated in the sleep substudy. Multiple linear regression analyses examined the association between age of menarche in years and dimensions of sleep health adjusting for age at survey completion, race/ethnicity, family structure, household income, and parental education.

Results: Among the full sample, 1 year later age of menarche was associated with.18 fewer nights/week having trouble falling asleep (p<.001) and.14 fewer nights/week staying asleep (p<.001). Among the actigraphy sub-sample, 1 year later age of menarche was associated with.20 fewer nights/week having trouble staying asleep (p=.016),.22% higher nightly sleep maintenance efficiency (p=.045), and 1.5 fewer minutes WASO/night (p=.010). Race/ethnicity moderated some results such that the association between later age of menarche and fewer insomnia symptoms was stronger in White adolescent girls compared to Hispanic adolescent girls and not significant among Black adolescent girls.

Conclusion: Later age of menarche is associated with better actigraphic sleep quality and fewer self-reported insomnia symptoms at age 15, particularly among White girls. Future research should examine whether age of menarche predicts sleep health later in life.

ASSOCIATIONS OF SLEEP AND ORAL MICROBIOME AMONG ADOLESCENTS AND YOUNG ADULTS IN THE UNITED STATES

Marie-Rachelle Narcisse[1], David Barker[2], Tsute Chen[3], Evangelia Morou[4], Kiara Medeiros[5], Mary Carskadon[6]

[1] Psychiatry and Human Behavior, Alpert Warren Medical School of Brown University, [2] Rhode Island Hospital / Alpert Warren Medical School of Brown University, [3] The Forsyth Institute, [4] Oral Biology, School of Dental Medicine University of Puerto Rico Medical Sciences Campus, [5] BrownHealth, [6] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: The human mouth is densely colonized by microbial species. Evidence suggests reduced microbial diversity has been associated with chronic physical and mental health conditions; however, most of these small-scale studies have implicated the gut microbiome and involved children or adults. We examined associations of oral microbiome diversity with self-reported sleep duration among a representative sample of adolescents and young adults ages 16-26 years in the United States.

Methods: This study used cross-sectional data from the National Health and Nutrition Examination Survey (NHANES, 2011-2012). Outcome variables: Oral microbiome alpha (α) diversity measures of richness and evenness: (1) Observed operational taxonomic units (OTU), (2) Faith's phylogenetic diversity (FPD), (3) Shannon-Weiner index (SWI), and (4) Inverse Simpson index (ISI). Sleep exposure variables: self-reported sleep hours on weekdays or school/work days were categorized as very short, short, healthy, and long sleep according to AASM recommendations. Four separate Generalized Linear Models (GLM) were fitted to the sample to investigate associations between each α diversity measure and sleep duration, controlling for covariates. All descriptive and regression analyses adjusted for NHANES complex survey design.

Results: The sample included 1,332 participants, of whom 463 were ages 16-18 years, and 869 were ages 19-26 years. The mean age was 20.9 years, and 50.4% were females. Five in ten teenagers (50.6%) reported the recommended hours of sleep (8-10 hrs), while six in ten young adults (61.2%) had the recommended hours of sleep (7-9 hrs). OTU mean was 128.0 [95% CI:122.35–133.64]; FPD mean was 14.24 [13.87–14.62]; SWI mean was 4.61 [4.54–4.67]; and ISI mean was 0.90 [0.89–0.90]. Findings from GLM estimates showed that compared to those with healthy sleep duration, teenagers and young adults with long sleep duration (3% of participants) had significantly higher oral microbiome diversity, according to OTU, FPD, and SWI indicators: 43.0 [22.3–63.72]; 2.96 [1.16–4.76]; and 0.64 [0.07–1.21], respectively. No significant association was found between ISI and self-reported sleep duration.

Conclusion: Oral microbiome diversity is positively associated with longer sleep duration among teenagers and young adults. Further research needs to determine the potential mechanisms behind the associations observed in this study.

SOCIAL MEDIA USE AND SLEEP IN COLLEGE: DIFFERENTIAL IMPACT FOR WOMEN

Sarah Lust[1], Lauren Danzey[2]

[1] Auburn University, [2] Brown University Health

Introduction: Recent research reveals significant impacts of social media use on students' sleep patterns and quality. Many young adults stay up late engaging with social media, affecting their physical and mental health, and academic performance. Frequent social media use is associated with delayed bedtimes, difficulties falling asleep, shorter sleep duration, and poorer sleep quality. Female college students who spend more time on social media report higher levels of anxiety and depressive symptoms compared to males. However, less is known about how social media use may directly or indirectly impact sleep differentially by gender.

Methods: Survey data was collected from four cross-sectional cohorts of college students from Psychology classes at a large Southeastern Research University in Fall 2020 (n=589), Fall 2021 (n=323), Fall 2023 (n=698), and Spring 2024 (n=445). Participants (n=2055) received partial course credit for completing a Qualtrics survey addressing fear of missing out (FoMO), social media use frequency, anxiety, depression, perceived stress, sleep quality (PSQI), and other sleep-related questions.

Results: A one-way MANOVA compared differences in mental health, FoMO, sleep quality, social media use, and texting habits by sex. Women reported higher levels of FoMO, anxiety, depression, and stress than men (ps <.01). Women also checked social media more frequently and spent over 35 minutes more per day on social media. Sleep satisfaction was similar between

genders (p >.05), but women reported slightly more sleep (M = 7.94 hours) than men (M = 7.73), p =.03. FoMO and social media use were negatively correlated with depression, anxiety, stress.
Conclusion: Results suggest female college students may struggle more with mental health and quality sleep. Future research should explore whether social media use predicts poor sleep quality and low well-being, or if mental health struggles increase social media appeal. Additionally, interventions to decrease social media use could be investigated for potential improvements in sleep quality and mental health factors.

RACIAL DISPARITIES IN PERCEIVED DISCRIMINATION AND SLEEP QUALITY AMONG COLLEGE STUDENTS

Evelyn Arana-Chicas[1], Andrea Spaeth[2], Caroline Chovanes[2]
[1] Rutgers Cancer Institute, [2] Rutgers University

Introduction: Insufficient sleep is a public health problem among college students. Approximately 71% of college students sleep less than eight hours per night, and one-third of students have trouble falling asleep at least once a week. Discrimination has been posited as a contributor to sleep disturbances. This study aims to determine whether perceived discrimination correlates with sleep quality among college students and whether these relationships differ by racial group.
Methods: This is an observational, cross-sectional survey study. Traditional college-age students (18-23 years) who attend a large, public university were recruited in the lobbies of classroom buildings and student centers, Sunday through Saturday. Participants completed the Perceived Ethnic Discrimination Questionnaire and the Pittsburgh Sleep Quality Index (PSQI) on a tablet. Descriptive statistics, chi-square tests, and Spearman's rho correlations were conducted.
Results: A total of 296 participants were enrolled in this study (51.7% White, 24.3% Asian, 24.0% Black). The mean age was 19.6 (SD=1.3). Most participants were female (63.8%), non-Hispanic (88.2%), and lived on campus (55.7%). Most participants shared a room (58.4%), were on financial aid (59.8%), and were unemployed (51.9%). Black and Asian students had significantly higher perceived discrimination compared to White students (mean scores=2.5, 1.9, and 1.5, respectively; p<.001) and Black students had significantly higher perceived discrimination than Asian students (p<.001). Perceived discrimination was associated with poorer sleep quality, as measured with the global PSQI score, in Black students (r=0.35, p=0.01) but not Asian (r=0.16, p=0.21) or White students (r=0.14, p=0.12). Black students were also significantly less likely to report sleeping at least 7 hours/night than Asian and White students (25.7% vs 40.0% vs 47.9%, respectively; p=0.002).
Conclusion: This study highlights significant racial disparities in perceived discrimination and its association with sleep quality among college students. Black students reported the highest levels of perceived discrimination, which correlated with poorer sleep quality compared to their Asian and White peers. These findings highlight the importance of studying discrimination as a potential contributor to sleep disparities and developing interventions to improve sleep health in Black student populations.

SLEEP DISTURBANCE AMONG BLACK COLLEGE STUDENTS: THE ROLE OF FOOD AND HOUSING INSECURITY

Abisha Ebenezer[1], Crishnaa Joshi[2], Jay Bradford[2], Ronald D. Taylor[2]
[1] Seton Hall University, [2] Temple University

Introduction: Experiencing food and housing insecurity have been linked to adverse health outcomes, and disproportionately affect marginalized populations. Among Black college students, these insecurities have been linked to poor physical and mental health, including sleep disturbances. Given the significant role of sleep in overall well-being and academic success, it is essential to examine how food and housing insecurity contribute to sleep disturbance in this population.
Methods: The sample consisted of Black students attending a large predominantly White institute (n = 263, 82.37% female, Mage = 20.3 years, 19.4% low SES). Sleep disturbance was measured using the Pittsburgh Sleep Quality Index (PSQI), with 81.4% of participants classified as having poor sleep based on the established 5-point cutoff. Food insecurity was measured with the Food Insecurity Experience Scale (FIES), and housing insecurity was measured by 6 items of the USDA Housing Security Scale. A multiple linear regression model was conducted to examine the relationship between housing and food security status and sleep disturbance.
Results: The model explained 8.55% of the variance in sleep disturbance (R2=.085, p <.001). Housing insecurity was significantly associated with greater sleep disturbance (B=1.25, p <.05), indicating that housing-insecure participants reported higher sleep disturbance scores compared to their housing-secure peers. Among food security levels, participants classified as moderately food insecure reported significantly higher sleep disturbance scores (B=4.38, p <.05) compared to food-secure participants. Mildly food insecure (B=3.54, p =.104) and severely food insecure (B=2.74, p =.154) participants also reported higher sleep disturbance scores, though this was not statistically significant. In terms of gender, compared to male participants, those identifying as "other" reported significantly higher sleep disturbance scores (B=3.68, p <.01), while females showed higher sleep disturbance scores (B=1.27) approaching statistical significance (p=0.087).
Conclusion: This study highlights the significant impact of housing insecurity, varying levels of food insecurity on sleep disturbance, and gender-based disparities in sleep health among Black college students. Comprehensive interventions targeting these insecurities are essential to improving sleep outcomes and promoting overall well-being in this population.

RATES OF INSUFFICIENT SLEEP IN UNIVERSITY STUDENTS FROM 2000 TO 2023

Michael Scullin[1], Allison Nickel[2], Blake Barley[1]
[1] Baylor University, [2] Beloit College

Introduction: Sleep is critical to health and functioning, but many university students habitually obtain insufficient sleep. We examined trends in sufficient sleep amongst university students across a 23-year period using data from a large, nationwide survey.

Methods: We conducted a secondary analysis of data from the American College Health Association–National College Health Assessment surveys (ACHA-NCHA). These surveys evaluated health behavior trends in university students across the United States. We analyzed data from fully-enrolled undergraduate students at four-year institutions across five surveys, including ACHA-NCHA I (2000 to Spring 2008), ACHA-NCHA II (Fall 2008 to Spring 2011), ACHA-NCHA IIb (Fall 2011 to Spring 2015), ACHA-NCHA IIc (Fall 2015 to Spring 2019), and ACHA-NCHA III (Fall 2019 to Spring 2023). Each survey asked participants "On how many of the past 7 days did you get enough sleep so that you felt rested when you woke up in the morning?"
Results: The sample averaged N=1,597,993 students across 47 semesters. The students averaged 20.74 years (SD=3.85) and the sample included 66.5% females (33.1% males, 0.4% transgender, non-binary, or other), and included 70.9% non-Hispanic White students (5.3% Black or African American; 8.6% Hispanic or Latino/a; 10.6% Asian or Pacific Islander; 1.5% American Indian, Alaskan Native, or Native American; 3.1% Biracial or Multiracial; 0.1% Other). There was a significant decline in sufficient sleep over time (F=305.90, p<.001), dropping from M=3.07 days/week in 2000 to M=2.42 days/week in 2023. During the earliest study wave, 39.5% of students indicated obtaining sufficient sleep ≤2 days/week (i.e., likely only on weekends); two decades later, this prevalence worsened to 59.8%. The decline over 23 years was larger in female students than male students (F=15.28, p<.001). Insufficient sleep was more common amongst BIPOC students than non-Hispanic White students (mean difference=0.314), but these groups showed similar rates of decline over time.
Conclusion: In contrast to sleep duration trends seen in the general U.S. adult population (Bureau of Labor Statistics), sleep has worsened amongst university students during the past two decades. Potential causes and consequences of these sleep changes will be discussed.

EARLIER SCHOOL START TIMES COMPROMISE SLEEP OPPORTUNITY IN KINDERGARTENERS

Elliott Shi[1], Maida Chen[2], Michelle Garrison[1]
[1] Purdue University, [2] Seattle Children's Hospital

Introduction: Shifting elementary school start times earlier to accommodate later high school schedules may impact children's sleep and health. While younger children lack adolescents' circadian delays, earlier starts could still misalign their sleep needs with external demands like parental work schedules.
Methods: We used data from the nationally representative Early Childhood Longitudinal Study-Kindergarten (ECLS-K) 2011 cohort, with descriptive and bivariate statistics, including ANOVA (for continuous variables) and chi-square (for categorical) to test for differences in outcomes across start times. Linear regression was used to examine the impact after adjusting for potential confounders while taking into account non-independence at the school level. School start times were divided into four categories: < 7:45, 7:46-8:15, 8:16-8:45, and >8:46.
Results: This analysis included 11,877 kindergarten children with a mean age of 6.1(SD 0.4) years, with start times before 7:45 AM being disproportionately likely in children who are Black, attend a Title I school, have a household income below $30K, and/or live in a rural area. Although earlier school starts are associated with somewhat earlier bedtimes (8:22PM for students with pre-7:45 AM starts vs. 8:33PM for students with starts post-8:46AM), the sleep opportunity potential (time from bedtime to school start) is still significantly less among students with the earliest start times by 77 minutes (95%CI [71-82]). There is also a statistically significant trend between school start time and the likelihood of having breakfast (whether at school or home), with 53.27%, 65.02%, 73.12%, and 77.27% of children respectively having breakfast each day across earliest to latest start times groups ($p < 0.001$).
Conclusion: Children with earlier school start times experience a greater mismatch between their sleep needs and schedules. After accounting for time to get ready and commute to school, the 11.2 (SD 0.6) hours sleep opportunity ceiling in the earliest start time group likely results in less than the recommended 10-11 hours. Especially given the overlap between known sleep disparities and those above in school start time assignments, this likely further disadvantages young students already at risk.

SCHOOL START TIMES, SLEEP OPPORTUNITY, AND ASTHMA IN ELEMENTARY SCHOOL CHILDREN

Pauline Esantsi[1], Weston Powell[2], Maida Chen[3], Michelle Garrison[1]
[1] Purdue University, [2] Center for Respiratory Biology and Therapeutics, Seattle Children's Research Institute, [3] Seattle Children's Hospital

Introduction: School start times influence the window of sleep opportunity in childhood. Inadequate sleep is a known risk factor for multiple chronic health conditions, including asthma. However, data linking school start times, especially in early childhood, with specific medical conditions are not well explored at the population level.
Methods: We utilized data from the nationally representative ECLS-K 2011 longitudinal cohort study. Metrics included annual school-reported school start times starting in kindergarten, and parent-reported diagnosis of asthma starting the year after kindergarten and annually for the subsequent 5 years. Unadjusted chi-squared tests and multivariate logistic regression analyses were used to evaluate the impact of kindergarten school start times on parent report of asthma diagnosis in subsequent years. Kindergarten school start times were grouped as 7:45 or earlier [group A], 7:45 to 8:15 [group B], 8:15 to 8:45 [group C], or after 8:45 AM [group D].
Results: 7,940 students were included. 17.6% had a kindergarten school start time that begins at 7:45 AM or earlier. Asthma prevalence was 15.4% and 17.2% at one and five years after kindergarten, respectively. In unadjusted analyses, asthma at 5 years after kindgergarten was significantly associated with earlier kindergarten school start times: 20.1% in group A, 17.1% in group B, 16.6% in group C, 14.5% in group C ($p< 0.01$). After adjusting for potential confounders (child sex, household income, urban location, and Title 1 school at the kindergarten baseline), early school start times remained a statistically significant predictor of parent-reported child asthma four and five years later (OR=1.31, 95%CI 1.02–1.69 and OR=1.47, 95%CI 1.14-1.88, respectively),

but was no longer statistically significant at the first three follow-up time points (with ORs of 1.22, 1.19, and 1.29 and p-values of 0.11, 0.15, and 0.05 respectively).
Conclusion: Kindergarten start times may influence both development and persistence of chronic childhood conditions such as asthma. Health problems associated with earlier kindergarten start times may be linked to shorter sleep duration/opportunity, or circadian timing of disease-related processes, such as airways inflammation in asthma.

OCCUPATIONAL PRESTIGE AS A STRUCTURAL DETERMINANT OF SLEEP HEALTH AMONG YOUNG AFRICAN AMERICAN WOMEN

Bethany Ogbenna[1], Symielle Gaston[1], DaNashia Thomas[1], Kennedy Williams[1], Aarushi Joshi[2], Anissa Vines[3], Quaker Harmon[4], Chandra Jackson[1]
[1] National Institute of Environmental Health Sciences, [2] University of North Carolina - Chapel Hill, [3] University of North Carolina at Chapel Hill, [4] NIEHS

Introduction: Structural determinants such as job strain and long work hours contribute to sleep health disparities. Relatedly, Black women in professional occupations report short sleep more than other women, including their non-professional counterparts. Therefore, Black women professionals may not experience the expected sleep health benefits of higher occupational prestige (OP), defined as the perceived social value of their occupation within society. Notably, the OP-sleep relationship remains uninvestigated.
Methods: We assessed cross-sectional and longitudinal associations between OP and sleep health among Black women in the Detroit, MI area who enrolled (2010–2012) in the Study of Environment Lifestyle and Fibroids. Participants were followed until 2014–2018. Baseline OP was measured using the Nakao-Treas Prestige Score (range: 0—100) and categorized into quintiles (Q1low–Q5high). Self-reported sleep dimensions (baseline and three follow-up collections) were dichotomized (yes vs. no): short sleep duration (< 7 hours), non-restorative sleep (well-rested < 4 days/week), insomnia symptoms (difficulty falling/staying asleep ≥10 days/month), and diagnosis of sleep apnea (at Follow-up 3). Adjusting for sociodemographic characteristics, we used Poisson regression with robust variance to estimate prevalence ratios (PRs) and confidence intervals (95%CIs) and applied generalized estimating equations to determine risk ratios (RRs) and 95%CIs.
Results: Among 1,053 participants working ≥10 hours/week, mean age was 28.9 (SD=3.4) years. Unadjusted prevalence ranges of short sleep (57% [Q4]—67% [Q1low]), non-restorative sleep (59% [Q5high]—69% [Q1low], insomnia symptoms (15% [Q1low]—21% [Q4]), and sleep apnea (3% [Q5high]—6% [Q1low]) were comparable across OP quintiles (p>0.05). High vs. low OP was marginally associated with lower prevalence of short sleep (PR-Q5 vs.Q1=0.93; 95%CI:0.87–1.00) and, conversely, with a marginally higher prevalence of non-restorative sleep (PR-Q5 vs.Q1=1.06; 95%CI:1.00–1.12). Longitudinally, women with high vs. low OP had lower risk of short sleep (RR-Q5 vs.Q1=0.70; 95%CI:0.58-0.85) and non-restorative sleep (RR-Q5 vs.Q1=1.14; 95%CI:1.03–1.27). OP was not associated with the remaining sleep disturbances.
Conclusion: Poor sleep health was highly prevalent. High vs. low OP was associated with a lower risk of short sleep, but a higher prevalence and risk of non-restorative sleep. Future research should leverage higher-income, nationally-representative cohorts of Black women and consider potential mediators (e.g., goal-striving work stress) of the OP-sleep relationship.

ASSOCIATIONS BETWEEN ACTIGRAPHY SLEEP AND OBESITY MARKERS IN BLACK EMERGING ADULTS; INITIAL RESULTS FROM SHOW STUDY

Jessica McNeil[1], Hannah Koch[1], Bryan Montero Herrera[1], Stephanie Pickett[1], Thomas McCoy[1], Laurie Wideman[1]
[1] University of North Carolina at Greensboro

Introduction: Short sleep duration, poor sleep efficiency, later sleep timing and greater day-to-day sleep variability are associated with greater obesity risk. Few studies have comprehensively assessed sleep and obesity markers in Black emerging adults (ages 18-28 years), despite higher risks of short sleep and obesity in this population. We examined preliminary, cross-sectional associations between actigraphy-assessed sleep (duration, efficiency, timing midpoint, and day-to-day variability calculated as coefficients of variation) with obesity markers (body weight, waist circumference and fat mass) in Black emerging adults from the Sleep, Health Outcomes and Body Weight (SHOW) study.
Methods: The SHOW study aims to recruit 150 Black emerging adults. Baseline data on 7-day actigraphy-assessed sleep and obesity markers are currently available in 48 participants (35 females; age, 20.1±1.8 years; weight, 78.7±23.0 kg; fat mass, 25.4±17.9 kg; sleep duration, 6h9min±1h12min; sleep efficiency, 71.2±9.3%; sleep timing midpoint, 5h32AM±1.1hrs), and these results are presented herein. Given the exploratory nature of these analyses, Spearman correlations assessed associations between sleep variables with obesity markers in all participants, and in males and females separately.
Results: In all participants, mean sleep duration (rs= -0.31, P= 0.03) and sleep timing (rs= 0.29, P= 0.04) were associated with body weight. Sleep duration variability was associated with body weight (rs= 0.30, P= 0.04), waist circumference (rs= 0.38, P= 0.01) and fat mass (rs= 0.36, P= 0.01). In females, mean sleep duration was associated with body weight (rs= -0.38, P= 0.02), waist circumference (rs= -0.41, P= 0.01) and fat mass (rs= -0.34, P= 0.04). Sleep duration variability was also associated with body weight (rs= 0.38, P= 0.03), waist circumference (rs= 0.42, P= 0.01) and fat mass (rs= 0.38, P= 0.02) in females. In males, mean sleep timing was associated with waist circumference (rs= 0.62, P= 0.02) and fat mass (rs= 0.64, P= 0.02).
Conclusion: These preliminary findings suggest that shorter sleep duration, later sleep timing and greater sleep duration variability are associated with higher obesity markers in Black emerging adults. Sex-based differences also emerged, with sleep duration and sleep duration variability being stronger risk factors in females, whereas sleep timing was a stronger risk factor in males.

ASSOCIATIONS OF POLYSOMNOGRAPHY-ASSESSED SLEEP WITH HEMODYNAMIC BURDEN IN BLACK EMERGING ADULTS

Sheldon Smith[1], Laurie Wideman[1], Austin Robinson[2], Jessica McNeil[1]

[1] University of North Carolina at Greensboro, [2] Indiana University Bloomington

Introduction: Black emerging adults (ages 18-28) have the highest prevalence of short sleep and cardiovascular disease (CVD) risk factors (e.g., hypertension) compared to age-matched individuals from other racial groups. Poor sleep architecture (e.g., lower proportion of slow wave sleep (SWS)) is associated with a greater risk of CVD. However, in Black emerging adults, data on sleep architecture and hemodynamic burden, a key clinical predictor of CVD risk, is limited. We examined preliminary, cross-sectional associations between polysomnography-assessed sleep architecture with hemodynamic burden in Black emerging adults.
Methods: Data collection for the Sleep, Health Outcomes and Body Weight (SHOW) study is ongoing. This analysis includes 10 Black emerging adults (age=20.76±1.01 years; body mass index (BMI)=28.72±8.42 kg/m2; 8 females). Home-based polysomnography-assessed sleep architecture included stage 2 sleep, SWS, and rapid-eye-movement (REM) sleep over 2 nights. Hemodynamic measures included resting brachial systolic, mean, and diastolic blood pressure (BP), resting estimated central (i.e., aortic) systolic, mean, and diastolic BP, pulse pressure, resting heart rate, carotid-femoral pulse wave velocity, central augmentation pressure (AP), and augmentation index) are presented herein. Spearman correlations assessed associations between sleep architecture and hemodynamic burden given the exploratory nature of these analyses.
Results: Participants' mean relative time in each sleep stage was stage 2: 49.8±9.4%, SWS: 20.1±8.0%, and REM sleep: 29.3±8.5%. Stage 2 sleep was positively associated with central systolic BP (ρ= 0.683, p=0.042), mean BP (ρ= 0.770, p=0.015), AP (ρ= 0.898, p< 0.001), and augmentation index (ρ= 0.849, p=0.004). SWS was inversely associated with brachial mean BP (ρ= -0.686, p=0.041), diastolic BP (ρ= -0.672, p=0.047), heart rate (ρ= -0.700, p=0.036), central diastolic BP (ρ= -0.817, p=0.007) and augmentation index (ρ= -0.723, p=0.028). No significant associations were noted between REM sleep duration with hemodynamic measures.
Conclusion: These preliminary findings suggest that more SWS and less stage 2 sleep is cross-sectionally associated with lower hemodynamic burden and may therefore be protective against CVD risk in Black emerging adults. Additional analyses with a larger sample size are planned for the SHOW study, with an aim of further exploring potential subgroup differences in these associations (e.g., biological sex and sociodemographic factors).

ASSOCIATIONS BETWEEN RACIAL SEGREGATION & SLEEP HEALTH IN CORONARY ARTERY RISK DEVELOPMENT IN YOUNG ADULTS STUDY

Morgann West[1], Kiarri Kershaw[1], Kristen Knutson[1], Mercedes Carnethon[1], Diana Chirinos[1]

[1] Northwestern University Feinberg School of Medicine

Introduction: Black adults in the US have shorter sleep duration, lower sleep efficiency, and worse sleep quality compared to Non-Hispanic White adults. Racial segregation may be a contributing factor to sleep disparities as individuals living in disadvantaged communities may have greater exposure to bright lights, noise, and poor air quality and may have more difficulties accessing resources. This study examines the cross-sectional associations between racial segregation and sleep health (sleep duration, efficiency, and quality) among middle-aged Black adults.
Methods: The sample included 366 Black adults who participated in the Coronary Artery Risk Development in Young Adults (CARDIA) Sleep Health Ancillary Study. The Sleep Health Ancillary study was conducted during the Y35 CARDIA examination (2020-2024). Racial segregation was measured using the Getis-Ord Gi* statistic, a measure of standard deviation (SD) between the neighborhood's racial composition and the surrounding area's racial composition. Sleep measures included sleep duration and efficiency (derived from actigraphy data using Actiware Software [version 6.2.0.39]) and subjective sleep quality (measured by the Pittsburgh Sleep Quality Scale [PSQI]). Linear regression models were fitted to examine associations between racial segregation and sleep health parameters.
Results: Participants were 68.8% female and a mean age of 60.7 years (SD=3.9). Mean G-scores were 2.4 (SD=2.8), suggesting greater racial segregation among Black adults. Mean sleep efficiency, duration, and quality values were 80.0% (SD=8.3), 384.6 min (SD=64.4), and 7.1 (SD=4.3), respectively. In univariate analysis, racial segregation was associated with significantly lower sleep efficiency (B=-0.45, 95% CI=-0.76 to -0.14), but there were no associations with sleep duration or subjective sleep quality. The association between racial segregation and sleep efficiency remained significant after adjusting for age, gender, education, and marital status (B=-0.37, 95% CI=-0.72 to -0.03) but was attenuated (B=-0.32, 95% CI=-0.68 to 0.04) after adjusting for cardiovascular risk factors (body mass index, diabetes, hypertension) and depressive symptoms.
Conclusion: There is an association between racial segregation and sleep efficiency among middle-aged Black adults in the CARDIA cohort. This association was not independent of cardiovascular risk factors or depressive symptoms. Future studies should evaluate the specific features of racially segregated neighborhoods that are strongly related to worsening sleep health.

PSYCHOSOCIAL AND BEHAVIORAL CORRELATES OF SLEEP OUTCOMES AMONG LESBIAN, GAY, AND BISEXUAL WOMEN

Jennifer Jabson Tree[1], Katherine Buchman[1], Michelle Garrison[1]

[1] Purdue University

Introduction: Sleep is an essential dimension of good physical and mental health. However, lesbian, gay, bisexual (LGB) women report worse sleep than heterosexual women, heterosexual men, and gay men. Bisexual women report more sleep problems and shorter sleep duration than LG and heterosexual

women. Multiple systematic reviews document the associations between psychological and social factors, health behaviors, and sleep outcomes, however, much less is known about how these factors relate to sleep among LGB women. We focused on six specific psychosocial factors known to be associated with sleep outcomes: social strain, social function, social support, optimism, negative emotional expressiveness, and hostility. Understanding more about the relationship between psychosocial factors and sleep duration and disturbances among LGB women could facilitate the development of efficacious interventions to improve sleep outcomes for this highly understudied group.
Methods: Data for this project were provided by the Women's Health Initiative (WHI). The sample size for this project was 38,100; 884 LG women, 552 bisexual women, and 36,664 heterosexual women. Sleep duration and sleep disturbance were the outcome variables. Associations between psychosocial characteristics and sleep outcomes were tested using multivariable, hierarchical, nested, linear regression models, calculated by sexual orientation group.
Results: Hours per sleep nightly varied by sexual orientation with bisexual women reporting the most sleep on average. Across hierarchical models, social strain, social function, optimism, and negative emotional expressiveness were significantly associated with sleep outcomes for LGB women, respectively. Psychosocial factors were not consistently nor strongly associated with sleep for heterosexual women. Health behaviors were not consistently nor strongly associated with sleep outcomes for LGB women but were for heterosexual women.
Conclusion: LGB women's sleep is an understudied area and lacks consideration of psychosocial factors as promising contributors to sleep. Our findings point to the importance of social strain, social function, negative emotional expressiveness, and optimism in LGB women's sleep. It is possible that LGB women's sleep could be improved by implementing evidence-based interventions that use our findings to support LGB women in coping with multi-level sources of discrimination and stigma.

RACE/ETHNICITY AND NATIVITY DIFFERENCES IN SLEEP DISORDER AMONG WORKERS AND RETIREES: A MULTILEVEL MODELING STUDY

Maki Karakida[1], Jeffrey Stokes[1]
[1] University of Massachusetts Boston

Introduction: Sleep disorder is a common problem seen in middle-aged and older adults. Poor sleep can lead to comorbidities, such as heart disease, obesity, and depressions, in later life. Work-related stress can also impact people's sleep quality, yet differences between working and retired older adults' sleep quality is unclear.
Methods: This longitudinal study examines the relationships between work, retirement, and sleep health, including their intersection with race/ethnicity and nativity, among 34,765 Americans aged 50 and older. We used the Health and Retirement Study samples (2014 – 2020) and multilevel linear regression to examine the associations between working/retirement status, race/ethnicity, birthplace, and sleeplessness, controlling for age, gender, birthplace, assets, education, marital status, smoking habits, exercise, and self-reported health.
Results: The mixed-regression model without interaction terms demonstrated that compared to retirees, older workers had a significantly higher likelihood of sleep disorder (95% CI 0.010, 0.119; $P < 0.05$). Markedly, non-Hispanic Black race (95% CI 0.155, 0.344; $P < 0.01$), assets, education, and age had positive and significant relationships with sleep problems, whereas martial loss (divorced, widowed, and never-married) and female gender had a significantly lower likelihood of poor sleep. In the model examining the intersection of race/ethnicity and nativity – interacted with work status – revealed that compared with US-born non-Hispanic White adults, US-born non-Hispanic Black adults (95% CI 0.112, 0.333; $P < 0.001$) and foreign-born non-Hispanic Black populations (95% CI 0.120, 0.933; $P < 0.05$) had a significantly higher risk of insomnia. In contrast, non-native Hispanic workers (95% CI 0.152, 0.525; $P < 0.001$) and foreign-born non-Hispanic Other workers (95% CI 0.082, 0.872; $P < 0.05$) had a significantly higher prevalence of sleep disturbances than US-born non-Hispanic White workers.
Conclusion: Multilevel findings suggest that the intersectionality of race/ethnicity and nativity plays a decisive role in the association of work status and sleep health outcomes among midlife and older adults in the US.

SUSTAINED IMPACTS OF NEIGHBORHOOD INVESTMENT ON SLEEP HEALTH IN BLACK AMERICANS: RESULTS FROM A NATURAL EXPERIMENT

Wendy Troxel[1], Ann Haas[1], Bonnie Ghosh-Dastidar[1], Andrea Rosso[2], Lauren Hale[3], Matthew Buman[4], Tamara Dubowitz[2]
[1] RAND Corporation, [2] University of Pittsburgh, [3] Stony Brook Medicine, [4] Arizona State University

Introduction: Neighborhood disinvestment is a downstream impact of structural racism, especially afflicting minoritized communities. Thus, neighborhood reinvestment may serve as a policy-level intervention to mitigate sleep and other health disparities. This study builds on previous work by leveraging a natural experimental design to evaluate the 5-year effects of neighborhood investments on residents' sleep.
Methods: Data are from the PHRESH Zzz study, a natural experiment conducted in two low-income, predominantly Black, urban neighborhoods, with a randomly selected cohort (n=567; mean age=54.8; 77.6% female). Sleep duration, wakefulness after sleep onset (WASO) and sleep efficiency were assessed via actigraphy and sleep quality via survey in 2013, 2016, and 2018. All publicly funded neighborhood investments between 2013 to 2016 were recorded and geocoded to calculate the distance from each respondent's residence to the investment. The primary exposure variable was residents' proximity to neighborhood investments (< 0.1 of a mile).
Results: The overall pattern of results showed worsening sleep over time, regardless of exposure to investments. However, over the 5-year period, those who lived physically close to investments (< 0.1 mile) experienced significantly smaller decreases in sleep efficiency and smaller increases in WASO, relative to those who lived farther away.
Conclusion: Previously we found that living near a neighborhood investment improved sleep outcomes over a short-term period of 3 years. Current results indicate that improvements were partially sustained over 5 years. Findings have implications

for policy initiatives targeting upstream, structural determinants of sleep health disparities.
Support (if any): National Institute on Aging (Grant No. R01AG072652), National Heart Lung Blood Institute (Grant No. R01 HL122460), and the National Cancer Institute (Grant No. R01CA164137).

HOUSING CONDITIONS AND SLEEP HEALTH: FINDINGS FROM THE PERSONALIZED ENVIRONMENT AND GENES STUDY

Symielle Gaston[1], Dayna Neo[2], W. Braxton Jackson[3], Farida Akhtari[1], Janet Hall[1], Alison Motsinger-Reif[1], Chandra Jackson[1]

[1] National Institute of Environmental Health Sciences, [2] DLH, LLC, [3] DLH Holdings Corp.

Introduction: Adverse housing conditions can contribute to, for instance, psychological stress and poor air quality, thereby worsening sleep health and related outcomes (e.g., asthma). Of the few prior studies of the housing-sleep relationship, investigations across demographically heterogeneous populations are sparse despite the disproportionate burdens of both adverse housing conditions and poor sleep health among socially and economically vulnerable groups.
Methods: Therefore, we used data collected from eligible adults residing primarily in North Carolina who were enrolled (2002 to present) in the Personalized Environment and Genes Study (PEGS) to investigate adverse housing conditions in relation to multiple sleep dimensions and to determine effect modification by sex, race and ethnicity, and housing type. Beginning in 2017, participants reported (yes vs. no) five adverse housing conditions, including no central heating system; no cooling/air conditioning; moisture, mildew, and/or mold; pests; and renovations in the home. Self-reported sleep dimensions included short sleep duration (< 7 hours), long sleep onset latency (≥20 minutes), difficult sleep maintenance, diagnosed insomnia, diagnosed sleep apnea, daytime dysfunction, and sleep medication use. Adjusting for sociodemographic and residential characteristics, we used Poisson regression with robust variance to estimate prevalence ratios (PRs) and 95% confidence intervals (CIs). We used interaction terms to test for effect modification.
Results: Among 3,070 adults (mean±SD age=53±15 years), 69% were women; 81% identified as White, 10% Black, 3.0% Hispanic, and 6.0% another race/ethnicity. Most participants (75%) resided in detached houses. Moisture, mildew and/or mold (44%); Pests (44%); and renovations (29%) were the most frequently reported while no central heating (7%) and no cooling (4%) were the least frequently reported. Moisture, mildew, and/or mold was associated with difficult sleep maintenance (PR=1.14 [95% CI:1.02-1.26]). Overall, participants who reported pests vs. no pests had a higher prevalence of short sleep duration (PR=1.12 [1.02-1.23]), diagnosed sleep apnea (PR=1.25 [1.03-1.51]), and sleep medication use (PR=1.35 [1.11-1.64]). Additionally, pests–sleep medication use associations were of higher magnitude among Black (PR=3.99 [1.35-11.78]) compared to White (PR=1.28 [1.04-1.57]) participants (p-interaction=0.03). There was little evidence of effect modification by sex and housing type.
Conclusion: Pests were consistently associated with poorer sleep health and may contribute to sleep health disparities.

SUBOPTIMAL SLEEP DURATION PREDICTS GREATER METABOLIC SYNDROME IN NHANES 2011-2014: DIFFERENCES BY NATIVITY STATUS

Isamar Almeida[1], Renee Kessler[2], Gabrielle Murillo[3], Danica Slavish[1]

[1] University of North Texas, [2] Indiana University Simon Comprehensive Cancer Center, [3] Arizona State University

Introduction: Both short and long sleep have been associated with risk for metabolic syndrome (MetS). However, this association has yet to be assessed among immigrants, whose health profiles and risk/protective factors differ from the U.S.-born population. We examined whether the association between suboptimal sleep duration and MetS severity score (MetSSS) varied by nativity status (foreign vs. U.S.-born) in a representative sample of U.S. adults.
Methods: We analyzed data from the National Health and Nutrition Examination Survey (NHANES) 2011-2014 cycles. We included adults (≥20 years) with complete data on sleep, sociodemographic, and MetS-related variables (N = 3,245). A composite MetSSS was created using waist circumference, fasting glucose, blood pressure, HDL cholesterol, and triglycerides. Actigraphy-measured sleep duration was obtained from 7 days of accelerometer data. Self-reported sleep duration was obtained using a one-time questionnaire. Suboptimal sleep duration was defined as sleep duration < 7 or >9 hours/day. The association between self-reported sleep duration (model 1) and actigraphy-measured sleep duration (model 2) with MetSSS, and the moderating role of nativity status were examined using multiple linear regression models adjusting for age, sex, race, income, and food security.
Results: In model 1, suboptimal self-reported sleep duration was associated with greater MetSSS (b = 0.27, p =.001). Nativity status was associated with MetSSS: compared to U.S.-born people, immigrants had lower MetSSS (b = -0.31, p < 0.001). The interaction between self-reported sleep duration and nativity status was not statistically significant (b = -0.19, p = 0.159). In model 2, the interaction between actigraphy-measured sleep duration and MetSSS was statistically significant (b = -0.32, p = 0.014), such that the relationship between suboptimal sleep duration and MetSSS was significant only among U.S.-born individuals (b = 0.22, p < 0.001).
Conclusion: Our results align with the immigrant paradox of health: suboptimal sleep duration was associated with metabolic syndrome in U.S.-born individuals but not immigrants. As an individual acculturates to the U.S., their health risks may increase. Immigrants may experience protective factors that buffer the effects of poor sleep on cardiometabolic risk. Future studies should examine potential protective factors (e.g., exercise, diet, social support) among immigrants.

RELIGIOSITY AS A STRESSOR AND A STRESS RELIEVER IN RELATION TO SLEEP HEALTH AMONG AFRICAN AMERICAN WOMEN

Rupsha Singh[1], Symielle Gaston[1], Jason Ashe[2], Quaker Harmon[3], Donna Baird[4], HAROLD KOENIG[5], Chandra Jackson[1]

[1] National Institute of Environmental Health Sciences, [2] National Institute on Aging, [3] NIEHS, [4] National Institute of Environmental Health Sciences, NIH, [5] Duke University Medical Center

Introduction: Religious/spiritual beliefs and practices may positively or negatively influence sleep through myriad bidirectional pathways. For instance, religion could reduce psychosocial stress by providing social support or amplify it through religious conflict. Coincidently, Black/African American (AA) women are highly likely to attend religious services, experience substantial stress, and be burdened by poor sleep health. However, religion-stress-sleep relationships are understudied, especially among Black/AA women.
Methods: We investigated associations between religiosity, stress, and sleep using data collected during enrollment (2010-2012) and over three follow-ups (2014-2018) in the Study of Environment, Lifestyle, and Fibroids. At baseline, participants self-reported importance of faith ('very-to-somewhat' vs. 'not at all'), religiosity/spirituality as a source of strength/comfort ('very-to-somewhat' vs. 'not at all'), and prayer/meditation frequency ('everyday', 'every week', or '≥ once/month' vs. '< once/month'). We defined self-reported sleep as: short sleep duration (SSD) < 7-hours, non-restorative sleep (NRS) as 'yes' vs. 'no' to waking up rested < 4 days/week, and insomnia symptoms (IS) as 'yes' vs. 'no' to difficulty falling or staying asleep. Day-to-day stress was dichotomized as 'very high/moderate' vs. 'mild/not at all.' Adjusting for sociodemographic and clinical characteristics, we estimated prevalence ratios (PRs) and 95% confidence intervals (CIs) using Poisson regression with robust variance and applied general estimating equations to estimate risk ratios. Interaction terms for religiosity/spirituality and stress were tested.
Results: Among 1,614 Black/AA women, mean age ± SD was 29.2 ± 3.4 years, 69.5% reported faith is of importance, 55.8% perceived religion/spirituality as a source of strength/comfort, 58.9% engaged in everyday prayer/meditation, and 43.4% reported very high or moderate day-to-day stress. Baseline prevalence of SSD was 54.6%, NRS 9.5%, and IS 17.9%. Compared to women who did not consider religion/spirituality a source of strength/comfort, women who did and reported very high/moderate day-to-day stress had higher prevalence of restorative sleep (PR=6.25 [95% CI:1.23-33.33]). Everyday prayer/meditation vs. < once per month/never was associated with higher prevalence of NRS (PR=3.11 [95% CI:1.15-8.41]). Religiosity/spirituality was not longitudinally associated with sleep.
Conclusion: Religion/spirituality as a source of strength was associated with restorative sleep among highly-stressed women while everyday prayer/meditation was associated with non-restorative sleep. Longitudinal studies are needed to address potential reverse causation.

CHRONIC PAIN AND SLEEP HEALTH AMONG A NATIONALLY REPRESENTATIVE SAMPLE OF US ADULTS

Philip Zendels[1], Symielle Gaston[1], Christopher Payne[2], W. Braxton Jackson[3], Chandra Jackson[1]
[1] National Institute of Environmental Health Sciences, [2] DLH Corporation, [3] DLH Holdings Corp.

Introduction: Chronic pain is bidirectionally associated with sleep. Pain increases psychological stress and inflammation, thereby impairing sleep, and poor sleep increases pain sensitivity. Studies including diverse populations are sparse, although older adults, women, and minoritized racial and ethnic groups are disproportionately affected by, for instance, internalized stigma along with biased pain assessments and mismanagement by healthcare providers.
Methods: Therefore, we investigated chronic pain and sleep among adults in the 2013-2018 National Health Interview Survey. Participants self-reported chronic pain over the past three months ('everyday'/'most days'=yes vs. 'some days'/'never'=no), short sleep duration (SSD; < 7 vs. ≥7 hours), insomnia symptoms (IS; difficulty falling or staying asleep ≥3 vs. < 3 times/week), and nonrestorative-sleep (NRS: waking feeling rested < 4 vs. ≥4 days/week). Adjusting for sociodemographic, health behavior, and clinical characteristics, we used survey-weighted Poisson regression with robust variance to estimate prevalence ratios (PRs) and 95% confidence intervals (CIs), stratifying by age, sex/gender, and race/ethnicity after testing for interaction.
Results: Among 90,810 participants, mean age±SE was 48±0.11 years and 53% were women, 24% of participants reported chronic pain. Adults aged ≥50 years had higher prevalence of chronic pain (64%) than adults 31-49 (27%) or 18-30 years (9.8%). Women (56%) reported chronic pain more than men (44%). By race and ethnicity, Non-Hispanic (NH)-American Indian/Alaska Native (35%), NH-multiple race (29%), and NH-White (27%) adults most reported pain. The chronic pain-lower prevalence of SSD association was stronger among younger (PR31-49years=0.78 [95% CI:0.75-0.81]) versus older adults (PR≥50years=0.86 [0.85-0.88]). Conversely, the chronic pain-higher prevalence of NRS association was stronger among older adults (PR≥50years=1.73 [1.67-1.79] vs. PR31-49years=1.48 [1.43-1.53]). Associations with IS (PRmen=1.82 [1.75-1.89] vs. PRwomen=1.57 [1.52-1.61]) and NRS (PRmen=1.75 [1.69-1.82] vs. PRwomen=1.59 [1.55-1.63]) were stronger among men than women. Associations with IS were stronger among Hispanic/Latine (PR=1.84 [1.70-1.99]) and NH-Black/African American (PR=1.79 [1.66-1.92]) adults than NH-White adults (PR=1.63 [1.58-1.67]).
Conclusion: Chronic pain was associated with higher prevalence of both IS and NRS overall and most strongly among men. Associations with IS were strongest among Hispanic/Latine and NH-Black/African American adults. Chronic pain was associated with lower SSD prevalence, and strongest among younger adults. Future longitudinal design studies with objective sleep measures are warranted.

SLEEP BELIEFS ASSOCIATED WITH SLEEP HEALTH IN A NATIONAL SURVEY OF NIGERIAN ADULTS

Jesujoba Olanrewaju[1], Leah Irish[1]
[1] North Dakota State University

Introduction: Despite its critical role in population health and well-being, sleep remains understudied in Africa and other developing regions, where unique cultural and contextual factors likely shape sleep outcomes. The beliefs individuals hold about their sleep may influence their sleep health-related behaviors (e.g., time in bed), yet little is known about these beliefs in low- and middle-income countries. This study addresses this critical

imbalance by examining the relationship between Theory of Planned Behavior (TPB)-based sleep beliefs and overall sleep health in a national survey of Nigerian adults (n = 1,046; Mean age = 33.64, SD = 9.29). We hypothesized that positive sleep attitudes, stronger subjective norms in support of healthy sleep behavior, and greater perceived behavioral control would be associated with adequate sleep duration and better overall sleep health.

Methods: In this cross-sectional study, participants completed TPB-based measures and the RU-SATED Questionnaire.

Results: Descriptive analysis revealed that Nigerian adults generally held positive attitudes towards sleep, while subjective norms showed varied responses, and perceived behavioral control over sleep was moderate to high. Multiple linear regression analysis revealed that belief factors explained a modest but significant portion of the variance in sleep health (R^2 =.027, p <.001). Both bivariate and multivariate relationships consistently showed that subjective norms (r =.101, p =.001; β =.084, p =.006) and perceived behavioral control (r =.136, p <.001; β =.134, p <.001) were positively associated with overall sleep health, while attitudes showed no significant relationship in either analysis.

Conclusion: Results suggest that while Nigerian adults hold generally positive sleep beliefs, these beliefs have limited association with overall sleep health. Western-held beliefs about sleep may not fully translate to better sleep outcomes, where broader socio-cultural and environmental factors likely play an important role. Future research should examine how cultural values, economic conditions, and social structures interact with sleep beliefs to influence sleep health in non-Western contexts.

Support (if any): The North Dakota State University Department of Psychology supported the project.

EXPLORING SLEEP BELIEFS, ATTITUDES AND BEHAVIORS IN WOMEN OF COLOR THROUGH THE LENS OF COMMUNITY HEALTH WORKERS

Clarisa Medina Poeliniz[1], Tumilara Aderibigbe[1], Sharon Talboys[1], Ivette Lopez[1], Sara Simonsen[1], Yeny Arones[1], Princess Bombyck[1], Doriena Lee[1], Kiese Mpongo[1], Valentine Mukundente[2], Fahina Tavake-Pasi[1], Kamaile Tripp-Harris[1], Jeanette Villalta[1], Cathy Wolfsfeld[3], Kelly Baron[1]

[1] University of Utah, [2] Best of Africa, [3] Calvary Baptist Church

Introduction: Community health workers (CHWs) are vital in bridging the gap between healthcare systems, researchers, and underserved communities. Due to their trusted roles, cultural familiarity, and ability to deliver accurate health information, CHWs offer great promise in sleep health promotion. We aim to understand perceptions of healthy sleep, barriers to sleep, and beliefs, attitudes, and behaviors in communities of color.

Methods: We conducted eight focus groups (N=77) with female CHWs ages 18-75 using community-matched CHW facilitators who also served as co-researchers. CHWs provided information about themselves and their communities. Community groups included Black/African American, Hispanic/Latinx, Native Hawaiian/Pacific Islander, and African Immigrant/Refugee. Focus groups were conducted in English and Spanish. A semi-structured topic guide was developed in collaboration with CHWs. Discussion topics included sleep routines, barriers and enablers to healthy sleep, knowledge and attitudes about sleep, socio-cultural context, and CHW roles in sleep health. Audio recordings were transcribed, translated, and uploaded to Dedoose for analysis. We thematically coded transcripts once, followed by subsequent emergent coding using deductive grounded theory approach.

Results: Within the CHWs and their respective communities, there was variability in sleep routines and attitudes about sleep. It was common to prioritize caregiving, household family members and extended family, and community obligations over good sleep, and participants identified strongly with their roles as matriarch and community leader. Cultural barriers include adjusting to the 'hustle' U.S. culture, communicating with family across time zones, and for some, either the cultural loss of naps or a strong cultural belief that napping is lazy. Sleep health was discussed as being a taboo topic in some communities. Barriers in accessing sleep-related healthcare included a fragmented approach at the primary care level, limited sleep health information, and cost, long waits for appointments, and access to specialty care. Other notable barriers included language, transportation, and health literacy gaps in both sleep health and navigating the healthcare system.

Conclusion: CHWs can effectively link community members to sleep health resources and offer insights into cultural beliefs, attitudes, and behaviors related to sleep practice, barriers, and social determinants that impact sleep.

RACIAL AND ETHNIC SLEEP DISPARITIES IN ADOLESCENTS: THE ROLE OF ACCULTURATION AND DISCRIMINATION

Danya Husein[1], Jessica Souhala[1], Emily Feldman[1], Danica Slavish[1]

[1] University of North Texas

Introduction: Adolescence is a critical developmental period marked by identity formation and heightened exposure to stressors, including discrimination. Acculturative stress and discrimination can negatively affect sleep, with adolescents' cultural identity influencing their experiences of these stressors. This study explored the relationship between discrimination, acculturative stress, and sleep duration in a diverse sample of youth.

Methods: Data was drawn from the Adolescent Brain Cognitive Development (ABCD) study, a ten-year longitudinal examination of youth (N = 8632, mean age = 12, 47.66% girls). Self-report measures assessed acculturation, discrimination, sleep duration, and demographics.

Results: Discrimination significantly predicted shorter weekday (B = -0.15, 95% CI [-0.20, -0.11], p < 0.001) and weekend sleep duration (B = -0.06, 95% CI [-0.11, -0.02], p = 0.008). Ethnic differences were observed, with Black/African (weekday: B = -0.24, 95% CI [-0.31, -0.16], p < 0.001; weekend: B = -0.22, 95% CI [-0.31, -0.14], p < 0.001) and MENA youth (weekday: B = -0.38, 95% CI [-0.71, -0.05], p = 0.023) sleeping less than White youth. Interactions between discrimination and ethnicity indicated that higher discrimination was associated with greater reductions in weekday sleep for Black/African (B = 0.15, 95% CI [0.09, 0.22], p < 0.001) and Latino/Hispanic youth (B = 0.11, 95% CI [0.05, 0.17], p = 0.001). An interaction between acculturation and ethnicity was found for weekend sleep, where higher acculturation predicted shorter sleep for Black/African youth (B = -0.20, 95% CI [-0.32, -0.08], p = 0.001).

Conclusion: These results emphasize the role of social determinants, such as discrimination and acculturative stress, in shaping sleep health during adolescence. OR The findings suggest that discrimination and acculturative play crucial roles in shaping adolescent sleep patterns. Implementing culturally informed interventions to address identity-related stressors may be a promising approach to support youth sleep health, with the potential to reduce sleep disparities.

RACIAL SLEEP DISPARITIES IN THE UNITED STATES: A SYSTEMATIC REVIEW OF LABOR PRACTICES AND SLEEP HEALTH ACROSS THE LIFESPAN

Zora Woolfolk[1], Jillian Silva-Jones[1], Ariana Calloway[2], Mattina Davenport[2], Lauren Whitehurst[1]
[1] University of Kentucky, [2] Nationwide Children's Hospital

Introduction: Black Americans, compared to other social groups, disproportionately experience poor sleep outcomes throughout their lifespan. In this systematic review, we examined how labor conditions in the US may contribute to sleep inequities among Black Americans.
Methods: We conducted keyword combination searches using sleep, age, labor, and race in university and publicly available databases, including Google Scholar and PubMed. We organized the resulting articles into six categories that identified fairness, safety, and health of the work environment (i.e., pay, work hazards, work hours, work accessibility, benefits, and hiring practices) and determined how each impacted the following sleep outcomes: duration, dysregulation/dysfunction, short/long sleep, sleep quality. We further categorized each article by lifespan category, adolescence, young and mid -adulthood, and older adulthood. Articles that took place outside of the US and review articles were excluded.
Results: Thirty-six articles met the criteria for the systematic review. One article examined the impact of pay inequity on sleep-related pregnancy outcomes, and six articles assessed the impact of parental labor on children/adolescents' sleep behavior. Twenty-eight articles focused on sleep and working conditions in young and mid-adulthood, whereas fifteen articles examined similar outcomes in older adults. Of these 28 articles, laborers who experienced inequitably lower pay also experienced shorter sleep durations in fifteen studies, increased sleep dysfunction in five studies, and reported higher incidence of sleep disorders in seven studies. Additionally, laborers who experienced unsafe working conditions experienced shorter sleep durations in two studies and worse sleep quality in two additional studies. In two studies, working in unsafe working conditions coincided with shift work. Workers with long work hours had decreased sleep durations in 7 studies and increased sleep disorders in 3 studies. In three studies, short sleep and sleep dysfunction increased for adults and older adults experiencing a lack of work.
Conclusion: Literature suggests that improving safe and healthy working conditions can promote sleep and reduce existing racial sleep inequities. Important gaps in the literature remain as few studies examined the impact of working and labor practices on pregnancy and infancy and few studies examined the longitudinal impacts of poor working conditions on sleep in retirees.

A COMMUNITY-ENGAGED QUALITATIVE STUDY OF FACTORS AFFECTING SLEEP AMONG HISPANIC/LATINOS WITH SHORT SLEEP DURATION

Sofia Vallejo-Riveros[1], Maria Jose Velasco-Burgos[2], Ana Sanchez-Birkhead[3], Jennifer Duffecy[4], Laura E.C. Flores Hernandez[3], Ricardo Quintana[3], Jason Wiese[3], Kelly Baron[3]
[1] Behavioral Sleep Medicine Lab - University of Utah, [2] Utah State University, [3] University of Utah, [4] UIC Resliency Center

Introduction: Despite having high prevalence of short sleep duration, poor sleep quality, and sleep disorders in adult Hispanics living in the US, there is limited understanding of the underlying barriers to sleep and effective interventions in these groups. This study aimed to increase understanding of sleep duration and attitudes toward sleep interventions among Hispanic adults.
Methods: We conducted 5 online focus group discussions with male and female participants aged 18-65 recruited from the Hispanic community who reported sleeping < 7 hours per night. Interviewers utilized a semi-structured interview guide to assess attitudes and beliefs about sleep and sleep interventions. Focus groups were conducted in Spanish, recorded, transcribed, and coded to elicit common themes.
Results: Focus groups included 31 participants (19=women) from 12 Hispanic nationalities. Coders identified three main topics: 1) Sleep perceptions, 2) External and internal factors that affect sleep, and 3) Feedback about sleep interventions. Participants discussed the importance of sleep and factors related to stress, family, environment, and acculturation. Sleep interventions were viewed as desirable, and the group discussed a variety of topics of interest. The use of consumer sleep technology was considered a favorable intervention despite few participants having experience with consumer sleep-tracking devices.
Conclusion: Results demonstrated that participants were aware of the importance of sleep and sleep duration recommendations. The discussion identified unique issues affecting sleep health in Hispanics as well as enthusiasm for sleep interventions, including interventions using consumer sleep trackers.

ASSOCIATIONS BETWEEN DIGITAL TECHNOLOGY AND SLEEP HEALTH BY COUNTRY, AGE, AND SEX

Lauren Hale[1], Dimitri Christakis[2], Gina Mathew[3], Isaac Rodriguez[1], Azfar Adib[4], Yasmin Aljedawi[5], Justin Thomas[5], Syed Ishtiaque Ahmed[6], sohailul Alvi[7], Mamunar Rashid[5]
[1] Stony Brook University, [2] University of Washington, [3] Stony Brook Medicine, [4] Concordia University, [5] Ithra, King Abdulaziz World Culture Center, [6] University of Toronto, [7] Imperial College London

Introduction: We investigated whether the widely-observed association between digital technology use and sleep health varied by country, age, and/or sex in a global sample of adults.
Methods: We used 2023 survey data from 35 countries (n=35,018, ~1000/country) to characterize the self-reported effects of digital technology on physical health, sleep quality,

and tiredness (see https://sync.ithra.com/research). We examined whether responses varied by country, age, and sex.
Results: Participants from 35 countries (52.2% male) ranged from 18-99 years old (mean=38); 18.7% of respondents were between 18-24, and 8.0% were 65+. Unadjusted analyses showed that across all participants, 31.7% reported that digital technology reduced their physical health. Respondents in China had the lowest prevalence (11.8%) of digital media worsening physical health, while respondents in Estonia had the highest prevalence (56.4%). Younger respondents (18-24) were more likely to report that digital technology worsened physical health than older (65+) respondents (38.5% vs. 21.9%). Females were slightly more likely (33.7%) than males (30.0%) to report that digital media worsened physical health. When asked which physical conditions were experienced after using digital technology for longer than usual, 40.5% reported tiredness, and 39.0% reported decreased sleep quality. Out of all 35 countries, prevalence was lowest in Italy for both the symptoms of tiredness (22.1%) and decreased sleep quality (19.7%), while they were highest in Ghana (60.6%) for tiredness and Malaysia (57.3%) for decreased sleep quality. Among the youngest age group (18-24-year-olds), 48.4% and 47.1% reported tiredness and decreased sleep quality, respectively, compared to 22.4% and 16.1% for 65+. Females were more likely to report tiredness (42.3%) and decreased sleep quality (40.9%) as symptoms compared to males (38.8% and 37.8%, respectively).
Conclusion: These novel global results show that over one-third of adult respondents believe heavy use of digital technology leads to sleep-related symptoms, with larger effects for younger and female adults. Variation by country suggests that cultural factors may affect the association between digital technology use and sleep health.

REM EEG EVENTS ARE MODULATED BY MENSTRUAL CYCLE AND SEX HORMONES

Yunke Chen[1], Alessandra Shuster[1], Allison Morehouse[1], Peremoboere Uzoigwe[2], Temilade Adekoya[1], Ali Ekhlasi[1], Jing Zhang[3], Negin Sattari[1], Marie Gombert[4], Fiona Baker[4], Katharine Simon[1], Sara Mednick[1]
[1] University of California, Irvine, [2] University of California, Irvine, CA, [3] Harvard Medical School/ Massachusetts General Hospital, [4] SRI International

Introduction: Studies have reported that NREM sleep, specifically spindle activity (12-15Hz), varies across the menstrual cycle. However, menstrual-related changes to REM sleep or its electrophysiological markers remain unclear. Animal studies suggest that periods of high estrogen and low progesterone may reduce low-frequency EEG activity (≤7Hz) via their effects on GABA. We recently investigated EEG burst activity during REM sleep within the theta (4-8Hz) and alpha (8-16Hz) frequency bands ('REM bursts') in relation to sleep-dependent memory. Here, we examined whether changes in sex hormones across the menstrual cycle affect REM burst activity. We hypothesize decreased theta burst activity during the high-estrogen, low-progesterone phase (pre-ovulation) compared to other menstrual phases.
Methods: 35 healthy women (18-35yrs) slept in-lab with polysomnography during four phases of their menstrual cycle: menses(low hormones), pre-ovulation(high estrogen), mid-luteal(high progesterone and estrogen), and late-luteal(decreasing hormones). At each visit, we collected hormone levels (estrogen/progesterone/testosterone) via saliva samples. Using a validated REM burst detection algorithm, we identified REM theta and alpha bursts and normalized each burst metric across the four visits to measure their relative levels for each individual. We used linear-mixed-models, with pre-ovulation as the reference phase, to assess menstrual phase differences in burst characteristics and performed Pearson's correlations between sex hormone levels and burst features.
Results: We successfully identified REM alpha and theta bursts in human scalp EEG, replicating prior findings of these events. Additionally, we showed menstrual cycle differences in REM sleep and REM burst characteristics. During pre-ovulation, we found 1) fewer alpha and theta burst occurrences, 2) greater alpha and theta burst power, 3) greater theta burst density, and 4) reduced REM sleep. Additionally, independent of menstrual phase, progesterone levels negatively predicted theta and alpha density, and testosterone positively predicted time in REM. In late-luteal, testosterone positively predicted theta power. No significant correlations with estrogen were found.
Conclusion: This study replicated the finding of discrete EEG events during REM sleep, i.e., theta and alpha bursts. Furthermore, we show that REM bursts are modulated by menstrual phases and hormonal fluctuations across the cycle. Next steps will be to examine how these REM sleep changes affect cognition.

GENDER AND RACE DISPARITIES IN SLEEP DISORDER DIAGNOSIS AND TREATMENT

Abigail Vance[1], Arash Assar[1], Mara Egeler[1], Veronica Floyd[2], Harrison Dickens[2], Jamie Walker[2], Ivan Vargas[1]
[1] University of Notre Dame, [2] University of Arkansas

Introduction: Significant racial and gender disparities have been observed among several health outcomes, including sleep. Previous research supports, for example, that the prevalence of sleep disorders among racial minorities is higher than the general population, even when controlling for other variables (e.g. socioeconomic status). The prevalence of sleep disorders is also higher among women. Despite this, racial minorities and women are treated in sleep disorder clinics at a significantly lower rate. The present study aimed to further explore racial and gender differences in sleep disorder diagnosis and treatments.
Methods: Participants (N = 2,975) from across the United States were surveyed using CloudResearch Connect and asked to respond to questions about their demographic information and history with and knowledge about sleep disorders and treatments. This sample was diverse with the participants being 33.6% BIPOC and 50% female.
Results: A chi-square test of independence was conducted to compare white and BIPOC participant responses. Compared to BIPOC participants, white participants reported higher rates of diagnosis of a sleep disorder ($X2(1) = 4.498$, $p = .034$), use of prescription sleep medications ($X2(1) = 20.817$, $p < .001$), and use of over-the-counter sleep medications ($X2(1) = 36.296$ $p < .001$).

Compared to men, women reported higher rates of diagnosis of a sleep disorder (X2(1) = 7.576, p =.006), use of prescription sleep medications (X2(1) = 15.995, p <.001), and use of over-the-counter sleep medications (X2(1) = 32.554, p <.001). There were no significant associations found between race or gender and previous experience with CBT-I.
Conclusion: Results suggest that there are significant race and gender differences in diagnosis of sleep disorders, as well as treatment using prescription and OTC medications. Findings support previous findings that racial minorities experience lower rates of sleep disorder diagnosis and treatment. Further research is needed to understand the specific sleep medicine experiences of racial and gender minorities.

PRISTINE INTERNAL TIME AND ITS DISCREPANCY FROM ACTUAL SLEEP: A POPULATION-BASED STUDY

Sun-Ku Han[1], Hyo-Jin Park[1], Sang Min Paik[1], Jae Rim Kim[1], Woo-Jin Lee[1], Daeyoung Kim[2], Kwang Ik Yang[3], Min Kyung Chu[4], Chang-Ho Yun[5]

[1] Department of Neurology, Seoul National University Bundang Hospital, [2] Department of Neurology, Chungnam National University Hospital, Chungnam National University School of Medicine, [3] Sleep Disorders Center, Department of Neurology, Soonchunhyang University Cheonan Hospital, Soonchunhyang University College of Medicine, [4] Department of Neurology, Severance Hospital, Yonsei University College of Medicine, [5] Department of Neurology, Seoul National University Bundang Hospital, Seoul National University College of Medicine

Introduction: Chronotype is commonly assessed using questionnaires such as Munich Chronotype Questionnaire (MCTQ). However, while the MCTQ accounts for sleep debt, it may not fully reflect individual's inherent chronobiological preferences due to external influences. Pristine internal time, defined as internal time free from external influences such as work and social obligations, offers an alternative perspective on individual's chronobiological preferences. This study aimed to characterize pristine internal time and evaluate its discrepancy from actual sleep behavior within the Korean adult population.
Methods: Data from the Korean Sleep Headache Study in 2018 were analyzed, involving 2,237 participants aged 19-92 years (48.1 % men). Pristine internal time was assessed through participants' responses to the following scenario, "Imagine you have two weeks just for yourself, free from obligations such as work, care responsibilities, or appointment. What would be your ideal sleep schedule at the end of the perfect day?" Actual sleep behavior was assessed using midsleep on free days corrected for sleep debt (MSFsc), derived from MCTQ.
Results: The mean(± standard deviation [SD]) sleep duration of pristine internal time was 509.5(± 85.6) minutes. The mean time of falling asleep was 11:03 p.m(± 01:10, SD), and the mean waking time was 7:33 a.m(± 01:31). The mean midsleep time of pristine internal time was 03:18 a.m(± 01:07). Women exhibited earlier midsleep times of pristine internal time than men(03:15a.m±01:03 vs. 03:22a.m±01:11, p=0.009), though sleep duration did not differ significantly. Participants with anxiety reported longer sleep duration than those without anxiety (p=0.036). Participants with excessive daytime sleepiness (EDS) reported earlier midsleep time than those without EDS (p< 0.001). Comparing pristine internal time and MSFsc, pristine midsleep time was 20.4(± 71.4) minutes earlier. The discrepancy was more pronounced in men than in women (24.6±76.2 min vs 16.8±67.2 min, p=0.010), while no significant discrepancy associated with mood symptoms and day sleepiness was observed.
Conclusion: This study provides insights into the characteristics of pristine internal time and its discrepancy with actual sleep behaviors. These findings suggest the need for further research to evaluate whether aligning external schedules with intrinsic chronobiology could improve mood symptoms, reduce daytime sleepiness, and enhance overall well-being.

STRUCTURAL RACISM PREDICTS AIR POLLUTION AND SLEEP QUALITY AMONG BLACK AMERICANS LIVING IN THE CONTIGUOUS UNITED STATES

Jillian Silva-Jones[1], Anna Smith[1], Tianjun Lu[1], Yisi Liu[1], Wendy Berry Mendes[2], Lauren Whitehurst[1]

[1] University of Kentucky, [2] Yale University

Introduction: Past socioeconomic and legal norms and policies have had a lasting impact on the environments that Black Americans sleep in today. For example, redlined neighborhoods from the 1950s currently experience suboptimal environmental conditions, including increased exposure to air pollutants. High rates of sleep deficiency and disorder in Black Americans may be due to the influence of these socioenvironmental determinants, but more investigation is needed. We assessed how structural neighborhood factors interact with air quality to influence sleep behavior in a geographically diverse sample of Black Americans.
Methods: 1,903 Black participants (N=883females, 1020males) aged 18-80 completed daily assessments of sleep behavior for up to 21 days (5,935observations) using a phone application. Participants reported sleep behavior, including duration, latency, wake after sleep onset, and sleep quality, which was rated on a Likert scale - 1 not all refreshed to 5 extremely refreshed. Participant-provided zipcodes were linked to geospatial tools to assess air pollution indicators (e.g., sulfur dioxide (SO2), ozone (O3), nitrogen dioxide (NO2), carbon monoxide (CO), and particulate matter (PM2.5 and PM10) and to the Structural Racism Effect Index (SREI), which uses publicly available census data to determine the impact of structural racism on neighborhoods (e.g., rates of building vacancy, incarceration, unemployment, poverty, etc.). Mixed effects linear regressions examined the impact of air pollution and structural racism on sleep features.
Results: Participants slept 6 hours a night (SD=1.65), with an average sleep latency of 21 minutes (SD=23.41), woke up 2 times per night (SD=1.74), spent 18 minutes awake after falling asleep (SD=23.81), and reported 3.22 (SD=1.11) for sleep quality. SREI was negatively associated with CO(ß=-.0001,p<.001) and NO2(ß=-.01,p<.001), and positively associated with PM2.5(ß=.003,p<.001) and SO2(ß=.0001,p<.001). Higher SREI scores (i.e., greater impact of structural racism) correlated with longer sleep latency (ß=.03,p=.03). PM10 was associated with lower sleep quality (ß=-.23,p=.02). PM10 and higher SREI predicted lower refreshed ratings (ß=-.21,p=.04). However, lower concentrations of CO(ß=.06,p=.03), NO2(ß=.0007,p=.03), and O3(ß=.0005,p=.01) interacted with higher SREI yielding shorter sleep durations.

Conclusion: We observed air pollutants and structural racism to have individual and interactive associations with poor sleep. Further investigation into the effects of neighborhood factors may improve interventions aiming to curb sleep inequities.

CHRONOTYPE ASSOCIATED WITH SOCIODEMOGRAPHICS, SLEEP HEALTH, AND MENTAL HEALTH AT THE US-MEXICO BORDER: DATA FROM THE NOCHES STUDY

Sherap Sangpo[1], Dora Valencia[1], Elizabeth Rasmussen[1], Karla Granados[1], Orfeu Buxton[2], Sanjay Patel[3], John Ruiz[1], Patricia Molina[1], Michael Grandner[4], Marcos Delgadillo[5]

[1] University of Arizona, [2] Penn State, [3] University of Pittsburgh, [4] University of Arizona College of Medicine, [5] The University of Arizona

Introduction: Chronotype (circadian preference) has been associated with a wide range of health variables but has not yet been explored in populations at the US-Mexico Border. Associations may inform public health efforts and sleep/circadian health interventions.
Methods: Data were obtained from N=983 adults age 24-60 years at the US-Mexico border, obtained in-person by promotoras (community health workers) during interviews and standardized questionnaires in English and Spanish. Chronotype was assessed using a single item to assess whether the participant was definitely morning type, more morning than evening, more evening than morning, or definitely evening type. This was assessed as an ordinal variable for eveningness. Sociodemographics (also included as covariates) were age, gender, ethnicity, socioeconomic status, education, acculturation (Mexican and Anglo, assessed via the ARSMA-II), survey language, language spoken at home, household size, immigration, and living situation. Additional variables explored were the Insomnia Severity Index (ISI), Pittsburgh Sleep Quality Index (PSQI), weekend and weekday sleep latency, wake after sleep onset, and sleep duration, PHQ9 depression and GAD7 anxiety scales, Perceived Stress Scale (PSS), and Social Vigilance Questionnaire (SVQ). Results expressed as Ordinal Odds Ratios (oOR) of more delayed type.
Results: Increased likelihood of later chronotype was associated with female gender (oOR=1.43, p=0.020), speaking mostly Spanish at home (oOR=1.44, p=0.036), ISI score (oOR=1.08, p< 0.0005), PSQI score (oOR=1.07, p=0.026), weeknight (oOR=1.12, p< 0.0005) and weekend sleep duration (oOR=1.21, p< 0.0005), weeknight (oOR=1.01, p< 0.0005) and weekend sleep latency (oOR=1.01, p=0.003), PHQ9 score (oOR=1.08, p< 0.0005), GAD7 score (oOR=1.08, p=0.001), and SVQ score (oOR=1.02, p< 0.05). Decreased likelihood of later chronotype was associated with older age (oOR=0.97, p< 0.0005), less than high school (oOR=0.44, p< 0.0005) or high school education (oOR=0.65, p< 0.0005), completing survey in Spanish (oOR=0.45, p< 0.0005), living in an apartment or rented room (oOR=0.93, p=0.024), and larger household size (oOR=0.93, p=0.024).
Conclusion: Later chronotype was associated with worse sleep and mental health overall, consistent with previous studies. Sociodemographic associations should be explored to delineate risk pathways, especially cultural (e.g., language) and structural (e.g., household) factors.

ACCULTURATION AND SLEEP HEALTH AT THE US-MEXICO BORDER: PRELIMINARY DATA FROM THE NOGALES CARDIOMETABOLIC HEALTH AND SLEEP (NOCHES) STUDY

Alexis Aguilar[1], Dora Valencia[1], Elizabeth Rasmussen[1], Karla Granados[1], Orfeu Buxton[2], Sanjay Patel[3], John Ruiz[1], Patricia Haynes[1], Patricia Molina[1], Michael Grandner[4], Marcos Delgadillo[5]

[1] University of Arizona, [2] Penn State, [3] University of Pittsburgh, [4] University of Arizona College of Medicine, [5] The University of Arizona

Introduction: Previous studies have shown that sleep health is associated with social and environmental factors that may influence health behaviors. Acculturation has emerged as a possible factor that influences sleep health, including at the US-Mexico Border.
Methods: Data from N=991 US citizen community members (mean age 43.1, 79% women) from the area around Nogales, AZ were recruited. Data were collected by promotoras de salud in community clinics. These data reflect self-reported questionnaires, including the Acculturation Rating Scale for Mexican Americans (ARSMA; Anglo and Mexican acculturation), Bicultural Involvement Questionnaire (BIQ; Americanism, Hispanicism, Biculturism), Insomnia Severity Index (ISI), Pittsburgh Sleep Quality Index (PSQI), Multivariable Apnea Prediction Index (MAP), Brief Index of Sleep Control (BRISC), and habitual weeknight and weekend sleep duration. Linear regression analyses were adjusted for age, sex, education level, and duration of family residence in the US.
Results: In this sample, mean ISI score was 6.4 (SD=3.9), mean PSQI score was 9.4 (SD=2.1), mean MAP score was 1.2 (SD=1.4), mean BRISC score was 2.5 (SD=1.1), mean weeknight sleep duration was 6.8 hours (1.5 hours), and mean weekend sleep duration was 7.5 hours (SD=1.8 hours). Mean ARSMA scores were 1.98 (SD=0.94) for Anglo and 3.20 (SD=0.58) for Mexican acculturation, and mean BIQ scores were 50.3 (SD=16.9) for Americanism, 63.8 (SD=9.0) for Hispanicism, and 13.6 (SD=21.1) for Biculturism. In regression analyses, none of the acculturation measures were associated with ISI, PSQI, MAP scores, or sleep duration. Increased perceived control over sleep (BRISC) was associated with greater ARSMA Anglo acculturation (B=0.140, 95% CI [0.057, 0.224], p=0.001), ARSMA Mexican acculturation (B=0.184, 95% CI [0.067, 0.302], p=0.002), BIQ Americanism (B= 0.007, 95% CI [0.003, 0.011], p=0.002), and lower BIQ Biculturism (B=-0.004, 95% CI [-0.008, -0.001], p=0.018).
Conclusion: In the present analyses, self-reported sleep duration and quality were not associated with acculturation. However, the degree to which individuals perceive control over their sleep was associated with cultural identification, both Mexican and American acculturation levels.

SOCIAL, EMOTIONAL, STRUCTURAL, AND FINANCIAL DETERMINANTS OF HEALTH IN THE US POPULATION ASSOCIATED WITH SLEEP HEALTH

Annie Chen[1], Suzanne Gorovoy[2], Elizabeth Rasmussen[1], Girardin Jean-Louis[3], Patricia Haynes[1], Michael Grandner[2]
[1] University of Arizona, [2] University of Arizona College of Medicine, [3] University of Miami Miller School of Medicine

Introduction: The development of sleep health interventions requires a better understanding of social and environmental determinants. Yet, little population-level data extends beyond simple metrics such as education and income.
Methods: Data from the 2022 Behavioral Risk Factor Surveillance System were used, the largest national survey conducted by the CDC. N=193,225 provided data on sleep and health determinants. Sleep duration was categorized as <=4, 5, 6, 7, 8, 9, or 10+ hours. Health determinants included availability of emotional support, social isolation, food insecurity, use of food stamps, housing insecurity, inability to pay utility bills, employment insecurity, lack of transportation, household income, education, and employment status. Additional covariates included age, sex, race/ethnicity and body mass index. Population-weighted multinomial logistic regression analyses with sleep duration (relative to 7h) as dependent variable were examined, with age, sex, race/ethnicity, income, education, employment and body mass index as covariates in all models.
Results: Those who "never" receive emotional support were more likely to experience <=4h, 5h, 6h, and 10+h. Those reporting social isolation "always" were more likely to report <=4h, 5h, 6h, and 10+h. Those who accessed food stamps were more likely to report <=4h, 5h, 6h, 8h, and 9h. Those with high food insecurity were more likely to report <=4h, 5h, 6h, and 10+h. Those reporting housing insecurity were more likely to report <=4h, 5h, 6h, and 10+h. Those were unable to pay utility bills were more likely to report <=4h, 5h, 6h, and 10+h. Those with employment insecurity were more likely to report <=4h, 5h, 6h, and 10+h. Those without access to transportation were more likely to report <=4, 5h, 6h, and 10+h. Replicating previous work, lower income, less education, and unemployment were also associated with short and 10+h sleep. In a forward stepwise model, unique variance was contributed by (in order) income, isolation, emotional support, age, body mass index, food insecurity, education, losing utilities, transportation, housing insecurity, sex, and food stamps.
Conclusion: Sleep health interventions should recognize real-world determinants, including social, environmental, and financial stressors that contribute to poor sleep.

RACIAL/ETHNIC DIFFERENCES IN PSYCHEDELIC USE AND SLEEP SATISFACTION: PRELIMINARY FINDINGS FROM THE HERBAL HEART STUDY

Denise Vidot[1], Amrit Baral[2], Bria-Necole Diggs[2], Ranya Marrakchi El Fellah[3], Kylee Krivijanski[3], Albert Garcia-Romeu[4], Winston de la Haye[5], Clarence Locklear[1], Girardin Jean-Louis[2]
[1] University of Miami, [2] University of Miami Miller School of Medicine, [3] School of Nursing and Health Studies, University of Miami, [4] Johns Hopkins University School of Medicine, [5] University of West Indies

Introduction: Research on psychedelic use and sleep satisfaction remains unclear despite increased use. This study examines the psychedelic use and sleep satisfaction among 18-to-35-year-olds enrolled in the Herbal Heart Study.
Methods: The exposure variables were lifetime self-reported use of any psychedelic (LSD, psilocybin, peyote, mescaline, ayahuasca/DMT) and psilocybin-alone. Sleep satisfaction was assessed via the WHO Quality of Life, "How satisfied are you with your sleep" (satisfied, dissatisfied, or neutral). Chi-squared tests compared psychedelic use across sleep satisfaction categories. Multinomial logistic regression adjusted for demographics, cannabis history, anxiety, and depression assessed associations between psychedelics and sleep satisfaction using "neutral" as the reference.
Results: Of the sample (N=200; mean age: 25.2 years, SD = 4.8), 65% were female, 54.5% identified as Hispanic/Latino, 18.5% non-Hispanic White (NHW), 17.5% non-Hispanic Black (NHB). Psychedelic use was reported by 39.5% of participants (49.5% Hispanics/Latinos, 21.6% NHW, 25.1% NHB, 42.1% Other p< 0.01); 32.8% of participants reported psilocybin use (40.8% Hispanics/Latinos, 19.4% NHW, 18.7% NHB, 28.9% Other; p=0.03). Overall, 54.5% of participants were satisfied with sleep, 23.0% were dissatisfied, and 22.5% neutral. No differences in sleep satisfaction were observed in the overall sample; however, race/ethnic differences emerged. Among Hispanics/Latinos, 33.9% of psychedelic consumers reported sleep dissatisfaction vs 17.2% of non-consumers (p=0.03). Similarly, 41.9% of Hispanic/Latino psilocybin-alone users reported sleep dissatisfaction vs 15.6% of non-consumers (p=0.005). Hispanic/Latino psychedelic consumers had higher odds of sleep dissatisfaction (AOR: 4.4; 95% CI: 1.1-18.1) and satisfaction (AOR: 4.4; 95% CI: 1.2-14.7) compared to being neutral. Psilocybin-alone consumers had higher odds of sleep dissatisfaction (AOR: 9.2; 95% CI: 1.9-43.9) than non-consumers. There were no associations among NHW/NHB/Other groups.
Conclusion: Findings indicate a complex association between psychedelic use and sleep satisfaction, particularly among Hispanics/Latinos. Further research should investigate underlying mechanisms, cultural, and bio-physiological factors that may mediate the association between psychedelic use and sleep satisfaction.

INVESTIGATING THE ASSOCIATION BETWEEN DIURNAL SALIVARY CORTISOL AND DISPARITIES IN SLEEP HEALTH

Lauren Barber[1], Regine Haardörfer[1], Byoungjun Kim[2], Susan Redline[3], Dustin Duncan[4], Dayna Johnson[1]
[1] Emory University, [2] New York University, [3] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [4] Columbia University

Introduction: Prior research in the Multi-Ethnic Study of Atherosclerosis (MESA) suggests a link between the stress biomarker, cortisol, and sleep health. However, research investigating cortisol's impact on sleep among subpopulations who may be susceptible to stress and poor sleep health is lacking. We examined the association between cortisol and objective sleep measures, stratified by gender, race, and ethnicity.
Methods: MESA is a longitudinal study of 6,814 Americans recruited in 2000-2002. Between 2010 and 2012, saliva samples were collected to measure diurnal cortisol curve features including: wakeup cortisol, peak cortisol, cortisol awakening response (CAR, wakeup to 30 minutes post-awakening), early decline slope (30 minutes to 2 hours post-awakening), late decline slope (2 hours post-awakening to bedtime), overall decline slope (awakening to bedtime), bedtime cortisol, and area under the curve. Participants also completed 1-week wrist actigraphy to measure sleep health characteristics, including sleep duration (minutes), sleep efficiency, and sleep irregularity. Using linear regression, we estimated separate multivariable associations between each cortisol feature and sleep outcome, overall and within strata of gender, race and ethnicity among 557 participants with available data.
Results: Overall, a 1-unit increase in wakeup and peak cortisol were associated with longer sleep duration (beta=8.91, 95% CI 1.03, 16.78; beta=9.80, 95% CI 2.42, 17.17, respectively) and higher sleep efficiency (beta=0.42, 95% CI 0.01, 0.83; beta=0.43, 95% CI 0.05, 0.81, respectively). Higher wakeup cortisol was also associated with reduced sleep irregularity (beta=-4.49, 95% CI -8.62, -0.37). Associations persisted across race and ethnicity. Additionally, we observed associations between early decline slope and sleep duration among Black participants, and between overall decline slope and sleep efficiency and CAR and sleep irregularity among White participants. Associations did not vary by gender.
Conclusion: In this study, favorable diurnal cortisol curve features (e.g., higher wakeup cortisol) were associated with better sleep health. However, associations may vary by race and ethnicity. Given racial and ethnic differences in stress, cortisol may contribute to sleep health disparities.

PILOT TESTING OF A CULTURALLY ADAPTED BEDTIME ROUTINE QUESTIONNAIRE AMONG BLACK FAMILIES WITH YOUNG CHILDREN

Alicia Chung[1], Laurie Brotman[1], Iheoma Iruka[2], Girardin Jean-Louis[3], Keng-Yen Huang[1]
[1] NYU Grossman School of Medicine, [2] UNC Chapel Hill, [3] University of Miami Miller School of Medicine

Introduction: Black children in the United States disproportionately experience sleep health disparities compared to Whites. Yet, existing pediatric sleep measures are largely developed and tested among White populations. We aimed to pilot test a new culturally tailored questionnaire, the Bedtime Routine Questionnaire for Black families with Young Children.
Methods: To develop the bedtime routine questionnaire, we apply the social-ecological framework of sleep to consider contextual factors in the home, via human-centered design empathy interviews with parents, developed from our previous qualitative study. We utilized three bedtime routine measures: The Parent-Child Sleep Interaction Scale (12items; sleep reinforcement, sleep conflict and sleep dependence constructs), Bedtime Routines Questionnaire (26 items; bedtime behaviors and routine environment, adaptive and maladaptive behavior constructs) and Child Routines Inventory Scale (21items; daily living and discipline routine constructs) tailored and adapted for Black families. Survey items were further selected and modified after formative research. A total of 75 items were finalized that captured 16 constructs (59 items from the 3 scales aforementioned, 6 additional questions on maladaptive behavior, sleep timing and independent sleep, 2 questions about family structure, and 9 new items about knowledge about child sleep were added. Next, we pilot test the new measure with 29 Black parents. To study measurement reliability, Chronbach's alphas for all aforementioned subscales were examined. Construct validity was examined by assessing the association between subscales and sleep outcomes.
Results: A sample of 29 Black parents (25 mothers and 4 fathers) completed the questionnaire. Parents self-identified as African American (52%), Jamaican (14%), and Haitian (10%). Children were 5 years old on average. The adapted new Bedtime Routine measure had adequate reliability for 8 subscales. Cronbach's alpha internal consistency across all measures was above acceptable level ranging from 0.69 to 0.86.
Conclusion: Our findings suggest a new measure is a promising tool that can be used for future sleep epidemiology research to understand underlining mechanisms between bedtime contextual and sleep health outcomes in Black families. A survey tailored with Black families, that captures the contextual factors in the home around sleep, is likely to better reflect participant behaviors.

SEX HORMONES SHAPE SPINDLE ACTIVITY ACROSS THE MENSTRUAL CYCLE

Ali Ekhlasi[1], Alessandra Shuster[1], Allison Morehouse[1], Peremoboere Uzoigwe[2], Negin Sattari[1], Jing Zhang[3], Marie Gombert[4], Fiona Baker[4], Katharine Simon[1], Paola Malerba[5], Sara Mednick[1]
[1] University of California, Irvine, [2] University of California, Irvine, CA, [3] Harvard University, [4] SRI International, [5] Nationwide Children's Hospital

Introduction: Studies examining how the female menstrual cycle and fluctuating sex hormones affect sleep have demonstrated a significant increase in non-rapid eye movement sigma frequency band (12-15Hz) in the luteal phase. However, existing literature often falls short by relying on small sample sizes, not employing within-subject designs, or failing to comprehensively evaluate multiple menstrual phases. The goal of our study was to conduct a comprehensive, within-subject, investigation of sleep and

sex hormones across the menstrual cycle (menses, pre-ovulation, mid-luteal, and late-luteal) in young, healthy women.
Methods: Thirty-five young, healthy women participated in a study to monitor their menstrual cycles for several months. We collected four in-lab, high-density electroencephalography sleep recordings during each of the four phases of their menstrual cycle, plus measured sex hormones. At each phase, we calculated the EEG power density ratio (PDR) in frequency bins 1-29Hz as power density ($\mu V^2/Hz$) divided by mean power density across the four phases. We extracted sigma PDR for frequencies between 12-15Hz, and detected spindles. Sigma PDR and spindle density were compared across menstrual phases using repeated-measures-ANOVAs, with Bonferroni-corrections plus Pearson's correlations between sleep/sex hormones.
Results: Across phases, sigma PDR varied significantly, lowest during pre-ovulation (p=0.005) and highest during mid-luteal (p=0.004). Results were similar for spindle density (p=0.005). Topographically, frontal regions showed greater cycle-related modulation in sigma power and fast spindle density compared to central, parietal, and occipital regions. Sex hormones impacted spindles. During pre-ovulation, progesterone negatively associated with sigma PDR (p=0.038), while during mid-luteal both progesterone (p=0.023) and estrogen (p=0.005) positively correlated with sigma PDR. Testosterone did not significantly predict sigma (p>.05). Spindle density correlated with progesterone in all phases except menses (pre-ovulation:p=0.34; mid-luteal:p=0.045; late-luteal:p=0.008), with especially strong correlations in the central channels (pre-ovulation:p=0.019; mid-luteal:p=0.043; late-luteal:p=0.008).
Conclusion: Our results demonstrate a significant shaping of sigma/spindle activity by the modulation of sex hormones across the menstrual cycle. Given the importance of spindles for sleep-dependent memory consolidation, future research should examine how these changes affect cognitive functioning and underlying brain networks.

ANTICIPATING RACISM IS ASSOCIATED WITH POORER SLEEP

Emily Hokett[1], Paris Adkins-Jackson[1], Kendra Sims[2], Tahlia Bragg[2], Adam Brickman[1], Jennifer Manly[2]
[1] Columbia University, [2] Boston University

Introduction: Racism has deleterious effects on general health, including sleep health. Higher interpersonal discrimination is associated with lower sleep duration and poorer sleep quality (i.e., poor sleep) in adults who are racialized as Black. Proposed mechanisms between discrimination and poor sleep among those racialized as Black include the stress of anticipating, ruminating over, or otherwise mentally preparing for future racist experiences. With accumulating racial discrimination across the life course, preparing for racist experiences may be associated with poorer sleep, but that association is understudied across the adult lifespan. Here, we hypothesized higher racism-related vigilance is associated with poorer sleep quality and lower sleep duration in women and men.
Methods: We used a subsample of the Offspring Study of Racial and Ethnic Disparities of Alzheimer's Disease, a community-based cohort study. In adults across the adult lifespan racialized as Black (n=265, 63% women, mean age = 57, SD = 11, range: 27 to 91), we measured racism-related vigilance with a questionnaire. The items involved how often participants prepared for possible insults, avoided certain social situations and places, and felt they had to be careful about their appearance to avoid harassment on a scale from (1) at least once a week to (5) never. To measure sleep duration and sleep quality, we used a modified version of the Pittsburgh Sleep Quality Index, which included items about the frequency of sleep disturbances (e.g., temperature, pain, bad dreams). We evaluated associations between vigilance and sleep with age-adjusted, linear regression models stratified in women and men.
Results: Higher racism-related vigilance was associated with poorer sleep quality. Associations between higher racism-related vigilance and poorer sleep quality were similar among men and women. We observed no reliable associations between vigilance and sleep duration.
Conclusion: Anticipatory experiences of racism are associated with poorer sleep quality. Specifically, the threat of racist experiences is associated with poorer sleep in men and women racialized as Black. Future research and policies should aim to reduce racism-related vigilance by intervening on negative environments that trigger vigilance responses to improve sleep health in adults racialized as Black.

EXPLORING THE IMPACT OF TRANSPORTATION MODES ON SLEEP

Sumin Im[1], Michelle Garrison[1]
[1] Purdue University

Introduction: Many workers struggle to achieve enough sleep due to demands of work, caregiving, and other commitments. Prior research has found that increased commute time is associated with decreased sleep, with the assumption that this is largely due to the time burden. However, the mode of commute – driving, carpooling, mass transit, biking, or walking – likely differ in terms of stress, physical activity, ability to multi-task, scheduling flexibility, etc., which may affect sleep as well. This study explores the relationship between commute time, transportation mode, and their impact on sleep duration.
Methods: This study utilizes data from the 2021 to 2023 American Time Use Survey (ATUS), which includes 24-hour time use diaries on a representative sample of adults in the United States. This analysis was restricted to those with at least two instances of commuting to or from work, and excluding those with airplane as a transportation mode. We categorized time use into five groups: commute, sleep, work, leisure, and non-discretionary activities (eating, household chores, caregiving, etc.), and used linear regression to examine the association between commute time and sleep duration, adjusting for potential confounders (work schedule, age, sex, and rural/urban location.)
Results: Each one minute increase in commute times was associated with a decrease in sleep time during the same 24-hour period, including 0.32 minutes (95%CI 0.24 to 0.40) for each

minute of driving, 0.26 minutes (95%CI 0.12 to 0.41) for sedentary non-driving commutes (such as bus, train, and carpooling), and 0.59 (95%CI 0.16 to 1.02) for active commute modes (such as walking or biking).
Conclusion: Contrary to expectations, the benefits of active commutes did not decrease the impact of commute time on sleep duration. However, we do see a decreased effect of non-driving sedentary commuting vs. driving, and hypothesize that this may be due to the ability to multi-task while a non-driver on a sedentary commute, potentially having a less stressful commute than those driving, and/or needing to stick to a stricter schedule on when to leave work. Further research is needed to better understand these differences, and to translate them into actionable strategies for urban planning and transportation policies.

SLEEP ON IT: HOW BASELINE SLEEP HEALTH INFLUENCES CIRCADIAN HEALTH INTERVENTION OUTCOMES--A PILOT EXPLORATION

Jamon Jex[1], Summer Snow[1], Kara Duraccio[1], Daniel Kay[1]
[1] Brigham Young University

Introduction: Adolescents face unique risks to circadian health, leading to poor sleep and mental health. Sleep interventions, such as the Transdiagnostic Intervention for Sleep and Circadian Dysfunction (TranS-C), have been shown to improve adolescent sleep. However, less is known about whether factors influence the effectiveness of TranS-C. This study evaluated whether demographic, psychological, sleep, and emotional factors predicted intervention success for adolescents who completed a TranS-C intervention.
Methods: Night-owl adolescents (ages 14-18; N = 31) participated in a six-week TranS-C study. Before and after the intervention, participants provided basic demographic information and completed the Depression-Anxiety Stress Scale-21, Difficulties in Emotion Regulation Scale-18, Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), and Morningness-Eveningness Questionnaire (MEQ). Furthermore, participants monitored their sleep for one week via actigraphy (Actiwatch 2). Six hierarchical regression analyses examined the contribution of baseline demographics (Step 1: sex, income, race, BMI), psychological and sleep factors (Step 2: anxiety, depression, and sleep regularity), and emotional factors (Step 3: stress, emotional regulation difficulties) on changes in sleep outcomes—sleep quality, daytime sleepiness, chronotype, sleep midpoint, and weekend sleep onset/offset.
Results: Across all outcomes, baseline demographics (Step 1) explained a small proportion of variance (R^2 range =.03–.37) but none emerged as significant predictors of success (p's>0.05). The addition of psychological predictors (Block 2) significantly improved the models (ΔR^2 range =.21–.45), with sleep regularity, depression, and anxiety significantly predicting differences in weekend sleep offset. The inclusion of emotion regulation and stress (Block 3) provided minimal additional variance (ΔR^2 range =.04–.00) and, in some cases, reduced model efficiency (adjusted R^2 decreasing); no emotional factors emerged as significant predictors of success (p's>0.05).
Conclusion: Overall, psychological predictors consistently accounted for the largest proportion of variance in TranS-C intervention success across all outcomes, while baseline demographics and emotion regulation factors contributed relatively less. Specifically, higher levels of depression/anxiety and greater sleep regularity both significantly predicted changes in weekend sleep offset times. As such, sleep clinicians may consider evaluating adolescent sleep regularity at baseline to assess for individuals who may need additional support to increase odds of intervention success.

THE IMPACT OF EVERYDAY DISCRIMINATION ON SLEEP DISTURBANCE IN PERINATAL WOMEN OF COLOR

Stacyca Dimanche[1], Joon Chung[2], Mary Carrasco[3], Carolina Scaramutti[2], Laurent Garchitorena[1], Jasmine Rubio[1], Dunia Mejia[4], Camila Pow-Sang[1], Daniela Torres[1], Judite Blanc[5], Debbie Chung[5], April Rogers[6], Ferdinand Zizi[1], Girardin Jean-Louis[7], Azizi Seixas[7]
[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Miami, [3] Lincoln Memorial University Debusk College of Osteopathic Medicine, [4] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [5] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [6] St. John's University, [7] University of Miami Miller School of Medicine

Introduction: Perinatal women of color often navigate the effects of everyday discrimination and poor sleep health at a vulnerable time, when their mental and maternal health are essential for both their well-being and that of their developing baby. While racial discrimination during the maternal period is well documented, the relationship between this psychosocial stressor and sleep quality has been ignored in research. This study explores the interplay between perceived discrimination and sleep disturbances in perinatal women of color, using virtual reality (VR).
Methods: A pre-and post-design study, Nurturing Moms, assessed the effectiveness of a maternal health and wellness VR program on maternal stress among expectant (0-36 weeks gestation) and postpartum (up to 12 months) Black and Latina and/or Hispanic women. Twenty-three expectant (29.3±4.8 years) and twenty-three postpartum (31.6±5.1 years) women completed baseline surveys using REDCap. Surveys included the Everyday Discrimination Scale (EDS) - Short Version and Patient Reported Outcomes Measurement Information Systems (PROMIS) Short Form v1.0 – Sleep Disturbance 4a, measuring subjective perceived discrimination frequency and perceptions of sleep quality, respectively. To investigate the relationship between discrimination and sleep we performed Spearman correlation and linear Regression analysis (adjusting for race, age, and income level) using the bootstrap method.
Results: A statistically significant correlation was observed between EDS scores and PROMIS scores (r_s= 0.318, $p < 0.05$), indicating that higher baseline everyday discrimination was associated with greater sleep difficulties. While the overall regression model was not significant, $F(4,41) = 1.53$, $p > 0.05$, frequent discrimination experiences were identified as a

significant predictor of sleep disturbance (β =.705, p =.020, 95% CI [.12, 1.29]), among perinatal women of color.
Conclusion: The analyses revealed a significant correlation between greater levels of discrimination and poor sleep quality among perinatal Black and Latina mothers, emphasizing the detrimental effects of psychosocial stressors on maternal sleep health. The overall regression model was non-significant, likely due to limited sample size and reduced statistical power, frequent discrimination experiences remained a key predictor. Future research should explore intersecting socio-determinants of health, on a larger and more diverse scale.

RISK AND PROTECTIVE FACTORS FOR SLEEP DISTURBANCES AMONG BLACK REPRODUCTIVE-AGED WOMEN IN THE US

Yuqing Guo[1], Priscilla Kehoe[1], Renaisa Anthony[2]
[1] University of California Irvine, [2] MoMentum Park

Introduction: Black women disproportionately experience sleep disturbances often linked to chronic stress including racial discrimination. Limited research explores both the risk and protective factors affecting sleep quality amongst Black reproductive-aged women. Understanding these factors is crucial for advancing sleep equity and health in this population.
Methods: A retrospective design was used. Data was collected at the 2024 Essence Festival using a tech-based platform. A total of 769 Black women who had given birth in the past 10 years consented to participate. The survey included measures of demographics (e.g., education, marital status), adverse experiences (e.g., domestic violence, adverse childhood experiences), mental health (e.g., perinatal depression/anxiety), coping levels, social support, the Everyday Discrimination Scale, and the PROMIS Sleep Disturbance Short Form. Descriptive statistics and regression analyses were conducted.
Results: Among participants, 95% self-identified as non-Hispanic Black, with 48% from New Orleans. The average age was 35.8 years (SD = 6.5). Approximately 43% graduated high school or had some college, while 55% obtained a bachelor's or graduate degree; 43% were married; 36% (n=274) reported adverse experiences and 43% (n=432) reported perinatal depression/anxiety. Notably, 85% reported sleep problems: 70% woke up tired, 65% did not get enough sleep, 52% had trouble staying asleep, 47% had difficulty falling asleep, and 33% snored. Adjusting for covariates, regression analysis identified that greater racial discrimination (β = 0.14, p< 0.001), adverse experiences (β = 0.10, p=0.005), and perinatal depression/anxiety (β = 0.12, p=0.001) were associated with higher sleep disturbances. Conversely, higher coping ability (β = -0.20, p< 0.001) and social support (β = -0.11, p=0.003) were associated with lower sleep disturbances.
Conclusion: This study highlights chronic stressors (racial discrimination, social adversity, and perinatal mental health challenges) are risk factors for sleep disturbances, whereas higher coping ability and social support serve as critical protective factors amongst Black reproductive-aged women. Our findings emphasize the need for multi-level interventions that enhance individual coping mechanisms, increase social support networks, and address systemic discrimination and adversity. Such interventions may advance sleep equity and overall health of Black reproductive-aged women.

MARITAL STATUS MATTERS: EXAMINING SEX DIFFERENCES IN REM SLEEP PERCENTAGE AMONG BLACK AMERICANS

Sadeaqua Scott[1], Debbie Chung[2], Michelle Thompson[3], Clarence Locklear[1], Nina L'Houtellier[1], April Rogers[4], Azizi Seixas[3], Girardin Jean-Louis[3]
[1] University of Miami, [2] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [3] University of Miami Miller School of Medicine, [4] St. John's University

Introduction: Rapid Eye Movement (REM) sleep plays a vital role in memory consolidation, emotional regulation, and overall well-being. REM Sleep Percentage (REM%), the proportion of sleep spent in REM, is a key marker of sleep quality due to its role in physiological recovery. Despite the critical importance of REM%, there is a notable lack of research exploring how social and demographic factors, such as marital status and sex, influence this measure of sleep architecture among Black Americans. Addressing this gap, the present analysis investigates the relationship of marital status with sex and REM% in a cohort of Black Americans (BA), offering insights into potential sex-specific patterns that may inform interventions to promote equitable sleep health.
Methods: The study analyzed 139 participants from the NIH-funded sleep studies, ESSENTIAL and MOSAIC, focusing on BA. Marital status was categorized as Married/Living with Partner, Separated, Widowed, Never Married, Divorced, and Single. REM% was analyzed by marital status using one-way ANOVA, separately for males and females. Tukey's HSD post hoc tests identified significant pairwise differences.
Results: For females (n = 93), significant differences in REM% were observed across marital status groups ($F(5, 87) = 3.232$, $p = 0.010$, $\eta^2 = 0.157$). Tukey's HSD showed that females in the Widowed group had significantly higher REM% than those in the Divorced ($p = 0.020$) and Single ($p = 0.020$) groups. Females in the Married/Living with Partner and Widowed groups had higher mean REM% than other groups. For males (n = 46), no significant differences were found ($F(5, 40) = 1.085$, $p = 0.383$, $\eta^2 = 0.119$).
Conclusion: This study highlights sex-specific patterns in the relationship between marital status and REM%. Among females, being Widowed was associated with the highest REM%, while Divorced and Single groups had the lowest. In contrast, males showed no significant differences. These findings suggest marital status may exert a stronger influence on REM% among females, reflecting potential psychosocial factors like partner support or stress from being unmarried. Future research should explore mechanisms behind these sex-specific associations to

inform interventions aimed at improving sleep health in Black Americans.

DISCRIMINATION IS ASSOCIATED WITH INSOMNIA SEVERITY IN HISPANIC COMMUNITIES

Mascha Korsch[1], Joon Chung[1], Ziyi Ding[1], Dunia Mejia[2], Jasmine Rubio[1], Camila Pow-Sang[3], Stacyca Dimanche[1], Mary Carrasco[1], Laurent Garchitorena[3], Carolina Scaramutti[1], Ferdinand Zizi[3], Alberto Ramos[1], Girardin Jean-Louis[4], Azizi Seixas[4]

[1] University of Miami, [2]University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [3] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [4] University of Miami Miller School of Medicine

Introduction: Socioeconomic determinants of health include ethnic and racial discrimination, with traditionally marginalized communities found to experience poorer health outcomes. Research has consistently reported an increased frequency of poor sleep among individuals experiencing perceived discrimination. Despite these findings, there remains a notable gap in understanding the effects of discrimination on insomnia severity within the urban-rural Hispanic population. This study addresses this gap by exploring the associations between discrimination and insomnia severity in a South Florida Hispanic adult cohort.

Methods: For this study, 231 (80 male, 151 female) Spanish-speaking participants from rural and urban areas of Florida were surveyed using the Williams Everyday Discrimination Scale (EDS) as part of the Determinants, Outcomes, Responses, and Markers of Insufficient Sleep in Rural-Urban (DORMIR) study. Higher scores on the EDS indicate worse discrimination. Insomnia was measured using the insomnia severity index (ISI) score, with higher scores reflecting more severe insomnia. Linear regression analyses were conducted to evaluate the association of EDS with ISI with the adjustment of age, sex, race/ethnicity, marital status, employment, income, and Body Mass Index.

Results: A significant correlation between EDS and ISI was observed. A one-unit increase in the EDS was associated with a -0.24 decrease in ISI scores (□ [95% Confidence Interval (CI)] = -0.24 [-0.37, -0.11]; $p < 0.001$). Among the components of the EDS scale, the categories “Treated as not smart”, “Treated with courtesy”, “Others felt superior”, “Treated as dishonest”, and “Poor service” showed the largest association with ISI scores.

Conclusion: Perceived discrimination could be significantly associated with insomnia severity in Hispanic communities. While male individuals reported overall higher discrimination experience than female individuals, the overall ISI score was lower in males than in females, indicating that women may be more susceptible to insomnia under stressors such as discrimination. Future studies should examine the relationship between insomnia and discrimination by sex as well as using longitudinal data collection.

MICE CARRYING A MATERNAL UBE3A DELETION ASSOCIATED WITH ANGELMAN'S SYNDROME DISPLAY ALTERED SLEEP ONTOGENESIS

Andree Croteau[1], Elizabeth Medina[2], Michael Rempe[3], Kaitlyn Ford[4], Abrar Al Maghribi[5], Katelyn Middleton[2], Kristan Singletary[2], Lucia Peixoto[3]

[1] Elson S. Floyd College of Medicine Washington State University, [2] Washington State University, [3] Sleep and Performance Research Center, Washington State University, [4] Seattle Children's Research Institute, Center for Developmental Biology and Regenerative Medicine, [5] Department of Neurology, Washington University School of Medicine

Introduction: Sleep problems are frequent in Angelman's syndrome (AS), a neurodevelopmental disorder caused by maternal deletion of the Ube3a gene (Ube3a m-/p+). AS is characterized by a high prevalence of autism and intellectual disability. While sleep issues significantly impact individuals and caregivers, their precise nature varies across clinical studies, which are predominantly based on non-objective measures using questionnaires in children and adolescents. Studies using the Ube3a m-/p+ mouse model use objective measures but are so far limited to adult animals and show variable agreement beyond a reduction in REM sleep. The goal of this study was to examine the effects of Ube3a maternal deletion on sleep architecture and homeostasis in juvenile mice.
Methods: Juvenile male and female Ube3a m-/p+ mice (n= 12) and wildtype littermates (n=11-12) were implanted with EEG/EMG electrodes at postnatal day 18 (P18). Mice underwent 24-hour baseline recording, 3-hour sleep deprivation (SD) via gentle handling, and 19-hour recovery sleep at P23/P24 and P29/P30. Vigilance states (REM and NREM sleep, wake) were assigned using SPINDLE and manually corrected with SleepSign. Statistical analysis was performed using ANOVAs with age and genotype as main effects, with Benjamini-Hochberg corrected post-hoc t-tests using MATLAB.
Results: Our data shows that Ube3a m-/p+ mice exhibit baseline REM sleep reduction from P23 to P29, driven by decreased REM bout duration, alongside increased NREM sleep, with a significant genotype-age interaction. Despite similar sleep pressure accumulation, Ube3a mutants showed reduced sleep latency after SD, with genotype differences more pronounced in REM and NREM sleep post-SD compared to baseline levels.
Conclusion: Our findings support Ube3a's role in sleep regulation, showing REM reduction and NREM increase. Thus, the mutation may impact REM sleep function earlier in life when REM quantities are greater. While sleep pressure accumulation remained unchanged, juvenile Ube3a mutant animals demonstrated reduced onset sleep latency post-SD. The sleep pressure and sleep onset results suggest that maternal Ube3a deletion induces abnormal REM/NREM sleep patterns in young ages.

DIFFERENTIAL OUTCOMES OF SLEEP AND COGNITION IN A GENETICALLY DIVERSE MOUSE PANEL OF ALZHEIMER'S DISEASE

Julia Kravchenko[1], Surjeet Singh[2], Amy Dunn[2], Kristen O'Connell[2], Catherine Kaczorowski[1]

[1] University of Michigan, [2] The Jackson Laboratory

Introduction: Alzheimer's Disease (AD) is known to contribute towards changes to sleep, including decreased sleep duration and increased sleep fragmentation. While significant advances have been made in characterizing these changes, the contribution of individual genetic makeup on the initiation and progression of AD-related sleep dysfunction and pathogenesis is yet unknown. As such, we decided to use a forward genetic approach to identify genes controlling sleep in AD in a panel of genetically diverse mice (AD-BXDs).
Methods: Female mice from 47 strains in the AD-BXD panel carrying the 5xFAD transgene (n=214) and non-transgenic (Ntg) littermate controls (n=216) completed sleep testing in the PiezoSleep Tracking System at 6 and 14 months of age. The percent of time spent sleeping was calculated over 4 testing days by automated sleep/wake scoring. After sleep phenotyping, animals were tested for learning and memory functions using contextual fear conditioning (CFC) at both ages – 6 and 14 months.
Results: At 14 months of age, 5xFAD mice sleep less over a 24-hour period than their non-transgenic (Ntg) and 6-month 5xFAD counterparts ($p< 0.0001$). This difference is particularly enhanced in the dark phase (ZT12-24), where the difference in sleep quantity between Ntg and 5xFAD animals is magnified by increased sleep in Ntg animals with age and a significant decrease in sleep in 5xFAD carrying animals with age ($p< 0.0001$ and $p< 0.05$ respectively). Further, mid-life sleep is positively associated with memory performance in genetically diverse 5xFAD mice, but not Ntg counterparts (Pearson's $R=0.54$, $p=0.0019$; Pearson's $R=0.036$, $p=0.85$). Heritability estimates for total sleep duration, the 12-hour light and dark period at 6 and 14 months of age were between 0.64-0.76 for both Ntg and 5xFAD animals. These results suggest that genetic background may largely explain the observed changes to sleep and its differential associations with cognition in AD.
Conclusion: Genetic background modulates the effect of AD and age on sleep in the AD-BXD panel. Since sleep is vital for memory consolidation, future work aims to map the genes modifying sleep in AD, identifying the mechanisms through which sleep causally influences cognitive decline in AD and age-related dementias.

SLEEP CHARACTERIZATION IN THE APP/NL-F MOUSE MODEL OF ALZHEIMER'S DISEASE AFTER REPETITIVE MILD TRAUMATIC BRAIN INJURIES

Victoria Carriquiriborde[1], Jefferey Yue[2], Taha Yildirim[3], Emad Shams[1], Wai Hang Cheng[4], Sean Tok[3], David J. Vocadlo[2], Cheryl L. Wellington[4], Brianne A. Kent[3]

[1] Simon Fraser University - Translational Neuroscience Lab, [2] Simon Fraser University - Department of Molecular Biology and Biochemistry, [3] Simon Fraser University, [4] University of British Columbia

Introduction: Sleep disturbances, such as insomnia and hypersomnia, are often reported by people who have experienced mild traumatic brain injuries (mTBIs). TBIs and sleep disturbances are both risk factors for neurodegenerative diseases, such as Alzheimer's disease (AD). The long-lasting effects of repetitive mTBIs (rmTBIs) on sleep outcomes and whether post-TBI sleep is an effective therapeutic target for reducing the risk of neurodegenerative disease are not yet well understood. Therefore, our study aims to characterize intracranial EEG activity during sleep and wake 3 and 9 months after rmTBIs in APPNLF mice.
Methods: We used the closed-head impact model of engineered rotational acceleration (CHIMERA) method to deliver 3 rmTBIs 48hr apart to female and male APPNL-F mice (n=42), at 6 and 12 months of age. At 15 months old, we implanted EEG cortical electrodes and recorded 72 continuous hours of EEG. Using the Sirenia Sleep Pro software and an in-house R code, we quantified sleep-wake patterns. Unpaired Welch t-tests with Holm-Šídák correction for multiple comparisons was used to compare the sleep-wake patterns between the rmTBI and sham groups. Additionally, the partial least squares regression method was used to analyze the spectral power data.
Results: Our results show no differences in the time spent in each vigilance state between the TBI and sham groups at either 3- or 9-months post-injury. There were no differences in the number of transitions between states, bout counts, or bout lengths between the experimental groups. However, in the power spectra analysis, we observed a statistically significant decrease in power at the lower frequencies (3-8Hz) and an increase in the power at the higher frequencies (18-30Hz) in the TBI group during wake at 9 months post-injury. There were no significant changes in the power spectra after 3 months post-injury, although there was a trend towards higher power in the TBI group in the lower frequencies during NREM.
Conclusion: This is the first study, to our knowledge, presenting the chronic effects of repetitive closed-head mTBIs on sleep and EEG power spectra.

MINERALOCORTICOID RECEPTOR BLOCKADE MITIGATES CARDIOVASCULAR DYSFUNCTION IN OBESE MICE EXPOSED TO CHRONIC INTERMITTENT HYPOXIA

Mohammad Badran[1], Shawn bender[1], Chastidy Bailey[1], Jacob Russel[1], David Gozal[2]
[1] University of Missouri, [2] Marshall University

Introduction: Obstructive sleep apnea (OSA) is common in obesity, characterized by cycles of intermittent hypoxia (IH), and promotes the risk of cardiovascular disease (CVD) and mortality. Mineralocorticoid receptor antagonists (MRAs) improve cardiovascular outcomes in CVD. Here, we examine whether MRAs, specifically spironolactone (SPL) and the more selective finerenone (FIN), mitigate coronary and cardiac dysfunction in mice subjected to chronic IH.
Methods: Male and female C57Bl/6J mice were fed a high-fat diet (HFD) or a low-fat diet (LFD) for 10 weeks, followed by exposures to IH (FiO2 cycles of 21% for 90s and 6% for 90s) or room air (RA, 21%) for 12 hours/day over 16 weeks. Animals were treated with SPL, FIN, or placebo. Key measures, including mean arterial pressure (MAP), echocardiography-derived ejection fraction (EF) and E/A ratio (diastolic function), and coronary flow velocity reserve (CFVR), were assessed. Left anterior descending coronary and renal arteries were examined in vitro for vascular reactivity (acetylcholine (ACh) and thromboxane A2 receptor agonist U46619).
Results: SPL and FIN treatments effectively normalized elevated MAP in male mice on HFD and those exposed to IH with LFD or HFD. Systolic function (EF) improved with both SPL and FIN in male mice exposed to IH with LFD but not in those on HFD or HFD-IH. Diastolic function (E/A ratio) did not improve post-MRA treatment in groups with reduced diastolic function, notably HFD-IH. FIN uniquely improved CFVR in HFD-fed males exposed to IH, indicating selective superiority. In coronary arteries, MRAs decreased vasoconstriction in IH with LFD but not in HFD or HFD-IH males. Endothelium-dependent relaxation was restored by FIN in both LFD and HFD mice exposed to IH, showing superior efficacy compared to SPL. In female mice, neither MRA altered elevated vasoconstrictive responses or impaired vasodilation following HFD-IH.
Conclusion: Chronic IH and diet-induced obesity impair cardiac and coronary function, particularly in males. MRA therapy, notably with the selective FIN, ameliorates dysfunction associated with IH and obesity in a diet- and sex-specific manner, highlighting its potential for targeted therapeutic interventions in CVD risk management among OSA patients.

BILATERAL TRANSECTION OF STYLOPHARYNGEUS MUSCLE ALTERS INSPIRATORY AIRFLOW IN CONSCIOUS RATS

Eriko Hamada[1], Yee-Hsee Hsieh[1], Denise Dewald[2], Kingman Strohl[3], Thomaz Fleury Curado[4]
[1] Case Western Reserve University, [2] MetroHealth Medical Center, [3] Case Western Reserve University / University Hospitals, [4] University Hospitals

Introduction: Upper airway patency is lost in obstructive sleep apnea (OSA). Research has primarily focused on the role of genioglossus muscle on maintaining airway patency. The stylopharyngeus muscle is an upper airway dilator muscle that supports the lateral pharyngeal wall. Its role in maintaining upper airway patency and effects on respiratory airflow is theoretical (Dewald, 2022) but functionally understudied. We hypothesize that bilateral transection of the stylopharyngeus muscles disrupts normal breathing. This study aims to assess the impact stylopharyngeus muscles have on respiratory airflow in conscious freely moving adult rodents.
Methods: Adult male Sprague Dawley rats were divided into two groups: 1) bilateral stylopharyngeus muscle transection (n=4) and 2) sham (muscle was exposed) surgery (n=2). Respiratory airflow was acquired using whole- body plethysmography before and 1 day after surgery. Epochs of stable breathing (minimum of

1 min) were selected from the airflow tracings for analysis using SPIKE CED.
Results: Significant alterations in respiratory airflow and tracings, particularly a flattening (plateau) in inspiratory flow, were observed on the first post-operative day in the transection group versus an early peak seen in the pre-operative airflow tracings. The average length of the inspiratory plateau among the transection group (0.23 ± 0.12s) was a 9-fold increase compared to the pre-operative values (0.02 ± 0.12s). The sham group did not exhibit a plateau and showed no significant changes in inspiratory airflow.
Conclusion: Bilateral stylopharyngeus muscle transections disrupt airflow in a conscious rodent model. The transections produce a flattening of the inspiratory airflow similar to inspiratory flow limitation traces seen in humans with upper airway resistance and OSA. Our results support the hypothesis that stylopharyngeus muscle plays a vital role in shaping respiratory airflow.

BEHAVIORAL AND PHARMACOLOGICAL INTERVENTIONS TO IMPROVE SOCIAL AFFILIATION IN PRAIRIE VOLES EXPOSED TO EARLY LIFE SLEEP DISRUPTION

Nathan McGuire[1], Noah Milman[2], Peyton Wickham[1], Katelyn Gutowsky[1], Jasmine Loeung[1], Noy Gurman[1], Carolyn Tinsley[1], Lezio Bueno-Junior[3], Brendon Watson[4], Miranda Lim[2]
[1] VA Portland Health Care System, [2] Oregon Health & Science University, [3] University of Michigan Medical School, Department of Psychiatry, [4] University of Michigan

Introduction: Rapid eye movement (REM) sleep peaks early in life and may represent a sensitive period for proper maturation of the neurobiological systems underlying the development of complex social behaviors. Prairie voles (Microtus ochrogaster) are a highly social rodent species that show affiliative behaviors throughout life and form pair bonds with opposite sex mates as adults. We have previously shown that experimentally reducing REM sleep early in life leads to long lasting impairments in both social affiliation and sleep in the prairie vole, characteristics similarly seen in autism spectrum disorder (ASD). Here we explored two different potential interventions: pharmacological treatment with donepezil hydrochloride, an acetylcholinesterase inhibitor that has been found to increase REM sleep in children with ASD, or behavioral intervention with environmental enrichment, shown to increase REM sleep in rodents.
Methods: Early life sleep disruption (ELSD) occurred via gentle home cage agitation from postnatal day (p) 14-21. Control animals were housed in the same room, but their home cages were left undisturbed. Pharmacological intervention occurred by daily intraperitoneal injections of donepezil or saline from p14-p40. Environmental enrichment (EE) intervention consisted of increased bedding, toys and nestlets starting at p21 and lasting until behavioral testing in adulthood. All animals underwent social behavioral testing as adults.
Results: Both of our interventions improved affiliative social outcomes in adults. Animals treated with donepezil early in life displayed increased affiliative social behavior as measured by side-by-side huddling compared to saline treated controls. This effect was present in both ELSD and Control groups. By contrast, animals exposed to EE did not have increased amounts of affiliative social behaviors but did show improved preference for a pair bonded mate after ELSD.
Conclusion: Our experiments describe two promising interventions for the impaired social phenotype produced by early life sleep disruption in the prairie vole. Future work will explore the sleep phenotype of these animals before and after these interventions to appreciate the significance of REM sleep on the development of affiliation.

SELF-REPORTED SLEEP METRICS ARE ASSOCIATED WITH THE COMPOSITION AND DIVERSITY OF THE GUT MICROBIOME IN YOUNG ADULTS

Joseph Lim[1], Roshonda Jones[2], Elizabeth Holzhausen[3], Kevin Clark[1], William Patterson[4], Jesse Goodrich[5], Zhanghua Chen[5], Tanya Alderete[6]
[1] University of Colorado Boulder, Department of Integrative Physiology, [2] North Carolina A&T State University, Department of Biology, [3] Johns Hopkins Bloomberg School of Public Health, Department of Environmental Health and Engineering, [4] University of Colorado Anschutz Medical Campus, Department of Biomedical Informatics, [5] University of Southern California, Department of Population and Public Health Sciences, [6] Johns Hopkins Bloomberg School of Public Health Department of Environmental Health and Engineering

Introduction: Sleep has been associated with compositional alterations of the human gut microbiome. However, relationships between sleep variables and the gut microbiome have yet to be comprehensively described. This study investigates associations between self-reported sleep variables and the gut microbiome in young adults.
Methods: The composition of the gut microbiome of 83 young adults from the Southern California Meta-AIR study was characterized using 16S rRNA sequencing. Participants' self-reported sleep characteristics included: snoring, workday and free-day bed and wake times. From this, sleep debt, average sleep duration, workday mid-sleep time (MSW) and free-day mid-sleep time (MSF) were calculated. Associations between sleep characteristics with alpha-diversity metrics at the genus level and the relative abundance of gut bacteria were examined using multivariable linear regression. These models adjusted for age, sex, body mass index, and diet via the healthy eating index (HEI). Benjamini-Hochberg Procedure adjusted p-values (FDRBH) are reported.
Results: MSF and snoring were positively associated with Shannon diversity (all FDRBH < 0.2) while work-day sleep duration reflected a negative association (FDRBH = 0.05). Average sleep duration was negatively associated with abundance of the phylum Bacteroidota and the class Bacteroidia (all FDRBH < 0.2) and negatively associated with abundance of the class

Negativicutes (FDRBH = 0.15). At the family level, work-day sleep duration was positively associated with Lactobacillaceae (FDRBH = 0.08) and Thermaceae (FDRBH = 0.14). Within the class level, free-day sleep duration was negatively associated with Negativicutes (FDRBH = 0.16). At the order level, MSW was positively associated with Enterobacterales (FDRBH = 0.08).
Conclusion: This study presents associations of specific sleep characteristics with the composition and diversity of the gut microbiome in young adults. Few studies have evaluated these associations within the young adult population; however, those evaluating children to middle-aged adults have found sleep characteristics to be associated with the phylum Bacteroidota and its taxa. These results suggest that certain sleep habits, particularly related to sleep duration, may alter the gut microbiome.

SLEEP DISCREPANCY IN ADULTS WITH ELEVATED BLOOD PRESSURE AND SELF-REPORTED SHORT SLEEP DURATION

Joshua Landvatter[1], Alena Wilson[1], Adam Bress[1], Christopher Sparks[1], Jennifer Duffecy[2], Molly Conroy[1], Sara Simonsen[1], Kelly Baron[1]
[1] University of Utah, [2] UIC Resiliency Center

Introduction: Nearly half of adults do not achieve the recommended 7 hours of sleep per night, a pattern associated with increased cardiovascular and metabolic health risks. However, sleep discrepancy—the difference between subjective and objective sleep duration—may indicate a bias in risk perception, as individuals may underestimate their sleep deficits. The goal of this study was to examine sleep discrepancy in self-reported short sleepers (< 7 hours) screened to participate in a sleep extension intervention.
Methods: Data were drawn from persons screened to participate in a randomized study of sleep extension among individuals with elevated blood pressure recruited from primary care clinics, online, and community sources. Participants had self-reported sleep < 7 hrs and standardized office blood pressure □120 mmHg systolic and/or 80 mmHg diastolic. Participants completed 7 days of wrist actigraphy, questionnaires including Insomnia Severity Index (ISI), Perceived Stress Scale (PSS), Epworth Sleepiness Scale (ESS), and PROMIS Sleep Disturbance and Sleep-Related Impairment scales. Sleep discrepancy was calculated as reported sleep minus objectively measured actigraphy sleep. Data were analyzed using regression models, including a full model (all predictors) and individual models (each predictor separately). Covariates included age, sex, and race.
Results: We included 195 participants with mean age of 42 years (SD=11); 36% were female. Average sleep discrepancy was -0.5 hrs (indicating self-report was 0.5 hr less than objective) and 54% was correctly identified as a short sleeper based on self-report (both self-report and objective sleep were < 7 hrs). Higher perceived stress (PSS) was significantly associated with sleep underestimation in both models, with the full model showing a negative association (b=-0.0948, 95% CI [-0.165, -0.025], p=.008). Sleep disturbance (PROMIS) was linked to underestimation in both models (b=-0.0420, 95% CI [-0.072, -0.012], p=.007). Insomnia severity (ISI) was associated with sleep underestimation in only the individual model (b=-0.0497, 95% CI [-0.086, -0.013], p=.008).
Conclusion: This study highlights the psychological significance of sleep perception among self-identified short sleepers. Higher perceived stress, sleep disturbance, and insomnia severity were linked to underestimating sleep duration and psychological distress. Screening data offered insights, emphasizing the need for combined subjective-objective assessments to address misperceptions.

CARDIOVASCULAR DISEASE INCIDENCE DIFFERS BY PATIENT CLUSTER BASED ON RAW POLYSOMNOGRAPHY DATA FOUNDATIONAL MODEL

Catherine Heinzinger[1], Matheus Lima Diniz Araujo[1], Erhan Bilal[2], Samer Ghosn[3], Kristen Beck[4], Nancy Foldvary-Schaefer[1], Carl Saab[3], Jeffrey L. Rogers[2], Reena Mehra[5]
[1] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [2] Digital Health, IBM T.J. Watson Research Center, Yorktown Heights, NY, [3] Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [4] Digital Health, IBM Almaden Research Center, San Jose, CA, [5] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, Seattle, WA

Introduction: Traditional sleep measures are not consistently associated with incident cardiovascular events in observational studies. We hypothesized deep learning approaches could uniquely identify distinct patient groups with varying cardiovascular disease (CVD) incidence, independent of traditional measures.
Methods: We used artificial intelligence to analyze N=10,000 polysomnograms completed at Cleveland Clinic (1/2012-12/2022) enriched with underrepresented populations. We created a time-series foundational model guided by sleep macro-architecture and respiratory annotations, generating embeddings to cluster patients into risk groups using k-means. Follow-up time was from polysomnogram until death or last follow-up. Propensity scores were estimated using multinomial logistic regression on age, sex, body mass index (BMI), and years of available data, then inverse probability weighted, stabilized, and trimmed at 1st and 99th percentiles to minimize bias introduced by extreme values. Cox proportional hazards regression examined risk groups as predictors adjusted for age, sex, BMI, and apnea hypopnea index (AHI) with comorbidities included per outcome. Patients with baseline disease were excluded.
Results: The cohort [age 50.4±24.7 years, 50% male, 44% White, 34% Black, 5.3% Asian, 14.8% multiracial] had follow-up of 4.4[2.0-7.5] years. A 5-cluster solution provided the best stratification: Risk Group 1 (RG1) was reference. RG5 (highest AHI and arousal index, lowest mean and minimum SaO2 and total sleep time(TST)) had the highest CVD incidence (major adverse cardiovascular events(MACE): HR=1.60, 95%CI=1.13-2.28, myocardial infarction: HR=1.75, 95%CI=1.07-2.88, atrial fibrillation: HR=1.83, 95%CI=1.15-2.93) and all-cause mortality (HR=2.76, 95%CI=1.98-3.84). RG4 (highest %time SaO2< 90%) had elevated incidence to a lesser degree than RG5. RG3 (intermediate) had the highest stroke (HR=1.38, 95%CI=1.13-1.69) and ischemic heart disease (HR=2.01, 95%CI=1.37-2.94) incidence, second highest MACE incidence (HR=1.34, 95%CI=1.12-1.60) and lowest all-cause mortality (HR=1.47, 95%CI=1.14-1.90). RG2 (lowest AHI and %time SaO2< 90%, highest mean and

minimum SaO2 and TST) had the lowest CVD incidence but not all-cause mortality (HR=1.47, 95%CI=1.14-1.90).
Conclusion: We created a large language model of raw polysomnogram data which identified groups that differed in CVD incidence after propensity score analysis. Risk groups were associated with adverse cardiovascular outcomes, thus supporting enhanced utility of a novel deep learning model over traditional approaches for CVD risk stratification. Future directions include validation with external data sources.

IMPACT OF SEX AND DIET ON CARDIOVASCULAR DYSFUNCTION FROM INTERMITTENT HYPOXIA IN OBSTRUCTIVE SLEEP APNEA

Mohammad Badran[1], Shawn bender[1], Chastidy Bailey[1], Jacob Russel[1], David Gozal[2]
[1] University of Missouri, [2] Marshall University

Introduction: Obstructive sleep apnea (OSA) is prevalent in obese individuals and is characterized by intermittent hypoxia (IH), a condition strongly associated with cardiovascular disease (CVD) and increased cardiovascular mortality. However, few studies have examined how diet-induced obesity and sex differences influence cardiac and coronary outcomes in OSA. This study tested the hypothesis that long-term IH differentially impacts cardiovascular outcomes in a sex- and diet-specific manner.
Methods: Male and female C57Bl/6J mice were fed a high-fat diet (HFD) or low-fat diet (LFD) for 10 weeks, followed by exposures to IH (FiO2 cycling between 21% for 90s and 6% for 90s) or room air (RA, 21%) for 12 hours/day over 16 weeks. Mean arterial blood pressure (MAP) and coronary flow velocity reserve (CFVR) were measured using the tail-cuff method and Doppler imaging, respectively. Cardiac function was assessed via echocardiography to determine ejection fraction (EF) and E/A ratio (diastolic function). Left anterior descending coronary arteries were analyzed in vitro for vascular reactivity using dose-response curves to acetylcholine (ACh) and thromboxane A2 receptor agonist U46619.
Results: MAP was significantly elevated only in male mice exposed to IH, HFD, HFD-IH, while MAP remained unaffected in females. In males, diet-induced obesity, IH exposure, or their combination resulted in significantly reduced systolic (EF) and diastolic (E/A ratio) functions, as well as decreased CFVR. Enhanced coronary vasoconstriction and impaired endothelium-dependent relaxation were observed in male mice exposed to IH, HFD, or HFD-IH. In females, enhanced vasoconstriction was observed only in IH-HFD, while endothelium-dependent relaxation was impaired by IH alone or in combination with HFD.
Conclusion: Cardiovascular dysfunction induced by intermittent hypoxia and diet-induced obesity exhibits substantial sexual dimorphism, with male mice showing greater susceptibility as evidenced by elevated blood pressure, impaired cardiac function, and altered coronary reactivity. These findings highlight the critical need for sex-specific approaches when assessing cardiovascular risks and therapeutic interventions in OSA, particularly among obese patients.

BETTER OBJECTIVE SLEEP IN HEALTHY ADULTS IS MARKED BY INCREASED BIFIDOBACTERIUM BREVE AND SAGUINI

Dana Withrow[1], Kate Sprecher[1], Antonio Gonzalez[2], Finn Livingston[3], Ellis Noteboom[3], Tina Burke[1], Christopher M. Depner[4], Monika Fleshner[3], Christopher Lowry[5], Fred Turek[6], Martha Vitaterna[6], Pieter Dorrestein[2], Rob Knight[2], Kenneth Wright[1]
[1] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA, [2] University of California San Diego, [3] University of Colorado Boulder, [4] University of Utah, [5] Department of Integrative Physiology and Center for Neuroscience, University of Colorado Boulder, Boulder, CO, USA, [6] Northwestern University

Introduction: Taxa level associations of the human gut microbiota have been reported in relation to sleep health; however, which taxa are associated with good sleep has yet to be determined. Many study methodologies rely on self-reported sleep metrics, 16S rRNA gene-amplicon sequencing or statistical methodologies not designed for gut microbiome assessments, which have limitations. We examined the association between sleep measures assessed by actigraphy followed by one night of in-laboratory polysomnography (PSG) and whole genome sequencing (WGS) gut microbiome taxa.
Methods: Fifteen healthy participants aged 26±4.0(SD) were instructed to maintain a consistent 8h sleep schedule for fourteen days at home. Wrist actigraphy and time stamped call-ins were assessed for adherence. Following fourteen days of monitoring, participants underwent 8h overnight in-laboratory PSG. Fecal microbiome samples were collected at PSG visit. WGS at the operational genomic unit (OGU) were then referenced against Web of Life 2 for taxonomic assignment. Differential abundance testing (ANCOM-BC) was performed to detect the OGUs associated with individuals with high (≥85%) or low (< 85%) sleep efficiency (SE) assessed via actigraphy. Following, linear regression associations between SE, sleep onset latency (SOL) and wake after sleep onset (WASO) from PSG were tested against these differentially abundant OGUs to determine: 1) whether these associations were maintained with PSG SE and; 2) whether these taxa were associated with SOL or WASO.
Results: ANCOM-BC determined Bifidobacterium breve and Bifidobacterium saguini species were increased in the high SE wrist actigraphy group (log fold change 2.2, q=0.002 and log fold change 2.0, q=0.006, respectively). Linear regression indicated increased breve and saguini were associated with higher PSG SE (β=0.0003, p=0.03, R^2=0.18 and β=0.0013, p=0.02, R^2=0.46, respectively). Further investigation into PSG SOL and WASO indicated that the higher SE was due to these strains being associated with decreased WASO, specifically (β=–0.09, p=0.04, R^2=0.38 and β=–0.58, p=0.04, R^2=0.40, respectively).
Conclusion: We find that higher SE, specifically by decreased WASO, is associated with higher levels of two Bifidobacterium species, breve and saguini. Bifidobacterium, commonly found in probiotics, may improve subjective sleep quality. Therefore, Bifidobacterium breve and saguini may be specific targets for improving human sleep.

EFFECT OF TRANSCUTANEOUS VAGAL NERVE STIMULATION (TVNS) ADMINISTERED DURING THE FIRST AND SECOND HALF OF THE NIGHT ON SLEEP STAGE ARCHITECTURE

Anjana Subramoniam[1], Lauren Whitehurst[1]
[1] University of Kentucky

Introduction: Transcutaneous vagal nerve stimulation (tVNS) may improve sleep quality. The impact of tVNS on specific sleep stages—NREM and REM sleep—remains under-explored. Here, in two separate in-lab, within-subject, sham-controlled, and counterbalanced studies, we investigated the impact of tVNS on NREM and REM sleep when administered during the first and second half of the night.
Methods: The Institutional Review Board of the University of Kentucky approved all experimental procedures. Seventy-five healthy adults aged between 18-40 (Mage = 23) completed two nights of polysomnographic recordings with either active tVNS or sham stimulation – counterbalanced across visits. For study 1 (N=50), stimulation was administered at the onset of NREM Stage 2/N2 sleep and continued for the first 90 minutes of the 8-hour sleep period. For Study 2 (N = 25), stimulation began in the third quartile of sleep (~3:30 AM) and continued for 90 minutes. Data collection for Study 2 is still ongoing. Repeated measures ANOVAs were conducted, with sleep stages as dependent outcomes, stimulation (sham vs active) as within-subject factors, and study as a between-subject factor.
Results: Active stimulation induced a 2% reduction in N3 sleep (p=0.02), which corresponded to an 8-minute difference in N3 sleep between active and sham stimulation conditions (p=0.05). N3 sleep reductions were more pronounced for the active vs. sham visits in Study 2 (p=0.03) compared to Study 1 (p=0.61). In Study 2, active stimulation during the second part of the night resulted in 5.5% less N3 sleep (p=0.03) and a reduction of nearly 16 minutes (p=.0.02). No other reliable statistical effects were detected.
Conclusion: tVNS applied during the second half of the night can cause N3 sleep reductions. The planned statistical analyses for this project include determining the impact of stimulation on 1) stage-specific oscillatory components and 2) temporal coordination of NREM spindles and slow oscillations.

THE INTERACTION OF HISTORICAL PSYCHEDELIC USE AND TIME SPENT IN BED ON SLEEP ARCHITECTURE

April Roper[1], Chase Stratton[1], Janeese Brownlow[1]
[1] Delaware State University

Introduction: Approximately 12% of U.S. adults report having used any type of psychedelic at some point in their lives, making it one of the most widely used recreational drugs. There exists a need for a better understanding of the consequences of use on objective sleep habits. Research on psychedelics effects on sleep indicate increased sleep duration, increased REM latency, and decreased slow wave sleep occur during and immediately after the post trip phase. The purpose of this study was to determine if psychedelic use was predictive of changes in total sleep time, time spent in each stage of sleep (REM, light, deep), and time spent awake and to describe sleep differences in users vs. non-users
Methods: Data were obtained from the All of Us research data base (n=21,076; Mean age = 56.55; Female= 67.3%). Participants indicated any type of psychedelic use and were grouped into users and non-users based on a yes (n=7,799) or no (n=13,277) response. Objective sleep measures included Fitbit sleep data to include number of minutes spent in each stage of sleep (REM, light, deep), minutes spent awake, and total sleep time in minutes.
Results: Data suggest that the interaction of history of psychedelic use and minutes spent in bed (users = 406 minutes; non-users = 405 minutes) predicts more time spent asleep (t=230.119, p<.001), less time spent in REM sleep (t=-256.7, p<.001), greater time spent in light sleep (t=176.58, p<.001), and increased time spent in deep sleep (t=177.71, p<.001). Additionally, small group differences were found between users and non-users on measures of total sleep time in minutes (t=19.075, p<.001; ES= 0.0087), minutes spent in REM sleep (t=-8.725, p<.001; ES= -0.0052), minutes spent in light sleep (t=30.262, p<.001; ES= 0.018), minutes spent in deep sleep (t=-33.701, p<.001; ES= -0.020) and minutes spent awake (t=7.43, p<.001; ES= 0.0044), however effect sizes were negligible.
Conclusion: Data suggests changes in objective sleep habits occur in those who use psychedelic drugs regardless of time of use. Differences in sleep staging among users was negligible.

DAY-TO-DAY RELATIONSHIPS BETWEEN ALCOHOL DRINKING AND ACTIGRAPHIC SLEEP PARAMETERS AMONG YOUNG ADULTS WHO REPORT HEAVY EPISODIC DRINKING

Nicholas Harris[1], Medha Kotti[2], Nina Oryshkewych[3], Daniel Buysse[4], Sarah Pedersen[3], Meredith Wallace[3], Brant Hasler[3]
[1] UPMC Children's Hospital of Pittsburgh/Western Psychiatry Hospital, [2] Western Psychiatric Hospital, [3] University of Pittsburgh, [4] University of Pittsburgh School of Medicine

Introduction: The impact of alcohol on sleep is complex and nuanced, often (but not always) showing initial sedation followed by later disruption alongside other more subtle changes, as demonstrated in both laboratory- and home-based studies. However, prior naturalistic work has relied on subjective measures, small samples, and/or participants with co-occurring sleep problems, limiting generalizability. Additionally, retrospective designs constrain fine-grained, day-to-day analyses. Here, we leverage real-time ecological momentary assessment (EMA) reports of alcohol consumption to examine its relationship with actigraphically measured daily sleep among young adults reporting episodic heavy drinking.
Methods: Young adults aged 21-30 years (N=88) engaging in episodic heavy drinking (4+/5+ drinks/night at least weekly) participated in a two-phase, 9-day EMA study assessing naturalistic alcohol consumption and sleep. Sleep was objectively measured by wrist-worn actigraphy devices. Linear mixed-effects models assessed day-to-day associations between drinks consumed and actigraphic sleep outcomes, adjusting for covariates including

age, sex assigned at birth, race, ethnicity, and baseline alcohol use.
Results: On average, participants consumed 5.3±0.2 drinks per drinking day (over 3.0±0.1 drinking days) in each 9-day EMA period. Higher alcohol consumption was associated with shorter sleep onset latency (SOL; square-root-transformed; ß_std=-0.13, p< 0.001) and later midsleep time (log-transformed; ß_std=0.12, p< 0.001). No significant associations were found with total sleep time (TST), sleep efficiency (SE), wake after sleep onset (WASO), sleep fragmentation, or snooze time (all p>0.05). All relationships were unaffected by sex assigned at birth.
Conclusion: This study extends prior work investigating day-to-day alcohol–sleep relationships, replicating alcohol-related delayed sleep timing and revealing shorter SOL with increased drink consumption, a finding previously only seen in laboratory-based studies. We did not observe expected disruptions in sleep continuity, which may reflect the complexity of within-night changes (initial sedation followed by later disruption) that our methods do not fully capture. Furthermore, delayed sleep timing may exacerbate alcohol-related morbidity if morning obligations constrain adequate rest. Future analyses will incorporate within-night changes, next day functioning, and consider co-use of cannabis, nicotine, caffeine, and other substances to fully elucidate these complex interactions.

SELF-SUPERVISED LEARNING AS A TOOL TO GRANULARLY PARSE THE STRUCTURE OF SLEEP

William Coon[1], Mattson Ogg[1]
[1] Johns Hopkins University Applied Physics Laboratory

Introduction: An individual's sleep architecture encodes an abundance of health information. At the same time, there is likely a wealth of information embedded within polysomnographic (PSG) signals that is not captured by these high-level summaries. To explore this, we pretrained two models: one foundation model (FM) using self-supervised learning (SSL) techniques to directly internalize sleep structure from different combinations of PSG signals, and a second model using traditional supervised learning techniques to perform 5-class sleep staging on the same data. We then performed a series of fine-tuning experiments to probe what health information could be extracted from these two models. We also tested different subsets of PSG signals. Finally, we examined the latent space encoded by the SSL FM and compared its structure, and individuals' trajectories through that state space, to the 5-state space of traditional sleep staging.
Methods: We pretrained two models (one FM, one supervised) on >10k overnight PSG recordings from 7 publicly available datasets, using full PSG, EEG-only, or EEG+EOG inputs. Each model was fine-tuned to predict cognition, mood, and health scores from the APPLES dataset, with Bayesian information criteria used to identify optimal state space mappings in the FMs' final embeddings.
Results: Using all PSG signals, SSL and supervised FMs performed similarly for WASI [r=.34, r=.31], POMS [r=-.02, r=-.07], SWMT [r=.14 vs..10], ESS [r=.09, r=.06], and sex classification [acc=79%, acc=78%]. The SSL FM significantly outperformed on HAMD [r=.20, r=.13], AHI [r=.68 vs..28], and BMI [r=.59 vs..46]. Across all nights, 25 states optimally described the SSL FM state space (optimal BIC), while 8 states best captured individual nights.
Conclusion: Our fine-tuning experiments suggest that the SSL FM not only retained information captured by the supervised model trained on 5-class sleep staging, but also captured more information on multiple dimensions (ex. cognition, general health, sleep health). Examining the structure of sleep internalized by the SSL FM revealed that, on any given night, an individual was most likely to traverse approximately 8 distinct physiological states rather than the 5 we expected. This hints at the possibility of more granular classification schemas for sleep.

PRECLINICAL MODEL TO TEST POTENTIAL THERAPEUTICS TO PREVENT PHENOCONVERSION OF REM SLEEP BEHAVIOR DISORDER TO PARKINSON'S DISEASE AFTER NEUROTRAUMA

Laura Dovek[1], Carolyn Tinsley[2], Kayla McDaniel[2], Lorenzo Nungaray[2], Katelyn Gutowsky[2], Ryan Leriche[2], Peyton Wickham[2], Charles Meshul[2], Vivek Unni[3], Jonathan Elliott[2], Miranda Lim[3]
[1] Oregon Health & Sciences University, [2] VA Portland Health Care System, [3] Oregon Health & Science University

Introduction: Neurotrauma, including traumatic brain injury (TBI) and/or post-traumatic stress disorder (PTSD), often results in persistent sleep disturbances and impaired neurological function. This includes an increased frequency for REM sleep behavior disorder (RBD), characterized by abnormally elevated skeletal muscle activity (i.e., REM sleep without atonia; RSWA) and overt dream enactment during REM sleep. RBD is one of the earliest clinical manifestations of synucleinopathies, including Parkinson's Disease (PD). Furthermore, the presence of both TBI and PTSD are significantly associated with an increased risk for later development of PD and related synucleinopathies. As the synucleinopathies progress, patients can develop parkinsonism characterized by impaired movements as well as a decline in cognition. No disease-modifying therapeutics to date have been successful in synucleinopathies. To address this gap, we designed a preclinical pipeline for evaluation of potential therapeutics using a mouse model of neurotrauma, RBD, and PD.
Methods: Mice underwent Single Prolonged Stress (SPS) and Controlled Cortical Impact (CCI) to model PTSD and TBI, respectively. Gait, sleep, and cognitive outcomes were evaluated across various cohorts and at three different time points following neurotrauma (2, 4 and 12 weeks) to assess the specific time course of biomarkers and disease progression.
Results: Our results reveal that SPS and CCI results in increased rates of EMG activity during REM sleep, consistent with RBD. REM sleep EMG activity was positively correlated with cognitive impairments as early as 2 weeks following neurotrauma. Furthermore, neurotrauma mice revealed gait and cognitive impairments consistent with a PD phenotype.
Conclusion: In summary, our preclinical pipeline for evaluation of potential therapeutics holds face validity to the

human conditions of neurotrauma, RBD, and PD, resulting in time-dependent changes in gait and cognition. This model will be useful for future studies investigating potential therapeutic interventions, to attenuate synuclein pathogenesis associated with neurotrauma.

INCREASED INTRA-THALAMIC AND THALAMO-CORTICAL FUNCTIONAL CONNECTIONS DURING REM SLEEP: A TWO-NIGHT EEG-FMRI STUDY

Nils Yang[1], Dante Picchioni[1], Jacco de Zwart[1], Peter van Gelderen[1], Jeff Duyn[1]
[1] National Institutes of Health

Introduction: Rapid Eye Movement (REM) sleep, characterized by vivid dreaming and muscle atonia, raises fascinating questions about how such immersive experiences occur without external sensory input. Building on a previous REM-locked fMRI study that reported concurrent activation in multiple sensory cortices and the thalamus following eye movements during REM sleep, we hypothesized that during REM sleep, particularly during vivid dreaming, thalamic subnetworks are simultaneously functionally connected to multiple sensory cortices, a pattern not observed during wakefulness.
Methods: We analyzed data from a state-of-the-art whole-night EEG-fMRI concurrent recording dataset collected in our lab. Twelve non-sleep-deprived participants completed two 8-hour whole-night experiments, reaching all sleep stages during the second night. The first night served as an adaptation night, so only data from the second night were included in the analysis. Dynamic functional connection (FC) was calculated using a sliding window approach (step size: 1 TR or 3 seconds, window length: 30 TR) for sleep episodes with a consistent sleep score lasting at least three epochs (90 seconds). The Seitzman 300-region brain atlas was used to define 14 cortical networks and five thalamic subnetworks.
Results: Supporting our hypothesis, REM sleep engages all five thalamic subnetworks to simultaneously connect with multiple sensory-related cortical networks, including visual, motor, auditory, and action-planning networks—connections that are not observed during wakefulness. For example, the thalamus-default mode subnetwork was not functionally connected to auditory and motor networks during wakefulness but established FCs with these networks during REM sleep. We found significantly higher intra-thalamic FC during REM sleep compared to wakefulness across all 11 participants with high-quality fMRI data during REM. Building on these findings, we further hypothesized that increased thalamus-related FC is specifically associated with phasic REM compared to tonic REM, as phasic REM is often linked to vivid dreaming. Using the Hidden Markov Model from our previous study to differentiate phasic and tonic REM states, we found that phasic REM exhibited significantly greater intra-thalamic and thalamo-cortical FCs than tonic REM.
Conclusion: These results suggest that thalamic subnetworks act collectively during phasic REM to distribute internally generated sensory information to sensory-related cortical networks, potentially underlying the neural mechanisms of vivid dreaming.

MORPHOLOGICAL DIFFERENCES IN SLEEP SPINDLES CHALLENGE CROSS-SPECIES COMPARISONS

Sophie Brennan-Saremsky[1], Ritchie Brown[2], Fumi Katsuki[3], Michael Prerau[1]
[1] Brigham and Women's Hospital, [2] VA Boston Healthcare System, [3] VA Boston Healthcare System/Harvard Medical School

Introduction: Sleep spindles have been identified as key potential biomarkers for numerous neurological and psychiatric disorders, as well as for aging. Thus, studying spindle mechanisms provides valuable insight into the pathophysiology of various disorders. In addition to translatable human studies, animal model studies can more directly and invasively probe and systematically alter spindle networks. While various animal studies have shown distinct morphological differences between human and animal model spindles, the assumptions underlying approaches to spindle detection remain relatively unchanged across species. To assess the generalizability and validity of existing studies, it is crucial to understand how spindle activity and detection assumptions vary across species. Recently, new quantitative approaches have identified broader classes of human spindle-like transient events that are more informative than traditionally detected spindles. In this study, we extend these approaches to non-human primates and rodents to characterize spindle activity across species, validate signal processing assumptions, and understand implications for past and future studies.
Methods: We analyzed sleep period electroencephalogram (EEG) recordings of central electrodes from adult humans and mature macaques (N=5), rats (N=8), and mice (N=4) from baseline or control data from previously published studies. For each record, we used the DYNAM-O toolbox to quantify and visualize the dynamics of thousands of spindle-like transient oscillatory peaks across the night.
Results: We find distinct morphological and distributional differences in spindles between species. With increasingly lower-order species, spindles become markedly less morphologically distinct and more variable in their dynamics. In humans, fast spindles (12-16Hz) appear on spectrograms as distinct events in clear, narrow-band frequency. In primates, spindles are less separable and fall within a wider frequency range (8-14Hz). In rats, we observe one diffuse mode (6-16Hz) with little separability in events. Mice (6-20Hz) possess the least separable events and the most variability.
Conclusion: Given the diffuse morphology and high variability of spindles in animal models relative to humans, traditionally detected spindles likely represent a very small fraction of the underlying activity. Thus, caution should be taken, particularly in rodents, in the interpretation of studies focusing on individual spindles and their relationship to other waveforms.

NREM SLEEP SIGNATURES OF BIPOLAR DISORDER

Naihua Gong[1], Nataliia Kozhemiako[2], Shaun Purcell[3], Jen Pan[4]
[1] Brigham and Women's Hospital, [2] Brigham & Women's Hospital, [3] Brigham and Women's Hospital, Harvard Medical School, [4]

Stanley Center for Psychiatric Research at Broad Institute of MIT and Harvard

Introduction: Sleep disruptions are ubiquitous across psychiatric diseases, and abnormalities in specific aspects of sleep architecture can provide insight into neurocircuit dysfunction. Prior work demonstrated specific disruptions in NREM sleep in schizophrenia that could reflect circuit-level disruptions. Bipolar disorder (BP) is a mood disorder characterized by episodes of mania and depression. Here, we expand our prior work to identify NREM biomarkers of BP, and determine whether they are shared with SCZ or disease-specific.
Methods: Overnight sleep polysomnography was performed with 64-channel high-density EEG at Wuxi Mental Health Center in Wuxi, China. Macroarchitecture measures as well as power spectral analysis, sleep spindle detection, connectivity measurements, and extraction of ultradian rhythm measures were performed with Luna, an open-source software for analyzing polysomnographic recordings.
Results: BP patients exhibited decreased N1 and sleep onset latency. Power spectral density analysis demonstrated decreased delta (0-4 Hz) and fast sigma frequency (13-15 Hz) band power in BP compared to controls, similar to what was observed in SCZ. Compared to controls, BP additionally exhibited increased power in the slow sigma frequency band (10-12 Hz) that was not present in SCZ. BP cases had increased duration of slow sleep spindles and decreased fast spindle density in both N2 and N3. Inter-channel connectivity as measured by the phase slope index was increased in BP in the 10-12 Hz range. Finally, we demonstrated distinctions in BP ultradian rhythm trajectories (i.e., changes in sleep architecture across the night) in spectral power across the night compared to controls in theta (4-8 Hz) and fast sigma frequency ranges.
Conclusion: We find distinct changes in BP NREM sleep that may reflect sleep-specific signatures of disease and neurocircuit changes. Specifically, increased power in the slow sigma frequency range in BP was reflected in increased duration of slow sleep spindles and inter-channel connectivity in this range. Specific measures of ultradian rhythms were additionally different in BP, suggesting abnormalities in sleep progression across the night. Together, our results suggest there are specific NREM sleep changes associated with BP. Ongoing work aims to utilize EEG-derived biomarkers to differentiate across psychiatric diseases, with a focus on BP and SCZ.

DETECTING CENTRAL SLEEP APNEA USING A MULTI-DIAGNOSTIC CHEST-WORN MONITOR

Rami Khayat[1], Kara Dupuy-McCauley[2], Behnam Molavi[3], Surina Sharma[4], Nancy Collop[5], Cathy Goldstein[6], Ilene Rosen[7]

[1] University of California Irvine, [2] Mayo Clinic, [3] Huxley Medical, Inc., [4] Emory University, [5] Emory University School of Medicine, [6] University of Michigan, [7] University of Pennsylvania

Introduction: Identifying central sleep apnea (CSA) during home sleep apnea testing is important to guide appropriate treatment for sleep-disordered breathing (SDB) and underlying cardiovascular conditions, including heart failure and atrial fibrillation. SANSA (Huxley Medical, Inc.) is a multi-diagnostic chest-worn monitor capable of detecting SDB, cardiac arrhythmias, and heart function. Using polysomnography (PSG) as a reference, we developed a machine learning (ML) method to classify respiratory events from this monitor as central or obstructive.

Methods: Data was analyzed from ninety-five subjects with suspected SDB who wore the chest monitor simultaneously with PSG overnight. To address known scoring heterogeneity of CSA, PSG records were scored for central apneas by two core laboratories (Core 1 and Core 2). Core 1 annotations from twenty-eight records were first used to train a random forest classifier to differentiate obstructive (N=680) and central events (N=388). The model used oximetry, respiratory effort, and snoring to classify events based on effort, duration, and other features. A five-fold cross validation was used to evaluate event-level performance. The model was then used to estimate subject-level CAI for all subjects and compared with Core 2 scores.

Results: Algorithm event-level sensitivity and specificity to detect central events was 72.7% and 81.0%. Subject-level CAI for all records between the chest monitor and Core 2 had a correlation coefficient of 0.90 and root mean squared error (RMSE) of 4.6 events/hour, versus 0.82 and 4.7 events/hour comparing Core 1 and Core 2. Sensitivity and specificity to detect CAI≥10 events/hour was 80.0% (4/5) and 98.9% (89/90), compared to 100% (3/3) and 98.9% (91/92) for CAI≥15.

Conclusion: An ML algorithm to differentiate obstructive and central events collected from the chest-worn monitor demonstrated favorable event-level performance and comparable CAI agreement to that between two PSG core laboratories. Home-based CSA detection alongside cardiac monitoring could identify high risk patients for expedited therapy, cardiology referral, or follow-up PSG. These results motivate further validation in a larger cohort as well as investigation of outcomes related to time to evaluation and management.

Introduction: Apnea-hypopnea index (AHI) considers only the rate of sleep apnea events, providing an incomplete view of sleep apnea and its adverse health outcomes. In contrast, this study considers temporal interactions among events from different organ systems. We analyzed novel temporal relationships between sleep apnea (from the respiratory system) and arousal (from the brain), thereby generalizing the concept of respiratory effort-related arousal (RERA).

Methods: We studied 3,502 participants in the Sleep Heart Health Study (SHHS) Visit 1. The temporal relationships between apnea and arousal were characterized using peri-event time histograms (PETHs) of arousals time-aligned to the end of sleep apnea. Binomial tests were utilized to identify the significant time regions compared with the null distribution independent of sleep apnea. Cox regression models adjusted for common covariates were used to test the associations between the characteristics of the PETHs vs. CVD mortality and all-cause mortality. We also compared the hazard ratio (HR) to that of AHI and hypoxic burden.

Results: For participants with arousals significantly enriched at certain time regions of apnea, the peak time of the PETH curves (i.e., time from the end of apnea to the following most arousal-intense time point) showed associations with both all-cause and CVD mortality. In females, the adjusted HRs per one-second increase in peak time were 1.04 [95% CI: 1.01–1.08, p=0.013] for all-cause mortality and 1.06 [1.01–1.12, p=0.019] for CVD mortality, which were more significant than those of AHI for all-cause mortality [HR=1.00 (1.00-1.01), p=0.373] and CVD mortality [HR=1.00 (0.99-1.01), p=0.991], and those of hypoxic burden (log-transformed and standardized) for all-cause mortality [HR=1.05 (0.94-1.18), p=0.344], and CVD mortality [HR = 0.97 (0.80-1.19), p=0.797]. Similar patterns were observed in males, with stronger associations than those for conventional indices.

Conclusion: These preliminary results suggest that, at the event level, temporal relationships between sleep apneas and arousals are important predictors for all-cause and CVD mortality. Future studies will extend the study-population to larger-scale sleep cohorts and incorporate additional sleep microstructure events, forming a network of multiple organ systems dynamically interacting with each other during sleep.

LEVERAGING LARGE LANGUAGE MODELS TO DEVELOP NATURAL LANGUAGE PROCESSING CODE FOR EXTRACTING SLEEP STUDY DATA

Nathanael Hwang[1], Dennis Hwang[2], Kendra Becker[1], Matthew Gratton[3], Jessica Jara[1], Joseph Kim[1], Matthew Klimper[1], Diego Mazzotti[3], Anupamjeet Sekhon[1], Jiaxiao Shi[1], Rosa Woodrum[1], Rui Yan[1], M. Brandon Westover[4]

[1] Kaiser Permanente, [2] Kaiser Permanente Southern California, [3] University of Kansas Medical Center, [4] Beth Israel Deaconess Medical Center

Introduction: Research involving big data depends on structured data, but most patient information exists in unstructured formats like clinical notes. Traditional natural language processing (NLP) methods take substantial development time and must be tailored to specific tasks, while Large Language Models (LLMs) often perform well "off the shelf" but face privacy and cost barriers. We developed two novel hybrid approaches leveraging LLMs to generate NLP regex code and tested their performance in extracting apnea-hypopnea index (AHI) and Epworth Sleepiness Scale (ESS) values.
Methods: Sleep study reports (2008–2023) from Kaiser Permanente Southern California were exported in a format that included MRN, CPT code (95800, 95806, 95810), and free-text narratives. Manually de-identified "sample" reports were used to develop three NLP regex algorithms for extracting AHI and ESS: 1) "Targeted" LLM algorithm--free-text segments containing AHI or ESS were pre-selected and used to instruct the LLM (ChatGPT-4o, OpenAI) to develop regex code in Python; 2) "General" LLM algorithm--entire sleep study "sample" reports were input into the LLM without pre-selecting segments, with instructions to generate regex code; 3) "Traditional" algorithm--regex code was manually programmed. These algorithms extracted AHI and ESS from a test dataset of 427 reports; accuracy was compared to manually confirmed ground truth values for AHI and ESS. Performance for both LLM algorithms was compared to the Traditional algorithm (Fisher's Exact Test.)
Results: Both LLM("Targeted" and "General") algorithms perfectly extracted MRN and Procedure Dates, while "Traditional" algorithm produced 34 errors (1 missed, 33 incorrect extractions). "Targeted" and "General" also outperformed "Traditional" algorithm in extracting AHI and ESS (AHI: 99.1% and 98.6% vs. 94.1% accuracy; both $p< 0.001$. ESS: 100% and 97.7% vs. 88.5% accuracy; both $p< 0.001$.) Not all 427 reports contained AHI or ESS values; among the 119 reports with AHI and the 87 reports with ESS, "Targeted" and "General" again demonstrated superior accuracy versus "Traditional" (AHI: 96.6% and 95.0% vs. 79.8%; both $p< 0.001$. ESS: 100% and 97.7% vs. 88.5%; $p=0.002$ and 0.03).
Conclusion: LLM-generated NLP algorithms demonstrated superior accuracy compared to a traditional approach. This scalable method can potentially support multi-center large-scale research, enabling advanced epidemiologic exploration of sleep disorder outcomes.

CLOSING THE GENDER GAP IN SLEEP APNEA DIAGNOSIS: AI-ENHANCED HOME SLEEP TESTING

Þóra Sigmarsdóttir[1], Vaka Valsdóttir[1], Sigurdur Jonsson[1], Ernir Erlingsson[2], Kristófer Montazeri[1], Eysteinn Finnsson[1], Daniel Wilcox[1], Guðný Árnadóttir[1], Hildigunnur Katrínardóttir[1], Megan McPhee[1], Rósa Hugósdóttir[1], Snorri Helgason[1], Heidi Riney[3], Jón Ágústsson[2]
[1] Nox Research, Nox Medical ehf., [2] Nox Research, Nox Medical ehf, [3] Nox Health

Introduction: Home sleep testing (HST) is the primary method for diagnosing sleep apnea. However, traditional HST cannot measure sleep stages and arousals, leading to the systematic underdiagnosis of patients who predominantly experience hypopneas that terminate in arousals. This issue disproportionately affects women. In this study, we present the validation of an AI algorithm, DeepRESP, which uses respiratory inductance plethysmography (RIP) signals to score sleep and arousals from a conventional HST.
Methods: The algorithm was validated using 814 clinical PSG sleep recordings from females. These recordings were manually scored using EEG, EOG, and EMG to determine sleep stages and arousals. The same recordings were automatically scored as if they were HST recordings, omitting any ExG signals, using two methods. Standard HST scoring was used as a reference, where respiratory events and desaturations are scored without considering sleep and arousal scoring, resulting in an REI value. The test method was the described algorithm, which used RIP signals to score sleep and arousals, along with respiratory events and desaturations, resulting in an AHI value. The results from these two methods were compared to manual scoring. Sensitivity, specificity, and accuracy were calculated when classifying the sleep recordings from women as having an REI/AHI value of 5 or 15 and above.
Results: The test method demonstrated sensitivity, specificity, and accuracy of 83.1%, 77.6%, and 82.6%, respectively, for classifying AHI ≥ 5. In comparison, the reference method showed 62.2%, 73.7%, and 63.3% for the same threshold. For AHI ≥ 15, the test method had sensitivity, specificity, and accuracy of 62.9%, 95.4%, and 78.4%, while the reference method achieved 35.9%, 93.8%, and 63.5%. Notably, the test method correctly classified 121 (23%) more sleep recordings as having AHI ≥ 15 compared to the reference method.
Conclusion: Females are more likely than males to have sleep apnea characterized by hypopneas that terminate in arousals. Consequently, they often receive inconclusive results from HST and require follow-up tests, which may make them less likely to continue seeking medical assistance for sleep apnea. By incorporating respiratory-based sleep and arousal scoring, females are more likely to receive conclusive HST results, thereby shortening their path to treatment.

DEEP NEURAL NETWORK USING SLEEP ELECTROCARDIOGRAPHY TO PREDICT FUTURE RISK OF ATRIAL FIBRILLATION

Younghoon Kwon[1], Leah Matthew[1], Shekhar Singh[2], Oguz Akbilgic[2]
[1] University of Washington, [2] Wake Forest University School of Medicine

Introduction: Sleep period may offer a unique opportunity for cardiovascular monitoring. Distinct modulations of the sympathetic and parasympathetic control of cardiac dynamics in sleep can be reflected in the electrocardiography (ECG). Sleep disordered breathing (SDB) has been linked to the risk of atrial fibrillation (AF). We investigated whether deep neural network model of sleep ECG is predictive of an incident AF risk and how it compares with a simple statistical model using commonly used

SDB metric alone, established cardiovascular risk factor alone or demographic factors alone.
Methods: We included participants of the Sleep Heart Health Study (SHHS) cohort without a known history of AF at the time of sleep study. We developed a convolutional neural network (CNN) model using a single lead ECG from polysomnography as an input and incident AF events as an outcome. We estimated the prediction of incident AF by the ECG-based CNN model and compared it with a conventional statistical model using SDB metrics alone, hypertension history alone, or age alone, which is the most potent AF risk factor. Data were split into 70% training, 10% validation, and 20% holdout testing.
Results: The dataset included 2,887 participants (86% white, 45% men, and mean age (SD) of 62.7 (±11.2) years old). Over the mean follow up of 5.3 years with incident AF rate of 11.5%. The final ECG-CNN model yielded an area under the curve (AUC) score of 0.72 on the hold out test set. However, the AUC was progressively higher when ECGs from deeper sleep stages were used (Wake: 0.68, N1: 0.71, N2: 0.73, N3: 0.78, rapid eye movement: 0.71). Conventional statistical models using SDB metrics alone yielded lower prediction (AUC for apnea hypopnea index: 0.57, obstructive apnea index: 0.59, central apnea index: 0.55). A conventional statistical model using hypertension history alone and age alone yielded AUC of 0.65 and 0.86, respectively.
Conclusion: ECG-based CNN model using a single lead ECG alone during sleep can predict AF risk with moderate accuracy, outperforming the conventional statistical model using SDB metrics alone. Notably, the performance of the prediction model was higher when a deeper sleep stage ECG was used.

SHELL SHOCKED: EVIDENCE OF SLEEP-LIKE STATES IN NON-NEURAL SYSTEMS SPARKS A REEVALUATION OF SLEEP-EEG RELIABILITY

Matthew Reid[1], Michael Smith[2], Lynn Nakad[3]
[1] Johns Hopkins School of Medicine, [2] University of Gothenburg, [3] Johns Hopkins University

Introduction: Despite widespread anecdotal reports of its efficacy in humans, the effects of pink noise on sleep states in non-neural systems are poorly understood. This study aimed to evaluate the impact of pink noise stimulation on sleep architecture and oscillations in a decentralized nervous system model using wireless sleep-electroencephalography (EEG) technology.
Methods: Participants (12 deceased Maryland Blue Crabs; Callinectes sapidus) were randomly assigned to either a pink-noise, or control condition. Sleep was monitored from 23:00 to 08:00 using a wireless EEG system (SleepProfiler) with electrodes affixed to the cephalothorax (shell). To limit confounding from residual neural tissue, all subjects were pre-processed by immersion in a 100°C bath for 20 minutes. Subjects were positioned in sound-attenuated, adjacent rooms in the sleep laboratory. Two automated sleep-stage classifiers (YASA; SleepProfiler) were employed to compare sleep-architecture between conditions.
Results: Curiously, both the control and pink noise conditions demonstrated clear evidence of sleep. The pink-noise condition demonstrated significantly higher sleep efficiency than the control condition, as well as greater REM, SWS and reduced N2. Both the YASA and SleepProfiler autoscore-algorithms further identified Slow-Oscillations and spindle-like oscillations, purportedly indicative of sleep-states. Ultimately, post-hoc dissection resolved the observed phenomena to be attributable to environmental noise and algorithmic misclassification, rather than neural phenomena, as the crabs were, indisputably, deceased. Our findings serve as a whimsical yet cogent reminder of the perils of overreliance on autoscore algorithms in sleep-EEG research, particularly when dealing with complex recording environments and populations, which may be more prone to artifact.
Conclusion: This experiment aims to spark critical discussions about reproducibility, and the broader implications of methodological missteps in sleep-assessment technology. As sleep research grows increasingly dependent on automated procedures, it is important to think critically about the hazards they present. Given the ever-growing presence of such algorithms, and the degrees of blind adherence to their output, more work is required to ensure fidelity in isolating true neural signal from the spurious or artifactual. Although these crabs may never truly sleep, their unwitting sacrifice offers a timely reminder of the importance of skepticism and rigorous validation in the evaluation of automated sleep-technologies.

AI-DRIVEN MAPPING OF UPPER AIRWAY OBSTRUCTIONS USING A PASSIVE SLEEP SONAR

Onur Kilic[1], Meagan Pitcher[1], Brittain Cross[1], Tariq Syed[2], Omar Ahmed[2], Masayoshi Takashima[2]
[1] Bairitone Health, [2] Houston Methodist Hospital

Introduction: Obstructive sleep apnea (OSA) is characterized by recurrent airway collapse, with obstruction sites varying by sleep stage, position, and respiratory effort. Precise identification of these obstructions is essential for guiding personalized therapies, including nerve stimulators, surgeries, or oral appliances. Drug-Induced Sleep Endoscopy (DISE) is the current standard but is invasive, costly, and limited to sedated conditions. Advances in artificial intelligence (AI) and machine learning (ML) offer a path toward scalable, non-invasive techniques. Here, we introduce a "passive sleep sonar" approach, an ML-driven method that uses transfer function analysis of tissue-borne vibrations to map upper airway obstructions during natural sleep.
Methods: This passive sleep sonar system records tissue-borne vibrations via three synchronized contact microphones placed on the patient's face. The signals are processed to derive relative transfer functions (RTFs), which reflect how changes in upper airway anatomy alter sound propagation. Initially, the ML model was trained on 60 speech samples (10 consonants per sample) selected for their well-defined airflow obstruction sites. These training data established a baseline for localizing obstruction patterns. The model was then adapted using transfer learning with data from six OSA patients undergoing DISE. Each patient provided the same speech samples before sedation, allowing calibration to individual anatomy and bridging the gap between speech- and sleep-based vibration profiles.
Results: The passive sleep sonar system demonstrated promising agreement with DISE findings. Across six prediction categories, including obstruction configuration for the velum and obstruction degrees for the velum, oropharynx, tongue base, and

epiglottis, the method achieved a Cohen's Kappa of 0.53, indicating moderate agreement. Its 84% concordance with DISE is comparable to the 87% inter-rater reliability reported for DISE itself. These results suggest that this non-invasive, AI-enhanced approach can identify multi-level obstructions and provide clinically meaningful anatomical insight.
Conclusion: By integrating ML-based transfer function analysis with a passive sleep sonar concept, we present a viable alternative to DISE for mapping upper airway obstructions in OSA patients. This non-invasive method enables assessment during natural sleep, offering a scalable tool for personalizing treatment and monitoring therapy outcomes. Ongoing work seeks to validate and refine this approach for broader clinical application.

DEVELOPMENT AND EVALUATION OF EXCLUSIVELY ECG-BASED DEEP LEARNING MODEL FOR SLEEP STAGING

Younghoon Kwon[1], Leah Matthew[1], Edward Kim[1], Taekyung Ha[2]
[1] University of Washington, [2] HoneyNaps Co., Ltd.

Introduction: Sleep staging is an essential component of sleep evaluation but requires polysomnography (PSG). The technical complexity and high cost associated with PSG limit its application beyond in-lab setting. On the other hand, the accuracy of sleep staging by existing and emerging sleep wearable technologies based on body movement detection and pulse rate analysis is variable and modest. Electrocardiograms (ECG) measures the electrical activity of the heart and is the most commonly used clinical grade tool to detect cardiac arrhythmia. ECG contains electrophysiological properties beyond interbeat intervals, which may be sleep state dependent. Thus, we hypothesized that machine learning analysis of ECG would enable sleep staging.
Methods: We developed a Temporal Convolutional Networks (TCNs), designed for analyzing time series data by capturing complex temporal patterns. When time-series data is given as input, the convolutional network (CNN) processes the sample features along the timeline. A dilated causal convolution with dilation factors d = 1; 2; 4 and filter size k = 3 was used. In each 270-second single lead ECG from PSG, we extracted the timings of R peaks and other ECG morphological features. Each deep neural network contained a feed-forward CNN that learned features pertaining to each epoch, and a TCN to learn temporal patterns among consecutive epochs. The model was trained in clinical PSGs (n=3972) and was validated in another set of PSG against the reference manually scored sleep stages.
Results: The validation cohort consisted of 30 subjects (mean age 44.6± 11 years old, female 43%). The ECG alone TCN model yielded the following accuracy for sleep staging: Wake 81.5%, REM 85.9%, N1 77.4%, N2 82.2%, N3 83%, and intra-class correlation of total sleep time was 0.97.
Conclusion: Deep learning of single lead ECG alone yielded excellent accuracy in sleep staging. Our findings provide the potential for deriving sleep information from ECG-based cardiac rhythm monitoring widely used in clinical practice. Furthermore, unveiling sleep state and stage specific distribution of cardiac arrhythmia events may provide useful insights into the interplay of sleep/circadian rhythm with arrhythmogenesis.

DREAMGPT: VALIDATION OF CHATGPT AS A TOOL FOR EMOTION ANALYSIS IN DREAM REPORTS

Garrett Baber[1], Nancy Hamilton[1], Matthew Gratton[1]
[1] University of Kansas

Introduction: Dream reports provide unique insights into emotional processing during sleep. While self-reports are the gold standard for assessing dream affect, natural language processing (NLP) tools like ChatGPT may offer scalable alternatives. This study evaluated ChatGPT's ability to estimate positive and negative affect from dream reports, comparing its performance against self-reported ratings.
Methods: A total of 136 participants provided one dream report each. Participants rated their positive and negative dream affect on a 0–10 scale. ChatGPT 3.5 Turbo was accessed via the OpenAI API using Python, where each dream report was analyzed and rated on identical scales. The model's outputs were programmatically appended to a CSV file for further analysis. Agreement between ChatGPT and self-reports was assessed using intra-class correlation coefficients (ICC3k) for consistency, mean absolute error (MAE) for deviation, and Bland-Altman plots for visual inspection of agreement.
Results: For positive affect ratings, ChatGPT demonstrated excellent agreement with self-reports (ICC3k = 0.844, 95% CI [0.781, 0.889], p <.001), with an MAE of 1.778. Negative affect ratings similarly showed excellent agreement (ICC3k = 0.857, 95% CI [0.799, 0.898], p <.001), with an MAE of 1.681. Bland-Altman plots for both affective dimensions indicated no systematic bias and acceptable limits of agreement upon visual inspection.
Conclusion: ChatGPT demonstrated strong agreement with self-reported dream affect ratings, supporting its potential as a scalable tool for analyzing emotional content in dream reports. These findings suggest that large language models can provide valid and reliable estimates of dream affect, which may advance sleep and affective science.

YASA AUTOMATED SLEEP STAGING PERFORMANCE IN SLEEP RESTRICTION CONTEXT

Zhiyi Chen[1], Natalya Pruett[1], Michael Scullin[1]
[1] Baylor University

Introduction: Traditionally, manual sleep stage scoring is conducted by at least one experienced technician, a process that is laborious and time-consuming. In contrast, automated sleep staging tools such as Yet Another Spindle Algorithm (YASA), leverage machine learning to extract features of sleep stages from large datasets, thereby reducing human effort and time costs. The current study compared YASA's automated sleep stage prediction to manual sleep staging in the context of an experimental sleep restriction protocol.
Methods: Seventy-five adults (mean age = 19.95 years, 55% female) participated in up to seven nights of laboratory-based polysomnography recording. The study involved one adaptation night, followed by three nights of normal sleep (9 hours time in bed) and three nights of restricted sleep (5.5 hours time in bed) in

counterbalanced order. Manual sleep staging was performed by a registered polysomnographic technician (>10 years experience) using TWin software. Sleep data were exported and processed using Python 3.12, MNE 1.8.0, and YASA 0.6.5; automated sleep staging was based on C4-A1, LOC-A2, and chin EMG.
Results: There was 82.88% overall agreement between YASA scoring and human manual scoring on 483 valid sleep nights. The highest agreement was observed for stage wake (93.34%), whereas N1 showed the lowest agreement (40.31%). Agreement for the other stages were moderate to good: N2 = 84.75%, N3 = 86.86%, and REM = 78.38%. YASA-manual agreement was highest during the baseline night (84.59%). Agreement was higher during normal sleep nights (83.65%) than sleep restriction nights (81.50%) ($\eta 2$=.082, $F(1,202)$=18.054, p<.001), particularly for N1 ($\eta 2$=.183, $F(1,202)$=45.131, p<.001), N2 ($\eta 2$=.054, $F(1,202)$=11.596, p<.001), and REM ($\eta 2$=.187, $F(1,202)$=46.312, p<.001; N3: p=.321); agreement for stage wake was higher during sleep restriction nights than normal sleep nights ($\eta 2$=.436, $F(1,202)$=156.28, p<.001).
Conclusion: YASA exhibited overall agreement with manual scoring. However, caution is needed when interpreting the results for N1, as well as in interpreting N1, N2, and REM on nights in which sleep duration is reduced to approximately five hours.

THE HYPNO-PC: UNCOVERING SLEEP DYNAMICS THROUGH UNSUPERVISED LEARNING

miriam Guendelman[1], *Oren Shriki*[1]
[1] Ben Gurion University of the Negev

Introduction: Traditional sleep research primarily depends on visually scored stages based on electrophysiological signals. This manual approach is time-consuming and subject to subjective biases, implicitly assuming that visually defined categories accurately represent the underlying biological processes. Recent advancements, however, have shown that complex brain activity can be effectively represented in low-dimensional spaces, offering valuable insights into the temporal organization and structure of physiological states. This raises the question of how such data-driven representations relate to and potentially refine our conventional understanding of sleep structure.
Methods: In this study, we developed a data-driven framework for identifying inherent brain states directly from continuous physiological signals. We applied Principal Component Analysis (PCA) to features extracted from overnight high-density EEG, EOG, EMG, and ECG recordings at 30-second and 4-second resolutions. After identifying the principal axes of variation, we employed a Gaussian Hidden Markov Model (GHMM) on the PCA-transformed data to delineate discrete states. To align the hidden states with the sleep labels, we used a minimally supervised approach—less than 0.5% of labeled data—and a cross-subject approach.
Results: The first principal component (PC1), termed the "Hypno-PC," showed a strong correspondence with the manually scored hypnogram, indicating that the largest source of variance in the spectral profile aligns closely with standard sleep staging. Furthermore, the GHMM-derived states achieved an agreement with conventional sleep labels at a level comparable to the reported inter-rater agreement. These results suggest that the states identified through purely data-driven means closely mirror established concepts of sleep architecture. Preliminary results on data from individuals with epilepsy indicate that this low-dimensional representation may reflect not only physiological but also pathological processes.
Conclusion: By integrating PCA and GHMM, we present a reproducible, scalable, and flexible methodology that complements traditional sleep scoring methods. While demonstrated with sleep and spectral features, this approach is adaptable to other continuous physiological signals. The findings support the notion that unsupervised, data-driven methods can uncover intrinsic patterns and structures in both normal and abnormal states. This perspective promotes a more nuanced understanding of the inherent organization of physiological and pathological state dynamics.

FEDERATED MACHINE LEARNING TO PREDICT SELF-REPORTED SLEEPINESS FROM HEART RATE AND PHOTOPLETHYSMOGRAPHY

Zachary Kissel[1], *Christopher Stuetzle*[1], *Melissa St Hilaire*[1]
[1] Merrimack College

Introduction: Federated learning (FL) is a machine learning framework that eliminates the need to aggregate data to a centralized location by distributing model training over a federation of independent parties (i.e., peers). The goal of FL is to maintain the privacy and security of sensitive information while enabling predictive models to be developed from larger, more diverse pools of data. Here we tested the ability of FL to predict self-reported sleepiness from heart rate and photoplethysmography data distributed over multiple peers.
Methods: We used a public dataset from Kaggle to train and test models in our decentralized (i.e., peer-to-peer, P2P) FL sandbox, which was built in Java. The dataset included 4,890,260 records with four predictors (heart rate and three photoplethysmography channels measured from a smartwatch) labeled as either "alert", "somewhat sleepy", or "sleepy". We filtered data to include only the records labeled as "alert" (n=2,105,348) or "sleepy" (n=1,417,578), and normalized and binned the four predictors. We used an 80/20 random split stratified by class label to generate our global training and test sets. We then randomly split the global training set into four equally-sized federated peers. To evaluate FL performance, we compared the accuracy and F1-score of predictions from the model trained across the federated peers to a model trained on the global training set using a categorical Naive Bayes classifier.
Results: The global model had an accuracy=94.4% and F1-score=0.931. The FL model had the same overall accuracy and F1-score. The models were not biased towards a particular class label (true positive rate=92.7%, true negative rate=95.6%).
Conclusion: This work is a proof-of-concept that FL can be used to train predictive models from decentralized data without significant loss of model accuracy. Developing and implementing predictive models of self-reported sleepiness and other sleep-loss-related impairment in a privacy-preserving federated environment can improve safety outcomes across several operational settings, including among medical personnel, long-haul truck

drivers, airline pilots, and first responders, without compromising private information from these individuals or exposing individual liability.

SLEEP-DEEP-LEARNER LETS YOU TEACH GOOGLENET TO SLEEP-WAKE SCORE LIKE YOU

David Uygun[1], Fumi Katsuki[2], Radhika Basheer[3], Ritchie Brown[4]
[1] VABHS Harvard Medical School Dept of Psychiatry, [2] VA Boston Healthcare System/Harvard Medical School, [3] Harvard Medical School-VA BHS- Boston VA Res Inst., [4] VA Boston Healthcare System

Introduction: Sleep-wake scoring in vivo electrophysiologic signals is necessary in many basic and translational studies. Performing this manually is a burden and bottleneck. Thus, many attempts have been made to automate it. Recently, with increased access to machine learning (ML) technologies, a new wave of attempts is occurring. The overwhelmingly common strategy deployed involves leveraging large datasets to train completely novel, yet relatively simple, ML-models. However, evidence suggests this does little to help with a common problem that is ML-models can perform poorly with new or unfamiliar data. Instead, transfer-learning – re-training highly sophisticated ML models – is known to be flexible and dependable, robustly dealing with novel data. We demonstrate transfer-learning of GoogLeNet provides highly dependable sleep-wake scoring across several diverse mouse electrophysiologic datasets, and matches the scoring of the person who trained it. We term our freely-available code "Sleep-Deep-Learner".
Methods: Transfer-learning was used to retrain GoogLeNet – accessed first unmodified, from the pretrained deep-neural-nets available via MATLAB. High-level final layers were replaced to classify wavelet transforms of epochs as wakefulness, NREM sleep or REM sleep.
Results: We used F1 scores to test how closely Sleep-Deep-Learner mimics two independent expert scorers. We validated performance in wild-type EEG, EEG altered by the hypnotic agent zolpidem, LFP data, data from an Alzheimer's disease model and even sub-cortical data (hippocampus). We also reproduced findings of a CRISPR-based study previously completed with manual scoring. We ensure accurate fine-grain sleep architecture with hypnograms and bout analyses. Automated scores were very similar to either expert scorer regardless of dataset. We estimate this reduces labor burden of scoring to one twelfth.
Conclusion: We provide a transfer-learning based approach to automating sleep-wake scoring. This has the advantage that automated sleep-wake scores agree with those of the expert scorer using the application. This, unbiased, flexible approach of retraining before each scoring session means there is no dependence on familiarity with novel data to perform accurately.

COMPARISON OF MACHINE LEARNING MODELS FOR FMRI-BASED SLEEP STAGING

Gawon Cho[1], Dong Woo Hahm[2], Adam Mecca[1], Brienne Miner[1]
[1] Yale University, [2] University of Southern California

Introduction: Changes in arousal result in fMRI signal fluctuations. Identifying sleep stage inside the MRI scanner can facilitate the study of sleep-associated changes in blood oxygen-level dependent signals. As simultaneous electroencephalography [EEG] is often not feasible, developing machine-learning-based algorithms for fMRI-based sleep scoring is needed.
Methods: Participants included 11 university students, who provided multiple 15-minute-long simultaneous EEG-fMRI scans (TR=2.1 seconds). This study used the first two scans from each participant. During fMRI sessions, participants completed visual-motor tasks and were asked to sleep. Sleep stage was scored based on the AASM criteria using simultaneous EEG. Preprocessed fMRI timeseries data was extracted from each region of the Automated Anatomic Labeling [AAL] atlas. We used Fisher's z-transformed correlations between all possible pairs of 166 AAL regions (13,695 in total) as features in training five different machine learning models to predict EEG-based sleep stage for each epoch: regularized multinomial logit classification (RMLC), random forest, linear support vector model (lSVM), radial SVM (rSVM), and extreme gradient boosting (XGBoost). The first 15 minutes of fMRI data was used for model training, and model performance was tested on the latter 15 minutes.
Results: Proportions of N1, N2, and Wake were: 35, 13, and 52%. lSVM had the highest receiver operating characteristics-area under the curve [ROC-AUC] for correctly predicted sleep stages in the validation dataset (68.6%). In general, lSVM had high sensitivity to wakefulness and high specificity to N1 and N2 sleep (sensitivity, N1=0.40, N2=0.56, Wake=0.88; specificity, N1=0.84, N2=0.95, Wake=0.62). On the other hand, XGB had the lowest validation ROC-AUC (60.2%). XGB also showed high sensitivity to wakefulness and high specificity to N1 and N2 sleep (sensitivity, N1=0.22, N2=0, Wake=0.88; specificity, N1=0.90, N2=0.99, Wake=0.18).
Conclusion: Despite a modest sample size, we found that lSVM showed acceptable performance in sleep stage prediction. While more work in larger samples is needed, our findings suggest that machine learning models may be used to develop algorithms for fMRI-based sleep staging and guide examination of sleep-dependent processes using MRI, potentially without simultaneous EEG.

VALIDATING THE PERFORMANCE OF ARTIFICIAL INTELLIGENCE-BASED AUTOMATIC POLYSOMNOGRAPHY SCORING SYSTEM

Young Jun Lee[1], Tae Kyoung Ha[2], Hyun Jun Kim[3], Yong Min Kim[4], Ji Ho Choi[5]

[1] Honeynaps Co. ltd, [2] Honeynaps, [3] Ajou University, [4] Chungnam National University, [5] Soonchunhyang University

Introduction: Polysomnography, the gold standard for diagnosing obstructive sleep apnea and other sleep disorders, requires manual scoring by trained sleep technologists or physicians to analyze its comprehensive physiological data. However, manual scoring is cost-intensive, prone to inconsistencies among scorers, and often causes delays in diagnosis and treatment initiation, potentially compromising patient outcomes. The purpose of this study is to validate the performance of artificial intelligence (AI)-based automatic polysomnography scoring system (SOMNUM) developed to overcome these limitations using a cross-sectional experimental design on a representative subjects of data recorded in the 3 sleep laboratories of university hospitals.
Methods: This study utilized a retrospective dataset of 400 polysomnography (PSG) recordings from three university hospitals: Soonchunhyang University Bucheon Hospital, Ajou University Hospital, and Chungnam University Hospital. Forty-eight full-night PSG studies were randomly selected from the dataset for the performance evaluation of SOMNUM, an AI-based automatic sleep scoring system. The performance of SOMNUM was assessed by comparing its scoring results with those of three human experts for four scoring functions: sleep staging, arousals, respiratory events, and periodic limb movements (PLMs). Performance metrics included positive percentage agreement, negative percentage agreement, and overall percentage agreement, calculated using R statistical software with relevant packages.
Results: The agreement rates between the scorer and AI-based automatic polysomnography scoring systems for each sleep stage (W, N1, N2, N3, R) were 89.96%, 77.93%, 91.13%, 84.04%, and 84.62%, respectively. The agreement rate between the scorer and AI for arousal was 82.5%, the agreement rate for respiratory events was 92.3%, and the agreement rate for periodic limb movements was 94.1%.
Conclusion: This study has demonstrated that SOMNUM is a valuable solution for automatic polysomnography interpretation. These results suggest that AI-based automated polysomnography scoring systems have the potential to advance the field of sleep medicine by improving diagnostic efficiency, reducing costs, and enhancing the consistency of sleep disorder diagnoses.

GETTING MORE FROM LESS: TRANSFER LEARNING TO IMPROVE SLEEP STAGE DECODER ACCURACY IN SLEEP WEARABLES

Diego Luna[1], Lauren Diaz[1], Mattson Ogg[1], William Coon[1]
[1] Johns Hopkins University Applied Physics Laboratory

Introduction: Consumer wearable devices such as smart-rings and smart-watches are increasingly being used to measure sleep in large-scale and longitudinal studies, but lack the fidelity to support accurate classification on the traditional 5-class sleep stage taxonomy (Wake, N1, N2, N3, REM). A way to extract higher fidelity sleep stage information from wearable sensors would be of tremendous value. Advances in artificial intelligence, particularly self-supervised learning (SSL) and transfer learning, now allow neural network-based decoders to be pre-trained on vast sleep EEG datasets and fine-tuned with minimal study-specific data. We hypothesized that models pretrained on sleep EEG could improve sleep stage decoding from peripheral wearable signals (such as pulse and respiration) by transferring their learned internalization of sleep structure, despite operating on fundamentally different physiological inputs.
Methods: We first pre-trained a transformer-based neural network model to classify sleep stage (Wake, N1, N2, N3, and REM) from EEG+EOG signals (C3 or C4, EOG) on a corpus of 10,897 overnights from 9,013 individuals compiled from 7 publicly available datasets hosted on the National Sleep Research Resource (sleepdata.org). We then fine-tuned this model by tasking it with 5-stage sleep classification using respiration and pulse time series from the MESA dataset (sleepdata.org) as inputs. For comparison, we also trained a from-scratch version of the model (without pretraining).
Results: The baseline from-scratch model showed overall accuracy on par with other reports at 68% [W: 81%, N1: 41%, N2: 59%, N3: 40%, R: 54%]. When pretrained on EEG+EOG instead of initialized with random weight values, however, the model's overall performance jumped to 77% [W: 87%, N1: 89%, N2: 64%, N3: 37%, R: 69%].
Conclusion: We observed a remarkable nearly 10 percentage point improvement in 5-class sleep stage decoding when applying transfer learning compared to training the same model from scratch. This improvement was associated with better overall accuracy on Wake, N1, and REM. These findings show that fine-tuning peripheral/wearable models pretrained on sleep EEG data significantly improves the accuracy of sleep stage classification from peripheral signals like respiration and pulse. This approach could enhance the reliability and utility of consumer wearables for sleep research.

AN OPEN SOURCE AND FREELY AVAILABLE SLEEP STAGE CLASSIFIER OPTIMIZED FOR FOREHEAD EEG DEVICES

William Coon[1], Matthew Reid[2], Mattson Ogg[1], Niloy Sikder[3], Paul Zerr[3], Matthias Krauledat[4], Martin Dresler[3]
[1] Johns Hopkins University Applied Physics Laboratory, [2] Johns Hopkins School of Medicine, [3] Donders Institute for Brain, Cognition and Behavior, [4] Rhine-Waal University of Applied Scie nces

Introduction: Forehead-mounted sleep EEG devices enable large-scale, real-world sleep monitoring but classifiers trained on traditional PSG underperform on them due to differences in electrode placement, referencing, poor sensor contact/movement, and unique signal noise characteristics. Therefore, specialized sleep-stage decoders optimized for the unique characteristics of signals recorded from frontopolar regions are needed. In response to these challenges, we trained a neural-network-based

sleep stage classifier on a dataset of forehead EEG recordings that extends the traditional 5-class decoder taxonomy (N1, N2, N3, REM, WAKE) to include an additional "artifact" class, and compared its performance against the traditional 5-class solution.

Methods: A transformer based neural network classifier with a convolutional front end (for feature extraction from 30-s epochs) and a recurrent back end (for modeling sleep-stage dynamics over a 50-minute period) was compiled in Tensorflow and trained on 72 overnight recordings (from n=72 participants) of sleep from the Wearnize+ dataset (Sikder et al., in-prep). An additional 9 subjects' nights were held out as a test set. To label epochs obscured by artifact for the 6-class model, we implemented automated artifact detection contingent on statistical thresholds derived from signal characteristics (e.g., Hjorth complexity and mobility, max amplitude, mean/median amplitude, and signal variance) present in the training set, and verified post-hoc by a trained expert sleep scorer.

Results: The 5-class decoder converged on a best-performing accuracy of 81.2% [W: 72.5%, N1: 20.0%, N2: 86.5%, N3: 74.6%, R: 91.5%]. The 6-class decoder converged on a best-performing accuracy of 84.2% [W: 75.7%, N1: 75.0%, N2: 84.0%, N3: 85.5%, R: 89.1%, A: 69.3%].

Conclusion: Although both models attained accuracies on par with modern decoders trained to operate on traditional polysomnographic recordings using standard 10-20 system electrode placements, the 6-class model demonstrated slightly more balanced performance across all sleep stages and higher overall accuracy. The comparatively lower accuracy of the Artifact class, possibly due to heterogeneity in artifact types, suggests significant room for improvement on artifact handling. To facilitate future research and algorithmic development using forehead EEG, trained models will be publicly released to the community and made freely available.

ARTIFICIAL INTELLIGENCE-DERIVED SLEEP AGE FROM HEARTBEAT AND RESPIRATORY SIGNALS

Jiong Chen[1], Yi Fang[2], Xuesong Chen[3], Song Gao[1], Shenda Hong[4], Yue Leng[5]

[1] Institute of Medical Technology, Peking University Health Science Center, [2] University of California, San Francisco, [3] Five Seasons Medical LLC, [4] National Institute of Health Data Science, Peking University, [5] Department of Psychiatry and Behavioral Sciences, University of California, San Francisco

Introduction: Sleep is intricately linked to overall health, with previous studies demonstrating that AI-derived sleep age from polysomnography (PSG) data can reliably predict critical health outcomes such as mortality. This study seeks to investigate the potential of using easily recorded heartbeat and respiratory patterns during sleep—without the need for complex medical monitoring—as a means to predict health outcomes with comparable effectiveness.

Methods: We used PSG data from the National Sleep Research Resource and Human Sleep Project, focusing on heartbeat and respiratory signals to predict age, sex, and BMI. A transformer-based model was pretrained on 31,927 nights of PSG data to capture physiological patterns via EEG prediction, then fine-tuned using a 9:1 training-validation split. The Sleep Heart Health Study (SHHS) dataset, excluded from pretraining and fine-tuning, served as an external test set. Cox proportional hazards models analyzed the sleep age results from SHHS, assessing associations with all-cause and cardiovascular mortality.

Results: In the SHHS dataset, the mean absolute error (MAE) for predicted age was 5.9 years. In age-adjusted model, each 10-year increase in sleep age was significantly associated with higher mortality risk. For all-cause mortality, the hazard ratio (HR) was 1.40 (95% CI: 1.24–1.57, $p < 0.01$), which attenuated slightly to 1.37 (95% CI: 1.22–1.55, $p < 0.01$) after further adjustment for gender, race, BMI, and smoking. For cardiovascular mortality, each 10-year increase in Sleep age yielded an HR of 1.75 (95% CI: 1.37–2.23, $p < 0.01$), decreasing to 1.66 (95% CI: 1.30–2.11, $p < 0.01$) with additional demographic and lifestyle adjustments. These findings demonstrate a robust association between sleep age and mortality risk, particularly for cardiovascular outcomes.

Conclusion: AI-derived sleep age strongly predicts mortality risk, particularly cardiovascular mortality. These findings align with prior studies using full PSG data and underscore the potential of leveraging heartbeat and respiratory signals in home-based settings for personalized health assessment and risk stratification.

COMBINING WEARABLES WITH NEARABLES: USING A MULTI-DEVICE MACHINE LEARNING APPROACH IMPROVES SLEEP TRACKING AT HOME

Elle Wernette[1], Olivia Walch[2], Christopher Drake[1], Philip Cheng[3]

[1] Henry Ford Health System, [2] Arcascope, [3] Henry Ford Health + Michigan State University Health Sciences

Introduction: Wearables have expanded access to sleep data, but proprietary algorithms are inaccurate and legacy actigraphy algorithms are outdated. Furthermore, legacy algorithms were trained on nighttime sleep, and only identify 50.3% of daytime sleep. This presents a unique challenge for night shift workers, who are prone to disordered sleep and need access to improved sleep measurement tools. We recently found machine learning (ML) algorithms using raw accelerometer and heart rate data from an Apple Watch could improve nighttime sleep tracking achieving up to 90% accuracy. However, wearables alone still do not capture environmental inputs needed to accurately classify sleep versus wake (e.g. sleep onset latency). We conducted a proof-of-concept study assessing the feasibility of a ML approach that combines inputs from nearables and a wearable to improve daytime sleep tracking at home.

Methods: Researchers installed a curated sleep tracking system in participants' bedrooms to continuously monitor activity and the environment for 30 days. This included a presence sensor to detect presence in bed, a luxmeter to measure changes in ambient light, and a wireless light switch with smart light bulbs to track when lights were turned on and off. We also collected raw heart rate and accelerometer data from Apple Watches and raw accelerometer data from iPhones. Participants completed daily sleep diaries and a user experience questionnaire.

Results: Preliminary results show our multi-device ML approach increases detection of daytime sleep by 43.4% in night shift workers. In nighttime sleepers, our ML approach achieves 93.7% sensitivity for sleep identification, while maintaining 97.2% specificity in wake classification. Participants report strong acceptance of the multi-device approach, with low perceived intrusiveness (1.0 of 10) and high willingness to continue use (8.8 of 10).
Conclusion: These findings support the feasibility of a multi-device ML approach for more accurate sleep tracking outside of the lab. We plan to expand this research to a larger sample of night shift workers to improve the precision of daytime sleep tracking, while assessing the sleep environment. Because our sleep tracking system contains smart technology, we ultimately aim to help inform personalized interventions to the bedroom environment to improve sleep outcomes.

ASSESSMENT OF ARTIFICIAL LIGHT EXPOSURE AND SLEEP PATTERNS IN LATE ADOLESCENTS BY USING AMBULATORY DRY EEG DEVICE

Manish Verma[1], Mayank Vashishtha[1], Vibha Gangwar[1], Rajani Bala Jasrotia[1]
[1] DrRMLIMS

Introduction: In addition to natural daylight, humans are exposed to a substantial amount of artificial light nowadays. This is often particularly the case within the evening hours, i.e. when the circadian system is most sensitive to light-induced phase delays. LED screens have repeatedly been suggested to interfere with sleep and therefore the physiological processes involved e.g., melatonin secretion. This study aims to investigate how using artificial light sources (modern electronic devices such as mobile, tablets, and LED lights) at bedtime affects healthy sleep patterns in late adolescent age group (16-25 yrs) participants.
Methods: This is an observational pilot study. Twenty healthy subjects aged 16 to 25 years were recruited and included in this study. All the subjects underwent one ambulatory home night monitoring with an EEG device (Dry EEG headband).
Results: There was significant correlation between duration of use of electronic device during bedtime and total sleep time and N1 stage of sleep with mean (SD) is 447.3 (64.7) min, 350.1 (27.1) min, and 262.7 (55) min and 44.8 (11), 32.5 (8.6), and 15.5 (6) ($P \leq 0.05$) for duration 0-1 hrs, 1-2 hrs and >2 hrs ($P \leq 0.05$) respectively. There was a significant correlation between use of mobile during bedtime with decreased TST, N1, N1% and N2 and NREM stage of sleep as compared to laptop users with mean (SD) values are 393.1 (62.4), 268.7 (55.9) ($P < 0.05$), 39.7 (7.9), 16 (6), 10.2 (1.3), 5.9 (1.7), 176.8 (26.7), 98.4 (30.3) and 303.6 (51.2), 199.8 (37.1) ($P < 0.05$) respectively.
Conclusion: The use of artificial light emitting sources such as mobile, laptop, and LED light in the hours leading up to bedtime is associated with shorter total sleep time, delayed sleep onset, and poorer sleep quality among youth. This study investigated the feasibility and acceptability of using the dry EEG-based headband, a sleep monitoring device, among adolescents. A high percentage of participants (80%) successfully met the one-night sleep recording requirement. The headband shows promise as a tool for screening, assessing, and monitoring sleep.

PREDICTING SLEEPINESS FROM VERBAL REACTION TIME DURING VERBAL COGNITIVE TESTING

Tue Te[1], Mary ReginaBoland[2], Sara Ghadimi[3], Joseph Dzierzewski[4], Cathy Alessi[5], Jennifer Martin[6], Arash Naeim[7], Constance Fung[8]
[1] University of California, Los Angeles, [2] 3. Department of Mathematics, Herbert W. Boyer School of Natural Sciences, Mathematics, and Computing, Alex G McKenna School of Business, Economics and Government, Saint Vincent College, [3] David Geffen School of Medicine at University of California, Los Angeles (UCLA), CA, USA, [4] National Sleep Foundation, [5] VA Geriatric, Research, Education and Clinical Center, VA Greater Los Angeles Healthcare System, [6] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System, [7] Department of Medicine, David Geffen School of Medicine at University of California, Los Angeles (UCLA); 2. Geriatric, Research, Education and Clinical Center, VA Greater Los Angeles, [8] Geriatric, Research, Education and Clinical Center, VA Greater Los Angeles

Introduction: Objective markers of sleepiness that can be collected passively, such as through voice data, can be helpful for detecting sleepiness in individuals with suspected sleep disorder and in situations in which sleepiness can pose health or occupational risk. We assessed verbal reaction time (VRT) as a vocalic marker of sleepiness in older adults with history of insomnia and Benzodiazepines receptor agonist (BZRA) use who were undergoing cognitive testing to determine whether VRT accurately reflected patient-perceived sleepiness.
Methods: Adults aged > 55 years without a diagnosis of dementia were recruited from within a BZRA deprescribing clinical trial (NCT03687086) into this ancillary study designed to test the feasibility of cognitive testing using out-of-office, self-directed mobile apps. Participants' working and episodic memory were assessed through recorded verbal responses to Verbal Paired Associates (VPA) tests, and patient reported sleepiness was assessed using ecological momentary assessments (EMA) of self-reported sleepiness (range: 1[not at all] to 4[more prominent]). Using a Generalized Additive Model (GAM), we examined the association between VRT during VPA testing and sleepiness, adjusting for sex, age, race, education, test parameters (difficulty, pass/fail status), caffeine intake, cognition, mood, and recent BZRA use (yes/no).
Results: 2230 audio samples from 19 patients were analyzed. VRT was operationalized as the time duration between recording start time and first epoch of speech. In the GAM model, longer (delayed) VRTs were positively associated with greater EMA sleepiness ($p=0.00151$). Our prediction model achieved 95% accuracy in classifying sleepiness levels after adjusting for other variables.
Conclusion: We found that longer VRTs are correlated with more self-reported sleepiness during cognitive testing. Voice data

have the potential be used as a marker of sleepiness in patients undergoing cognitive testing and in situations during which a method for capturing sleepiness that does not require patient input can inform care.

ESTIMATING CENTRAL CIRCADIAN PHASE WITH WRIST-WORN SPECTROPHOTOMETER IN AMBULATORY ENVIRONMENT

Boyu Zhang[1], Szymon Fedor[1], Robert Stickgold[2], Michael Freedman[3], Viswam Nathan[3], Varun Viswanath[3], Shadab Rahman[4], Jeanne Duffy[5], Charles Czeisler[4], Rosalind Picard[1]

[1] Massachusetts Institute of Technology, [2] Massachusetts Institute of Technology, [3] Samsung Research America, [4] Harvard Medical School, [5] Brigham & Women's Hospital, Harvard Medical School

Introduction: The central circadian pacemaker regulates essential physiological processes from cardiometabolism to mood and neurobehavioral performance. Accurate estimation of central circadian phase has broad implications for improving public health. Traditional laboratory-based methods are time- and resource-intensive. Advances in wearable technology, including wrist-worn spectrophotometers, enable continuous, non-invasive monitoring of light exposure with spectral information. This study evaluates the feasibility of using melanopic irradiance measured on the wrist to estimate central circadian phase in ambulatory settings.

Methods: We monitored healthy non-shift-worker adults (N=25, age: 18-54) wearing a wrist spectrophotometer continuously for two weeks while adhering to their habitual schedules. The devices recorded melanopic irradiance, photopic illuminance, rest-activity data, and off-wrist intervals concurrently. At the end of the two weeks, saliva samples were collected under dim-light conditions to assess dim-light melatonin onset (DLMO), serving as the gold-standard reference for central circadian phase. We evaluated the DLMO estimation performance of three van der Pol oscillator models using melanopic irradiance and photopic illuminance as inputs. Habitual sleep onset minus two hours was used as a baseline comparator.

Results: Melanopic irradiance-based estimation outperformed photopic illuminance- and habitual sleep onset-based estimations, achieving mean absolute errors of 40-43 minutes versus 50-52 minutes and 70 minutes, respectively ($p<.001$, Friedman test). Lin's concordance correlation coefficients for melanopic irradiance ranged from 0.94-0.95, significantly higher than 0.89-0.90 for photopic illuminance and 0.80 for habitual sleep onset ($p<.001$, Friedman test). Furthermore, 84% of participants had phase estimation within one hour of their saliva DLMO using melanopic irradiance, a 16% improvement over using photopic illuminance, and a 60% improvement over using habitual sleep onset.

Conclusion: This study demonstrates the superiority of melanopic irradiance-based methods for estimating central circadian phase in ambulatory environments. The estimation performance improvement of using melanopic irradiance is statistically significant but marginal, and its clinical impact requires further investigation. Future work should also test these methods among shift workers and patients with sleep and circadian rhythm disorders. Overall, the current results support incorporating spectral information, in addition to photopic illuminance and sleep timing, to improve the estimation of central circadian phase from wearables.

Support (if any): This research is sponsored by Samsung Research America.

SELF-SUPERVISED PRETRAINING FOR WRIST-WORN ACCELEROMETER DATA IMPROVES ACTIVITY AND SLEEP-WAKE DISCRIMINATION

Niels Lorenzen[1], Emmanuel Mignot[2], Andreas Brink-Kjær[1], Poul Jennum[3]

[1] Technical University of Denmark, [2] Stanford University, [3] Danish Center for Sleep Medicine/Rigshospitalet-Glostrup

Introduction: Wearable accelerometers are popular for monitoring activity and sleep habits in the general population. However, publicly available labeled datasets are often small and constrained to scripted behavior, with most remaining proprietary to wearable companies. This limits the adoption of deep learning methods in academia, as these require larger datasets. Here, we use self-supervised pretraining on a large unlabeled dataset to pretrain a model, which was then adapted to selected downstream tasks using smaller datasets.

Methods: A transformer masked autoencoder was pretrained using ~700,000 days of wrist-worn accelerometer data from 109,000 subjects in the UK Biobank. The model takes 50-minute windows of triaxial accelerometer data sampled at 30Hz as input. During pretraining, 60% of the input is masked in 10-second patches, and model was tasked with reconstructing the masked signal. For downstream tasks, the frozen encoder from the pretrained model was used to train a small classifier. For comparison, we also trained the full model from scratch. The model outputs a label for each 10-second patch. We used two labeled datasets: the Capture-24 dataset, with ~24 hours of accelerometry from 151 subjects with daytime activity labels of bicycling, walking, sitting-standing, vehicle, and mixed derived from body-cam recordings and sleep from a sleep diary, and a second dataset with 35 nighttime accelerometer recordings with concurrent polysomnography (PSG). For this study, the PSG-derived hypnogram was reduced to sleep-wake labels. An 80-20 subject-wise train-validation split was used for both tasks.

Results: In the Capture-24 validation set, we obtained balanced accuracies of 0.65 and 0.85, and Cohen's kappas of 0.69 and 0.81 for predicting activities and sleep, using the model trained from scratch and the pretrained model, respectively. For sleep-wake classification in the PSG cohort, balanced accuracies of 0.76 and 0.83, and Cohen's kappas of 0.52 and 0.59, were obtained. A high degree of overfitting was observed with the models trained from scratch.

Conclusion: Pretraining using masked reconstruction effectively improves activity recognition and sleep-wake distinction from wrist-worn accelerometer data on small, labeled datasets. This work highlights the value of foundation models for accelerometry in various downstream tasks. Future work will focus on predicting sleep stages and sleep disorders.

ESTIMATION OF SLEEP STAGES FROM ACCELEROMETER AND PHOTOPLETHYSMOGRAM DERIVED FEATURES ACQUIRED FROM A WRIST-WORN WEARABLE DEVICE

Conor Heneghan[1], Ryan Gillard[1], Michael Dixon[1], Marius Guerard[1], Logan Niehaus[1], Logan Schneider[1]
[1] Google

Introduction: Typical data derived from a wrist worn device include accelerometer and photoplethysmogram (PPG) sensor signals. These reflect underlying movement, heart rate, and vascular dynamics that contain sleep stage information which can be extracted using machine learning algorithms. However these signals can be difficult to upload to backend processing in raw format, due to memory and power constraints. We investigate the performance on sleep staging of reduced-size features derived from these signals, as such features can be more readily transmitted to a backend processing server.
Methods: A convolutional neural network (CNN) was proposed for application to two sets of features derived from PPG and accelerometer (i.e., movement and inter beat interval information). Output labels were mapped to four classes (wake, light sleep, deep sleep, and REM sleep) where light sleep is defined as Stages N1 and N2. The system was trained and evaluated on an internal set of records obtained under IRB approval from adults with corresponding scored PSG sleep stage labels. Data augmentation techniques were used to create additional training data. The system was then tested using a withheld data set of 76 records, containing subjects with sleep apnea (22 healthy patients, 25 with mild OSA, 29 with moderate and severe OSA). The overall performance of the system was evaluated by calculating two stage (wake versus sleep) and four stage accuracy and Cohen's kappa values (□).
Results: The overall performance for two-stage wake/sleep classification was an accuracy of 89% and □=.58. For four stage classification, the accuracy was 75% and □=0.57.
Conclusion: Compressed features derived from raw accelerometer and PPG signals contain a significant amount of information related to underlying sleep stages, and can be trained to produce hypnograms which approach the accuracy of human scorers. This may provide utility to backend sleep algorithms serving wearables or medical devices aiming at tracking sleep stages.

COGNITIVE PERFORMANCE CORRELATES WITH A METRIC OF ACTIGRAPHY-DERIVED SLEEP IN A WILDLAND FIRE-FIGHTER DISPATCH ENVIRONMENT

Abishek Kafle[1], Austin Vandegriffe[1], V. Samaranayake[2], Matthew Thimgan[2]
[1] Missouri S&T, [2] Missouri University of Science and Technologys

Introduction: Sleep deprivation is associated with cognitive decrements. These assessments are usually performed under controlled laboratory conditions. Yet, it is still unclear what sleep patterns are related to cognitive decrements in real-world situations, where sleep loss may be more subtle and inconsistent. We have applied a novel actigraphy analysis algorithm, called the Wasserstein Algorithm for Classifying Sleep and Wakefulness (WACSAW) to determine sleep and wakefulness during their work shifts. WACSAW also returns interim metrics that can be used to associate cognitive metrics with a mathematical reflection of the night's sleep.
Methods: Dispatch firefighters from the Mark Twain National Forest in Rolla, Missouri and the Cleveland National Forest in California (n=31) were monitored from 2 weeks to 3 months over 3 different data collection periods. Actigraphy was measured using a high-frequency collection device and sleep metrics were derived using WACSAW. In addition, we collected cognitive data using the 3 min tablet-based Psychomotor Vigilance Task (PVT) and Digit Symbol Substitution Task (DSST) at the beginning and end of each shift. As WACSAW determines sleep and wakefulness, the algorithm produces interim metrics that provide a distributional representation of the night's sleep. We used the mean and tail of the distribution to create a score for each for each sleep segment for the night. Scores within and between individuals were compared to cognitive performance metrics to determine significant relationships.
Results: WACSAW scores were significantly associated with cognitive performance metrics. Variables derived from the analysis of sleep and wakefulness segments over the night of interest correlated with subjective sleepiness from the Karolinska Sleepiness Scale (KSS) in both the morning and evening. Moreover, a different set of variables significantly correlated with reaction time performance on both the PVT and DSST in the morning and evening.
Conclusion: Preliminary data indicate that interim metrics produced by WACSAW add information about how an individual sleeps under natural conditions and what types of sleep pattern are related to optimal and cognitive decrements. As our understanding of how the distributions relate to cognitive performance that may act as biomarker to suggest when an individual may not be cognitively optimal in a real-world situation.

WACSAW ESTIMATES OF SLEEP CORRELATE WITH SLEEP IN A WILDLAND FIREFIGHTER POPULATION

Jennifer Harrell[1], Robin Verble[1], V. Samaranayake[2], Jesse Rhoades[3], Sarah Hercula[1], Bryan Held[1], Miranda Ragland[1], Jim Cornelius[4], Matthew Thimgan[2]
[1] Missouri S&T, [2] Missouri University of Science and Technology, [3] University of North Dakota, [4] US Forest Service

Introduction: Our understanding of sleep and the impacts of sleep deprivation in people will depend on understanding how real-life sleep patterns vary and how they relate to human health and cognitive performance. Actigraphy has emerged as a method that can potentially track sleep and wakefulness during normal life and activities. We have developed a novel algorithm to convert activity data into sleep and wakefulness, called the Wasserstein Algorithm for Classifying Sleep and Wakefulness (WACSAW). We assessed sleep duration from dispatchers with the Mark Twain National Forest firefighters. We aimed to evaluate whether WACSAW-derived sleep assignments correlated with reported sleep amounts and metrics.
Methods: Wildland dispatch firefighters were monitored for three data collection periods spread out over a year and a half. Each period lasted for 45-60 days. Each participant (n=31) wore

a MEMS actimeter for high-frequency data collection. Sleep and wakefulness durations were determined using WACSAW and compared to the estimate from survey data taken each morning and afternoon that they attended work by correlation analysis. In addition, participants answered additional survey questions regarding sleep, sleep quality and attitudes toward work administered through a Qualtrics portal and data were analyzed within and between subjects.
Results: We applied WACSAW to the data collected from long-term actimetry collected during normal activity patterns during fire season and a low workload portion of the fire season. We also determined that WACSAW assigned sleep duration significantly correlated with the subjective sleep estimates provided by participants in morning questionnaires about the previous night. We also were able to track those changes in self-declared sleep tracked with WACSAW determined sleep and sleep quality responses, as well.
Conclusion: WACSAW can be applied to data collected from the field and reflect the sleep that a person sleeps under normal life circumstances. Not only can WACSAW provide sleep duration information, but it will also provide interim metrics that can act as an alternative representation of the night that can be correlated to other outcomes to provide more interpretable information about an individual's sleep at night.

NOVEL CONTACTLESS MONITORING OF SLEEP PHYSIOLOGY

Darshan Panesar[1], Kang Lee[2]
[1] Ontario Institute of Studies in Education; University of Toronto, [2] Ontario Institute for Studies in Education; University of Toronto

Introduction: The unobtrusive measurement of sleep psychophysiology is fundamental to understanding how we sleep. Our current understanding of sleep psychophysiology is still limited, due to the fact that conventional measures are disruptive and impractical to measure natural sleep. This pilot study examined sleep using a novel method of completely contactless psychophysiological monitoring called infrared-video photoplethysmography (IR-VPPG) in comparison with the conventional gold standard sleep physiological (e.g., ECG) monitoring. We predicted that IR-VPPG measurements of psychophysiology would demonstrate high accuracy and strong agreement with conventional measures of psychophysiology specifically heart rate.
Methods: We assessed 9 adult participants (Mage = 25.8 +/-4.1) during a 90-minute nap in a controlled lab environment. We monitored participants during their nap using specialized infrared recording, ECG and respiratory monitoring. Using specialized video processing and machine learning models we extracted a wide range of psychophysiological activities including Heart Rate from the participants video data. We then contrasted this data to the conventional sleep physiological measures.
Results: Comparison of heart rate between methods demonstrated a high accuracy of 96.49%, a low error of 3.51%, and high agreement (Mdiff = -0.99 +/- 2.77) between our novel IRPPG and the conventional ECG monitoring.
Conclusion: This pilot study provides evidence for a revolutionary contactless method, IRPPG to accurately monitor sleep psychophysiology, notably heart rate naturalistically. We are currently testing large sample while expanding the use cases of IRVPPG providing additional physiological measurements and assessing longitudinal use cases. Ultimately we hope to provide this contactless tool to users, researchers, and clinicians to monitor and measure psychophysiological features during sleep. Potential applications of this technology in research and other fields are discussed.

OBSTRUCTIVE SLEEP APNEA DETECTION USING AN ARTIFICIAL INTELLIGENCE-ENABLED WIRELESS ABDOMEN-WORN SENSOR

Thi Hang Dang[1], Min-seong Choi[1], Sung-Nam Hwan[1], Hyung-Ki Min[1], Hye-Min Ahn[1], Franklin Bien[1]
[1] Ulsan National Institute of Science and Technology

Introduction: Obstructive sleep apnea (OSA) diagnosis traditionally relies on polysomnography (PSG), a costly, inconvenient procedure with limited accessibility due to sleep lab requirements and long waiting times. Artificial intelligence (AI)-enabled wireless wearable devices, such as smartwatches, rings, and chest-worn sensors, have emerged as promising alternatives to address these limitations. However, most wearable devices lack direct measurements of respiratory signals, body positions, and movements—key indicators for accurate OSA event detection. This study presents an automated deep learning-based algorithm for detecting moderate-to-severe OSA using data collected by a wireless abdomen-worn sensor (Soomirang device), which integrates a capacitive sensor for respiratory effort-like data measurement and a 3-axis accelerometer.
Methods: Two hundred participants with suspected OSA underwent overnight in-laboratory PSG alongside simultaneous data collection from an abdomen-worn sensor (sampling rate: 5 Hz). Sleep clinicians manually scored the PSG data, and OSA severity was classified based on the Apnea-Hypopnea Index (AHI), with moderate-to-severe OSA defined as AHI ≥ 15. Respiratory effort-like signals and 3-axis accelerometer data were synchronized with PSG data, preprocessed, and labelled as apnea or normal. The MLP-Mixer model was employed for automated apnea/normal classification due to its superior performance to the transformer and long short-term memory models. The classified apnea/normal outcomes were used to calculate the Respiratory Event Index (REI), with REI ≥ 15 indicating moderate-to-severe OSA. Seven recordings were excluded due to low-quality data, leaving 100 subjects for training and validation, and 93 for testing. Model performance was evaluated using sensitivity, specificity, accuracy, and F1-score. Agreement between AHI and REI was assessed through Pearson correlation and Bland-Altman analysis.
Results: The model achieved an accuracy of 89%, a sensitivity of 92.5%, a specificity of 81.8%, and an F1-score of 91.9% for detecting moderate-to-severe OSA. The correlation between AHI and REI was 0.92. Bland-Altman analysis indicated a mean difference between AHI and REI of 3, with limits of agreement averaging 34.
Conclusion: The deep learning-based algorithm using data from an abdomen-worn device achieved a strong performance in detecting moderated-to-severe OSA. These findings highlight the potential of this simple AI-enabled wireless wearable device as an accessible and effective tool for OSA screening.

PERFORMANCE OF AN AI ALGORITHM IN SCORING RESPIRATORY AND NON-RESPIRATORY AROUSALS USING RESPIRATORY INDUCTANCE PLETHYSMOGRAPHY SIGNALS

Eysteinn Finnsson[1], Ernir Erlingsson[2], Sigurdur Jonsson[1], Eydis Arnardottir[1], Kristófer Montazeri[1], Daniel Wilcox[1], Guðný Árnadóttir[1], Heidi Riney[3], Snorri Helgason[1], Jón Ágústsson[2]
[1] Nox Research, Nox Medical ehf., [2] Nox Research, Nox Medical ehf, [3] Nox Health

Introduction: Arousals are brief awakenings from sleep that can occur spontaneously or in response to stimuli, including respiratory disturbances, limb movements, or environmental factors. They impact sleep architecture and are key to diagnosing sleep disorders, including obstructive sleep apnea (OSA). Respiratory-related arousals are closely tied to breathing disturbances, making them potentially detectable in respiratory signals. However, many arousals arise independently of respiratory events. This study examines the performance of the Nox BodySleep 2.0 deep learning algorithm in detecting both respiratory-related and non-respiratory arousals across OSA severity levels using respiratory inductance plethysmography (RIP) signals.
Methods: The algorithm was validated using clinical sleep recordings from 1,299 adults with suspected sleep disorders. Participants were stratified by apnea-hypopnea index (AHI): AHI< 5, 5≤AHI< 15, 15≤AHI< 30, and AHI≥30. Agreement for the arousal index (ArI) was analyzed using Bland-Altman bias, limits of agreement (LoA), and intraclass correlation coefficients (ICC). To explore the algorithm's ability to detect non-respiratory arousals, the proportion of scored arousals preceded by respiratory events was assessed, identifying arousals linked to respiratory events versus those from non-respiratory causes.
Results: ArI agreement metrics across OSA severity groups were as follows: - AHI< 5 (n=118): Bias (LoA) = -3.63 (-23.85, 16.59) events/hour; ICC = 0.68 (95% CI: 0.57, 0.78). - 5≤AHI< 15 (n=416): Bias (LoA) = -3.08 (-22,.91, 16.75) events/hour; ICC = 0.67 (95% CI: 0.57, 0.76). - 15≤AHI< 30 (n=344): Bias (LoA) = -3.61 (-24.95, 17.73) events/hour; ICC = 0.54 (95% CI: 0.42, 0.66). - AHI≥30 (n=421): Bias = -6.46 (-44.26, 31.34) events/hour; ICC = 0.62 (95% CI: 0.53, 0.69). The proportion of respiratory-related arousals across sleep recordings had a 95% central range from 10% to 90%. This indicates that while the algorithm is highly effective at detecting respiratory-related arousals, it also identifies non-respiratory arousals, capturing variability across sleep recordings.
Conclusion: The algorithm demonstrates consistent performance in detecting arousals across OSA severity levels. Its ability to detect both respiratory-related and non-respiratory arousals broadens its utility for arousal assessment. This enhances the value of respiratory signal-based models in home sleep testing, addressing a broader spectrum of arousal-related disturbances.

Introduction: DeepRESP is a cloud-based software designed to overcome the limitations of type III sleep recordings, which traditionally lack the signals required to score sleep stages, arousals, and thus hypopneas ending in arousals. These limitations can lead to systematic underestimation of key metrics, such as the apnea-hypopnea index (AHI), increasing the risk of missed sleep apnea diagnoses, especially in patients with poor sleep efficiency or a high proportion of hypopneas ending in arousals. By utilizing respiratory inductance plethysmography (RIP) signals, the software enables estimation of sleep states (Wake, REM, and NREM), as well as scoring of arousals, desaturations, and respiratory events. This method aims to give more accurate AHI and central apnea-hypopnea index (CAHI) values from type III recordings that more closely reflect the values obtained from type I recordings.
Methods: The primary objective was to evaluate sleep apnea severity classification agreement for AHI and CAHI (using thresholds of AHI ≥ 5, CAHI ≥ 5, and AHI ≥ 15) between the software and manually scored type I and II recordings. Secondary objectives included assessing epoch-level agreement for sleep states (Wake, NREM, REM), respiratory events, and arousals. Positive, negative, and overall percentage agreement (PPA, NPA, OPA) values were calculated using confusion matrices, with 95% confidence intervals (CI) derived via bootstrapping.
Results: Our method demonstrated high overall agreement across critical metrics compared to manual scoring. For sleep apnea severity classifications, OPA was 90.2% for AHI ≥ 5, 96.8% for CAHI ≥ 5, and 83.6% for AHI ≥ 15. Sleep state classification also showed high agreement, with an OPA of 93.0% for Wake, 89.7% for NREM, and 95.7% for REM. The OPA for arousal scoring was 82.2%, and for respiratory event scoring was 85.1%.
Conclusion: The results highlight the ability of this method to estimate critical sleep parameters and clinical indices from type III recordings that show high agreement with what would have resulted from a type I recording. This method may enhance accuracy in sleep apnea diagnoses made using type III home sleep testing.

QUANTIFICATION OF HOW HYPOGLOSSAL NERVE STIMULATION AFFECTS UPPER AIRWAY NEUROMUSCULAR CONTROL USING COMPUTATIONAL AIRFLOW MODELING

Qiwei Xiao[1], Daniel Ignatiuk[1], Chamindu Gunatilaka[1], Keith McConnell[1], christine Schuler[1], Ann Romaker[2], Stacey Ishman[3], Robert Fleck[1], Raouf Amin[1], Alister Bates[1]

Introduction: Hypoglossal nerve stimulation (HGNS) has emerged as an alternative treatment for obstructive sleep apnea (OSA) patients in patients who cannot tolerate continuous positive airway pressure therapy. While clinical trials of HGNS have demonstrated reductions in the Apnea-Hypopnea Index (AHI), treatment efficacy remains variable. Current assessment methods

like polysomnography and drug-induced sleep endoscopy have limitations in quantifying the complex interaction between upper airway anatomy and airflow. Novel methods are needed to understand how HGNS treats OSA by counterbalancing inspiratory upper airway collapse.
Methods: Three male participants underwent four-dimensional computed tomography (4DCT) scanning during natural non-REM stage 2 (N2) sleep, both with and without HGNS. The 4DCT images had an in-plane resolution of 0.445x0.445 mm, slice thickness of 0.25 mm, and field of view of 210x210x160 mm, extending from the superior nasal cavity to the glottis. Simultaneous electroencephalographic monitoring and airflow measurements were recorded. Computational fluid dynamics (CFD) simulations were performed using anatomical data and airway dynamics from 4DCT imaging combined with measured airflow patterns. We assessed: 1) changes in airway cross-sectional area (CSA), 2) the mechanical work performed by muscles and air pressure in airway dilation and collapse, and 3) airway flow resistance.
Results: HGNS led to substantial increases in neuromuscular work for airway dilation (reaching 490%) and airway CSA (up to 300%). The most pronounced effects were observed in the oropharyngeal region, while responses in the nasopharynx and hypopharynx showed inter-subject variability. All participants exhibited increased minute ventilation (15-36%), alongside marked reductions in airway resistance (73-97%).
Conclusion: The quantitative parameters established in this study may provide insights into the variable therapeutic responses to HGNS in OSA treatment. These analytical methods hold potential for identifying non-responders, understanding treatment limitations, and optimizing device settings in clinical practice. This novel approach combines dynamic imaging with CFD simulation to reveal the underlying balance between neuromuscular control and air pressure, offering additional insights of HGNS efficacy in addition to traditional methods.

HYPOXIA AFFECTS GLYMPHATIC EFFICIENCY: ASSESSING GLYMPHATIC DISRUPTION IN OBSTRUCTIVE SLEEP APNEA USING NEAR-INFRARED SPECTROSCOPY

Sujasha Gupta[1], William Coon[2], Franck Amyot[3], Angeliki Pollatou[4], Angelica Lee[1], Elizabeth Metzger[5], John Werner[1]

Introduction: Near-Infrared Spectroscopy (NIRS) is a non-invasive imaging technique that monitors cerebral oxygenation and hemodynamic changes, making it valuable for studying sleep apnea. Obstructive sleep apnea (OSA), marked by recurrent airway obstruction during sleep, disrupts oxygen homeostasis and is linked to neurocognitive and cardiovascular dysfunction. This study explores a novel surrogate measure of glymphatic clearance in OSA subjects, focusing on sleep-related fluctuations in oxyhemoglobin (HbO) and water dynamics, using phase differences between water and HbO as proxies for flow changes.
Methods: NIRS measured changes in HbO and water concentrations during sleep in OSA participants (N=9) and healthy controls (N=18). Data were preprocessed to remove motion artifacts and bandpass filtered (0.01-0.2 Hz) to isolate low-frequency oscillations. The modified Beer-Lambert law was applied to extract phase and amplitude of HbO and water. Statistical analyses assessed differences in phase-amplitude coupling between HbO and water in OSA and controls. Phase shifts between water and HbO were used to indicate glymphatic clearance efficiency during sleep. Additionally, we also examined HbO and water concentrations in OSA subjects throughout sleep.
Results: Healthy individuals exhibited a distinct phase difference between HbO and water across sleep stages, absent in the OSA group. Post-hoc tests identified significant phase-amplitude coupling differences ($P < 0.05$) during N3 and Wake in healthy participants, while no differences were found in the OSA group. Moreover, HbO concentrations significantly decreased ($P < 0.01$) during REM sleep in OSA participants compared to other sleep stages, whereas healthy controls showed consistent HbO levels across sleep stages
Conclusion: Disrupted phase shifts between HbO and water in OSA subjects may indicate impaired glymphatic function, particularly during deep sleep, critical for waste clearance. Reduced HbO concentration during REM sleep for OSA subjects could imply severe oxygen desaturation and its potential systemic and neurological impacts.

FIRST STUDY TO ESTABLISH MINIMUM NIGHTS FOR RELIABLE SLEEP METRICS USING WEARABLES & AI IN INSOMNIA AND COMISA

Betty Hai Ka Young[1], Isaac Chak Yan Kwok[2], Chih-Wei Tsai[3], Lydia Leung[3], Cynthia Cheung[3], Amy Pui Ling Kwok[4]
[1] Department of Medicine and Rehabilitation, Tung Wah Eastern Hospital, Hong Kong, [2] Department of Clinical Psychology, Tung Wah Eastern Hospital, Hong Kong, [3] Belun Technology Company Limited, Hong Kong, [4] Department of Clinical Psychology, Pamela Youde Nethersole Eastern Hospital, Hong Kong

Introduction: Sleep metrics are essential for diagnosing insomnia and co-morbid insomnia with obstructive sleep apnea (COMISA). Single-night polysomnography (PSG) is insufficient for comprehensive evaluation, and actigraphy lacks the capability to measure apnea-hypopnea index (AHI). The optimal number of nights required for reliable assessment of insomnia and COMISA has not been established. This study aims to determine the minimum nights needed for accurate estimation of sleep metrics using the Belun Ring (BR).
Methods: Sixty-six participants with insomnia complaints (median age: 61 years; 61% female; 30% COMISA; median BMI: 23.6) were screened by a clinical psychologist and pulmonologist and underwent multiple-night BR testing. Insomnia was defined by an Insomnia Severity Index (ISI) ≥15 or a diagnosis per ICSD-3 criteria, and COMISA by insomnia criteria with PSG-AHI ≥15 events/h. Sleep metrics included total sleep time (TST), sleep efficiency (SE), REM sleep, wakefulness, sleep onset latency (SOL), wake after sleep onset (WASO), AHI4% and HRV time-domain metrics. Reference values were calculated as the average of all available nights. Concordance correlation coefficient (CCC) assessed agreement between 1-N night averages and reference values, with 1,000 bootstrapped simulations performed for each N-night scenario.

Results: Participants completed a median of 5 nights (IQR: 4–6; ≥100 minutes/night). Actual data showed key metrics reached a lower 95% CI CCC of ≥0.95 by the fourth night (e.g. AHI 4%, WASO, SOL, TST, SE, REM, RMSSD, SDNN, PNN50). Simulations confirmed that 4 nights were sufficient for good agreement (CCC ≥0.85) across most metrics, though SOL variability persisted beyond 6 nights. Sensitivity analysis, restricted to participants with ≥6 nights (N=27), yielded consistent results, with all metrics stabilising after 4 nights.
Conclusion: This study establishes that a minimum of four nights is required for reliable sleep metric assessment in insomnia and COMISA using the BR. This duration ensures accurate evaluation of HRV, OSA, and insomnia-related metrics. The BR offers significant advantages over PSG, actigraphy, and self-reports, delivering more precise diagnostics. The findings highlight how wearable-based sleep evaluations enhance the detection and management workflow for insomnia and underdiagnosed COMISA, especially in psychiatric settings.

USE OF NATURAL LANGUAGE PROCESSING TO IDENTIFY PATIENTS WITH DIAGNOSIS OF NARCOLEPSY

Malihehsadat Chavooshi[1], Amin Ramezani[1], Shahram Moghtader[1], Amir Sharafkhaneh[1], Javad Razjouyan[1]
[1] Baylor College of Medicine

Introduction: Narcolepsy is a rare chronic neurological disorder that requires precise identification for timely diagnosis and intervention. It is undocumented or underdiagnosed in the electronic health records due to lack of standardized template in reporting polysomnography. A validated natural language processing (NLP) pipeline can efficiently identify patients with narcolepsy from clinical notes.
Methods: We identified 240 with narcolepsy and 192 without narcolepsy with either diagnosis of sleep apnea or insomnia. Patients' diagnoses were determined using the International Classification of Diseases (ICD) 9th and 10th codes. We curated notes related to the index date of diagnosis. We extracted Concept Unique Identifiers (CUIs using MedCAT. CUIs, as integral components of the Unified Medical Language System (UMLS), serve as standardized identifiers for medical concepts across various terminologies and ontologies, enabling the integration and interoperability of diverse medical data sources. We performed a cascade of most important variables selection: prevalence ≥1%, p-value ≤0.1 in univariate analysis, and Random Forest (RF). We optimize the RF by constraining the complexity of forest, specifically by controlling tree depth and the number of leaves.
Results: Initially, 5,960 CUIs were extracted. The 1% prevalence reduced the set to 2,286 CUIs and the univariate analysis was yielded to 1,479 CUIs. The RF analysis reduced the feature set to 40 CUIs. We reached accuracy of 0.90 in discriminating narcoleptics notes from non-narcoleptic notes.
Conclusion: Our results confirmed the use of CUIs in identifying patients with probable narcolepsy diagnosis. Utilizing the proposed pipeline on a larger scale note as the initial filter for identifying patients with narcolepsy in the electronic health record can pave the road to enricher cohort definition. Additionally, it will reduce the possibility of under diagnosis.

SUPERIOR WAKE-PROMOTING AND ANTI-CATAPLEXY EFFECTS OF GUBOX, A DUAL OX1R/OX2R PEPTIDE AGONIST

Cathrine Fog-Tonnesen[1], Louise Dalbøge[1], Line Zachariassen[1], Stanislav Nagy[1], Anthony Murray[1], Lisbeth Elster[1], Jens Christian Nielsen[1], Morten Schlein[1], Morten Lundh[1], Michele Cavalera[1], Silas Rasmussen[1], Henrik Hansen[1]
[1] Gubra

Introduction: Narcolepsy type 1 (NT1) is associated with severe loss of orexin neurons and characterized by excessive daytime sleepiness and cataplexy. Because orexin receptor type 1 (Ox1R) and type 2 (Ox2R) have complimentary roles in the regulation of wakefulness, dual Ox1R/Ox2R agonists could have significant therapeutic potential in NT1. Here, we report the characterization of GUBox, a highly potent dual Ox1R/Ox2R peptide agonist, in a standard mouse model of NT1.
Methods: Chow-fed male orexin/ataxin-3 transgenic mice (25 weeks of age) were randomized into treatment groups according to baseline body weight (n=8 per group). Animals received a single subcutaneous dose of GUBox, danavorexton (TAK-925, small molecule selective Ox2R agonist), or vehicle. 24h automated real-time recording of activity/wakefulness and cataplectic attacks was performed using an in-house AI-based behavioural monitoring platform. Body weight and food intake was measured 24h after dosing. Tail blood samples were collected for drug exposure analysis in wild-type littermate controls (n=3 per time point)
Results: Orexin/ataxin-3 transgenic mice displayed a clear narcolepsy-cataplexy phenotype, characterized by severe inactivity and the presence of highly frequent cataplexy-like episodes during the dark (active) phase. Narcoleptic mice consistently showed increased body weight (≈10%) compared to controls. GUBox dose-dependently increased wakefulness time and decreased the number and duration of cataplectic episodes in narcoleptic mice. GUBox demonstrated prolonged benefits on both wakefulness time and cataplexy (up to 12h post-dosing) compared to danavorexton (up to 3h post-dosing). The differential efficacy profiles were supported by extended systemic exposure of GUBox compared to danavorexton. GUBox, but not danavorexton, promoted a moderate body weight loss (≈5%) without affecting food intake in narcoleptic mice.
Conclusion: We report superior wake-promoting and anti-cataplexy effects of GUBox, as compared to danavorexton, in narcoleptic mice. Only GUBox improved body weight in narcoleptic mice. Collectively, our findings support the therapeutic potential of GUBox for the treatment of NT1.

COMPARISON OF RADIOIMMUNOASSAY AND ENZYME-LINKED IMMUNOSORBENT ASSAY FOR HYPOCRETIN DETECTION IN CEREBROSPINAL FLUID IN NARCOLEPSY PATIENTS

Yimeng Zhang[1], Huimin Zhang[1], yannan yang[1], Shuqin Zhan[1]
[1] Xuanwu Hospital of Capital Medical University

Introduction: Narcolepsy is a neurological disorder characterized by excessive daytime sleepiness, cataplexy, sleep paralysis, and hypnagogic hallucinations, with its pathogenesis linked to hypocretin/orexin deficiency, a key regulator of the sleep-wake cycle. This study compares the diagnostic performance of radioimmunoassay (RIA) and enzyme-linked immunosorbent assay (ELISA) in measuring cerebrospinal fluid (CSF) hypocretin levels in narcolepsy patients.
Methods: Twenty-five narcolepsy patients were diagnosed based on clinical symptoms and electrophysiological tests. CSF hypocretin levels were measured using RIA and ELISA, with a hypocretin level of < 110 pg/ml considered diagnostic for narcolepsy type I according to established criteria.
Results: RIA showed a significantly lower average hypocretin level (9.77±5.65 pg/ml) compared to ELISA (134.56±57.21 pg/ml). Among the 25 patients, 17 were diagnosed with narcolepsy, all of whom had RIA measurements below 110 pg/ml, achieving 100% sensitivity. In contrast, only 4 patients had hypocretin levels < 110 pg/ml using ELISA, resulting in a sensitivity of 23.53%. RIA demonstrated higher sensitivity for detecting low hypocretin concentrations, while ELISA was more accurate for higher concentrations but less sensitive at lower levels.
Conclusion: RIA demonstrated superior sensitivity and accuracy in detecting low cerebrospinal fluid (CSF) hypocretin levels, which makes it highly valuable for the early diagnosis and ongoing monitoring of the disease. Despite these advantages, its complexity and associated costs pose significant limitations to its widespread clinical applicability. In contrast, ELISA, while less sensitive at very low concentrations, offers greater accessibility and is more suitable for large-scale screening programs. Clinicians are advised to select the most appropriate method based on their specific diagnostic requirements. This study not only contributes to the refinement of diagnostic strategies for narcolepsy but also offers valuable insights that could be applied to broader neurological disorders.

CONTINUOUS NOCTURNAL BLOOD PRESSURE MONITORING USING AN INTEGRATED PRESSURE SENSING MATTRESS PAD

Yu-Jen Cheng[1], Edward Kim[2], Andrew Ho[3], Arikta Trivedi[3], Zachary Leonen[3], Younghoon Kwon[2], Jae-Hyun Chung[1]
[1] Mechanical Engineering Department, University of Washington, [2] University of Washington, [3] Cardiovascular/Critical Care/Sleep Medicine, University of Washington

Introduction: Nonintrusive and continuous nocturnal blood pressure (NBP) measurement is crucial but challenging, as it relies on repeated cuff inflations that disrupt sleep. Intermittent BP measurements also miss episodic surges caused by events like sleep apnea. This study introduces an integrated pressure-sensing mattress designed to capture heartbeat signals from two major arterial sites. We suggest that the time difference between these sites represented pulse transit time (PTT), the time for an arterial pulse to travel between two locations, which is inversely correlated with BP and serves as the foundation for cuffless BP monitoring.
Methods: Subjects lay on a mattress pad embedded with a nanofabricated capacitive pressure sensor array that detected subtle heartbeat signals from the chest and leg (popliteal) areas in contact with the sensors. PTT, heart rate, low frequency of heart rate variability, pulse wave morphology, and anthropometric data were obtained. These variables were incorporated into a machine-learning algorithm to estimate BP. Standard BP was measured using an arm cuff and a finger cuff for continuous monitoring. BP perturbation maneuvers were performed to induce BP changes.
Results: A total of 30 subjects were enrolled, providing 140 BP data points for comparison with stationary BP readings. The results showed a high correlation (r = 0.9 for systolic BP [SBP] and r = 0.93 for diastolic BP [DBP]). The mean absolute error (MAE) ± standard deviation of absolute error (SDAE) was 3.1 ± 3.2 mmHg for SBP and 2.2 ± 2.6 mmHg for DBP. For continuous BP monitoring, 8 subjects were enrolled, showing a high correlation (r = 0.93 for SBP and r = 0.86 for DBP) and good MAE ± SDAE: 6.4 ± 5.2 mmHg for SBP and 5.1 ± 3.7 mmHg for DBP.
Conclusion: This novel capacitive pressure sensing array embedded in the mattress holds promise for unobtrusive, continuous tracking of NBP, causing less sleep disruption and effectively capturing episodic BP surges from sleep events.

TARGETED DREAM INCUBATION TO ENHANCE CREATIVITY AND REDUCE PTSD SYMPTOMS USING AN EEG-BASED SOFTWARE PLATFORM

Robert Stickgold[1], Alon Shamir[2], Noa Brande-Eilat[3], Karen Ginat[2], Miri Bar-Halpern[3], Shiran Simonov[2], Adam Horowitz[4], Laila Stedman[3], Shai Kalev[3], Alex Amirhov[3], Andres Arciniegas[3], Ben Kogan[3], Kuan-Jung Chiang[3], Eitan Kay[3], Dan Furman[3]
[1] Harvard Medical School, [2] Mazor Mental Health Center, [3] Arctop, Inc., [4] Massachusetts Institute of Technology

Introduction: Recent studies and anecdotal reports suggest that sleep-onset hypnagogic dreams can contain creative insights, in some cases leading to Nobel prizes. While such reports are rare, targeted dream incubation (TDI) can induce dreams on pre-selected topics, such as "a tree," in 70% of dream reports collected shortly after sleep onset, as well as a subsequent increase in creativity around the targeted topic. Here we describe a new software platform for TDI and plans to use this platform to increase creativity around topics of concern for individuals suffering from PTSD following the October 7th terrorist attacks in Israel.
Methods: "Arctop Sleep" is a mobile app built on an Application Programming Interface developed by Arctop, Inc. (Los Angeles, CA), that allows communication between the app and an EEG headband. Here we used the dry electrode 4-channel Muse EEG headband (interaXon, Toronto). The app connects wirelessly with the headband, identifies sleep onset in real time, plays a prerecorded message to awaken the user and, once awakened, prompts them to dictate a dream report. Users are then prompted to return to sleep while thinking about the chosen topic. The app produces serial awakening with the user awakening, reporting, and returning to sleep repeatedly, for a 90-minute time interval.
Results: Early pilot studies have demonstrated successful integration with the EEG headband, with accurate detection of sleep onset in real time (verified by clinically scored PSG). Serial awakenings and dream reports were successfully recorded

for participants with PTSD. Analysis of these reports revealed both direct and metaphorical references to the preselected topic. Furthermore, participants showed an improvement in creativity and resilience related to the preselected topic on post-sleep tasks compared to baseline measures. Users reported the process was comfortable, with minimal complaints.
Conclusion: The Arctop Sleep platform demonstrates promising usability and potential for leveraging targeted dream incubation to enhance creativity around specific topics. This innovative approach has direct applications for individuals experiencing PTSD, and, by fostering constructive engagement with challenging topics in a controlled sleep environment, could facilitate better sleep and more effective cognitive and emotional processing of trauma memories.

A FOUNDATIONAL TRANSFORMER LEVERAGING FULL-NIGHT, MULTICHANNEL SLEEP STUDY REPRESENTATIONS ESTIMATE CARDIOVASCULAR MORTALITY RISK

Benjamin Fox[1], Sajila Wickramaratne[2], Girish Nadkarni[2], Ankit Parekh[3]
[1] Icahn School of Medicine at Mt. Sinai, [2] Icahn School of Medicine at Mount Sinai, [3] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Sleep disorders and deprivation disrupt daily activities, mental health, and longevity and are closely linked to cardiovascular (CV) disease, which accounts for 33% of global deaths. Early detection and management of CV disease are critical for mitigating risk. Polysomnography (PSG) offers valuable data for assessing CV risk due to the relationship between sleep disorders, such as obstructive sleep apnea, and CV disease. PSG involves collecting electrophysiological data during sleep, which is manually annotated for staging, cardiac, and respiratory events. Cohort datasets, such as the Sleep Heart Health Study (SHHS), also provide long-term health outcome labels. Advanced machine learning models, such as the transformer (the model behind ChatGPT), are well-suited for modeling time-series data and can learn multichannel signal representations via self-supervision. These representations can be leveraged to predict risk for various outcomes, including CV disease, by training of an additional classifier model.
Methods: We utilized the Human Sleep Project (HSP, n=24,986), Osteoporotic Fractures in Men (MrOS, n=3,925), and Multi-Ethnic Study of Atherosclerosis (MESA, n=2,055) to train a foundational transformer using masked autoregression. The model learned representations of full-night (8 hour) sleep studies across seven channels: a single EEG (C4-M1 or C3-M2), left EOG, chin EMG, lead II ECG, SpO2, and abdomen and thoracic respiratory rates. Following self-supervised training, these representations were input into a deep neural network that was trained via linear probing to predict CV mortality risk, including stroke, myocardial infarction, and coronary heart disease using the SHHS dataset.
Results: A foundational transformer was trained with 30,966 sleep studies (1.7 million hours of signal data). The classifier achieved an AUROC of 0.74 for CV mortality risk, indicating good discriminative performance. Average precision was 0.98 for low-risk individuals and 0.18 (> 4 times higher than the class proportion of 0.04) for high-risk individuals.
Conclusion: A foundational transformer can learn relevant representations of full-night, multichannel PSG data and these representations can predict CV mortality risk. Future work should be done to examine other methods to best represent sleep study data and utilizing representations for other relevant outcomes in sleep.

CHATBOT-LED SLEEP INTERVENTION FOR BLACK/AFRICAN AMERICAN YOUNG ADULTS WITH CARDIOMETABOLIC RISK

Xiaopeng Ji[1], Sanaz Taherzadeh[1], Janeese Brownlow[2], Elizabeth OrsegaSmith[1], Jingwen Zhang[3], Philip Gehrman[4], Bradley Wolgast[1], Leighanne Hsu[1], Kathleen McCoy[1], Freda Patterson[1]
[1] University of Delaware, [2] Delaware State University, [3] University of California Davis, [4] University of Pennsylvania

Introduction: Young Black/African American (BAA) adults disproportionately report unhealthy sleep that increases cardiometabolic risk. While digital sleep health interventions have shown promise, they lack customization and interactive services. Artificial intelligence chatbots can address these limitations with human-like conversations. This study tested the preliminary efficacy of a chatbot-delivered sleep intervention for young BAA adults with short or poor sleep.
Methods: In this single-arm study, participants with short sleep (< 7 hours/night) or insomnia symptoms (Insomnia Severity Index>10) and at least one cardiometabolic risk factor were recruited from higher education institutions in Delaware. A 4-week transdiagnostic sleep intervention was delivered using personalized algorithms through a chatbot mobile app. The intervention included weekly chatbot-led sleep coaching (20–45 minutes) based on CBT-I guidelines and the Behavior Change Wheel, daily sleep tracking, and weekly goal setting with progress reviews. Pre- and Post-intervention assessments included sleep regularity (standard deviation of sleep midpoints), timing, efficiency, and duration (ActiGraph GT9X for 7 days), self-reported sleep satisfaction (Pittsburgh Sleep Quality Index, PSQI), and daytime alertness (Epworth Sleepiness Scale, ESS). A composite unhealthy sleep metric (range=0-6) was calculated by summing the number of unhealthy sleep domains, with higher scores indicating worse sleep health.
Results: Seventeen participants (19.47±1.36 years, 12 females) completed the intervention. At baseline, 16 participants (94%) self-reported poor sleep quality (PSQI > 5), and 9 participants (53%) slept < 7 hours/night. The post-intervention assessment showed significant improvement in composite sleep health (3.85 vs. 2.62, p = 0.01) and sleep satisfaction (PSQI: 8.59 vs. 5.94, p = 0.01). Although the changes in other sleep variables were not statistically significant, there is a noticeable trend suggesting improvements in sleep efficiency, duration, regularity, daytime sleepiness, and a delayed sleep midpoint.
Conclusion: This study demonstrates the preliminary efficacy of a chatbot-delivered sleep intervention to improve sleep health among young BAA adults. This approach offers an accessible, autonomous, and scalable method to address poor sleep in this

high-risk population, and underscores the potential of personalized digital health interventions.

REAL-TIME SLEEP STAGE-BASED BED TEMPERATURE ADJUSTMENTS IMPROVE SLEEP AND CARDIOVASCULAR METRICS

Tatiana Ediger[1], Emma Cary[1], Megan Holm[1], Emma Tracy[1], David He[1], Nicole Moyen[1]

[1] Eight Sleep

Introduction: Temperature is a key factor in regulating sleep, and modifying bed temperatures throughout the night can improve heart rate (HR), deep, and REM sleep. However, we are unaware of studies examining whether modifying bed temperature for a specific sleep stage could increase time spent in that stage. The Eight Sleep Pod adjusts bed temperature throughout the night in real-time based on a user's current sleep stage (Sleep Stage Autopilot). Thus, this study evaluated how the Pod's Sleep Stage Autopilot affects sleep metrics in new Pod users.

Methods: Thirty-four new Pod users (10 female, 24 male; 43 ± 11 years) completed ≥7 nights of no Pod (baseline) and on the Pod with Sleep Stage Autopilot, while wearing Oura Rings. The Pod's Sleep Stage Autopilot adjusted temperatures in real-time, depending on the sleep stage. Paired t-tests assessed overall changes in sleep stages, HR, and heart rate variability (HRV). Correlations evaluated the magnitude of change from baseline to Sleep Stage Autopilot.

Results: Sleep Stage Autopilot significantly improved average HR (-2.3 bpm), HRV (+4.9 ms), deep sleep duration (+4.7 min), and deep sleep percentage (+1.2%; all $P < 0.05$). Light sleep percentage decreased by 1.4% ($P < 0.05$), likely as a trade-off for increased deep sleep. Those with lower sleep efficiency at baseline had larger improvements with Sleep Stage Autopilot (both $r = -0.41$, $P < 0.05$). Warmer (>25°C) temperatures correlated with less wake ($r = -0.38$), more light sleep ($r = 0.38$), and improved sleep efficiency ($r = 0.38$; all $P < 0.05$).

Conclusion: The Eight Sleep Pod's Sleep Stage Autopilot significantly improved sleep and cardiovascular metrics. To our knowledge, this is the first study to improve sleep via real-time sleep stage-based temperature adjustments. Modifying bed temperature real-time improves deep sleep and minimizes wake. The Eight Sleep Pod could be an effective non-pharmacological intervention to improve sleep and cardiovascular recovery.

LLM-DRIVEN CLASSIFICATION OF MULTIDIMENSIONAL SLEEP HEALTH MENTIONS FROM FREE-TEXT CLINICAL NOTES

Syed-Amad Hussain[1], Ariana Calloway[2], Joseph Sirrianni[3], Eric Fosler-Lussier[1], Mattina Davenport[2]

[1] The Ohio State University, [2] Nationwide Children's Hospital, [3] Nationwide Childrens Hospital

Introduction: Large language models (LLMs) provide an opportunity for high-throughput extraction of multidimensional sleep health (MSH) information from unstructured clinical text to support cohort identification and the development of detection tools in clinical care. However, class imbalance and data sparsity present challenges for MSH information. Here, we investigated the optimal methods and performance limitations for using LLMs to extract 9 MSH categories from narrative text in the EHR: behaviors, satisfaction/quality, daytime sleepiness/alertness, timing, efficiency, duration, disorders, medication, and interventions.

Methods: Classification performance of Llama-3.1-8B (general domain) and BioMistral-7B (medical domain) is investigated over 300 notes annotated for 9 MSH classes (e.g. medication). We compare 7 context window sizes and 5 different few-shot (reference examples in the prompt) quantities. Few-shot examples are sampled using semantic relevance to the test example and come from a subset of annotated examples (in-domain) or MIMIC ICD-10 and SDOH annotated examples (out-of-domain, OOD).

Results: The best performing configuration showed moderate overall performance (F1: 0.43, Recall: 0.66, Precision: 0.32). Balancing maximum context window size for the GPU VRAM limit (6000 characters on our H100) was critical for performance (0.2 F1 over 1000 characters). BioMistral-7B outperformed Llama-3.1-8B by ~0.02 F1. In-domain few-shot examples outperformed OOD few-shot examples by ~0.03 F1. In the best configuration, classification of sleep medication (F1: 0.64), disorder (F1: 0.49), and efficiency (F1: 0.50) mentions evaluated best while sleep timing (F1: 0.35), duration (F1: 0.20), and behavior (F1: 0.31) classification evaluated worst.

Conclusion: Current LLMs demonstrate moderate success (e.g., sleep medication category). Nuanced sleep health categories (e.g., sleep duration) remain challenging due to complex representations and model limitations in temporal understanding. High recall rates and minimal performance loss when using OOD few-shot examples suggest potential for iterative screening of clinical notes, with annotation needed mainly for validation. Balancing context window size and the number of few-shot examples is critical for performance, while other parameters have little meaningful effect, especially in application. Current LLMs show a base level of competency, and our analysis points to future research foci: better representation of challenging sleep health classes, finetuning strategies, and addressing security barriers that limit access to more advanced models.

RULE-BASED VOCABULARY FOR IDENTIFICATION OF MULTIDIMENSIONAL SLEEP HEALTH MENTIONS IN PEDIATRIC CLINICAL NOTES

Joseph Sirrianni[1], Ariana Calloway[2], Syed-Amad Hussain[3], Mattina Davenport[2]

[1] Nationwide Children's Hospital, [2] Nationwide Children's Hospital, [3] The Ohio State University

Introduction: Extracting multidimensional sleep health (MSH) information in clinical notes to improve pediatric learning health systems' cohort identification, surveillance of sleep health symptoms, and determining whether sleep disparities exist in detection and care among pediatric populations. Natural language processing (NLP) has emerged as a tool to capture sleep condition information (e.g., insomnia) among adults. Implementation of NLP in pediatrics is emerging. We present a novel, low-resource

sleep vocabulary that can be applied to pediatric clinical notes to identify MSH mentions automatically.
Methods: Using a combination of existing medical sleep ontologies, interviews with clinicians, and examination of clinical note narratives, we develop a novel vocabulary of MSH terms and phrases that covers both technical terms, abbreviations, and colloquial keywords used in describing pediatric sleep health. We compare our vocabulary against a set of manually annotated clinical notes to determine the effectiveness of our vocabulary for identifying notes with MSH mentions.
Results: Our vocabulary was able to correctly identify clinical notes with MSH mentions with a recall of 99.2 and a precision of 0.852. Most false positives were in progress notes that had either noted no MSH problems or MSH mentions not related to patient sleep health status (e.g. medication side effects). Keywords from our vocabulary appeared in 77.1% of the text spans within the note tagged as sleep mentions. However, the keywords also appeared in many non-patient related MSH mentions as well. For example, "nocturnal enuresis" appeared in sleep mention tagged text only 13 of 17 times (76.5%).
Conclusion: Our vocabulary showed excellent performance for identifying MSH mentions at the clinical note level and decent performance for identifying the specific text containing patient MSH mentions. However, keywords also appeared in other contexts, which can cause results to be noisy. A higher resource model, such as machine learning, is likely required to identify/classify patient MSH mentions. Thus, our low-resource vocabulary, which can be deployed in almost any compute environment, can serve as an identifying first pass over clinical notes to identify which notes/note sections should be further processed by more advanced models or manual review to identify more narrow mentions.

EVALUATING THE QUALITY OF CHATGPT'S RESPONSES TO ADOLESCENTS' AND CHILDREN'S SLEEP-RELATED QUESTIONS

Hannah Kim[1], Hea Ree Park[2], Pamela Song[2], Jae Wook Cho[3], Jee Hyun Kim[4]

[1] Princeton Day School, [2] Department of Neurology, Inje University College of Medicine, Ilsan Paik Hospital, [3] Department of Neurology, Pusan National University Yangsan Hospital, Pusan National University School of Medicine; Sleep Tech Research Center, Bitsensing Inc., [4] Ewha Womans University Seoul Hospital, Ewha Womans University College of Medicine

Introduction: The application of artificial intelligence (AI) in medical education and public health communication has gained increasing attention. Recent studies have investigated the utility of large language models, such as ChatGPT, in addressing health-related queries, including those concerning sleep. The current study aims to assess the accuracy, educational value, and age-appropriate nature of ChatGPT-generated responses to common sleep-related questions posed by children and adolescents. Additionally, we compare differences in the content and quality of responses tailored to different age groups.
Methods: We selected 18 frequently asked questions by children and adolescents regarding sleep-related issues, including daytime sleepiness, sleep talking, nightmares, nap duration, and appropriate sleep schedules. Each question was posed to ChatGPT-4.0 twice, once with the speaker framed as a 10-year-old child and once as a 16-year-old adolescent. Four sleep physicians independently evaluated the responses. Each expert rated the responses on a 1-to-5 scale for five domains: (1) age-appropriateness, (2) general informational value, (3) personal tailoring to the question, (4) comprehensibility, and (5) suitability as a recommended answer.
Results: For age-appropriateness, responses scored 4.05 ± 0.34 for children and 4.38 ± 0.50 for adolescents. General informational value ratings were 3.87 ± 0.55 for children and 4.00 ± 0.52 for adolescents. Personal tailoring was rated 3.01 ± 0.42 for children and 3.05 ± 0.45 for adolescents. Comprehensibility was rated 4.34 ± 0.65 for children and 4.83 ± 0.21 for adolescents. Overall suitability as a recommended answer was 3.65 ± 0.51 for children and 4.05 ± 0.57 for adolescents. Notably, only 22% of responses to children and 27% of responses to adolescents recommended consulting a healthcare provider. Additionally, ChatGPT's responses were significantly longer when addressing the adolescent audience.
Conclusion: Our findings suggest that ChatGPT-generated responses to pediatric and adolescent sleep-related queries demonstrate strong comprehensibility and general informational value, with responses appearing more appropriate and informative for adolescents than children. However, personal tailoring was limited, and explicit guidance on seeking medical consultation was infrequent. Greater caution and refinement are warranted before integrating ChatGPT responses into educational materials for pediatric and adolescent sleep-related concerns.

ENABLING CLICK-AND-RUN ACCESS TO ARTIFICIAL-INTELLIGENCE-READY SLEEP PARAMETERS FOR CLINICIANS AND RESEARCHERS

Samvrit Rao[1], Mithun Ganapathy Arun[2], Robert Thomas[2], Haoqi Sun[2], M. Brandon Westover[2]

[1] Thomas Jefferson High School for Science and Technology, [2] Beth Israel Deaconess Medical Center

Introduction: The polysomnography (PSG) signals contain rich phenotypes critical for understanding the function and pathology of multiple organ systems. Sleep clinicians often develop intuitions of these signal phenotypes throughout their clinical practice, which become an integral part of their decision-making. With the heated development of artificial intelligence (AI), many sleep clinicians with first-hand ideas from their patients need to use AI to test their hypotheses. However, quantifying their intuition into sleep parameters becomes the first burden that halts the development of many new ideas. On the other hand, sleep researchers with non-analytical backgrounds face a similar situation.
Methods: Here, we present Sleep Phenomics and Annotator (SPA), a website for click-and-run style quantification of PSG signal phenotypes. The user uploads a de-identified PSG signal file in European Data Format (EDF). The user can also upload an annotation file in any tabular format. Then, the system calculates the sleep parameters and shows a download button to save a tabular file onto their local computers. Importantly, the user will be responsible for data safety. The website displays a message to remind the user to de-identify the data thoroughly before uploading. The website immediately deletes the file once the analysis is done.
Results: The SPA website calculates sleep parameters including (1) sleep stages, if not provided in annotation, and standard

sleep architectures; (2) from brain wave: multitaper-based spectral powers in frequency bands, sleep spindles, slow oscillations (SO), spindle-SO coupling, arousals, and brain age; (3) from chin muscle: amplitude, sleep atonia index; (4) heart rate and heart rate variability; (5) respiration rate and apnea/hypopnea detections; (6) periodic limb movement detections; (7) from oxygen saturation: average SpO2 and hypoxic burden. All sleep parameters are stratified by sleep stages if applicable. The system is designed with a modular architecture, where each sleep parameter can be added separately.
Conclusion: By providing a clinician/researcher-friendly interface, the SPA website bridges the gap between clinical sleep medicine and quantitative sleep research, enabling reproducible sleep analysis at scale. The website is being actively deployed by the Beth Israel Deaconess Medical Center IT team and will become publicly available.

THE EFFECTS OF 1-4 HZ BINAURAL BEATS ON DELTA BRAIN WAVE DURING SLEEP IN UNIVERSITY STUDENTS: A PILOT STUDY

Thananchanok Anuekjit[1], Ukkrit Jansri[1], Jirayos Chintanadilok[1]
[1] King Mongkut's Institute of Technology Ladkrabang

Introduction: Sleep is crucial for the maintenance of both physical and mental health; however, a significant number of individuals are currently experiencing sleep disturbances or deprivation, which results in lower sleep quality, especially in university students. The N3 stage, deep sleep stage, has the importance of sleep quality enhancement and a delta brain wave with frequency of 1-4 Hz is generated in this stage. Binaural beats are believed to help improve sleep quality by helping the human brain to generate brain waves during sleep according to the frequency of the binaural beats. Binaural beats with frequency of 1-4 Hz have been proposed to induce delta waves in the brain, thus, the deep sleep stage will increase and eventually improve sleep quality. Therefore, the objective of this pilot study is to evaluate the effects of 1-4 Hz binaural beats in generating delta waves to increase the deep sleep stage (N3), as measured by electroencephalography.
Methods: A total of 9 right-handed participants (Male, n = 6; Female, n = 3) from KMITL institution with age of 18-25 years old (21.2 ± 0.97) were included in this pilot study, which utilized within-subjects study. 1-4 Hz binaural beats were created by musical chords to prevent monotony from using only one value of frequency and this 1-4 Hz binaural beats will generate a frequency of 1-4 Hz by using the difference of sound frequency between two ears. On the first night, participants slept without listening to binaural beats, while on the second night (7 days interval), they listened to 1-4 Hz binaural beats for 30 minutes during sleep. Electroencephalograms were recorded using polysomnography throughout the study.
Results: The results of this pilot study shows that the specific binaural beats increase total sleep time (TST), sleep efficiency, sleep onset, N1, N3 and REM stages but only N3 stage is statistically significant (p= 0.033). For the N2 stage, it decreases with statistical significance (p = 0.049), as calculated by the Wilcoxon-Signed Ranks test by SPSS software.
Conclusion: 1-4 Hz Binaural beats can help stimulate delta waves to increase the deep sleep stage (N3) with statistical significance.

ENHANCEMENT OF SLEEP SLOW WAVES USING TRANSCRANIAL ELECTRICAL STIMULATION WITH TEMPORAL INTERFERENCE (TES-TI)

Erin Schaeffer[1], Ido Haber[1], Zhiwei Fan[2], Beril Mat[1], Simone Bruno[1], Florian Missey[3], Adam Williamson[3], Peter Achermann[4], Esra Neufeld[5], Niels Kuster[5], Richard Davidson[1], Stephanie Jones[1], Chiara Cirelli[1], Melanie Boly[1], Giulio Tononi[1]
[1] University of Wisconsin-Madison, [2] International Institute for Integrative Sleep Medicine (IIIS), [3] International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic, [4] Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland, [5] Foundation for Research on Information Technologies in Society (IT'IS), Zurich, Switzerland

Introduction: Slow waves are a key feature of high-quality, restorative sleep that occur during non-rapid eye movement (NREM) sleep, which comprises 75–80% of total time spent in sleep. Left ventromedial prefrontal cortex (vmPFC) regions have been shown to be a prominent "hot spot" where slow waves are generated. Slow-wave activity (SWA) is homeostatically regulated, which is believed to reflect the renormalization of synaptic strength that counteracts synaptic potentiation and cellular stress during wake. Disrupted SWA has been implicated in poor cognitive performance. Conversely, enhancement of slow waves has been shown to improve performance. Here, we used a novel neuromodulatory tool called Transcranial Electrical Stimulation with Temporal Interference (TES-TI) to enhance SWA.
Methods: Twenty-eight healthy participants (μ=30.5±10.0 years, 18 Female) received TES-TI interventions (STIM or SHAM) targeting left vmPFC during NREM sleep overnight for one (STIM-LOW) or two (STIM-HIGH) nights a week for four weeks. Simultaneous 256-channel high-density electroencephalography recordings were performed. TES-TI parameters were: 15,000Hz carrier frequency, 5mA, 15-second ramp, 3-minute stimulations repeated up to 10 times during NREM sleep. Difference frequencies were 1Hz for STIM and 0Hz for SHAM. Data were preprocessed and analyzed using MATLAB and EEGLAB. SWA (spectral power 0.5–4Hz) was quantified before (PRE), during (STIM), and after (POST) stimulations. Percent changes in SWA during (STIM-PRE) and after (POST-PRE) stimulation were calculated and evaluated for statistical significance using paired-samples t-tests with Bonferroni correction. Independent samples t-tests were used to compare STIM-HIGH and STIM-LOW.
Results: On combined first and last nights, twenty-one STIM participants (μ=31.5±10.0 years, 12 Female) showed a significant increase in SWA during (t=6.65, p=3.56x10-6) and after (t=7.11, p=1.38x10-6) TES-TI stimulation; whereas seven SHAM participants (μ=27.4±9.8 years, 5 Female) showed no significant changes in SWA (during: t=2.24, p=0.148; after: t=2.47, p=0.098). STIM-HIGH participants (N=10, μ=32.9±11.2 years, 7 Female) had greater increases in SWA during stimulation on the last night as compared to the first night when compared to STIM-LOW participants (N=7, μ=31.6±10.4 years, 2 Female) (t=1.89, p=0.039).
Conclusion: This study is the first to provide evidence supporting the ability of TES-TI to enhance SWA during NREM sleep overnight.

SLEEP DURATION, TIMING, AND CONTINUITY THROUGHOUT MILITARY TRAINING IN UNITED STATES NAVY AVIATION PERSONNEL

Alice LaGoy[1], Alaide Cahill[1], Josue Uriarte[1], Genieleah Padilla[1], Cara Kneeland[2], Leslie Kindling[2], Rachel Markwald[3]

[1] Naval Health Research Center, [2] Commander, Naval Air Force, U.S. Pacific Fleet, [3] Sleep and Chronobiology Laboratory, Department of Integrative Physiology, University of Colorado Boulder, Boulder, Colorado, USA

Introduction: Military environments are characterized by inadequate sleep and high fatigue, which heighten safety-related risk. Specific demands, roles, and operational events likely influence the presentation of inadequate sleep and the extent to which it can be mitigated. Here, we characterized sleep in a sample of U.S. Naval Aviation Enterprise personnel throughout a prolonged training event and examined the influence of work-related factors on sleep.
Methods: Personnel (n = 195, age = 28 ± 7 years [mean ± SD], 21% female) from an aviation squadron (n = 62) and an aircraft carrier air department (n = 133) were monitored prior to, during, and after an extended training exercise (~30 days at sea). Sleep was monitored continuously using a commercial sleep tracking device (Oura™ Ring Generation 3). Outcomes of interest included average total sleep time (TST), sleep efficiency (SE), and sleep midpoint for each training phase. ANOVAs were performed to examine the effects of training phase, study cohort, and rank (officer vs. enlisted personnel) on sleep outcomes.
Results: Across the training exercise, TST ($F_{2,279.28} = 6.70$, $p = .001$), SE ($F_{2,284.58} = 12.69$, $p < .001$), and sleep midpoint changed ($F_{2,282.12} = 42.58$, $p < .001$). Participants slept less pre-training (6.46 ± 0.95h) than during (6.68 ± 0.91h) or post-training (6.66 ± 0.99h). Conversely, SE decreased from pre-training (87.0 ± 4.4%) to during (85.5 ± 4.3%) and post-training (85.4 ± 5.0%). Further, average sleep midpoint was later during training (06:53 ± 4:50) than pre-training (03:84 ± 01:41) or post-training (04:37 ± 02:32). Differences in sleep were found by rank; officers slept longer and earlier than enlisted personnel.
Conclusion: Sleep varied across training phase in Navy personnel; sleep was shorter prior to a prolonged training event and sleep timing shifted when the training event started. Notably, while changes in TST and SE were modest, there was a marked shift in sleep timing due to the increased need for around-the-clock manning during training. In seeking to optimize sleep and reduce fatigue risk in operational settings, external constraints such as role and schedule demands must be considered.

SLEEP HEALTH AMONG FARMERS IN IOWA AND NORTH CAROLINA

Symielle Gaston[1], Alma Solis[2], Christine Parks[3], Dale Sandler[4], Chandra Jackson[1]

[1] National Institute of Environmental Health Sciences, [2] Duke University, [3] National Institute of Environmental Health Sciences, National Institutes of Health, [4] NIEHS

Introduction: Famers generally awake earlier and work longer hours than the average US worker, limiting time for sleep. Moreover, farmers are increasingly exposed to high temperatures and face psychological stress due to, for example, climate change-related crop loss–via drought or flooding, which can disrupt sleep. Farmers from socially disadvantaged groups (e.g., racially and ethnically minoritized) face added difficulties, yet sleep health and sleep health disparities among farmers remain understudied.
Methods: To (1) describe sleep characteristics and (2) assess sleep disparities among farmers, we used cross-sectional Agricultural Health Study survey data collected across multiple years from licensed pesticide applicators in Iowa or North Carolina. Sleep characteristics were self-reported during enrollment (1993-1997; insomnia symptoms); 2013-2015 (short sleep duration (SSD) [< 7-hours], excessive sleepiness, daytime napping); and 2019-2021 (sleep-disordered breathing (SDB), diagnosed sleep apnea (DSA)). After applying inverse probability weights for missingness, we estimated the prevalence of each sleep measure. Using cross-tabulations and Chi square tests, we described differences by age, sex, race and ethnicity, and educational attainment.
Results: Among 34,574 participants (mean age±SD=47±18 years), 98% were men; 93% identified as Non-Hispanic (NH)-White, 1.3% various races and ethnicities (American Indian, Alaska Native, Asian or Pacific Islander, Hispanic/Latino, multiracial, 'other'), 1.1% NH-Black, 4.1% missing race and ethnicity; and 8.4% attained < high school (HS). SSD (37%), napping < 30-minutes (27%), and SDB (26%) were most prevalent, overall. The oldest farmers (aged≥55 years) had the highest prevalence of excessive sleepiness (9.2%) and napping ≥30-minutes (31%) (all $p < 0.05$). Women had a higher prevalence of SSD (41% vs. 37%) and no napping (64% vs. 54%), but men were more likely to report SDB (27% vs. 14%) and DSA (23% vs. 10%) (all $p < 0.05$). SSD was substantially more prevalent among NH-Black (56%) than NH-White farmers (37%, $p < 0.01$). Farmers with < HS vs. ≥HS had higher prevalence of insomnia symptoms, excessive sleepiness, and napping but lower prevalence of SSD, SDB, and DSA (all $p < 0.05$).
Conclusion: Poor sleep characteristics were highly prevalent among farmers, and there were disparities by age, sex, race and ethnicity, and education. Identifying environmental and sociocultural determinants may inform sleep interventions among farmers.

SEX-SPECIFIC ASSOCIATIONS BETWEEN ORGANOPHOSPHATE INSECTICIDE METABOLITES AND SLEEP BEHAVIORS AMONG U.S. ADULTS

Deepali Ernest[1], Bipin Singh[2], Asha Collier[3], Aparajita Chandrasekhar[2], Sarah Messiah[4]

[1] University of Texas Health Science Center at Houston, School of Public Health, [2] University of Texas Health Science Center at Houston School of Public Health, [3] UT Austin School of Human Ecology, [4] UT Southwester Peter O'Donnell Jr. School of Public Health

Introduction: Dialkyl phosphate metabolites (DAPs) are common metabolites of organophosphate pesticides (OPPs)

that have been associated with suboptimal sleep behaviors in the United States (U.S). However, sex-specific differences in these associations have not been extensively studied. Therefore, this study aimed to examine the influence of exposure to common OPP metabolites on sleep behaviors among U.S. adults.

Methods: A cross-sectional analysis of National Health and Nutrition Examination Survey data (2015-2020) was conducted (N=4,149 adults, 18-80 years). Demographics and sleep behaviors were collected via interviews/questionnaires and concentrations of DAP metabolites were extracted from urine samples using solid phase extraction-high coupled with isotope dilution-ultrahigh performance liquid chromatography(UHPLC)-tandem mass spectrometry. Weighted multivariable logistic regression models determined the age-, socioeconomic status (SES) and body mass index (BMI)-adjusted associations between each DAP and sleep behavior. A sex-stratified analysis adjusting for the same covariates examined differences in these associations. All DAP metabolites were log-transformed to account for their skewed distribution.

Results: The mean age of the sample was 47.3 years (52.8% female, 16.5% Hispanic/Latino, 62.4% non-Hispanic White, 11.3% non-Hispanic Black, 5.9% non-Hispanic Asian, and 3.8% other or multiple races). Over half the sample (54.1%) had overweight or obesity, and 13.6% were socio-economically disadvantaged (below poverty line). About 23.7% did not meet the recommended 7-hour sleep duration, 24.8% reported trouble sleeping, 45.5 % snored ≥3 times a week, 24.5% reported excessive daytime sleepiness ≥15 times a month, and 11.5% experienced snorting or breath cessation ≥3 times a week. After adjusting for age, SES, and BMI, diethyldithiophosphate (DEDTP) was associated with a 69% increase in the likelihood of having trouble sleeping [aOR=1.69; 95% CI: 1.01,2.86; p< 0.05]. Sex-based stratification showed an increased likelihood of males having trouble sleeping when exposed to diethyl phosphate (DEP) [aOR=1.11; 95% CI: 1.01,1.23; p< 0.05] and DEDTP [aOR=2.56; 95% CI: 1.14,5.77; p< 0.05].

Conclusion: Findings suggest that exposure to certain DAP metabolites is associated with insomnia-related sleep behaviors, especially among adult males. Further research is needed to understand the causal relationships between DAP metabolites and sleep behaviors.

HOW DO COLLEGE ATHLETICS IMPACT SLEEP AND MENTAL HEALTH?

Jacqueline Leete[1], John Richmond Sy[2], Kelly Kim[1], Alisa Huskey[3], Ethan Olson[1], Kiley Pauck[1], Sarah Emert[4], Ruth Brombach[2], Kenneth Bottrill[1], Jessica Dietch[2], Daniel Taylor[1]

[1] University of Arizona, [2] Oregon State University, [3] The University of Arizona, [4] Idaho State University

Introduction: Sleep disturbances and mental health concerns are highly prevalent among college students, but it is unknown whether college athletics may be a protective or risk factor for sleep or mental health concerns. Therefore, we aimed to investigate whether insomnia severity, diary- and wearable-derived sleep, and mental health symptoms differ in college student athletes versus non-athletes.

Methods: Participants were 144 college student athletes and 195 college student non-athletes recruited from two universities in the Pac-12 athletic conference (total N=339). Participants completed a baseline survey, 14-days of daily diaries, and wore a wearable device (Fitbit Sense) for 28 days. Statistical analysis was conducted using t-tests and linear regression models adjusted for age and gender.

Results: ISI scores were significantly lower/better (d=.34, p=.002) in college student athletes (M=6.4[4.6]) compared to non-athletes (M=8.0[4.9]). Diary- and wearable-derived sleep midpoint was significantly earlier in college student athletes (diary: M=3:31[0:55], wearable: M=3:48[1:01]) compared to non-athletes (diary: M=4:37[1:18], d=.92, p<.001, wearable: M=4:45[1:16], d=.80, p<.001). Diary- and wearable-derived SOL, WASO, TWAK, TIB, TST, SE, sleep quality, and sleep medication use did not significantly differ between athletes and non-athletes. All mental health variables were significantly better in college student athletes (PSS-4: M=4.1[2.3]; GAD-2: M=.7[.8]; PHQ-2: M=.4[.7]; PROMIS-Fatigue SF: M=7.8[2.1]) compared to non-athletes (PSS-4: M=5.3[2.6], d=.49, p<.001; GAD-2: M=1.5[1.2], d=.70, p<.001; PHQ-2: M=1.0[1.2], d=.62, p<.001; PROMIS-Fatigue SF: M=8.9[3.0], d=.41, p<.001). Caffeine and alcohol use were significantly lower in college student athletes (caffeine: M=.7[.9]; alcohol: M=.1[.3]) versus non-athletes (caffeine: M=.9[.9], d=.27, p=.028; alcohol: M=.3[.6], d=.34, p=.001). Athlete status remained a significant predictor of all outcomes described above (p's<.05), after adjusting for age and gender.

Conclusion: Participation in collegiate athletics may be protective against developing insomnia and mental health symptoms, potentially attributable to earlier sleep schedules, increased physical activity, and/or additional support, social resources, and monitoring provided to college athletes. Future directions include investigating daily relationships between sleep timing and mental health symptoms in athletes and non-athletes.

Support (if any): This study was supported by a Pac-12 Student-Athlete Health and Well-Being Initiative Grant and an in-kind grant from Fitbit Inc. Dr. Dietch's effort on this project was supported by a National Heart, Lung and Blood Institute grant 1K23HL157698.

ASSOCIATIONS BETWEEN SLEEP HEALTH AND OBJECTIVELY MEASURED SOUND, TEMPERATURE AND LIGHT IN THE HOME

Kristen Knutson[1], Katharine Harrington[1], Shaina Alexandria[1], Sabra Abbott[1], Nathan Kim[2], Swaty Chapagai[1], Stephen Thomas[3], Cora Lewis[3], Pamela Schreiner[4], Kathryn Reid[1], Mercedes Carnethon[1]

[1] Northwestern University Feinberg School of Medicine, [2] Northwestern University, [3] University of Alabama at Birmingham, [4] University of Minnesota, Minneapolis, MN

Introduction: Sleep health plays a vital role in overall health and understanding the various factors that impair sleep would inform development of effective interventions to improve sleep health. Our objective was to identify environmental factors in the home associated with poor sleep health.

Methods: In the CARDIA Sleep Ancillary Study, we collected 7 days of wrist actigraphy and measured monitoring light,

temperature and sound levels in the participants' bedrooms using small devices placed near the bedside. Sleep health measures included total sleep time (TST), sleep percentage (TST/sleep period), sleep fragmentation and wake after sleep onset (WASO). We examined the night-to-night associations between environmental and sleep health measures within individuals using linear mixed models. Results are interpreted as the estimated difference in the outcome associated with a 1SD increase in the exposure.
Results: Our sample included 356 adults (51% Black, 49% White; 65% Women) aged 52-66 years. A greater amount of time above 10 lux within individuals was associated with longer TST (beta=10.5 minutes, p<.01), lower sleep percentage (beta=-0.6%, p<.01), greater sleep fragmentation (beta=1.3%, p<.01), and greater WASO (beta=4.7 minutes, p<.01). Similar associations were observed for time above 0 lux. Greater variability in temperature across the night was associated with longer TST (beta=18.7 minutes, p<.01), lower sleep percentage (beta=-0.7%, p<.01), greater sleep fragmentation (beta=0.8%, p<.01), and greater WASO (beta=5.8 minutes, p<.01). A larger mean sound level during the night was associated with lower sleep percentage (beta= -1.0%, p<.01), greater sleep fragmentation (beta=1.1%, p<.01), and greater WASO (beta=6.6 minutes, p<.01). Mean lux, proportion of time above 60 decibels, and proportion of time within optimal temperature range (18.3-21.1 degrees C) were not associated with any of the sleep health measures.
Conclusion: Compared to an individual's typical levels, longer duration of light exposure, more variable temperatures and higher sound levels during the sleep period were associated with poorer objectively measured sleep quality (percentage, fragmentation, WASO). They were also associated with longer TST, perhaps reflecting sleep extending into daytime hours due to later timing, greater fragmentation or WASO. Mitigating these environmental factors could improve sleep health.

INSOMNIA SYMPTOMS AND COGNITIVE FRAILTY IN OLDER INDIANS: FINDINGS FROM A NATIONALLY REPRESENTATIVE SURVEY

Waad Ali[1], Muhammad Thalil[2]
[1] Sultan Qaboos University, [2] The Pennsylvania State University

Introduction: Cognitive frailty, the co-existence of physical frailty and cognitive impairment, is a significant predictor of adverse outcomes, including disability and death, in older adults. Existing studies on the relationship between insomnia and cognitive frailty have predominantly been conducted in high-income settings, with limited investigations in low- and middle-income countries (LMICs), where healthcare contexts and social determinants differ substantially. This study investigated the association between insomnia symptoms and cognitive frailty in older Indians using a nationally representative sample and examined sex-specific variations.
Methods: This study utilized data from the Longitudinal Aging Study in India (LASI, 2017–18) and included a sample of 26,175 community-dwelling older adults aged ≥ 60 years. Insomnia symptoms included sleep onset insomnia, sleep maintenance insomnia, early morning awakening and daytime sleepiness. Frailty was assessed using Fried's phenotype and cognitive impairment was assessed based on multiple domains of cognition such as memory, orientation, arithmetic function, executive function, and object naming. Multivariable logistic regression models adjusted for sociodemographic, health, and behavioral covariates were employed to examine the association between insomnia symptoms and cognitive frailty. Stratified analyses were used to explore sex differences.
Results: The prevalence of cognitive frailty was 5.8% among older adults. Individuals reporting insomnia symptoms had significantly higher odds of cognitive frailty (adjusted odds ratio [aOR], 1.53; 95% confidence interval [CI]: 1.20–1.97) than those without insomnia symptoms. Sleep-onset insomnia was significantly associated with cognitive frailty in older men (aOR: 1.67, 95% CI: 1.01–2.76). Among women, all four insomnia symptoms—sleep onset insomnia (aOR: 1.50, 95% CI: 1.12–2.00), sleep maintenance insomnia (aOR: 1.60, 95% CI: 1.25–2.05), early morning awakening (aOR: 1.50, 95% CI: 1.15–1.95), and daytime sleepiness (aOR: 1.34, 95% CI: 1.07–1.68)–were independently associated with cognitive frailty.
Conclusion: Insomnia symptoms are strongly associated with cognitive frailty in older Indian populations, especially among women. Addressing insomnia through cost-effective interventions and lifestyle modifications may potentially mitigate cognitive frailty. Gender-based public health strategies that prioritize sleep health awareness and integrate sleep care into geriatric frameworks are essential to support healthy aging in LMICs.

THE ASSOCIATION BETWEEN REST-ACTIVITY CIRCADIAN RHYTHM AND SHIFT WORK PROFILES AMONG HONG KONG NURSES: AN ACTIGRAPHY-MONITORED STUDY

Beixi LI[1], Lap Ah Tse[1]
[1] The Chinese University of Hong Kong

Introduction: Shift work, particularly night shift, has been linked to poor sleep, which could increase the risks of various chronic diseases and mental health issues through potential disruptions in the rest-activity circadian rhythm (RAR) caused by the changing shift schedules. While recent studies have shown that day and afternoon shift nurses had better RAR than night shift nurses, the extent to which night shifts affect nurses' RAR is underexplored. Therefore, our study aimed to investigate the association between different shift work schedules and RAR parameters among Hong Kong nurses using actigraphy accelerometers.
Methods: This was a 7-day device-monitored study that recruited 201 nurses and 100 daytime office workers. Actigraphy accelerometers were applied to collect RAR, sleep and activity metrics over a consecutive 168 hours. Of the 301 participants, 277 participants had at least 96 hours of valid data. A self-reported questionnaire including sociodemographic characteristics, lifelong occupational history, and lifestyle information was completed by the participants. Multivariate logistic regression models were used to calculate the odds ratios (ORs) and 95% confidence intervals (CIs) for the relationships between RAR parameters and different shift work profiles.
Results: Nurses in our study tended to be younger, had higher monthly earnings, and possessed shorter work durations compared to the daytime counterparts. Furthermore, a higher prevalence of poor mental health and sleep disturbances was observed

among the nurses than daytime workers. There were 182 nurses, and 95 daytime workers had valid actigraphy data. Involving in night shift schedule (aOR=3.12, 95%CI: 1.78-5.49) and working frequent night shifts (≥ 2 nights) in the past 7 days (aOR=10.94, 95%CI: 3.67-32.64, ptrend =0.011) were significantly associated with reduced amplitude, indicating dampened RAR among nurses. Additionally, male sex and low levels of physical activity modified the association between work schedules and reduced RAR amplitude.

Conclusion: In conclusion, reduced RAR amplitude was significantly associated with shift work schedules and frequent night shift work, and the effect was particularly high among male shift workers. While frequent night shift work is not recommended for male shift nurses, high levels of physical activity might help shift nurses better adapt to night shift work.

INNOVATIVE APPROACHES TO UNDERSTANDING BASIC NEEDS AND INSOMNIA SEVERITY: EXPLORING HEALTH AND SOCIOECONOMIC FACTORS IN A LATINO POPULATION IN FLORIDA

Jasmine Rubio[1], Joon Chung[1], Ziyi Ding[1], Dunia Mejia[2], Camila Pow-Sang[3], Stacyca Dimanche[1], Laurent Garchitorena[3], Carolina Scaramutti[1], Mary Carrasco[1], Alberto Ramos[1], April Rogers[4], Michael Grandner[5], Ferdinand Zizi[3], Girardin Jean-Louis[6], Azizi Seixas[6]

[1] University of Miami, [2] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [3] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [4] St. John's University, [5] University of Arizona, [6] University of Miami Miller School of Medicine

Introduction: Research suggests that individuals' basic needs, including housing stability, and financial security significantly influence sleep quality. This study aims to investigate how these basic needs relate to insomnia severity among a diverse Latino/a and Hispanic population residing in Florida providing valuable insights in an under-studied population.

Methods: Data are drawn from the Determinants, Outcomes, Responses, and Mechanisms of Insufficient sleep in Rural-urban settings (DORMIR) study which investigated environmental factors influencing sleep and their association with cardiovascular health in a diverse Latino/a population in Florida. Among 603 participants, housing stability (steady place to live, insecure housing, do not have a steady place to live), financial ability to meet basic needs (very hard, somewhat hard, not hard at all), and worries over food security (often true, sometimes true, never true) were assessed using the Social Needs Screening Tool (AHC HRSN). Additionally, respondents answered the Insomnia Severity Index (ISI). The Insomnia Severity Index (ISI) was regressed on each of the basic needs in 3 separate models in linear regressions, each adjusting for age, sex, race/ethnicity, Hispanic origin, marital status, employment, income, Body Mass Index, and whether the participant answered the Spanish or English version of the questionnaire.

Results: Respondents who are financially secure, when compared to those with who reported "very hard" and "somewhat hard" to meet financial obligations, had 2.40 and 1.66 higher ISI scores, respectively (β [95% Confidence Interval] (95% CI) = 2.40 [0.73, 4.08], p=0.005; 1.66 [0.60, 2.72], p=0.002). For housing security, compared to those who have a steady place to live, those who were worried about losing their housing had 3.08 higher ISI scores (β [95% CI] = 3.08 [1.81, 4.35], p< 0.001). For food security, those who were worried "often" or "sometimes" about their food security when compared to food secure respondents, had 2.80 and 1.97 higher ISI scores (β [95% CI] = 2.80 [0.81, 4.79], p=0.006; 1.97 [0.81, 3.13], p=0.001).

Conclusion: Insomnia severity was associated with financial security, housing security, and food security. Basic needs security—specifically housing, food, and finances—may be critical factors to mitigate insomnia severity within the Latino/a population.

WAKING UP TO THE ROLE OF OCCUPATIONAL PRESTIGE: DOES YOUR JOB TITLE AFFECT YOUR SLEEP?

Ishana Kapoor[1], Marleigh Treger[2], Veronica Van Rossen[1], Cynthia Fellman-Couture[1], Elle Wernette[3], Christopher Drake[3], Philip Cheng[4]

[1] Henry Ford Sleep Research, [2] Henry Ford Health, [3] Henry Ford Health System, [4] Henry Ford Health + Michigan State University Health Sciences

Introduction: Socioeconomic status (SES) is a robust risk factor for insomnia and is commonly measured with income and/or education; however, these factors may better capture access to resources instead of social status (i.e., the "status" part of SES). One way to better capture social status may be through occupational prestige, which reflects societal respect and status that comes with occupational title. We hypothesized occupational prestige would be significantly associated with sleep outcomes, specifically for insomnia severity and sleep reactivity (i.e., vulnerability to sleep disturbances).

Methods: Participants (n = 524) completed a survey assessing occupational prestige (categorized by job title), income, and education. Jobs were classified into high, medium, or low prestige using a validated ranking system. Only participants who were active in the workforce and had insomnia were included. The survey also included measures for insomnia severity (ISI), and sleep reactivity (FIRST). Data were analyzed using two ANOVAs with job prestige as the independent variable, and ISI and FIRST as the dependent variables.

Results: Results revealed that sleep reactivity differed by occupational prestige, $F(2,521) = 4.7$, $p < .01$. Higher-prestige occupations showed lower sleep reactivity ($M = 22.6 \pm 6.3$) compared to low ($M = 24.9 \pm 6.0$) and middle-prestige ($M = 25.1 \pm 5.9$) occupations. Insomnia severity, however, did not differ by occupational prestige.

Conclusion: These findings suggest that while job prestige may not be associated with the severity of insomnia, it is associated with sleep reactivity. One potential explanation may be that higher-prestige occupations serve as a protective factor against stress, reducing sleep reactivity and leading to better sleep outcomes. This may be because individuals in higher prestige

occupations are more likely to have greater self-esteem due to higher social status, or because higher prestige jobs often confer greater agency (e.g., these are often decision makers), there may also be greater internal locus of control. Additionally, lower prestige roles may involve unique stressors that exacerbate sleep disturbances. Future research should examine workplace stress and its impact on sleep across occupations to better understand SES influences and inform interventions and policies.

SLEEP AND FLOURISHING: A NATIONAL SLEEP FOUNDATION POPULATION STUDY OF THE BENEFITS OF GETTING HEALTHY SLEEP

Joseph Dzierzewski[1], Alysa Miller[1], Spencer Nielson[1], John Lopos[1]

[1] National Sleep Foundation

Introduction: Decades of research and public education have focused on the negative consequences of poor sleep health, which spans mood deficits, cognitive challenges, a host of physical complications, and social difficulties. Less is known about the potential positive effects of healthy sleep, which could include wellness, productivity, goal achievement, and social functioning—all of which can be cumulatively referred to as "flourishing." This study aimed to document the public's experiences with the myriad benefits of getting healthy sleep.

Methods: Data were drawn from an online, national survey utilizing a probability-based, random sample of 1,372 U.S. adults, oversampled for both Black and Hispanic individuals. The survey was administered in English or Spanish, and included demographic information and questions probing about the potential personal, occupational, home, goal achievement, and social benefits of good sleep. Measures of central tendency were used to characterize responses, and $\chi 2$ were used to examine group differences in the benefits of good sleep health.

Results: The overwhelming majority of adults in the US reported positive impacts of getting healthy sleep on their happiness (87%), work productivity (90%), home productivity (87%), goal achievement (86%), and social life (80%). The positive impact of getting healthy sleep was robust, observed across all groups; however, interesting group differences were observed with older adults and males generally reporting lower rates of positive benefits of getting healthy sleep compared to younger adults and females. Interestingly, no group differences emerged regarding the positive impact of getting healthy sleep on work productivity, while women and people working full-time were more likely to report positive impacts of healthy sleep on home productivity. People with a Bachelor's degree or more and those working full-time reported higher rates of getting healthy sleep positively impacting their goal achievement. Finally, women were more likely to report a positive impact of healthy sleep on their social life.

Conclusion: Getting healthy sleep has a meaningful, positive impact on people's happiness, work and home productivity, goal achievement, and social life. While the sleep field has traditionally focused on reducing deficits, sleep appears to serve as a crucial tool to help people flourish.

LIFE SATISFACTION IN RELATION TO SLEEP HEALTH AMONG A NATIONALLY REPRESENTATIVE SAMPLE OF US ADULTS

Bethany Ogbenna[1], Symielle Gaston[1], Christopher Payne[2], W. Braxton Jackson[3], Chandra Jackson[1]

[1] National Institute of Environmental Health Sciences, [2] DLH Corporation, [3] DLH Holdings Corp.

Introduction: Although satisfaction with life can influence sleep health and vice versa, few studies have investigated this relationship, especially in a nationally-representative sample of US adults. Even fewer studies have investigated potential disparities in this relationship despite evidence of sociodemographic groups having differential exposure to structural and social determinants of life satisfaction such as socioeconomic position and health status.

Methods: Therefore, we assessed associations between satisfaction with life and sleep health using cross-sectional data from the 2022 National Health Interview Survey. Life satisfaction was dichotomized as 'very satisfied/satisfied' vs. 'dissatisfied/very dissatisfied.' Sleep duration was defined as 'recommended' vs. 'short' (≥7 vs.< 7 hours), insomnia symptoms as difficulty falling or staying asleep: 'yes' [most days/every day to either] vs. 'no' [never/some days for both]), and non-restorative sleep as feeling well rested in the past 30 days: 'yes' [never/some days] vs. 'no' [most days/every day]. Adjusting for sociodemographic, behavioral, and clinical characteristics, we used survey-weighted Poisson regression with robust variance to estimate prevalence ratios (PRs) and 95% confidence intervals (CIs) for each sleep dimension. We tested interactions by sex/gender along with race and ethnicity.

Results: Among 25,090 adults, mean age ± SE was 48.1±0.2 years and 54% were women. Life satisfaction was reported by 93% of Non-Hispanic (NH)-American Indian/Alaska Native adults 94% NH-Multiracial/other, 95% NH-Black, 95% NH-White, 97% Latine, and 98% NH-Asian adults. Overall, satisfaction vs. dissatisfaction with life was associated with higher prevalence of recommended sleep duration (PR:1.14 [95% CI:1.07-1.21]). Satisfaction with life was more strongly associated with higher prevalence of restorative sleep among men vs. women (PRmen:1.26 [95% CI:1.21– 1.32] vs. PRwomen:1.17 [95% CI:1.12– 1.22]; p-interaction< 0.05). Satisfaction vs. dissatisfaction with life was most strongly associated with a 39% lower prevalence of insomnia symptoms among Latine adults (PRLatine:0.61 [95% CI:0.47-0.78] followed by a 34% lower prevalence among NH-Black adults (PRNH-Black:0.66 [95% CI:0.50-0.87] compared to a 14% lower prevalence of insomnia symptoms among NH-White adults (PRNH-White:0.86 [95% CI:0.78-0.95]; p-interaction< 0.05).

Conclusion: Satisfaction with life was associated with better sleep health. Specifically, life satisfaction was more strongly associated with restorative sleep among men and less insomnia symptoms among Latine and NH-Black adults.

THE EFFECT OF THE 2024 US PRESIDENTIAL ELECTION ON SLEEP, PSYCHIATRIC HEALTH, AND HEALTH BEHAVIORS

Tony Cunningham[1], Seo Ho Song[1], Shengzi Zeng[1], Lindsay Scola[2], Ryan Daley[3], Jaclyn Ford[4], Jessica Payne[5], Elizabeth Kensinger[4], Eric Fields[6]

[1] Beth Israel Deaconess Medical Center, [2] Scola Strategies, [3] Gordon College, [4] Boston College, [5] University of Notre Dame, [6] Westminster College

Introduction: Growing evidence suggests that major socio-political events can have dramatic impacts on "public mood" and emotional well-being. Our 2020 election study found that the effects can extend to other health behaviors, such as sleep and alcohol use. Here, we aimed to replicate these findings during the 2024 US Election and expand our understanding by assessing the impact on additional health outcomes, such as cannabis and nicotine use, dietary habits, exercise, optimism, hopefulness, worry, and anxiety.
Methods: A non-representative, primarily liberal-leaning (71.9%) convenience sample of US- (n=297) and non-US-residing (n=54) participants were recruited. Participants responded to daily online surveys assessing their affect, sleep, alcohol consumption, and other health measures during a baseline period (October 7-19, 2024) and in the days surrounding the 2024 election (October 27-November 9, 2024).
Results: Preliminary analyses have been conducted on measures of sleep, mood, depression, and alcohol consumption, with plans to report all listed measures at the time of presentation. We again found a statistically significant reduction in sleep on Election Night followed by recovery sleep post-election. Stress again peaked on Election Day but took twice as long (4 days) to return to baseline compared to 2020. Alcohol use, negative affect, and depression all significantly increased with a substantially greater increase in depression after this election compared to 2020. Positive affect significantly decreased and did not recover for the remainder of the assessment period, unlike 2020. Exploratory analyses indicated that more liberal-leaning participants were the most affected, with poorer outcomes during the election period in measures of sleep, stress, depression, and negative and positive affect.
Conclusion: We have replicated the negative sleep and psychiatric health outcomes brought on by stressful socio-political events. While measures followed the same general trajectory, we saw a protracted return to baseline in several measures compared to 2020. Exploratory analyses also suggest that more severe negative impacts correlated with being more liberal-leaning. We plan to build upon these findings and report the impact on additional measures of psychiatric health and health behaviors.
Support (if any): Project was supported by funding from Boston College (to EAK) and discretionary research funds from JDP, SHS.

REPRESENTATIVE SUBSAMPLING AND CLINICAL IMPACT IN THE NATIONAL SLEEP RESEARCH RESOURCE

Victor Borza[1], Raghu Upender[2], Bradley Malin[2]

[1] Vanderbilt University School of Medicine, [2] Vanderbilt University Medical Center

Introduction: Representation biases occur when research cohorts do not reflect the distribution of subgroups in a target population. These biases can contribute to several types of harms, so recent research has worked to assess and address representation biases in datasets, including within sleep medicine. Aggregating data from multiple studies can help overcome the representation biases of individual studies, and this is one rationale behind the National Sleep Research Resource (NSRR). In this study, we systematically assess representativeness within NSRR compared to a U.S. Census target and evaluate the impact of representative subsampling on cohort representativeness and clinical covariates.
Methods: We evaluated three large NSRR studies: the Multi-Ethnic Study of Atherosclerosis (MESA), Sleep Heart Health Study (SHHS), and Wisconsin Sleep Cohort (WSC). We extracted harmonized demographic data from the first NSRR timepoint and assessed representativeness via Kullback-Leibler divergence (KLD), a measure of distribution similarity, to a comparable subset of Census population estimates. We then subsampled records for representation using a variation of our previously described methodology,12 both from each dataset individually and together. Because of stochasticity in record selection, experiments were repeated 40 times and mean values with 95% confidence intervals were reported.
Results: Total cohort KLDs for MESA, SHHS, WSC, and the combination of all datasets were, respectively, 1.17, 0.36, 0.62, and 0.33 (lower being more representative). Subsampling records yielded significantly more representative cohorts, with respective mean minimum KLDs [95% CI] of 0.61 [±0.001], 0.16 [±0.001], 0.29 [±0.001], and 0.09 [±0.002] achieved at sample sizes of 348, 140, 131, and 251 (i.e., most representative subsets). Representative subsampling did not shift mean cohort body mass index, apnea-hypopnea index with 3% desaturation criteria, total sleep time, and wake after sleep onset index in a clinically substantial manner.
Conclusion: We demonstrate that representative cohorts may be subsampled from NSRR and how combining datasets may improve representation, as postulated. While representative subsamples differ substantially in their demographics, they do not substantially differ in mean clinical covariates from their respective total cohorts, supporting the feasibility of dataset aggregation in future studies.
Support (if any): VAB was funded by F30HL168976. NSRR funding information is available at https://sleepdata.org.

COMBINING SLEEP EDUCATION WITH FINANCIAL INCENTIVES FOR SLEEP: A RANDOMIZED CONTROLLED TRIAL

Ariadne Dias Godinho[1], Michael Scullin[1]

[1] Baylor University

Introduction: Insufficient sleep is prevalent among college students and is linked to poorer health, lower academic performance, and reduced well-being. Educating students on the importance of sleep typically has minimal impact on nighttime behaviors. One potential solution is to complement sleep education with financial incentives to encourage greater prioritization of good sleep habits (e.g., earlier bedtimes). Using a randomized

controlled design, we investigated whether a combined education+incentive intervention initially improves sleep patterns and whether effects persist following removal of incentives.
Methods: Following a one-week baseline, 110 college students (mean age = 18.34 years, 71.9% female, 45.6% non-Caucasian, 76.3% freshman) completed a sleep education program and were randomized into two groups. The Intervention group received financial incentives for achieving 8+ hours of sleep per night. The Comparison group earned compensation based on performance on a sleep-related quiz. Sleep was measured objectively with actigraphy and subjectively through diaries and questionnaires. One month later, participants completed follow-up actigraphy and questionnaires (no incentives provided during this phase). Randomization was automated, instructions were delivered via pre-recorded videos, and analysts were blinded to group assignments. Materials and hypotheses were registered to https://osf.io/a2yck.
Results: There was a significant group-by-time interaction, F(1, 105)=9.11, p< 0.01, such that the Intervention group showed an increase of 23 minutes/night from baseline (M=411.31 minutes, SD=41.01) to post-intervention (M=434.34, SD=51.57) whereas the Comparison group showed a decrease of 2 minutes/night (baseline: M=412.60, SD=58.49; post-intervention: M=410.29, SD=49.63). Sleep efficiency did not change across groups or phases (ps>.10). There was a delay in both rise times and bedtimes across phases (ps<.05), but the financial incentive Intervention led to relatively earlier bedtimes during the post-intervention phase (F(1,106)=7.89, p< 0.01). At the one-month follow-up, sleep duration returned to baseline levels (ps>.10).
Conclusion: Financial incentives temporarily improve sleep duration by encouraging earlier bedtimes; however, the benefits are lost one month later when the incentive had been discontinued.

HEALTHY SLEEP DURATIONS APPEAR TO VARY ACROSS CULTURES

Christine Ou[1], Nigel Lou[1], Steven Heine[2], Benjamin Cheung[2], Kosuke Takemura[3]
[1] University of Victoria, [2] University of British Columbia, [3] Shiga University

Introduction: Sleep duration is a reliable predictor of health outcomes. However, average sleep duration varies significantly across countries, with Japan and other East Asian countries reporting the shortest average sleep durations, and some Western European countries the longest. These disparities exceed 90 minutes, raising the question of whether countries with shorter sleep durations may be suffering from worse health. These striking differences highlight the need for cross-cultural research to better understand the relationships between culture, sleep duration, and health.
Methods: We conducted a pre-registered cross-national survey of approximately 5000 participants across 20 countries regarding sleep duration and current health using Qualtrics sampling panels. We used multilevel modeling to explore the relationships between self-reported sleep duration and health both within and between countries.
Results: France had the longest average sleep duration at 7 hours 52 minutes, whereas Japan had the shortest average sleep duration at 6 hours and 18 minutes for a range of 94 minutes. Within countries, participants with longer sleep duration had better health on a health composite variable that included mental health, subjective health, and chronic conditions (b = 0.09, 95%CI = [0.07-0.10], p = < 0.001). In contrast, national sleep duration did not predict health (b = 0.09, 95%CI = [-0.10, 0.27], p = 0.349). ANOVA revealed a significant difference between sleep durations that are associated with optimal scores on the health composite variable F(19, 4913) = 44.97, p <.001, partial η2 =.15, 90%CI [.13,.16]. Participants who slept closer to their cultural ideal sleep duration had higher health composite scores (b = -0.06, 95%CI = [-0.08, -0.10], p = < 0.001).
Conclusion: The optimal amount of sleep, as it relates to health, appears to vary across countries suggesting that sleep needs are flexible within limits and shaped by cultural norms.

EXPLORING THE ADVERSE IMPACT OF MATERNAL STRESS ON SLEEP QUALITY IN PERINATAL WOMEN OF COLOR

Stacyca Dimanche[1], Matthew Coppello[2], Joon Chung[3], Mary Carrasco[4], Carolina Scaramutti[3], Laurent Garchitorena[1], Jasmine Rubio[1], Dunia Mejia[5], Camila Pow-Sang[1], April Rogers[6], Judite Blanc[2], Debbie Chung[2], Ferdinand Zizi[1], Girardin Jean-Louis[7], Azizi Seixas[7]
[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [3] University of Miami, [4] Lincoln Memorial University Debusk College of Osteopathic Medicine, [5] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [6] St. John's University, [7] University of Miami Miller School of Medicine

Introduction: Perinatal women experience numerous physiological and behavioral challenges, including heightened stress and sleep difficulties. These issues are more prominent among minority women of color. Studies have highlighted the adverse impact of maternal stress on sleep quality. Yet, research exploring this relationship among underrepresented groups remains limited. This study uses a virtual reality (VR) program to investigate the relationship between stress and sleep among a marginalized perinatal woman, addressing a critical research gap.
Methods: A pre-and post-design study, Nurturing Moms, assessed the effectiveness of a maternal health VR program on stress among expectant (0-36 weeks gestation) and postpartum (up to 12 months) Black and Latina and/or Hispanic women. Forty-six women completed baseline surveys (expectant: 29.3±4.8 years; postpartum: 31.6±5.1 years) via REDCap. Surveys included the Perceived Stress Scale (PSS) and Patient Reported Outcomes Measurement Information Systems (PROMIS) Short Form v1.0 – Sleep Disturbance 4a, measuring stress and sleep quality, respectively. Spearman Correlation and Linear Regression with Bootstrap (adjusting for race, age, and income level) examined the relationship between stress and

sleep. The stratified analysis explored variations across racial subgroups.
Results: A statistically significant correlation was observed between PSS scores and PROMIS scores (rs =.379, p =.009), indicating that higher maternal stress level was associated with greater sleep difficulties. While the overall regression model was not significant, F (4, 41) = 1.41, p > 0.05, maternal stress was identified as a significant predictor of sleep disturbance (β =.396, p =.026). The stratified analysis revealed a stronger correlation (rs =.398, p =.044) between higher stress levels and sleep disturbances among Latina and/or of Hispanic origin compared to perinatal women of color.
Conclusion: The analyses emphasize a significant correlation between maternal stress and sleep disturbance, with a stronger association observed among Latina and/or Hispanic women. Although the overall regression model was non-significant, likely due to limited sample size and reduced statistical power, maternal stress remained a key predictor. Future research should explore socio-cultural factors and additional moderators, on a larger and more diverse scale.

PATTERNS OF NIGHTTIME CAREGIVING AND PARENT-INFANT SLEEP OUTCOMES: A LATENT CLASS ANALYSIS

Christine Ou[1], Guanyu Chen[2]
[1] University of Victoria, [2] University of British Columbia

Introduction: Parental-infant sleep and sleep problems are a significant source of stress for parents. Although greater paternal involvement in childcare is broadly associated with improved maternal and infant sleep outcomes, there is limited understanding of how different patterns of nighttime caregiving are distributed across families and their unique implications for parent-infant sleep. Identifying distinct caregiving arrangements and their relationships with sleep outcomes could provide critical insights into optimizing nighttime care practices for families.
Methods: We recruited 138 parent dyads who had an infant between 6 to 18 months of age to complete an online questionnaire about parental division of nighttime care, parental sleep, infant sleep, parental mental health, and relationship satisfaction.
Results: These nighttime caregiving patterns were identified as: Mother Exclusive, Mother Dominant, Mother More than Partner, Equal Contribution, and Partner More than Mother. Significant differences in parental sleep duration and quality and number of infant night wakes were observed across groups (p < 0.001). Patterns involving greater paternal involvement, such as Equal Contribution and Father Major, were associated with reduced parental fatigue and improved parental sleep quality.
Conclusion: A greater proportion of nighttime infant care is provided by mothers compared with partners. The findings suggest that greater paternal involvement is associated with better parental sleep quality. Longitudinal and experimental studies are needed to further investigate causal relationships between nighttime caregiving patterns and family sleep outcomes. Additionally, exploring barriers to greater paternal involvement and strategies to encourage equitable caregiving could inform interventions aimed at optimizing family functioning and well-being.

OBSERVED CHANGES IN SLEEP DURATION ACROSS THE MENSTRUAL CYCLE FROM WEARABLE DATA

Conor Heneghan[1], Belen Lafon[1], Logan Schneider[1], Nichole Young-Lin[1]
[1] Google

Introduction: Prior studies on changes in sleep duration over the course of the menstrual cycle in women of child-bearing age has shown mixed evidence on any systematic variation in duration or sleep stage. However such studies have either relied on a limited number of observed nights in a sleep laboratory or self-reported sleep values. Consumer wearable devices offer the capability of tracking sleep longitudinally in a large cohort of users, and revealing patterns of interest.
Methods: Users of commercially available wearable devices (Fitbit devices) are enabled to record the timing of their menstrual cycles (e.g. date of period or onset), and can consent to allow such data to be analyzed at an aggregate level for research. This analysis reviewed wearable recorded sleep parameters from 5409 users (not using hormonal birth control) who recorded at least 51 periods and 1200 nights of recorded sleep stage over a 58 month time segment. By using the date of period onset as an anchor timing (Day 0), we considered changes in estimated sleep duration, and the distribution of sleep stages across the menstrual cycle.
Results: The population had an average age of 36± 7 yrs at study start, and BMI of 27.5±6 kg/m2. There was a small but significant change in population sleep patterns over the course of the menstrual cycle. Sleep duration was at its lowest in the pre-menses phase (nadir at Day -2), then climbed steadily during the menses and follicular phase (peak at Day 3), before dipping again around ovulation, followed by an increase in mid-luteal phase. However, the overall range of variation was small with a deviation of approximately 7 mins from nadir to peak. The population level trends were somewhat blunted in women using hormonal birth control versus those not using such birth control, consistent with a hypothesis that the changes in estrogen and progesterone have a small effect on sleep parameters over the course of the menstrual cycle.
Conclusion: Consistent with self-report sleep duration and smaller scale laboratory studies, we demonstrated that sleep duration varies over the course of the menstrual cycle.

SEX-SPECIFIC DIFFERENCES IN PAIN FOLLOWING 1-YEAR OF SHIFTWORK

Sophia Kogan[1], Brooke Shafer[1], Stacy Stoffregen[1], Steven Shea[1], Ryan Olson[1], Andrew McHill[2]
[1] Oregon Health & Science University, [2] Oregon Institute of Occupational Health Sciences, Oregon Health & Science University, Portland, Oregon, USA

Introduction: Shiftwork is associated with an increased risk for adverse health outcomes, including higher incidence and exacerbation of pre-existing pain compared to non-shiftworkers. Evidence suggests that men and women have different pain sensitivity responses; however, it is unknown if there are sex-specific effects of shiftwork on pain. Therefore, we examined how pain was affected by shiftwork in a sex-specific fashion.
Methods: General pain levels were assessed on a 10-point scale (0=no pain, 10=worst imaginable pain) during a baseline daytime work schedule among 89 participants (66 males) and reassessed following 1-year of working as a new transit bus operator. Based on self-reported work schedules, participants were classified into work groups as either having mostly worked a day schedule or a shiftwork schedule (>33% of hours outside 0800-1700) across the year. Baseline differences between sexes were assessed using independent t-tests. Mixed effects models were used to assess the within-sex effects of time (baseline vs. 1-year) and work group (day vs. shift) on pain. The relationship between percent days working shiftwork at 1-year and pain was assessed using Pearson correlation analyses.
Results: There was no significant difference in age between males and females (mean±SD; 44±14.2yrs vs. 42±12.1yrs, respectively, p=0.53). Overall, pain levels decreased by 40% across the year (1.37±1.7 vs. 0.82±2.2, p< 0.01). Among males, there was an interaction between time and work group (p=0.02) such that pain was significantly reduced in the day group at 1-year (3.38±1.71 vs. 2.00±2.12; p<.01), yet did not significantly change in the shiftwork group (2.37±1.14 vs. 2.11±1.53; p=0.70). There was no effect observed among females (p=0.81), but there was a non-significant trend for percent shiftwork being positively correlated with pain among males (r=0.23; p=0.07).
Conclusion: Night shiftwork may be one contributing factor for maintaining pain levels, particularly amongst males. While global pain questionnaires provide modest insight into changes in pain over time, further work is needed to identify how different pain conditions respond to shiftwork. Additionally, more work is needed to consider sex-specific pain modulation that may be masking shiftwork's effect on pain in females.

SOCIAL DETERMINANTS AND GENDER DIFFERENCES IN SLEEP HEALTH DISPARITIES: PRELIMINARY FINDINGS FROM A DESCRIPTIVE ANALYSIS IN HONG KONG 2024

Veeleah Lok[1], Melinda Liu[1], Roger Chung[1], Jean Kim[1]
[1] JC School of Public Health and Primary Care, The Chinese University of Hong Kong

Introduction: Sleep health is influenced by social and structural factors such as income, housing, commuting, and noise. This study examines sleep duration, sleep latency, and sleep adequacy and associated factors in Hong Kong, the city with high income inequality and the lowest per capita living space in the world.
Methods: An anonymous, cross-sectional telephone survey was conducted on adults in Hong Kong, 2024 (n=500). Descriptive statistics (mean, standard deviation, and frequencies) summarized sleep data: (1) sleep duration, (2) time to fall asleep (sleep latency), and (3) sleep adequacy. Associated sociodemographic (e.g. sex, income), behavioural (e.g. exercise habits, commuting time) and environmental factors (e.g. housing type, ambient noise, residential area) were also examined to identify patterns in sleep disparities using multivariable regression analyses.
Results: Preliminary findings show that sociodemographic factors are significantly associated with sleep. In particular, females and people with lower income reported shorter sleep duration (mean < 6.1 hrs), longer time to fall asleep (mean > 36 minutes), and lower sleep adequacy (mean < 7.6 hrs) than higher income groups and males (p< 0.05). Noise disturbances were more also common in lower-income groups, worsening sleep outcomes. Behavioural and environmental factors also contribute significantly to poor sleep quality (p< 0.05).
Conclusion: Targeted interventions are required to address sleep inequalities in those sociodemographic groups with poor sleep such as women and lower income individuals. Since personal and environmental factors contribute to sleep health disparities in Hong Kong, there is a need for sleep interventions that go beyond the personal level. As sleep is a vital component of good health, sleep health should be included in public policy discussions in high population density, urban environments.

HIGH BMI ASSOCIATED WITH POORER OVERNIGHT DECLARATIVE MEMORY IN OLDER MEN WITH OSA

Crystal Kwan[1], Lanna Avetisyan[1], Christian Harding[1], Breanna Holloway[1], Pamela DeYoung[2], Ina Djonlagic[3], Sarah Banks[1], Sonia Ancoli-Israel[4], Atul Malhotra[2]
[1] UC San Diego, [2] University of California, San Diego, [3] Beth Israel Deaconess Hospitals, Harvard Medical School, [4] UCSD

Introduction: Sleep-dependent declarative memory is negatively affected by obstructive sleep apnea (OSA) in middle-aged adults. Older age is associated with deficits in learning and cognition. Three age-related comorbidities that may contribute to this relationship are OSA, Alzheimer's, and weight gain. We hypothesize that, as in middle-aged adults, poorer health would be associated with worse declarative memory in older adults.
Methods: Seventy-nine adults (65-83 years; mean age=70; 44% female) were enrolled as part of a larger study. Participants completed polysomnography to assess OSA status, defined as >5 apnea-hypopnea events/hour (3% AASM Recommended Criteria). Participants with APOE4+ status, identified via saliva-based genetic screening, were classified as high risk for Alzheimer's. Overnight declarative memory was assessed using the San Diego Word Pairs Associates (WPA), where participants learned 40 semantically related word pairs prior to sleep and tested after sleep. Linear regression modeled the effects of OSA status, Alzheimer's risk, and overweight status (BMI>25) on WPA performance with post-hoc t-tests. Spindle oscillations (slow: 9-12Hz, fast: 12-15Hz) were measured from central EEG electrodes during NREM sleep.
Results: There was a significant fixed effect of overweight status on WPA performance (f(1,75)=4.4, p=0.04) but not for OSA (f(1,75)=0.6, p=0.93) or Alzheimer's risk (f(1,75)=127, p=0.18). Post-hoc analysis suggested that overweight participants recalled fewer word pairs than their normal/underweight counterparts (102.3% vs 107.1% recalled, t(70)=-2.6, p=0.01), and this effect was seen only among men, t(34)=5.3, p<.001). Overweight participants also had a lower density of fast sleep spindle density (1.5 vs 1.9 spindles per minute, t(45)=-2.1, p=0.04) but no difference in slow sleep spindle density (1.5 vs 1.4 spindles/minute, t(58)=0.8, p=0.4).

Conclusion: Overweight older men exhibited poorer overnight declarative memory alongside reduced density of fast sleep spindles, which are critical for memory consolidation. OSA was not associated with memory deficits, likely due to the limited number of participants without OSA (72 vs. 7). This imbalance may have masked the effect of OSA on cognition or suggests that alternative mechanisms underlie OSA in older adults, particularly among men. Moreover, men may face greater metabolic impacts of excess weight, potentially impairing memory-related neural processes during sleep.

HEAT STRESS IN RELATION TO SLEEP HEALTH AMONG FARMERS

Wensu Zhou[1], Symielle Gaston[1], Christine Parks[2], Dale Sandler[3], Chandra Jackson[1]

[1] National Institute of Environmental Health Sciences, [2] National Institute of Environmental Health Sciences, National Institutes of Health, [3] NIEHS

Introduction: Sleep is sensitive to daytime and nighttime temperature extremes, which are being amplified by climate change. Many prior studies have not accounted for heat stress, which includes temperature, humidity, wind speed, sun angle, and solar radiation. Furthermore, weather-exposed workers such as farmers may be particularly vulnerable but are understudied.
Methods: To address these important literature gaps, we used survey data from the Agricultural Health Study of farmers in Iowa and North Carolina (NC), linked to heat stress data from the National Centers for Environmental Prediction for including daily measures from May–September of 2013–2015. Absolute heat exposure was based on the average of wet bulb globe temperatures (WBGT) 2 days prior to the interview date. Relative heat exposure was defined as the difference between absolute heat exposure and the 92.5th percentile of WBGT. Sleep measures included short sleep duration (< 7 hours vs. ≥7 hours), daytime sleepiness (≥3 days/week vs. < 3 days/week), daytime napping (yes vs. no), and long nap duration (≥30 minutes vs. < 30 minutes). Adjusted for sociodemographic characteristics, log-binomial models were used to estimate prevalence ratios and 95% confidence intervals (PR[CI]) in NC and Iowa, separately.
Results: Among 9,261 farmers, median age was 63.0 [IQR= 56.0–72.0] years and most (75.7%) were from Iowa. Overall, 37.2% reported short sleep duration, 9.2% reported daytime sleepiness, 47.2% reported daytime napping, and 27.0% reported long naps Mean absolute heat measures were 78.7 °F (IQR= 72.2–84.5) in NC and 70.8 °F (IQR 66.5-74.7) in Iowa, and relative measures were –7.7°F (IQR= -12.3, -4.2) in NC and -7.7°F (IQR= -11.8, -4.0) in Iowa. A standard deviation (SD) increase in WBGT was not associated with short sleep (PR-NC=1.00 [95% CI: 0.99–1.02]; PR-Iowa=1.01 [1.00-1.02]) nor daytime sleepiness (PR-NC=1.00 [0.99–1.01]; PR-Iowa=1.00 [0.99-1.00]). WBGT was associated with a higher prevalence of daytime napping in NC (PR=1.03 [1.01-1.04]), but not in Iowa (PR=1.00 [1.00-1.01]) and not for long naps (PR-NC=1.02 [0.97–1.02]; PR-Iowa=0.99 [0.98-1.00]). Relative heat exposure was associated with daytime napping in NC (PR=1.02 [1.00-1.03]).
Conclusion: Heat stress was associated with more daytime napping among farmers in NC.

EXAMINING THE PREDICTORS OF SLEEP DISTURBANCE AND OUTCOMES IN BLACK COLLEGE STUDENTS

Crishnaa Joshi[1], Abisha Ebenezer[2], Jay Bradford[1], Ronald D Taylor[1]

[1] Temple University, [2] Seton Hall University

Introduction: Sleep disturbance is a significant concern among Black college students linked to diminished mental and physical health and poor college adjustment. Identifying key predictors of sleep disturbance is crucial to understanding its etiology in this population. Thus, we examined both the predictors of sleep disturbance as well as the subsequent effect of sleep disturbances on their mental health.
Methods: The sample consisted of Black students attending a large predominantly White university (n = 263, 82.37% female, Mage = 20.3 years, 19.4% low SES). Sleep disturbance was assessed via the Pittsburgh Sleep Quality Index (PSQI), with 81.4% of participants reporting poor sleep based on the recommended 5-point cutoff. The first multiple linear regression model examined the predictors of sleep disturbance, which included individual and collective race-related stress, ethnic identity, online racism, self-efficacy, gender, age, and income. All predictors were centered to interpret effects relative to the mean. Additional models explored the effect of sleep disturbance on depressive and anxiety symptoms.
Results: Race-based and gender-based differences in sleep quality emerged. Overall, our model explained 23.6 percent of the variance in sleep disturbance (R2=.236, p <.01). Individual race-related stress (B=.095, p <.01) and online racism (B=.069, p <.01) were positively associated with sleep disturbance, indicating that greater exposure to these stressors predicted higher sleep disturbance. Ethnic identity (B=−.079, p <.01) was inversely associated with sleep disturbance, suggesting a buffering role. Gender differences emerged, with participants identifying as "other" reporting significantly higher sleep disturbance (B=3.80, p <.01) than males. Females also reported higher sleep disturbance, nearing significance (B= 1.21, p= 0.085). Higher family income (401% or above the federal poverty level) was associated with lower sleep disturbance (B=−1.72, p <.05). Collective race-related stress, self-efficacy, and age, were not significantly associated with sleep disturbance. Sleep disturbance was significantly associated with higher levels of depression (B=1.76, p<.01, R2=0.29) and anxiety (B=2.06, p<.01, R2=0.286).
Conclusion: Our findings emphasize the importance of addressing systemic and interpersonal stressors, such as online racism and individual race-related stress in interventions targeting sleep health as well as promoting protective factors such as ethnic identity in Black college students.

SLEEP AND ACADEMIC PERFORMANCE IN UNIVERSITY STUDENTS: A CRITICAL APPRAISAL

Blake Barley[1], Ariadne Dias Godinho[1], Michael Scullin[1]

[1] Baylor University

Introduction: Conventional wisdom is that sleep loss is harmful to students' academic performance. Yet, previous meta-analyses

investigating the association between sleep quantity/quality and academic performance indicate small-sized correlations (r=.03 to r=.15). The goal of this work was to critically evaluate the study design characteristics in the sleep-academic performance literature to inform why effect sizes may be low overall, as well as to evaluate whether causal direction can be determined by existing work.
Methods: We systematically searched three databases (PubMed, PsycInfo, and Web of Science) through September 2023. Studies were included if they were published in English, were original research published in a peer-reviewed journal, included college or university student participants, assessed sleep, and assessed academic performance/achievement. All studies were screened by two independent reviewers. Extracted variables included study author, publication year, study country, study sample size, mean age, percentage of females, study population, study design, type of sleep measurement, type of academic performance measurement, covariates used in analyses, and sleep-academic performance outcomes. Sleep variables of interest were sleep quality, sleep duration, sleepiness, bedtime, rise time, and chronotype.
Results: 282 studies reported associations between academic performance and sleep variables, with 62.1% reporting at least one significant association. Academic outcomes were often assessed by self-reported grades (65.2%, k=184) and very few studies (3.9%) used objective measurements of sleep (e.g., actigraphy). Most studies relied on cross-sectional rather than longitudinal designs (81.2%, k=229), and fewer than half of studies adjusted for potential confounding variables in analyses (38.4%, k=108). All studies focused on correlational analyses; no studies used randomized controlled experimental designs.
Conclusion: Small effect sizes for sleep-academic associations may be explained by non-optimal measurement (self-report) and minimal use of longitudinal sleep monitoring. The true relationship between sleep and academic outcomes may be larger, but rigorous experimental designs will be necessary to disentangle the causal direction(s) between sleep and academic performance.

SLEEP DISTURBANCE AND ALCOHOL USE DURING THE COVID-19 PANDEMIC: A QUALITATIVE ANALYSIS OF YOUNG ADULTS WITH COMORBID INSOMNIA AND HEAVY DRINKING

Mairead Moloney[1], Justin Verlinden[2], Karen Ingersoll[3], Lee Ritterband[4], Jessica Weafer[5]
[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Kentucky, [3] University of Virginia School of Medicine, [4] University of Virginia, [5] Ohio State University

Introduction: The COVID-19 pandemic significantly impacted both sleep patterns and alcohol consumption, yet little is known about these effects in individuals with pre-existing sleep disturbance and heavy drinking. This study examined how young adults with comorbid insomnia and heavy drinking perceived pandemic-related changes to their sleep and alcohol use patterns.
Methods: Heavy drinking men (n = 28) and women (n = 42) with insomnia were interviewed as part of a study evaluating digital cognitive behavioral therapy for insomnia. Semi-structured qualitative interviews were conducted at baseline and after program completion. Interviews were digitally recorded, professionally transcribed, and coded using a multi-stage, inductive process aided by NVIVO software.
Results: Most participants were female (60%) and white (81%) with an average age of 26 (SD 6.1). Participants described significant pandemic-related disruption to sleep timing and quality. Many reported temporal structure loss: "At the beginning of the pandemic, I had no sense of time at all. I didn't know the difference between night and day. I was sleeping during the day, staying up and partying at night." While some participants reported that flexible schedule improved their sleep ("I think it's helped... I'm able to sleep in until my meetings start,") others reported deterioration due to increased demands: "a lot of professors just think we're at home, so we can do 18,000 assignments... I think my sleep has been impacted by that." Similarly, loss of temporal structure impacted drinking patterns. Some participants, particularly students, reported increased drinking ("all of our classes are online...so our schedules are more flexible to drink if we want to,") while others noted reduced alcohol consumption due to quarantine: "during the thick of COVID, it made me drink less because nothing was open."
Conclusion: The pandemic altered sleep patterns among young adults with pre-existing sleep disturbance, particularly affecting sleep timing and circadian organization. While increased schedule flexibility benefited some, loss of temporal structure often exacerbated sleep difficulties. Effects on alcohol use were also variable. These findings highlight the need for targeted interventions addressing both sleep and substance use behaviors during periods of environmental and social change.

AGE AND GENDER-SPECIFIC ASSOCIATIONS BETWEEN SEVERE SLEEP APNEA AND ALL-CAUSE MORTALITY IN FEMALE VETERANS: INSIGHTS FROM A RETROSPECTIVE COHORT STUDY

Amin Ramezani[1], Mehrnaz Azarian[2], Arash Maghsoudi[2], Susan Redline[3], Thomas Penzel[4], Javad Razjouyan[2], Amir Sharafkhaneh[2]
[1] IQUEST, [2] Baylor College of Medicine, [3] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [4] Charité - Universitätsmedizin Berlin

Introduction: Sleep apnea (SA) is a prevalent sleep disorder associated with increased health risks, including mortality. While previous studies largely focused on male populations, gender-specific associations remain underexplored. This study aimed to investigate the association between severe SA and all-cause mortality in a large cohort of female veterans, emphasizing age-specific interactions and their clinical implications.

Methods: This retrospective cohort study analyzed 19,334 female veterans referred for sleep evaluation between 1999 and 2022. A validated natural language processing (NLP) tool extracted apnea-hypopnea index (AHI) from electronic medical records, stratifying participants into severe SA (s-SA, AHI ≥30; 33%) and no SA (n-SA, AHI < 5; 67%). Participants were further stratified into age groups: Young (≤40 years), Middle-aged (40< age < 65 years), and older adults (≥65 years). Mortality risks were analyzed using Cox proportional hazards models, adjusted for age, body mass index (BMI), race/ethnicity, and

Charlson Comorbidity Index (CCI). Kaplan-Meier survival curves examined survival trends.
Results: Participants with s-SA exhibited higher BMI (34.32±6.73 vs. 30.86±6.01) and greater comorbidity burden (CCI ≥2: 16.86% vs. 8.55%) compared to the n-SA group. All-cause mortality (4.66% vs. 3.28%) and the prevalence of cardiovascular (47.54% vs. 34.54%) and metabolic conditions (56.86% vs. 35.81%) significantly exceeded in s-SA compared to n-SA. The unadjusted odds ratio for mortality in s-SA compared to n-SA was 1.44 (95% CI: 1.24–1.68), which decreased to 0.64 (95% CI: 0.54–0.76) after adjusting for covariates. The Kaplan-Meier analysis revealed that only in older adults (≥65 years) with s-SA all-cause mortality was lower than in n-SA. In the other two age groups, mortality did not differ in s-SA compared to n-SA.
Conclusion: In female veterans, severe SA was associated with increased mortality, particularly in younger and middle-aged individuals, driven by a higher burden of cardiovascular and metabolic comorbidities. However, this association diminished in older adults, suggesting potential adaptive physiological mechanisms. These findings highlight the need for age- and gender-specific approaches in the diagnosis and management of severe sleep apnea among female veterans.

INVESTIGATING THE FEASIBILITY OF COLLECTING SLEEP AND READINESS DATA PRIOR TO DEPLOYMENT ON A U.S NAVY SHIP

Andrew Kubala[1], John Ferrand[1], Genieleah Padilla[1], Robyn Englert[1], Cameron McCabe[1], Evan Chinoy[1]
[1] Naval Health Research Center

Introduction: Maintaining optimal readiness and adequate sleep is essential for Navy sailors, particularly when preparing for deployment. However, assessment of performance factors (e.g., sleep and fatigue, occupational and environmental stressors, mental and behavioral health concerns) is challenging in an operational environment. We conducted a pilot study leveraging wearable technology for sleep and behavioral health surveillance in a shipboard environment. Here, we describe preliminary feasibility data from that study.
Methods: Sailors (n= 244, 27.2±8 years, 14% female) aboard a U.S. Navy ship were monitored in-port for 5 weeks prior to leaving for a deployment. They were asked to complete a baseline and post-study questionnaire, brief weekly questionnaires, and to continuously wear a wearable device (Oura Ring; Gen 3) to collect daily sleep duration data. Sailors were asked to report device comfort and usability. Oura data yield was calculated as the ratio of (number of days in which sleep data were obtained across the entire sample) / (total number of possible days of sleep data, given the enrolled sample). Descriptive data are presented as proportions and mean and standard deviation.
Results: Response rates for questionnaires varied across the 5 weeks: baseline= 100%; week 2= 69%; week 3= 51%; week 4= 34%; post study= 72%. Across each study day, 73±9% of potential sleep data was collected. Across the study period, 10% of participants slept more than 7 hours per night, 82% slept 5–7 hours, and 8% slept fewer than 5 hours, on average. 77% of participants found the ring to be "somewhat" or "very" comfortable, and 88% reported the ring was "somewhat" or "very" convenient to manage.
Conclusion: The present study demonstrated that adequate amounts of questionnaire and wearable sleep data can be collected, even under the many constraints of shipboard settings (e.g., high operational tempo, varied leave and work schedules, preparations for deployment). Future analysis of this data aims to categorize associations with the sleep data collected and measures of command climate, stress, and mental health to create actionable recommendations for military personnel and leadership.

CROSS-SECTIONAL EVALUATION OF SLEEP HEALTH, BURNOUT AND PROFESSIONAL SATISFACTION IN ACADEMIC PHYSICIANS

Hannah Wang[1], Philip Gehrman[1], Jennifer Goldshmeid[1], Nayeli Nunez Cruz[1], Indira Gurubhagavatula[1], Ilene Rosen[1]
[1] University of Pennsylvania

Introduction: Burnout has reached crisis portions in health workers in recent years. Evidence suggests many medical professionals do not get adequate sleep, which may lower well-being and contribute to burnout. We investigated the relationships between sleep health and burnout among the Department of Medicine (DOM) physician faculty at a major academic medical institution.
Methods: We provided virtual 30-minute educational sessions during regular conference or meeting times to divisions within the DOM which covered impaired sleep and its related impact in personal and professional domains. Immediately following each presentation, attendees were invited to complete the Penn Sleep Health Survey via REDCap. Survey items included metrics regarding 1) sleep disturbance: Epworth Sleepiness Scale (ESS), Insomnia Severity Index (ISI), Multivariable Apnea Prediction 2) burnout (Maslach Burnout Inventory (MBI), with subscales on emotional exhaustion (EE), depersonalization (DP) and personal accomplishment (PA); and 3) demographics. We used Pearson correlation coefficients to determine the association between the presence of any sleep disorder and MBI, and each of its subscales (EE, DP, and PA). The thresholds for moderate burnout were: 18-29 (EE); 6-11 (DP), and 34-39 (PA).
Results: Of N=280 faculty attendees, 55.8% identified as female and 70.7% identified as White with a mean (SD) age of 45.5 (11.9) years. A total N=226 (80.7%) completed the surveys. Of these, N=125 (55.3%) flagged positive for at least one sleep disturbance. Among those with sleep disturbances, 76.8% had at least moderate burnout on EE or DP compared to 48.5% of those without sleep disturbance (chi sq(1)=19.4, P< 0.0001). Correlations (all $p < 0.05$) between the subscales of the MBI and ESS, ISI, and MVAP were as follows: 1) EE: 0.21, 0.43, 0.25; 2) DP: 0.22, 0.39, 0.21; 3) PA: -0.09, -0.18, -0.11.
Conclusion: Impaired sleep and sleep disturbance was common in academic medical physician faculty at a tertiary health center and associated with increased burnout and burnout subscales, including greater emotional exhaustion and depersonalization and less personal accomplishment. Future work should incorporate sleep health education and targeted interventions to improve sleep health into physician wellness programs and assess the impact of these approaches on burnout.

BEDTIME PROCRASTINATION EXPERIENCES AMONG CHINESE CLINICAL NURSES: A QUALITATIVE STUDY

Jia Yin RUAN[1], Wing Fai Yeung[1]
[1] The Hong Kong Polytechnic University

Introduction: Bedtime procrastination, a phenomenon previously overlooked but more recently receiving attention, has been shown to be linked to negative health outcomes. Different population groups often delay their bedtimes. However, there is a lack of research exploring the experiences of bedtime procrastination among shift workers, including clinical nurses. The study aimed to explore the bedtime procrastination experiences among Chinese clinical nurses and depict how they cope with the negative impacts caused by delaying their bedtime.
Methods: A descriptive qualitative design was adopted. Purposive sampling, combined with maximum variation and snowballing sampling strategy, was employed to select Chinese clinical nurses with bedtime procrastination experiences from healthcare institutions with different levels in two cities in Zhejiang Province, southeast China. From June 2023 to October 2024, data were collected through online, audio-recorded semi-structured individual interviews, and analyzed using conventional content analysis.
Results: Sixteen participants, with an average age of 28, took part in the study. Four main themes and nine subthemes were identified. Theme 1: staying connected to both me and the external world (e.g., enjoying personal time). Theme 2: bedtime procrastination being a habitual behavior (e.g., fostering sleep by delaying going to bed). Theme 3: experiencing negative feelings and cognitive arousal prior to and during bedtime procrastination (e.g., getting lost in negative feelings). Theme 4: trying to decrease negative impacts from bedtime procrastination (e.g., taking advantage of any opportunities to reduce sleep deprivation)
Conclusion: This study highlighted the diverse bedtime procrastination experiences among Chinese clinical nurses. This study also uncovered the strategies that nurses have employed to cope with the negative effects of bedtime procrastination. Future interventions, supported by dual-process models, using personalized-based design and with the incorporation of sleep hygiene education, are needed to decrease bedtime procrastination. This may foster the forming of health behavior among clinical nurses, which can lead to improved sleep health and overall well-being.

MONITORING VIGILANCE DECREMENT IN PHYSICIANS-IN-TRAINING USING WEARABLE SENSORS

Ji-Eun Kim[1], Jiaxin Li[1], Elizabeth A. Higgins[1], Veronika Kettel[1], Victoria A. Roach[1], Michael Meno[1], Younghoon Kwon[1]
[1] University of Washington

Introduction: Vigilance decrement, or the decreased ability to remain attentive after conducting tasks for more than 5-10 minutes, is frequently reported in the clinical environment due to shift work and long working hours resulting in sleep deprivation. This context underscores the importance of continuously monitoring vigilance decrement in the clinical environment given its threatening repercussions for patient safety. This study aims to identify factors and physiological responses associated with vigilance decrement in physicians-in-training.
Methods: We recruited six internal medicine residents (1 female-identified, 5 male-identified) between the ages of 27 and 35 (mean = 30.167, SD=2.858). The participants visited an experimental unit twice: once after having at least six hours of continuous sleep and once after having less than five hours of sleep. During each visit, the participants completed two tasks: the standardized Psychomotor Vigilance Test (PVT) and an electrocardiogram (ECG) reading test that asked if each ECG image included signs of acute myocardial infarction. We developed the ECG test as a clinically relevant task that requires vigilance. During the experiment, participants' electrodermal activities, skin temperature, and heart rates were recorded. Each visit lasted about 45 minutes.
Results: The mixed-effects regression model revealed that lower sleep quality, measured by the Pittsburgh sleep quality index, contributed to vigilance decrement indicated by prolonged response time when completing both the PVT ($\beta = 14.878$, $p = 0.034$) and ECG reading tests ($\beta = 0.807$, $p = 0.042$). Such prolonged response times were associated with decreased heart rates (beats per minute) ($r = -0.162$, $p = 0.05$ for PVT; $r = -0.507$, $p < 0.001$ for ECG) and electrodermal activities ($r = -0.321$, $p < 0.001$ for PVT; $r = -0.534$, $p < 0.001$ for ECG) during both tests, revealed by repeated-measures correlations.
Conclusion: The significant variables associated with vigilance decrement identified in this study will be used to construct predictive models of vigilance decrement, with the potential for integration into shift schedules and personalized interventions toward improving the self-care and well-being of healthcare practitioners.

WHO LASTS LONGER – SLEEP REACTIVITY PREDICTS DURATION OF NIGHT SHIFT WORK

Anna Pockrass[1], Marleigh Treger[2], Izza Peeran[1], Jonny Russell[3], Elle Wernette[4], Christopher Drake[4], Philip Cheng[5]
[1] Henry Ford Sleep Research, [2] Henry Ford Health, [3] Henry Ford Sleep Research Center, [4] Henry Ford Health System, [5] Henry Ford Health + Michigan State University Health Sciences

Introduction: Shift workers experience disturbed sleep that worsens over time. Emerging studies have implicated sleep reactivity as one causal mechanism in these sleep disturbances that predict health outcomes, such as diagnoses of Shift Work Disorder. As such, sleep reactivity may predict how long individuals work night shifts, given that healthier employees are more likely to stay in their occupation. Here, we assessed whether a relationship exists between sleep reactivity and tenure of night shift work and predicted individuals who have lower sleep reactivity would be more likely to work the night shift longer.
Methods: We collected data from 1022 night shift workers (Mage = 37.09 ± 10.93), who were at high risk for Shift Work Disorder (Shiftwork Disorder Screening Questionnaire) and worked night shift consistently for an average of 54.30 ± 71.55 months. Participants completed a measure of sleep reactivity (FIRST) and reported their duration of night shift work in months. We conducted a Pearson correlation to examine the relationship between these factors.

Results: Results indicated a small negative correlation between sleep reactivity and duration of night shift work (r = -.08, p <.01), suggesting the better their sleep reactivity scores were, the longer an individual worked night shifts were. However, the duration of night shift work only accounted for 0.06% of the variance in sleep reactivity.
Conclusion: Our findings suggest that although sleep reactivity was associated with the duration of night shift work, sleep reactivity is likely not the primary explanation for individual differences in the duration of night shift work. Instead, sleep reactivity may be part of a larger factor that explains night shift worker tenure, such as employee health, which predicts how long individuals remain in their job. Thus, this study can be used as a steppingstone for deeper exploration into health-related factors that affect tenure in night shift workers. This finding may also inform the hiring process, suggesting that individuals who are more vulnerable to sleep-related disturbances may be more likely to contribute to employee turnover.

EFFECTS OF WESTWARD LONG-HAUL BUSINESS CLASS TRAVEL ON SLEEP BEFORE, DURING, AND AFTER THE FLIGHT

Joshua Gooley[1], Marissa Titus[1], Cindy Leow[1], Yi Hong Tan[1], Venetia Kok[1], Yichen Zhu[1], Rachel Charoenthammanon[1]
[1] Duke-NUS Medical School

Introduction: Travel across time zones can disrupt sleep and cause jet lag. Here, we measured effects of westward long-haul flights on sleep in business class passengers. We hypothesized that sleep would be earlier and more misaligned relative to local clock time (i.e., jet lag) after night flights compared with day flights.

Methods: We studied 53 business class passengers (34 women; mean age ± SD=42.1y ± 9.6y) who travelled westward (6-8 time zones) from Singapore to Europe. Passengers took day flights that arrived in the evening (n=27) or night flights that arrived in the morning (n=26). Sleep was tracked before, during, and after the flight using actigraphy watches and daily diaries. Estimation statistics were used to measure effect sizes for associations of flight time (day vs. night) and time period (pre-flight, in-flight, post-flight) with sleep timing and duration.
Results: Day-flight passengers slept about 1.7 h less than usual on the night before their flight (M=-1.7 h, 95% CI -2.4 to -1.1 h, P< 0.001), but they obtained about 2 h of in-flight sleep (2.0 h ± 1.3 h). Night-flight passengers obtained about 6 h of in-flight sleep (6.1 h ± 1.7 h), which was about an hour less than their usual nocturnal sleep duration (M=-1.2 h, 95% CI -1.9 to -0.6 h, P=0.001). Post-flight sleep timing (onset, offset, midpoint) was earlier relative to local clock time after both day and night flights and realigned gradually with local clock time over 4 days. However, sleep midpoint on the first post-flight night was about an hour earlier for night flights compared with day flights (M=-1.2 h, 95% CI -2.1 to -0.4 h, P=0.048).
Conclusion: Day flights and night flights differentially impacted sleep and jet lag. Morning departures shortened pre-flight sleep, whereas late-night departures shortened in-flight sleep. Sleep on the first post-flight night was more misaligned with local clock time after night flights versus day flights. Our findings show that the timing of long-haul flights is an important determinant of sleep behavior before, during, and after the flight.

EVALUATING DAYLIGHT SAVINGS EFFECTS ON SLEEP IN THE MIDDLE AND END OF THE SUMMER PERIOD IN AUSTRALIA

Reece Kemp[1], Leon Lack[1], Robert Adams[2], Jenny Haycock[1]
[1] Flinders University, [2] Adelaide Institute for Sleep Health, Flinders University

Introduction: It has been suggested that Daylight Saving Time (DST) contributes to a variety of health risks. Many studies attribute these risks to disrupted sleep patterns following the transition from standard time to DST, particularly during the immediate post-transition period. In response, sleep research societies have called for the elimination of Daylight-Saving Time (DST). However, no research has comprehensively explored the effects on sleep health later in the DST period. This study aimed to address this gap by investigating the impact of DST on sleep timing measures, sleep health measures and daytime functioning during the middle-to-late parts of the DST period.
Methods: Two analyses were conducted using Australia-wide samples including participants from both DST states and those states staying on standard time. The first involved a population-representative sample (N = 1,011, 70% from DST states) during the final month of DST, while the second focused on individuals with clinical insomnia symptoms (Insomnia Severity Index > 14, N = 402, 85% from DST states) during the mid summer period. Sleep/wake timing, total sleep time (TST), various sleep health measures, and subjective daytime functioning measures were compared between participants from DST and Standard Time (ST) states.
Results: Results from both the population representative sample and the insomnia sample were very consistent. Individuals in DST states went to bed and woke up at somewhat later clock times than those in ST states (12 – 35 minutes) with some differences reaching significance. However, there were no significant differences in total sleep time, sleep quality, or subjective daytime functioning measures between the participants from the DST and ST states.
Conclusion: These findings suggest that the disruptive effects of DST do not persist well into the DST period. This research highlights the need for further longitudinal studies to precisely measure the duration of initial disruptive effects of the transition onto DST in order to more fully evaluate the extent of its possible negative impacts.

MEDIA REPRESENTATION FAVORS PERMANENT DAYLIGHT-SAVING TIME

Alfredo Colon-Marrero[1], Parnitha Karapakula[2], Karin Johnson[3]

[1] Baystate Medical Center, [2] Shrewsbury High School, [3] UMass Chan School of Medicine- Baystate

Introduction: The scientific and medical community endorse permanent standard time (pST), but many politicians and public polls still favor permanent daylight-saving time (pDST) to end clock change. Media representation may adversely influence attitudes by favoring daylight saving time and advancing myths and misconceptions. It is our objective to evaluate the quantity and content of DST and ST representation in the media.
Methods: Web search found 183 articles including DST and ST terms between the years of 2018-2024 from five news sources (CBS, Wall St Journal, The Hill, Washington Examiner, New York Times). Articles were excluded if text, repeats in same news cycle, is unrelated to DST or only referential to another article. Two independent readers reviewed and quantified the stance, myths, and message of each article and discrepancies were resolved. Stance was considered in favor of a particular viewpoint if there were quotes, myths or data disproportionally supportive of one position or failed to mention other viewpoints.
Results: 168 articles were included. Media coverage has increased; 2018 (n=8), 2019 (n=14), 2020 (n=9), 2021 (n=16), 2022 (n=36), 2023 (n=42), 2024 (n=43). Article stance was pro-pDST (n=55,32.7%), pro-pST (n=19,11.3), pro-seasonal DST (n=2,1.2%), pro-ending clock change (n=41,24.4%), or neutral (n=48,28.6%) and one for shortening DST duration, one for Saturday clock change, and one referring to the effects of sudden policy change. The number of pro-pST articles generally increased from 2018-2024 (n=0,0,1,1,7,4,6; 2018-2024 respectively). In 2024, 14.0% were pro-pST and 27.9% pro-pDST, 28.0% anti-switch and 30.2% neutral. Articles noted scientific concerns about short-term effects of clock shifts only (n=69,41.1%), long term effects of DST (n=21,12.5%), both (n=29,17.3%) or neither (n=46,29.2%). Commonly reported misconceptions included that DST lengthens days or increases sunlight duration (n=23,13.7%) and that DST improves physical health (n=18,10.7%) and mental health (n=23,13.7%) and that effects of DST are only due to switching clocks (n=79,47.0%).
Conclusion: Media representation of DST and ST has been increasing. A growing number of articles are favorable toward pro-pST or neutral, but close to a third still more positively portray pDST. More research into the impact of media representation on DST vs ST public policies is needed.

ESTIMATING ALGORITHMIC FAIRNESS AND BIAS IN PREDICTING SLEEPING DIFFICULTIES USING ARTIFICIAL INTELLIGENCE AND MACHINE LEARNING

Sonal Yadav[1], Yanjia Zhang[1], Zhenwei Zhang[1], Md Ahmed[2], Vedant Tripathi[1], Venkataraghavan Ramamoorthy[1], Mukesh Roy[1], Muni Rubens[1], Anshul Saxena[2]

[1] Baptist Health South Florida, [2] Baptist Health South Florida, Inc

Introduction: Sleeping difficulties are associated with several adverse outcomes such as cardiovascular disorders, metabolic syndrome, and higher levels of road traffic accidents. Better predictive abilities could help in early detection and improved control over these adverse outcomes. However, identifying and accounting for algorithmic biases in predictive models across different ethnic groups remains a challenge. We used advanced machine learning techniques and fairness metrics to investigate for potential disparities in predicting sleeping difficulties between different racial and ethnic groups.
Methods: We analyzed a cohort of participants from NHANES with sleeping difficulties between August 2021 and August 2023. We utilized 45 features to predict sleeping difficulties across different racial ethnic groups. The features included demographics, body composition measures, past medical history, and comorbidities. Feature importance values were analyzed to identify the most influential features and consistent trends. Fairness was assessed with emphasis on demographic parity difference and equalized odds between the racial and ethnic groups.
Results: There were 8,153 eligible participants; 55% were women; median age [Q1, Q3] was 55 [36,68] years; and 50% reported sleeping difficulties. Majority of the patients were of White race (57.7%), followed by Hispanic (17.4%), and Black race (12.8%). Feature importance scores from the best model (CatBoost) showed that sleeping difficulties were associated with other depressive symptoms (54.4%), followed by factors such as poverty to income ratio (6.0%), increasing age (4%), higher BMI (4.0%), sedentary lifestyle (2.8%), household size (2.0%), total working hours (2.0%) and number of medications (1.6%). Overall accuracy of the CatBoost model for predicting sleeping difficulties was 84.6%. The highest difference in demographic parity (15%) and equalized odds (13%) were observed between White and Asian groups. Using threshold optimizer, demographic parity difference between the same groups decreased by 27%.
Conclusion: Despite high accuracy in predicting sleeping difficulties, our models were biased and fair-unaware. Due to high demographic parity differences in the models for predicting sleeping difficulties, Asian participants might receive fewer necessary screenings. Threshold optimizer technique decreased algorithmic bias and increased model fairness. Our findings underscore the critical importance of assessing fairness and bias in predicting clinical outcomes using machine learning approaches.

CAN SELF SLEEP HEALTH SCREENING INCREASE ACCESS TO SLEEP HEALTH CARE? A PILOT STUDY

Michael Perlis[1], Matthew Kearney[2], Joseph Teel[2], Knashawn Morales[2], Donn Posner[3], Michael Grandner[4], Alexandria Muench[2], Mark Seewald[2], Karen Klingman[5]

[1] Department of Psychiatry, University of Pennsylvania, [2] University of Pennsylvania, [3] Stanford University, [4] University of Arizona College of Medicine, [5] SUNY Upstate Medical University

Introduction: While primary care may be the ideal place to assess for, detect, and triage sleep health care, multiple barriers prevent the integration of sleep medicine into standard primary care. Obstacles include time constraints during patient visits and the lack of training for PCPs. To address this issue, a self-administered sleep health screener was developed. To evaluate the potential of the screener to affect clinical practice, we conducted a pilot study on the effects of placing posters in primary care practices that simply ask "How's your sleep health?" and provide URL and QR codes to access the screener.
Methods: 20 primary care practices were identified for inclusion; 10 practices were selected for "postering" and 10 practices served as controls. Matching was by location and practice size. The posters were 2x3' in size. The screener (The SDS-CL-25) is comprised of 25 symptom items scaled from 0-4 by frequency of symptom occurrence. When completed, the respondent may view and/or email as PDFs their completed survey and report. Both outputs clearly indicated which (if any) of 13 sleep disorders the respondent is symptom positive for. If positive, the report suggests further evaluation by a primary care provider, or a sleep specialist, may be warranted. The number of referrals and diagnoses related to sleep disorders were measured for three months prior to poster placement, and for ten months of postering. Generalized estimating equations for repeated count data (Poisson family with log link) were fit to both outcomes with group, time, group-by-time interactions, and practice size as covariates.
Results: Referral rates increased in all practices but more so for the practices with posters. Significant differences were observed at 5 months where postered practices had 23% more referrals than practices without posters (95%CI= 3%, 46%). Significant differences in diagnosis rates were observed at 3 months of postering where postered practices had 19% more sleep diagnoses than practices without posters (95%CI= 9%, 30%).
Conclusion: The data from this pilot is promising. It suggests that the simple intervention proposed may allow for greater access to sleep health care and potentially the realization that 'better sleep is better health'.

VALIDATION OF IOWA RESISTANCE TO SLEEPLESSNESS TEST- CHINESE VERSION IN INSOMNIA PATIENTS

Ya-Chuan Huang[1], Siou-Tong Huang[2], Chien-Ming Yang[2]

[1] National Chengchi University, [2] Natioanl Cheng-Chi University

Introduction: Sleep loss vulnerability refers to individual differences in susceptibility to performance impairments in responding to sleeplessness. The Iowa Resistance to Sleeplessness Test (iREST) is designed to assess this trait by rating negative consequences in affective, cognitive, and somatic dimensions due to sleep loss. It has been shown to correlate with dysfunctional beliefs, sleep quality and sleepiness in young normal sleepers, suggesting the possibility that sleep loss vulnerability may play a role in the pathology of insomnia. This study evaluates the reliability and validity of the Chinese version of iREST (iREST-C) among patients with insomnia in order to serve as a tool for future study.
Methods: A total of 119 insomnia patients (F:M = 31:68, age = 33.38 ± 8.41) completed the iREST-C, ISI, and the Ford Insomnia Response to Stress Test (FIRST), with 79 participants retested 1.5 months later. Exploratory Factor Analysis (EFA) was conducted to identify factor structure and Chronbach's alpha to assess internal consistency. Pearson correlations were used to evaluate test-retest reliability and correlations with the FIRST and ISI.
Results: EFA revealed that the IREST-C comprises three dimensions: affective, cognitive, and somatic (KMO = 0.895; Bartlett's test: χ^2 = 1508.109, p <.001). The items included were the same as the original scale, except that item 13 changed from somatic to affective dimension with a low factor loading (0.410). After excluding item 13, Cronbach's α coefficient showed good internal consistency (affective: 0.924; cognitive: 0.933; somatic: 0.818). Test-retest reliability showed significant correlations for all subscales (affective: r = 0.475; cognitive: r = 0.477; somatic: r = 0.493) and the total iREST score (r = 0.579, p <.001). Significant correlations were found between the FIRST score and the cognitive (r = -.201, p <.05) and somatic (r =.229, p <.05) subscales of iREST-C, but not the affective subscale. No correlations were obtained between the ISI and iREST-C scores.
Conclusion: The iREST-C demonstrates good construct validity and test-retest reliability in insomnia patients. Vulnerability to sleep loss is associated with stress-related sleep reactivity but not with insomnia severity, indicating that it may be associated with arousal but not with insomnia directly.

PSYCHOMETRIC EVALUATION OF THE STRUCTURED CLINICAL INTERVIEW FOR SLEEP DISORDERS-REVISED (SCISD-R): A RELIABILITY STUDY

Rebecca Campbell[1], Kristi Pruiksma[2], Jessica Dietch[3], Allison Wilkerson[4], Sophie Wardle-Pinkston[5], Samantha Nagy[1], Sarah Emert[6], Jacqueline Leete[1], Hatty Lara[1], Kelly Kim[1], Justin M. Palmer[1], Jasmine Benjamin[7], Daniel Taylor[1]

[1] University of Arizona, [2] University of Texas Health Science Center at San Antonio, [3] Oregon State University, [4] Medical University of South Carolin, [5] Southern AZ VA, [6] Idaho State University, [7] Frye Psychology

Introduction: Structured clinical interviews are the optimal means for assessing certain sleep diagnoses, yet no such interview existed. To address this gap, the Structured Clinical Interview for Sleep Disorders (SCISD) was developed to evaluate DSM-5 sleep disorders. The SCISD-Revised (SCISD-R) was updated to align with DSM-5-TR criteria but has not yet undergone psychometric evaluation. This study, funded by the AASM Junior Investigator's Award, focuses on assessing the inter-rater reliability of the SCISD-R to confirm its utility in both clinical and research contexts.
Methods: Data for this study were obtained from a randomized clinical trial evaluating different modalities of Cognitive Behavioral

Therapy for Insomnia in adults aged 50–65 years. The sample is primarily White (88%), female (83%), and non-Hispanic (88%), with an average age of 57.99 years (SD = 4.92). A random sample of 100 SCISD-R interviews, conducted by trained clinicians, was selected for double-rating. Each interview consists of a general information section and modular assessments aligned with DSM-5-TR criteria. The double-rating process is ongoing, and inter-rater reliability will be assessed using the percent agreement and Cohen's Kappa.

Results: The SCISD-R is predicted to have high inter-rater reliability across modules with sufficient prevalence, similar to the SCISD for DSM-5. Preliminary data (n = 47) show strong consistency in clinician ratings for insomnia (97%), circadian disorders (82%), and obstructive sleep apnea (77%). Data analysis will be completed by January 2025.

Conclusion: The SCISD-R is expected to demonstrate robust inter-rater reliability, supporting its future use as a reliable diagnostic tool for DSM-5-TR sleep disorders. These findings will provide a critical foundation for upcoming research and enhance assessment in clinical settings, paving the way for broader validation studies and adaptations for diverse populations.

Support (if any): This study was supported by the American Academy of Sleep Medicine Focused Projects for Junior Investigators Award (PI: Campbell).

EVALUATING DIFFERENTIAL ITEM FUNCTIONING OF THE INSOMNIA SEVERITY INDEX USING MODERATED NONLINEAR FACTOR ANALYSIS

Yumei Chen[1], William Wohlgemuth[2], Maria Llabre[1]

[1] University of Miami, [2] Miami VA Medical Center

Introduction: Insomnia is common among veterans, particularly those with mental health conditions like depression and anxiety and can lead to significant health complications. Routine screening in healthcare settings is crucial to prevent chronic insomnia. The Insomnia Severity Index (ISI), a widely used and validated tool, has been adapted for diverse populations, but its differential item functioning (DIF) remains underexplored. This study uses moderated nonlinear factor analysis (MNLFA) to address this gap. This flexible approach allows for simultaneous modeling of multiple sources of bias based on individual characteristics, which can improve accuracy of insomnia severity ratings.

Methods: Veterans (N = 620) from the Miami VA sleep center completed a baseline psychosocial assessment, HSAT (mean AHI=18), and medical/psychiatric diagnoses were extracted from medical records. MNLFA was used to model nighttime (ISI items1a,b,c) and daytime symptoms (items 2–5) separately, examining the effects of age, gender, race/ethnicity, depression, anxiety, PTSD, and chronic pain on DIF. DIF-adjusted factor scores, confirmatory factor analysis (CFA) factor scores, and sum scores were compared.

Results: The veteran sample (N=620) was middle-aged (M=52, SD=14.5), predominantly male (83.5%), and White (57.3%), with 50% diagnosed with chronic pain and 51% with clinical depression. DIF analysis showed ISI1 had intercept bias for age, Hispanic/White identity, chronic pain, and depression, as well as factor loading bias for age. ISI3 had intercept bias for depression. ISI4 exhibited intercept and factor loading bias for male gender. ISI5 and ISI6 showed intercept bias for age, and ISI7 showed both intercept and factor-loading bias for PTSD. No DIF was found for AHI. Factor scores derived from MNLFA, CFA, and sum scores were highly correlated across both factors.

Conclusion: This study examined the DIF of ISI by investigating how an array of psychosocial factors influences insomnia severity ratings. Six of the seven ISI items demonstrated bias based on age, gender, race, depression, PTSD, and chronic pain. Differences observed between groups with these characteristics may be influenced. MNLFA demonstrated methodological advantages by allowing simultaneous modeling of DIF testing. Although difficult to implement in primary care, MNLFA-based factor scores hold promise for secondary predictive models.

EXPLORING DIMENSIONS OF DAILY DYSFUNCTION IN INSOMNIA AND THE PREDICTIVE ROLE OF PHYSIOLOGICAL SLEEP FEATURES

Ruda Lee[1], Olivia Larson[1], Magdy Younes[2], Bethany Gerardy[3], Allan Pack[4], Brendan Keenan[1], Philip Gehrman[1]

[1] University of Pennsylvania, [2] University of Manitoba, [3] YRT Ltd, [4] University of Pennsylvania Perelman School of Medicine

Introduction: Insomnia significantly impairs daily functioning, but the underlying dimensional structure of daily dysfunction and its physiological predictors remain underexplored. This study aims to better characterize the daily dysfunction in individuals with and without insomnia and examines the physiological predictors of this dysfunction.

Methods: Data from the Sleep Apnea Global Interdisciplinary Consortium (SAGIC) were analyzed, including 1058 participants (50% female; age 45.3±14.7 years) without obstructive sleep apnea (OSA) or shift work. Insomnia was defined by self-reported difficulty falling or staying asleep ≥3 nights/week for >3 months (n=387, 57% female; age 49.0±14.5 years). The dimensionality of self-reported daily dysfunction items (e.g., bother, affecting work, affecting social life, affecting sex life, affecting others, irritability, trouble concentrating, fatigue, and sleepy) was assessed using exploratory factor analysis (EFA). The role of EEG metrics (macro and micro-architecture and Odds-Ratio-Product [ORP]) in determining daytime dysfunction was examined using linear regression analyses to evaluate the predictive value of sleep metrics, group differences, and interaction effects.

Results: EFA identified a single-factor structure, explaining 60.4% of the variability in measures of daily dysfunction (KMO = 0.93; > 0.80, Bartlett's test: $\chi^2(36) = 2452.844$, $p < 0.001$). The single factor represents overall daily dysfunction, with higher values indicating greater severity. All variables load in the same direction, meaning that as values increase, dysfunction worsens. Linear regression analyses revealed that longer sleep onset latency (SOL) and higher ORP-9, reflecting fragmented and unstable sleep, significantly predicted greater daily dysfunction in individuals with insomnia. In the ORP model, the higher ORP-9 × group (insomnia yes/no) interaction predicted worse daily dysfunction, while higher ORP wake was unexpectedly associated with better functioning. This suggests that preserved arousal stability may buffer some negative effects of insomnia. The interaction examines whether the effect of ORP-9 on daytime dysfunction differs between the insomnia groups. The linear regression models accounted for 19–23% of the variance in daily dysfunction.

Conclusion: These findings highlight the role of fragmented sleep and altered arousal stability in daily dysfunction among individuals with insomnia, emphasizing the value of combined sleep metrics in understanding sleep-related functional impairments.

PREDICTORS OF PARENTAL BEDTIME PROCRASTINATION USING MACHINE LEARNING

Yeji Lee[1], Aly Suh[2], Maristella Lucchini[3], Natalie Barnett[3], Shambhavi Thakur[3]

[1] Department of Psychology, Sungshin University, [2] Sungshin Women's University, [3] Nanit Lab

Introduction: Bedtime procrastination (BP) is defined as "going to bed later than intended, without having any external factors for doing so". BP is an important health behavior associated with sleep health. Caregivers of young infants are significantly affected by lack of sleep, yet often intentionally postpone their bedtime after their child sleeps. This study aimed to explore predictors of parental bedtime procrastination.

Methods: A total of 477 parents with children aged 0–25 months were categorized into high and low BP groups based on the Bedtime Procrastination Scale (BPS) groups (cutoff score 33). Participants completed questionnaires including demographic information, the Insomnia Severity Index (ISI), Smartphone Addiction Scale (SAS), Sleep Readiness Scale (SRS), Solitude and Unfulfilled Aspects Scale (SolAS), Difficulties in Emotion Regulation Scale (DERS), Edinburgh Postnatal Depression Scale (EPDS), and a perceived reward scale. Demographic variables included income, age, and residence type. Child sleep variables included total sleep time (TST), wake after sleep onset (WASO), nighttime sleep stretch (NSS), sleep onset latency (SOL), total nap time, bedtime routine consistency, perceived sleep problems, and sleep management difficulties. The model included 20 variables using eXtreme Gradient Boosting (XGBoost), a tree-based ensemble learning algorithm. Feature importance of each variable is based on their contributions to predictive performance.

Results: Among the 477 participants, 52.4% of infants were boys, with a mean age of 11.04 months (SD = 6.02). Most caregivers were mothers (82.2%), married (97%), and aged 30–34 years (46.5%). XGBoost analysis identified insomnia severity (13.8%), difficulties with emotion regulation (9.5%), smartphone addiction (8.4%), sleep readiness (7.7%), and desire to be alone (7.1%) as the most significant predictors of bedtime procrastination, with the model achieving an area under the curve (AUC) of 0.707.

Conclusion: This study underscores the importance of psychological factors, including insomnia severity, emotion regulation difficulties, and smartphone addiction, in parental bedtime procrastination by impairing sleep quality, increasing nighttime arousal, and disrupting sleep readiness. These results suggest that bedtime procrastination among caregivers is driven less by child-related sleep and more by their own psychological and behavioral patterns.

LARGE LANGUAGE MODELS STREAMLINE THE IDENTIFICATION OF AN INSOMNIA PHENOTYPE IN ELECTRONIC HEALTH RECORDS

Guillermo Lopez-Garcia[1], Davy Weissenbacher[1], Lauren Gryboski[2], Noor Abu-el-Rub[2], Jared Heavens[3], Diego Mazzotti[2], Subhajit Chakravorty[4], Graciela Gonzalez-Hernandez[1]

[1] Cedars-Sinai Medical Center, [2] University of Kansas Medical Center, [3] The University of Kansas, [4] Crescenz VAMC - Perelman School of Medicine

Introduction: Insomnia is a common disorder characterized by difficulty falling and/or staying asleep. Its association with other health conditions and impact on quality of life underscore the importance of studying it at the population level. However, documentation of insomnia in electronic health records (EHRs) is inconsistent, and the condition is likely underdiagnosed. This study proposes the use of Natural Language Processing (NLP) methods to address the under-documentation of insomnia in EHRs, evaluating the performance of two Large Language Models (LLMs) in detecting an insomnia phenotype in clinical notes.

Methods: Two corpora of de-identified clinical notes were utilized in this study: 237 from the publicly available MIMIC-III database and 777 from patients in the University of Kansas Health System (UKHS) with family medicine encounters. Insomnia identification criteria were adapted from diagnostic guidelines, and gold standard datasets were created by manually annotating each note and labeling them as "Insomnia" or "Not Insomnia." Two open-source LLMs, Llama3-70B and Llama3-405B, were trained to detect insomnia in the notes using prompt engineering. Values for precision, recall, and F1 score were used to evaluate LLM performance against more traditional NLP models. The LLM trained on the MIMIC-III was used to classify the UKHS notes.

Results: Both LLMs outperformed the conventional NLP models in detecting insomnia in a set of 70 test notes. Llama-3-405B achieved the highest values for precision (95.8), recall (100.0), and F1 score (97.9), and made the fewest classification errors. Both Llama3-70B and Llama3-405B both had a higher binary classification accuracy than proportion of error-free explanations for the same set of test notes. Transportability to UKHS notes revealed a decrease in performance, but with reasonable results (Llama3-405B precision 73.5, recall 86.2, F1 score 79.4).

Conclusion: The LLMs used in this study not only performed better than more traditional NLP models when detecting an insomnia phenotype from notes in EHRs but also exhibited adherence to a set of rules and provided explanations for their classifications. These results support the potential of generative AI to advance the study of insomnia on a larger scale through the reliable and accurate identification of a computable phenotype for insomnia.

ASSOCIATION BETWEEN INSOMNIA DISORDER AND HEALTHCARE RESOURCE UTILIZATION IN THE UNITED STATES MILITARY HEALTH SYSTEM

Vincent Capaldi[1], J. Kent Werner[2], Jeph Herrin[3], Benoit Stryckman[4], Scott Williams[2], Wendy Funk[5], Jennifer Albrecht[4], Emerson Wickwire[4]

[1] Uniformed Services University of the Health Sciences, [2] Uniformed Services University, [3] Yale University, [4] University of Maryland Baltimore, [5] Kennell and Associates, Inc.

Introduction: Insomnia disorder is common among U.S. military personnel and negatively impacts health and military readiness. Among civilians, insomnia is associated with substantial economic burden; yet, little is known about the burden of insomnia within the US Military Health System (MHS). The MHS is a large, integrated healthcare delivery system with worldwide operations and thus ideal for health services research. This study

aimed to determine the association between insomnia disorder and healthcare resource utilization (HCRU) in the MHS.
Methods: Our data source was the Military Data Repository (MDR) between years 2016-2021. This large data repository includes encounter, procedure, medication, and durable medical equipment information for active-duty military personnel, military dependents, National Guard, and Reserves. Demographic and military information was obtained from the MDR. Inclusion criteria were age < 65 years, active-duty military personnel, 12 months of continuous enrollment before and after first insomnia diagnosis (i.e., the index date), and no evidence of insomnia during the 12 months prior to first diagnosis. Insomnia and comorbid medical and psychiatric conditions were defined based on International Classification of Disease-10th Edition codes. Beneficiaries with insomnia were matched 1:1 with non-insomnia controls on >20 demographic, military, and medical and psychiatric comorbidity variables. Mixed effects models were used to compare non-insomnia related HCRU between groups across multiple points of service: outpatient, inpatient, and emergency department (ED).
Results: We identified 40,978 MHS beneficiaries with insomnia and 40,978 matched non-insomnia controls. Most (35.9%) beneficiaries with insomnia were between ages 25-34 years, and 20.7% were women. 4.2% of beneficiaries with insomnia had one comorbid medical or psychiatric condition, and 1% had >2 comorbid conditions. Relative to matched non-insomnia controls, beneficiaries with insomnia demonstrated greater 12-month HCRU at every point of service (all p values< 0.001). The incident rate ratio for non-insomnia inpatient visits was RR (95% CI) = 1.96 (1.85,2.08); for non-insomnia outpatient visits was 2.24 (2.23,2.24); and for non-insomnia related ED visits was 1.60 (1.57,1.63).
Conclusion: Insomnia is associated with substantially increased healthcare resource utilization in the US military health system. Future research should seek to advance personalized medicine approaches to improve outcomes of evidence-based insomnia care.

DEEP LEARNING MODELS TO IDENTIFY INSOMNIA USING HEART RATE DATA DURING WAKE BEFORE SLEEP ONSET

Yan Ma[1], Jiamin Chen[2], Wanli Xu[3], Chen-Hsiang Yu[2]
[1] Osher Center for Integrative Health, Division of Preventive Medicine, Brigham and Women's Hospital and Harvard Medical School, [2] Multidisciplinary Graduate Engineering, College of Engineering, Northeastern University, [3] Nursing, University of Connecticut

Introduction: Stress and hyperarousal are common factors in patients with insomnia, especially those with difficulty falling asleep. Recent research has revealed altered physiological dynamics during the transition from wakefulness to sleep, including findings on autonomic systems (e.g., sympathetic and parasympathetic regulation) that can be assessed by heart rate dynamics. In this study, we aimed to compare deep learning models for identifying patients with chronic insomnia disorders solely with raw heart rate data during wake before sleep onset.
Methods: We used data from a multi-center cohort (Sleep Heart Health Study) and we included 1810 subjects (age 40-90 years, mean age 62.2±11.2 years, 50.5% male) who had overnight polysomnography with validated sleep scorings, where rate data during sleep onset was extracted for analysis. We tested multiple deep learning models, including Convolutional Neural Networks (CNN), Long Short-Term Memory Networks (LSTM), Gated Recurrent Units (GRU), Recurrent Neural Networks (RNN), Multilayer Perceptrons (MLP) and Transformers. We used balanced/unbiased data (random samples from all participants with or without insomnia on a 1:1 ratio) with 80% data for training and 20% for testing.
Results: From 5-fold cross-validation and five iterations on each model, we compared the mean accuracy of each model, and the highest accuracy for detecting insomnia was achieved by Transformers (88.3%), followed by CNN (85.8%). The mean accuracy of other models ranged between 50% to 70%. The performance of Transformers and CNN surpassed the other tested models in the detection of insomnia.
Conclusion: Deep learning models may identify the presence of insomnia with raw heart rate data during wakefulness before sleep. Given the popularity and easy access of wearable sensors, heart/pulse rate data may be useful in tracking insomnia or assisting long-term management of insomnia by providing longitudinal recordings for assessing interventions targeting sleep onset difficulties.

THE FEASIBILITY OF HOME-BASED ESTIMATION OF CIRCADIAN TIMING IN VETERANS WITH INSOMNIA AND PAST TRAUMATIC BRAIN INJURY: PRELIMINARY FINDINGS

Daniel Reis[1], Adrieann Armstrong[1], Christin Miller[1], Teodor Postolache[2], Jeri Forster[1], Lisa Brenner[3], Nazanin Bahraini[1]
[1] Rocky Mountain MIRECC for Veteran Suicide Prevention, [2] VA VISN [5] MIRECC, [3] University of Colorado Anschutz Medical Campus

Introduction: Veterans with a history of traumatic brain injury (TBI) are significantly more likely to develop insomnia than their non-injured peers, which contributes to functional impairment and diminished quality of life. Emerging evidence suggests that circadian abnormalities may underlie a sizeable subset of sleep disturbances following TBI, yet such abnormalities remain under-detected in this patient population. Pragmatic methods that estimate circadian timing (e.g., dim light melatonin onset [DLMO]) in the homes of veterans may help address this clinical gap. Preliminary findings are presented for a study examining the feasibility of two home-based methods of estimating DLMO among veterans with insomnia and a history of TBI.
Methods: Veterans with insomnia and a history of TBI are being recruited to provide feedback on two different methods for estimating DLMO at home (target N = 30). The first method involves estimation of DLMO using salivary samples self-collected by veterans. The second method involves prediction of DLMO (pDLMO) using actigraphy-derived light data and the Kronauer

limit-cycle model. Feasibility for each method is defined as the ability to measure DLMO for ≥70% of participants.
Results: To date, 20 veterans have been enrolled and 18 have completed the study. Saliva-based DLMO could only be estimated for 9 of 17 veterans (53%) who submitted collection kits. Potential explanations for undetermined DLMO estimates include difficulties using the collection kit and excessive light exposure. Additionally, all 9 veterans for whom DLMO could be estimated were exposed to light greater than 50 lux within 30 minutes of collecting the saliva samples ultimately used to determine DLMO. pDLMO was successfully estimated for 17 of the 18 veterans (94%) who returned actigraphy data.
Conclusion: Estimation of pDLMO using actigraphy-derived light data appears to be a feasible method for estimating circadian timing in veterans with insomnia and past TBI. Data collection and analyses are ongoing.

PRE-SLEEP SALIENCE NETWORK CONNECTIVITY PREDICTS SUBSEQUENT REM DURATION AND SLEEP EFFICIENCY

Lucas Koch-Kreher[1], David Negelspach[1], Salma Patel[1], William Killgore[1]
[1] The University of Arizona

Introduction: The hyperarousal theory of insomnia proposes that excessive physiological and psychological arousal contributes to the etiology of insomnia. Previous neuroimaging studies have corroborated this by finding that large-scale neural networks, such as the default mode network (DMN), show higher connectivity in individuals with insomnia. Less is known about the salience network's (SN) involvement in hyperarousal mediated insomnia; however, it's hypothesized that increased connectivity in the SN would also be correlated with more severe insomnia.
Methods: As part of a larger study investigating the effects of transcranial magnetic stimuliation (TMS) on insomnia, participants (n=20, 12 female) scoring at least a 7 on the Insomnia Severity Index (ISI) underwent fMRI resting state scans taken before sleeping overnight in the lab, where polysomnography data were collected. Only data from the sham condition were used for this analysis.
Results: Seed to voxel analyses, using the mean of individual SN nodes (i.e., supramarginal gyrus, insula, rostral prefrontal cortex, and anterior cingulate cortex) as a single seed region, revealed significant functional connectivity correlations with REM duration and sleep efficiency. Specifically, sleep efficiency and REM duration were each associated with greater functional connectivity between the SN and a region of the lateral occipital cortex (Corrected P <.05). Correlations with other sleep stages were non-significant.
Conclusion: Neuroimaging of participants with self-reported insomnia symptoms suggests that SN connectivity to the lateral occipital cortex correlates with better sleep efficiency and greater REM duration. These findings suggest that increased connectivity between the SN and lateral occipital cortex before bedtime may contribute to more consolidated REM sleep. It is plausible that this may occur as a consequence of use-dependent synaptic potentiation of these regions during wake due to high levels of visual stimulation. Alternatively, greater connectivity of these systems prior to bedtime may also be evidence of interactions between the visual and circadian systems, indicating more robust photoentrainment. This would explain why there is both greater REM duration— a component of circadian regulated sleep process — and greater sleep consolidation, which has also consistently been attributed to increased circadian consolidation. Future work may be able to address these possibilities.

STEADY HEARTS, SLEEPLESS MINDS: ANALYZING HEART RATE VARIABILITY IN INDIVIDUALS WITH CHRONIC INSOMNIA

Lauren Duffy[1], Devon Hansen[2]
[1] Elson S. Floyd College of Medicine Washington State University,
[2] Washington State University

Introduction: Autonomic hyperarousal is thought to be a pathogenic mechanism in chronic insomnia, characterized by elevated heart rate (HR) and reduced heart rate variability (HRV), indicating greater sympathetic nervous system activity. Spectral analysis links HR changes to central nervous system activity, with low frequency (LF) reflecting sympathetic activity and high frequency (HF) indicating parasympathetic activity. This study examined differences in HR and HRV between individuals with insomnia and healthy control sleepers during total sleep deprivation (TSD).
Methods: 7 individuals with chronic sleep-onset insomnia (M=29.0y, SD=6.2y, 6 females) and 7 age-matched healthy control sleepers (M=29.0y, SD=6.6y, 4 females) completed a 5-day (4-night) laboratory study. After an adaptation day and baseline day (each 10h time in bed, 22:00-08:00), participants underwent 38h of TSD followed by a recovery day (10h time in bed; 22:00-08:00). They were fitted with a 5-lead Holter monitor (DMS 300-3A Digital Holter Recorder) for continuous ECG recording. Mean HR was extracted in 5-minute bins, and power in the LF (0.04–0.15 Hz), HF (>0.15–0.40 Hz), and the LF/HF ratio components of HRV were determined by spectral analysis. Data were analyzed using mixed-effects ANOVA with a fixed effect of group (insomnia vs. controls) and period (daytime 08:00-22:00 vs nighttime 22:00-08:00) and their interaction with a random effect of subject on the intercept.
Results: Overall, the insomnia group exhibited lower LF power ($F_{1,1299}=5.38$, $P=0.021$) or greater parasympathetic activity as compared to the healthy control sleepers. There was a significant effect of period for all measured parameters, indicating a shift toward greater parasympathetic activity at night (all $F>17.7$, $P<0.001$). However, the significant period-by-group interactions revealed that this shift was less pronounced in the insomnia group for all measured parameters (all $F>2.24$, $P<0.02$).
Conclusion: Our findings suggest an interplay of homeostatic, circadian, and sleep related effects on sympathovagal balance, with more pronounced sympathetic effects observed in the healthy controls compared to individuals with insomnia. This dampened response in the insomnia group may be a result of their chronic sleep deficiency, making them less responsive to sleep and TSD due to underlying hyperarousal.

EVALUATING THE RELATIONSHIP BETWEEN INSOMNIA, PAIN INHIBITORY CAPACITY, AND TEMPORAL SUMMATION OF PAIN IN OLDER ADULTS USING ENDOTOXIN

Lynn Nakad[1], Katrina Hamilton[2], Matthew Reid[3], Sheera Lerman[1], Claudia Campbell[3], Michael Smith[1]

[1] Johns Hopkins University, [2] Johns Hopkins University School of Medicine, [3] Johns Hopkins School of Medicine

Introduction: Chronic pain is a leading cause of disability in older adults, with insomnia identified as a major risk factor, particularly in women, though mechanisms remain unclear. Aging, insomnia, and chronic pain are associated with increased systemic inflammation. To explore inflammation as a pathway connecting insomnia and chronic pain, we randomized pain free older adults with and without an insomnia diagnosis to endotoxin or placebo conditions and assessed central pain inhibitory capacity [conditioned pain modulation (CPM)] and pain facilitation [temporal summation (TS)] with quantitative sensory tests (QST) linked with chronic pain pathophysiology.
Methods: We conducted a double-blinded, randomized, placebo-controlled, clinical trial. Participants were randomized to endotoxin (0.8ng/kg) or placebo (saline) injection. CPM and TS were assessed using QST approximately 5.5hrs post-injection. ANCOVAs (2x2: insomnia vs. normal sleeper; endotoxin vs. placebo), controlling for time since injection and sex, examined whether insomnia increases TS and decreases CPM after endotoxin compared with normal sleepers. Twelve blood samples were collected over 8hrs to measure inflammatory cytokines.
Results: Analysis included 114 older adults (insomnia n=42; endotoxin n=44; M Age=62.88±6.41). Compared to placebo, endotoxin increased area under the curve for all inflammatory markers (IL-6, TNF-α, IL-1β) ($P<.05$). However, we found no significant interaction effects of Endotoxin X Insomnia on inflammation. Endotoxin significantly reduced CPM ($F(1,100)=5.734$, $P=.019$; model: $R^2=.093$, $P=.042$), but had no significant effect on primary measure of TS ($P>.05$). We found no interaction effects of insomnia X endotoxin on CPM or TS. Planned secondary analyses including sex as a moderator and BMI, age, race/ethnicity, education, and baseline pain as covariates ($R^2=.259$, $P=.010$) identified a significant three-way interaction of Endotoxin X Insomnia X Sex on TS ($F(1,87)=4.820$; $P=.031$). Females with insomnia had a greater TS response to endotoxin than males with insomnia, whereas males without insomnia showed heightened TS with endotoxin compared to males with insomnia and males receiving placebo.
Conclusion: Findings suggest that older adults with insomnia do not exhibit exaggerated inflammatory response to endotoxin. Endotoxin impaired pain inhibition, suggesting a pathway linking inflammation to chronic pain in late life. Insomnia may influence the effects of systemic inflammation on central pain facilitatory processes differently by sex.

THE IMPACT OF PAIN INTERFERENCE ON INSOMNIA SEVERITY AMONG OLDER SURGICAL PATIENTS

Anaëlle Charles[1], Mili Jimenez Gallardo[1], Andrea Castillo Suárez[1], Elizabeth Sugg[2], Daniel Tobert[3], Kyle Alpaugh[3], Fulton Kornack[3], Hany Bedair[3], Kun Hu[4], Lei Gao[4]

[1] Massachusetts General Hospital/Harvard Medical School, [2] Massachusetts General Hospital, [3] Mass General Hospital, [4] Massachusetts General Hospital/ Harvard Medical School

Introduction: Approximately one-third of adults over the age of 65 undergoing surgery exhibit symptoms of sleep-related disorders, such as insomnia. Decades of research have demonstrated that insomnia-related sleep disturbances can weaken the immune system, delay recovery, and reduce pain tolerance – effects that are particularly pronounced in older adults. However, the relationship between pain and sleep disturbances in this population remains underexplored. Given the rising hospitalization rates among older adults, we hypothesized that greater pain interference would be associated with higher insomnia severity.
Methods: A cohort of 17 older adults (≥70 years) scheduled for total knee, total hip, or spine surgery, was recruited. One week before their scheduled surgery, participants completed the Insomnia Severity Index (ISI) questionnaire and the Patient-Reported Outcomes Measurement Information System (PROMIS) to assess pain interference. A simple linear regression model analysis was used to examine the influence of pain interference on sleep disturbance before surgery. Additional model predictors were used to control for the variance across surgery type, sex, and age.
Results: In line with our initial hypothesis, pain interference, as measured by the PROMIS scale, was positively associated with insomnia severity (ISI). Specifically, our model predicted that for one SD increase in pain interference scores, ISI scores would increase by 0.076 SD ($SE = 0.038$, $p = 0.07$). While this trend was marginally non-significant, our findings are promising as data is still being collected for this study. Additionally, analysis of variance revealed that surgical type significantly influenced insomnia severity ($F = 4.11$, $p = 0.047$), with total hip and total knee surgeries showing distinct patterns compared to the spine surgery patients. Sex also emerged as a significant predictor, with males showing higher ISI scores compared to females ($p = 0.027$).
Conclusion: Overall, these preliminary results highlight the potential relationship between pain interference and insomnia severity in older surgical patients, warranting further investigation with a larger sample size.

BLUNTED CORTISOL STRESS REACTIVITY TO THE TRIER SOCIAL STRESS TEST AMONG INDIVIDUALS WITH GREATER INSOMNIA SYMPTOMS

Harrison Dickens[1], Veronica Floyd[1], Jamie Walker[1], Mikayla Tolliver[1], Anastasia Mahkanova[1], Arash Assar[2], Mara Egeler[2], Ivy Bassinger[1], Ivan Vargas[2], Abigail Vance[2]

[1] University of Arkansas, [2] University of Notre Dame

Introduction: Insomnia is a highly prevalent disorder, impacting roughly 10% of the population. Evidence suggests that insomnia may be a disorder of hyperarousal, but it is unclear whether individuals with insomnia exhibit a generalized hyperarousal or if this hyperarousal only occurs in response to sleep-related stressors. The HPA-axis, one of the primary stress-related neuroendocrine systems, plays a pivotal role in responding to stressors but also in regulating sleep. Little is known the extent to which HPA-axis reactivity to non-sleep-related cues (i.e., psychosocial stressors) plays in the pathophysiology of insomnia. This study aimed to investigate the association between HPA-axis reactivity to a psychosocial stressor and insomnia symptom severity.
Methods: Data was collected from 312 participants (69.9% women,72.7% white, mean age = 21.3 years) who completed the Trier Social Stress Test (TSST), an in-lab psychosocial stress task. Saliva samples were used to measure the cortisol stress response and were collected at the start of the TSST, as well as 35, 45, and 55 minutes post-stressor. Insomnia symptom severity was also assessed using the Insomnia Severity Index.
Results: We examined whether there was an effect of insomnia symptom severity on cortisol stress reactivity with and without adjusting for gender. As expected, men (compared to women) had a greater cortisol stress response to the TSST (linear, b=0.055, t(786)=1.67, p=< 0.001, quadratic, b=0.00006, t(552)=2.64, p=< 0.01). While the overall main effect of insomnia on cortisol reactivity was not statistically significant (linear, b=0.0001, t(790)=-1.78, p=0.08, quadratic, b=0.000001, t(554)=1.15, p=0.25), the linear slope was significant while adjusting for gender, linear, b=-0.0002, t(788)=-2.25, p=0.03. Specifically, among men, greater insomnia symptom severity was related to a blunted cortisol response to the TSST.
Conclusion: Results from these analyses suggest that there is a small, but significant, association with blunted cortisol reactivity and greater insomnia symptoms in men. These findings support that, at least in men, greater insomnia symptoms may be related to HPA-axis dysregulation, but that a different pathway may exist for women.

SLEEP RELATED ATTENTIONAL BIAS AND INSOMNIA PHENOTYPES BASED ON OBJECTIVE SLEEP DURATION IN ADOLESCENTS

Yee Lok Wong[1], Hao Fong Sit[1], Shirley Li[1]
[1] Sleep Research Clinic and Laboratory, Department of Psychology, The University of Hong Kong, Hong Kong SAR

Introduction: Adolescence is a crucial developmental stage that is often associated with various psychosocial and biological changes, increasing one's risk for developing sleep problems including insomnia. Insomnia with objective short sleep duration (ISSD) has been proposed as a unique phenotype associated with heightened physiological arousal and more severe clinical presentations, but its underlying mechanism remained unclear. Sleep-related attentional bias may perpetuate insomnia but limited research has looked into this cognitive factor in adolescents with insomnia, especially those with objectively short sleep duration. This study aimed to investigate the role of objective short sleep duration in differentiating behavioural profile in sleep-related attentional bias in adolescents with insomnia.
Methods: Adolescents aged 12-20 were recruited. Participants in the insomnia group met the DSM-5 criteria for insomnia disorder, and those in the healthy control group (HC) without any neuropsychiatric or sleep disorders and reported an average sleep duration of 7-10 hours. All participants underwent a clinical interview to ascertain their eligibility and completed questionnaires, sleep-related dot-probe task, and 7-day objective sleep monitoring by actigraphy. Participants with objective sleep duration ≤ 7 hours were classified as ISSD, and others (> 7 hours) were classified as insomnia with objective normal sleep duration (INSD).
Results: Total 106 participants were recruited (age: 18.22 ± 1.52, 12-20, female: 64%, ISSD = 50, INSD = 33). ISSD and INSD had more severe insomnia symptoms, poorer subjective sleep quality, longer objective sleep onset latency and poorer objective sleep efficacy, compared to HC (all p <.05). ISSD had a higher sleep interference index than INSD (adj p = 0.026), indicating more vigilance to sleep-related stimuli in ISSD compared to INSD.
Conclusion: The result suggested that ISSD and INSD show different attentional responses toward sleep-related stimuli. It may provide evidence on psychological understanding on insomnia phenotypes with the potential implications for early detection of insomnia and interventions. Further investigation with neuroimaging is needed to understand sleep-related attentional bias between phenotypes.

THE ASSOCIATION BETWEEN SLEEP VULNERABILITY AND INTEROCEPTIVE SENSITIVITY: A HEP STUDY

Yu-Jing Wang[1], Shao-Wei Lu[1], Chien-Ming Yang[2]
[1] National Chengchi University, [2] Natioanl Cheng-Chi University

Introduction: Previous research has explored sensory hypersensitivity in both wakefulness and sleep among insomnia patients. Compared to healthy individuals, insomnia patients exhibit heightened sensitivity not only to external stimuli but also to internal bodily signals, known as "interoception." Interoceptive sensitivity can be assessed using physiological measures, such as heartbeat-evoked potentials (HEP), as well as self-reported questionnaires. However, it remains uncertain whether heightened interoceptive sensitivity is a predisposed trait associated with an increased vulnerability to sleep disturbances or if it is a consequence of chronic insomnia. This study aims to investigate the association between sleep vulnerability and interoceptive sensitivity by comparing HEP between individuals with high and low levels of sleep vulnerability.
Methods: Thirty-one normal sleepers participated in the study (average age = 23.91 years; M:F = 15:16). Among them, 14 were classified as high sleep vulnerability (HV) and 17 as low sleep vulnerability (LV), determined by the Ford Insomnia Response to Stress Test (FIRST). Participants completed the Multidimensional Assessment of Interoceptive Awareness (MAIA) questionnaire to assess self-reported interoceptive sensitivity. Additionally, a 5-minute HEP recording was obtained in the evening during a wakeful, eyes-open resting state as a physiological index of interoception. Correlation analyses were conducted to evaluate the relationship between MAIA scores and HEP amplitudes at frontal electrodes, specifically 300 to 650 ms

after the R peak. T-tests were performed to examine group differences in interoception measures between the HV and LV groups.
Results: Frontal HEP amplitudes exhibited a positive correlation with the Noticing subscale of the MAIA (r = 0.358, p = 0.048), but no significant correlations were found with the other subscales. Additionally, t-tests showed no significant differences in HEP amplitudes or MAIA scores between the HV and LV groups.
Conclusion: The positive correlation between HEP amplitudes and the Noticing subscale suggests that greater awareness of bodily sensations is associated with enhanced physiological interoceptive processing. Furthermore, the absence of significant differences in interoceptive sensitivity between individuals with high and low sleep vulnerability indicates that heightened interoceptive sensitivity in insomnia patients may be a consequence of chronic sleep disturbances rather than a predisposing trait for sleep disturbances.

INSOMNIA WITH SHORT SLEEP DURATION IS ASSOCIATED WITH HYPERTENSION: EVIDENCE FROM THE UK BIOBANK COHORT

Slobodanka Pejovic[1], Yimeng Shang[2], Lan Kong[2], Fan He[3], Julio Fernandez-Mendoza[3], Kristina Lenker[3], Nikolaos Athanasiou[1], Alexandros Vgontzas[1]

[1] Sleep Research and Treatment Center, Penn State College of Medicine, [2] Department of Public Health Sciences, Penn State College of Medicine, [3] Penn State College of Medicine

Introduction: Evidence from both the general population and clinical samples based on polysomnography suggests that insomnia with objective short sleep duration (ISSD) represents a biologically severe phenotype of the disorder, characterized by adverse cardiometabolic outcomes, i.e., hypertension and diabetes. No longitudinal study to date has examined the association of this type of insomnia with incident hypertension using ecologically friendly, home-based, cost-effective sleep-monitoring tools, which could replace PSG, in a large general population sample. The aim of this study is to assess the risk of ISSD with incident hypertension in the large Biobank cohort based on self-reported insomnia and objectively measured habitual sleep duration by accelerometer.
Methods: We identified 96219 participants from the UK Biobank who underwent a 1-week objective sleep measure during 2013-2016. Short sleep duration was defined as ≤ 7.3 hours/night (i.e., median), after excluding participants who slept ≤ 3 hours/night or ≥11 hours/night. Self-reported insomnia symptoms obtained ± 1-year within the objective sleep measure, which was available from 8,762 participants, was used to define insomnia status. Participants reported "Usually" having insomnia symptoms (vs. Never/Rarely/Sometimes) were categorized as having insomnia. Four sleep phenotypes based on the presence of short sleep duration (Yes/No) and/or insomnia symptoms (Yes/No) were created. Major confounding factors, including age, sex, BMI, smoking, alcohol intake, sleep apnea diagnosis were extracted from the study visit closest to the objective sleep measure. To evaluate the associations between the sleep phenotypes with incident hypertension, multivariable-adjusted Cox proportional hazards models were used. The effective sample sizes for analysis on hypertension was 4451.
Results: Compared to normal sleepers with normal sleep duration, only ISSD phenotype was associated with significant risk for hypertension (HR=1.20, 95%CI=1.03-1.41, P=0.02), after controlling for confounding factors. In contrast, neither the insomnia normal sleep duration group (INSD) nor the normal sleepers short sleep duration group were associated with increased risk for hypertension.
Conclusion: These data from the large UK biobank database using an ecologically friendly method to assess habitual objective sleep duration suggest that it is the combination of insomnia plus short sleep duration (ISSD), that increase significantly the risk for hypertension.

INSOMNIA WITH IMPAIRED MENTAL RESILIENCE IS ASSOCIATED WITH ALTERED REM SLEEP MACROSTRUCTURE AND SLEEP MISPERCEPTION

Chris Xie Chen[1], Weng Ian Ao[1], Suyi Xie[1], Mingqing Zhou[1], Chun Hei Sin[1], Xuetong Wang[1], Joey Chan[2], Bei Huang[1], Yun-Kwok Wing[2], Ngan-yin Chan[2]

[1] The Chinese University of Hong Kong, [2] Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong

Introduction: Insomnia is prevalent and often precipitated by stress. Individuals with high severity of insomnia have been reported to show low resilience capacity, which renders them prone to stress-related disorders. It is important to understand how sleep is related to impaired mental resilience in insomnia, particularly prior to development of stress psychopathology. Therefore, this study aimed to examine the associations between sleep and resilience in adults with insomnia disorder.
Methods: After the semi-structural clinical interview (SCID-CV), a total of 189 participants without stress-related disorder were included. Resilience outcome was calculated by the residual approach in a linear model with negative life stressful events as independent variable and the quality of life (WHOQOL-BREF mean score) as dependent variable. Resilience capacity was measured by the Connor Davidson Resilience Scale (CDRS). Being non-resilient was defined by the combination of having low-level resilience capacity (CDRS < 27) and also non-resilient outcome despite negative life stressful events in the past year (residual value < 0). Sleep wake pattern was measured by 7-day actigraphy, and sleep macrostructures were measured by the ambulatory polysomnography (Nox A1 and Nox SAS solutions). Comparisons and associations of sleep macrostructures and sleep wake pattern between resilience groups were conducted by the generalized linear model, with covariates adjusted.
Results: The non-resilient group had more anxiety and depressive problems, higher insomnia severity, but longer total sleep time, compared to the resilient group. When adjusted for age, sex, and apnea-hypopnea index, the greater REM sleep percentage and shorter REM sleep onset latency were associated with higher risk of non-resilience (REM%: B= 0.04, p=0.03; REM latency: B= -0.01, p=0.01). Besides, the non-resilient group also perceived themselves sleeping less and falling asleep longer than actual sleep time, than the resilient group.
Conclusion: REM sleep macrostructures and sleep misperception are associated with impaired resilience in insomnia disorder. Future studies should target examining the underlying mechanism explaining REM sleep, sleep misperception and resilience.

DOES SLEEP REACTIVITY MODERATE THE ASSOCIATION BETWEEN DAILY FLUCTUATIONS IN STRESS AND SLEEP ONSET AND MAINTENANCE PROBLEMS?

Mara Egeler[1], Arash Assar[1], Abigail Vance[1], Ivan Vargas[1]
[1] University of Notre Dame

Introduction: Sleep reactivity, or the tendency to experience sleep disturbances in response to stressful life events, is considered to be a vulnerability factor for insomnia. According to the sleep reactivity hypothesis, those individuals with high sleep reactivity tend to experience greater sleep onset and maintenance problems following a stressor. Few studies, however, have observed whether this phenomenon occurs at the daily level. That is, are day-to-day fluctuations in stress related to changes in sleep onset and maintenance problems among individuals with greater sleep reactivity?
Methods: Participants included 60 adults from the greater Northwest Arkansas area (63.9% White, 67.2% Female, 30-79 years old) who completed 10 consecutive days of sleep monitoring. Sleep was assessed objectively through actigraphy and subjectively through sleep diaries. Variables examined included actigraphy and diary based total sleep time (TST) and total wake time (TWT). Sleep reactivity was assessed using the Ford Insomnia Response to Stress Test (FIRST). Daily stress level was assessed using daily diaries. Participants were asked to rate how "stressed they were that day" on a scale of 1 (being not stressed at all) to 7 (being extremely stressed). Linear regression models were conducted with sleep variables as the outcome. Daily stress and FIRST scores were mean-centered and entered as independent variables. Race, gender, and age were entered as covariates.
Results: FIRST scores were associated with lower diary TST (β = -2.76, p = 0.02) and greater diary TWT (β = 0.18, p < 0.01). Daily stress was not found to be associated with any sleep variable. FIRST score was not found to moderate the relationship between daily stress level and diary TST (β = 0.63, p = 0.19), diary TWT (β = -0.03, p = 0.13), actigraphy TST (β = 0.54, p = 0.18), or actigraphy TWT (β = 0.07, p = 0.56).
Conclusion: While sleep reactivity (as assessed via the FIRST) has been consistently linked to greater risk for developing insomnia disorder, the data from the present study suggest that this effect may be cumulative and not observed at the daily level.

HOW ARE INSOMNIA SYMPTOMS ASSOCIATED WITH WORKING HOURS AND WORK PERFORMANCE IN NEW PARENTS?

Maristella Lucchini[1], Daniela Macia[1], Liat Tikotzky[2], Sarah Berger[3], Natalie Barnett[1]
[1] Nanit Lab, [2] Ben-Gurion University of the Negev, [3] College of Staten Island, City University of New York

Introduction: The relationship between insomnia symptoms, productivity, and long working hours has been linked to poor sleep and diminished workplace performance. However, the literature remains sparse when it comes to new parents, a group uniquely vulnerable to sleep disturbances and facing delicate work transitions, such as returning from parental leave and managing work-life balance after the birth of a new child. This study addressed this literature gap, investigating the complex interplay between sleep, performance, and working hours in new parents.
Methods: Among Nanit camera users, we recruited 376 working parents (72% Mothers) of infants 1-7 months old (mean infant age 4.2 months). Participants completed the Insomnia Severity Scale (ISI; < 7 healthy; 7-14 Subclinical insomnia; >15 Clinical insomnia) and responded to questions relative to their employment status, performance at work in the past month (How would you rate your overall job performance on the days you worked during the past 28 days?1-10) and working hours. Data were analyzed using linear or multinomial regressions.
Results: Among parents, 10% reported symptoms of clinical insomnia, 38% subclinical and 52% no symptoms, with no significant differences between mothers and fathers. Mothers reported poorer work performance than fathers (β=-0.47±0.19,p< 0.001). Among mothers, those who had subclinical or clinical levels of insomnia reported poorer work performance in the last month than those with no insomnia symptoms (respectively β=-0.60±0.22,p=0.007; β =-0.98±0.35,p=0.005), but there were no associations in fathers. In addition, parents with subclinical levels of insomnia were more likely to report 'working more than expected' than those with no insomnia symptoms (respectively OR=1.9 CI:1.1-3.4), but the association was not significant when stratified by mothers and fathers. The number of working hours was not associated with perceived performance (p=0.4).
Conclusion: Insomnia symptoms in new parents were associated with poorer work performance and working more than expected, but working hours were not associated with performance. Further investigation is needed to better understand the relationship between overwork, performance and poor sleep in new parents.

THE IMPACT OF LIFETIME TRAUMA ON SLEEP REACTIVITY IN ACUTE TRAUMA PATIENTS: THE ROLE OF VICTIMIZATION TRAUMAS

Anthony Reffi[1], David Moore[2], Lily Jankowiak[2], Christopher Drake[1]
[1] Henry Ford Health System, [2] Henry Ford Health

Introduction: Sleep reactivity is a vulnerability to sleep disturbance after stress that increases risk for insomnia and myriad negative health outcomes. Previous research shows life stress can heighten sensitivity of the sleep system, exacerbating sleep reactivity. This study investigated the relationship between lifetime trauma exposure and sleep reactivity among patients hospitalized for acute trauma.
Methods: We recruited 88 patients hospitalized in Detroit, MI within one week following traumatic injury (Mage = 39.53 ± 14.31, 67.0% male, 67.0% Black). Patients reported their lifetime exposure to traumatic events using the Life Events Checklist for DSM-5 (LEC-5). We summed all positive trauma exposures to compute a "trauma load" variable, with greater scores indicating cumulative lifetime trauma experiences. Additionally, we computed three empirically derived clusters of trauma types previously shown to differentially correlate with mental health: Accidental/injury traumas (e.g. transportation accident),

victimization traumas (e.g. physical assault), and predominant death threat traumas (containing mostly death-related traumas, e.g. assault with a weapon). Participants reported their sleep reactivity using the Ford Insomnia Response to Stress Test (FIRST) and insomnia using the Insomnia Severity Index (ISI).
Results: Reactive sleepers (FIRST ≥ 20) reported significantly more traumatic life events (M number of events = 7.64 ± SD 3.72) than nonreactive sleepers (M number of events = 5.91 ± SD 4.12), p =.041. High sleep reactivity was uniquely associated with greater lifetime exposure to victimization trauma types (F(1, 84,) = 4.22, p =.043, ηp2 =.048), adjusting for sex and insomnia (ISI ≥ 11). Specifically, 59.0% of patients with a history of physical assault had high sleep reactivity, whereas 41.0% had low sleep reactivity (χ2 = 4.94, p =.026). Similarly, 69.0% of patients with a history of sexual assault had high sleep reactivity, whereas only 31.0% had low sleep reactivity (χ2 = 5.50, p =.019).
Conclusion: Acute trauma patients with high sleep reactivity report greater lifetime exposure to traumatic events, particularly physical and sexual assault. These results highlight the potential link between victimization traumas and increased sensitivity of the sleep system, independent of insomnia status, which may contribute to the development of insomnia and other negative health outcomes.

LONGITUDINAL BI-DIRECTIONAL RELATIONSHIP BETWEEN INSOMNIA SYMPTOMS AND FAMILY INVOLVEMENT AMONG FULL-TIME WORKERS

Wilson Lam[1], Marc Kaizi-Lutu[2], Chunyu Liu[2], Zewen Liu[3], Angel Lee[3], Sanjana Subramanyan[3], Adam Spira[1], Zhiqing Zhou[1]
[1] Johns Hopkins Bloomberg School of Public Health, [2] Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, [3] Johns Hopkins University

Introduction: For full-time workers, family involvement (i.e., level of involvement in family activities) and sleep are important aspects of their nonwork life. While both sleep and family involvement may help buffer the effects of work demands on health, they also may affect each other. Specifically, greater involvement in family activities may disrupt or promote workers' sleep; meanwhile, having high-quality sleep may help workers have more energy and resources to devote to family activities after a day's work. In this study, we examined a potential bi-directional relationship between insomnia symptoms and family involvement among full-time workers in a longitudinal study.
Methods: We analyzed survey data from 199 full-time employees in the U.S. who provided ratings of their experience of four insomnia symptoms over the preceding few weeks (1 = to a very small extent, 5 = to a very large extent) and level of involvement in family activities across three waves with 6 weeks in between. Their average age was 38.2 years (SD = 8.5), 78.9% were white, and 69.3% were male. These employees reported working an average of 41.8 hours per week and came from a variety of industries, including manufacturing (16.1%), finance (15.1%), medical/social services (14.1%), service (13.1%), education (12.1%), and information technology (10.1%).
Results: We performed cross-lagged panel analyses to examine the lagged associations between insomnia symptom severity (averaged across the four items) and subsequent family involvement (while controlling for previous level of family involvement, hours worked per week, industry, age, sex, and race) and between family involvement and subsequent insomnia symptom severity (while controlling for previous insomnia symptom severity, hours worked per week, industry, age, sex, and race). Greater insomnia symptom severity was negatively associated with lower subsequent family involvement (b= -0.11, SE=.03, p <.01), but family involvement was not significantly associated with subsequent insomnia symptoms (b= -0.02, SE=.05, p =.739).
Conclusion: Our findings suggest that insomnia symptoms may decrease workers' involvement in family activities, perhaps by decreasing workers' energy and resources to cope with work demands. In contrast, involvement in family activities may not affect workers' sleep quality.

Introduction: Marriage confers a degree of benefit for a range of health factors, including sleep behaviors and outcomes. Veterans are more likely to report sleep difficulties (e.g., insomnia) and have less social support than the general population. As such, it is important to examine associations between marital status and the occurrence of sleep issues among veterans.
Methods: This study utilizes baseline visit data from veterans in Los Angeles reporting sleep concerns who were enrolled across four structured cognitive behavioral therapy for insomnia intervention trials. Measures included the Pittsburgh Sleep Quality Index (PSQI) total and factor scores, Insomnia Severity Index (ISI), sleep efficiency (measured with actigraphy), and the Patient Health Questionnaire (PHQ-9). Overall, 1,411 veterans had available data (74.1% male; mean age: 63.4 years; 43.3% married/living as married, 21.9% separated, 17.0% single/never married, 10.5% divorced, 7.2% widowed). Multilevel models were constructed to evaluate associations between marital status

and sleep measures after controlling for sex, age, and depressive symptoms. Individuals were nested within the four different sleep trials and "married" served as the reference group.
Results: Multilevel modeling showed that separated individuals had scores indicative of worse sleep compared to married individuals (PSQI total score: β = 0.18, p <.01, N = 1,181; PSQI Sleep Efficiency factor score: β = 0.18, p =.017, N = 1,188; sleep efficiency per actigraphy: β = -0.23, p = 0.014, N = 845). Differences by marital status were not found for the PSQI Perceived Sleep Quality factor, PSQI Daily Disturbances factor, or ISI. Divorced, widowed, and single/never married compared to married did not show differences for any of the sleep measure outcomes.
Conclusion: Using cross-sectional data, we found that veterans who are separated have more severe sleep concerns compared to veterans who are married/living as married. Given this difference, separated veterans may represent a group that are particularly at-risk for sleep difficulties and they may benefit from evaluation of sleep concerns and management of sleep disorders. Findings align with past work showing that marital status can impact measures of health.

JOB DEMANDS AND JOB CONTROL: LINKS WITH SUBJECTIVE AND OBJECTIVE SLEEP QUALITY IN A COMMUNITY-BASED COHORT

Wilson Lam[1], Casandra Nyhuis[2], Marc Kaizi-Lutu[3], Chunyu Liu[3], Zewen Liu[4], Angel Lee[4], Sanjana Subramanyan[4], Lehan Yang[5], Marla O'Shea-Bulman[1], Yul Lee[4], Brion Maher[3], William Eaton[1], Adam Spira[1], Zhiqing Zhou[1]

[1] Johns Hopkins Bloomberg School of Public Health, [2] Department of Public Health Sciences, Penn State College of Medicine, [3] Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, [4] Johns Hopkins University, [5] Johns Hopkins Bloomsberg School of Public Health

Introduction: Existing research links higher levels of perceived job demands (i.e., aspects of work that require workers' efforts, including physical demands and psychological demands) and lower levels of perceived job control (i.e., aspects of work over which employees can exert control, including decision authority and skill discretion) with poorer sleep quality. However, prior studies primarily have focused on self-reported, rather than objectively measured, sleep quality. We examined the associations of job demands and job control with both self-reported and actigraphic sleep quality.
Methods: We analyzed data from 269 participants (52.2±6.1 years, 61% female, 36.8% non-white) in the Baltimore Epidemiologic Catchment Area (ECA) Study who participated in Waves 4 (2004-05) and 5 (2016-22), reported being employed, had complete job demands and control data at Wave 4, and completed the Pittsburgh Sleep Quality Index (PSQI) and 7.0±1.3 nights of wrist actigraphy at Wave 5. We examined associations between Wave 4 job demands and control and Wave 5 PSQI global scores (higher scores indicate poorer sleep quality) and Wave 5 actigraphic sleep efficiency using multivariable linear regression models that adjusted for age, sex, race, education, and self-reported total sleep time in a 24-hour period at Wave 4.
Results: In adjusted analyses, higher psychological demands at work were associated with lower PSQI global scores (b= -0.28, p <.05). Both higher psychological demands (b= 0.64, p <.05) and decision authority (b= 0.77, p <.05) were associated with higher actigraphic sleep efficiency. Physical demands and skill discretion were not associated with PSQI global scores (b= 0.13, p=0.07 and b= -0.12, p=0.25, respectively) or actigraphic sleep efficiency (b= -0.22, p=0.15 and b= -0.11, p=0.62, respectively).
Conclusion: In a community-based sample of working adults, higher levels of perceived psychological job demands were associated with better self-reported sleep quality and actigraphic sleep efficiency, and higher perceived decision authority was linked to higher actigraphic sleep efficiency. Findings suggest that higher levels of psychological demands and decision authority may allow workers to be more engaged at work, develop better sleep patterns to recover from work, and experience better sleep quality.

GEOGRAPHIC AND DEMOGRAPHIC DISTRIBUTION OF AN INSOMNIA PHENOTYPE IN THE ALL OF US RESEARCH PROGRAM

Lauren Gryboski[1], Soniya Mishra[1], Zachary Nicholas[2], Tetyana Zayats[3], Subhajit Chakravorty[4], Diego Mazzotti[1]

[1] University of Kansas Medical Center, [2] Johns Hopkins University School of Medicine, [3] Broad Institute of MIT and Harvard, [4] Crescenz VAMC - Perelman School of Medicine

Introduction: Insomnia is common among adults, but individuals' experiences with the condition may not be well-reflected in electronic health records (EHRs). This leads to inconsistencies when using these codes alone to study insomnia. A computable phenotype for insomnia incorporating diagnosis codes, drug codes, and self-reported insomnia status could help us better understand the condition at the population level. This study aimed to use both EHR data and survey responses to understand the prevalence, geographic distribution, and demographic correlates of insomnia in a large cohort of adults in the All of Us Research Program.
Methods: Data from 99,824 participants who responded to the Personal/Family Health History survey and provided EHR and genomic sequencing data were included. We used an algorithm to identify individuals meeting a stringent (≥2 insomnia condition codes and ≥1 drug code in the EHR) or a broad (≥1 condition codes, drug codes, or self-reported insomnia) definition of insomnia. We estimated the overall clinical prevalence for each definition of insomnia among all participants, and stratified by sex, race, ethnicity, and geographic location.
Results: From included participants, 29,972 (30%) met the broad definition for insomnia and 17,596 (17.6%) met the stringent definition. For both definitions, groups that were overrepresented among insomnia cases relative to their proportion of the sample population included males, those identifying with a sex other than male or female, Non-Hispanic individuals, those identifying with an ethnicity other than Hispanic or Non-Hispanic, and White individuals. Black individuals were overrepresented among insomnia cases when the stringent, but not broad definition was used. Among U.S. states, Kansas had the highest insomnia prevalence according to both definitions (55.71% for

broad and 39.5% for stringent), and North Dakota had the lowest (5.5% and 0%, respectively).
Conclusion: Using the broad definition resulted in a much greater estimated insomnia prevalence, reinforcing the idea that insomnia is underdiagnosed and underreported in EHRs. However, both definitions produced similar demographic and geographic trends. Further research should involve validating the algorithm used in this study to identify individuals with insomnia.

WHEN PAIN MEETS PLACE: UNDERSTANDING RURALITY'S IMPACT ON FATIGUE AND SLEEP DISTURBANCES

Marlee Richardson[1], Melanie Stearns[2], Kevin McGovney[3], Ashley Curtis[2], Christina McCrae[2]
[1] University of Missouri (School of Medicine, Department of Psychiatry), [2] University of South Florida, [3] University of Missouri (Department of Psychology)

Introduction: A long-standing body of research supports the intricate relationship between chronic pain, fatigue, and sleep, yet these complex variables are not uniform among different populations. Moreover, many rural individuals experience health disparities related to sleep, fatigue, and pain, which may be related to limited care access. Herein, we examined whether urbanity/rurality moderated the relationship between pain and sleep disturbance and pain and fatigue in women with pain complaints.
Methods: Women (N=261, Mage=41.8, SD=13.9, 61% urban) with sleep and pain complaints completed surveys during the baseline assessment of an RCT in mid-Missouri. Measures included sleep (PROMIS-Sleep Disturbance, fatigue (PROMIS-Fatigue), pain (McGill Pain Questionnaire), and rurality (Y/N, according to Census Bureau data for 2020 as reported by Rural Health Information Hub's Am I Rural? tool). Using SPSS PROCESS, we examined moderation analyses while controlling for age, employment status (Y/N), and whether individuals live in a low-income area (Y/N) based on the Human Resources and Services Administration low-income city service area designation as specified by the Am I Rural? Tool.
Results: A significant interaction was found between pain and rurality predicting fatigue, $F(1, 252)=8.72$, $p=.003$. Greater pain was associated with greater fatigue in only rural individuals, $\beta=0.21$, $t(252)=4.72$, $p<.001$. Similarly, there was a significant interaction between pain and rurality predicting sleep disturbances, $F(1, 252)=5.78$, $p=.012$. This was only observed in rural individuals, $\beta=0.34$, $t(252)=3.40$, $p<.001$, such that increased pain was related to increased sleep disturbances.
Conclusion: Living in rural areas may increase the risk of experiencing increased pain, fatigue, and sleep disturbance. While this may be partly due to limited access to care, future studies should utilize longitudinal and experimental methodology to determine the causality of these relationships and examine physiological measures of sleep and pain. Further exploration is important for targeted support and consideration of disparities (including access to care) in women struggling with pain, sleep, and fatigue in rural areas.

RACIAL AND ETHNIC DISPARITIES IN INSOMNIA DIAGNOSIS AND TREATMENT AMONG COLLEGE STUDENTS

Rygel Ginete[1], Michelle Garrison[1]
[1] Purdue University

Introduction: The aim of this study was to explore racial and ethnic disparities in clinical insomnia diagnosis among college students. Our a priori hypothesis suggests that cultural stigmas, limited awareness, and other systemic barriers disproportionately affect students from marginalized racial groups in obtaining a clinical insomnia diagnosis. These disparities have significant implications for access to medical treatment and care.
Methods: This study utilized data from the ACHA-NCHA, a national cross-sectional survey of U.S. college students, collected between Fall 2019 and Spring 2023. Insomnia was identified based as experiencing one or more self-reported symptoms at least four or more times per week, including taking over an hour to fall asleep, difficulty falling asleep, or trouble staying asleep. Participants also reported clinical insomnia diagnoses, medical provider visits within the past year, and current treatment status. Racial and ethnic groups were self-reported and non-mutually exclusive. Logistic regression was used to examine the likelihood of clinical insomnia diagnoses across racial and ethnic groups among those reporting insomnia symptoms.
Results: A total of 180,929 students participated in the survey, with most participants being white (58.5%). The regression revealed that students with insomnia symptoms from marginalized racial groups were significantly less likely to receive a clinical diagnosis compared to white students with insomnia symptoms. Specifically, Asian students had an odds ratio (OR) of 0.582 (95% CI [0.535, 0.633]), Black students had an OR of 0.699 (95% CI [0.585, 0.730]), and Hispanic students had an OR of 0.654 (95% CI [0.646, 0.755]).
Conclusion: This approach highlights the gap between experiencing insomnia symptoms and reporting a formal diagnosis, underscoring inequities in healthcare access and awareness among different racial groups. Given that most research on insomnia focuses on individuals already receiving care, further investigation is needed into students experiencing insomnia symptoms but lacking access to care. Understanding these underserved populations is crucial, as treatment approaches may differ for those unable to engage with healthcare services.

ASSOCIATION BETWEEN ACCULTURATIVE STRESS AND INSOMNIA SEVERITY AMONG SPANISH-SPEAKING LATINOS IN FLORIDA

Dunia Mejia[1], Joon Chung[2], Ziyi Ding[3], Jasmine Rubio[3], Camila Pow-Sang[3], Laurent Garchitorena[3], Mary Carrasco[4], Carolina Scaramutti[2], Stacyca Dimanche[3], Alberto Ramos[2], Joao Nunes[5], April Rogers[6], Ferdinand Zizi[3], Girardin Jean-Louis[7], Azizi Seixas[7]
[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Miami, [3] University of Miami Miller School of Medicine, Department

of Informatics and Health Data Science, [4] Lincoln Memorial University Debusk College of Osteopathic Medicine, [5] CUNY School of Medicine, [6] St. John's University, [7] University of Miami Miller School of Medicine

Introduction: Latinos, particularly those who have recently migrated to the United States, often encounter significant acculturation stressors while adapting to the U.S. culture, language, and environment. These challenges, in turn, can negatively impact sleep quality and duration while exacerbating the prevalence of sleep disorders. Our primary focus was to study individuals who primarily speak Spanish, as individuals who do not speak English often experience heightened acculturative stress due to the language barrier. This study aims to explore the relationship between acculturative stress and insomnia severity among a Spanish-speaking population residing in Florida.
Methods: Survey data were collected from the Determinants, Outcomes, Responses, and Markers of Insufficient Sleep in Rural-Urban (DORMIR) study at the University of Miami. Acculturation stress levels were assessed using the Multidimensional Acculturative Stress Inventory (MASI), where higher scores indicate greater levels of stress. Insomnia symptoms were assessed using the Insomnia Severity Index (ISI), a self-reported instrument designed to measure the nature, impact, and severity of insomnia. Both MASI and ISI scores were gathered from a sample of 231 Spanish-speaking adults residing in Florida. ISI scores were regressed on MASI scores using linear regressions, adjusting effects of age, sex, race/ethnicity, Hispanic origin, marital status, income, education, employment, and Body Mass Index.
Results: A one-unit increase in MASI scores (min, max = 0, 109) was associated with a 0.15 increase in ISI scores (b [95% Confidence Interval]: 0.14 [0.08, 0.20], p< 0.001). Of the individual items of the MASI, experiences of being treated rudely or being discriminated against due to English ability, discomfort with English, not feeling accepted by Americans, being expected to know of American ways, and feeling looked down upon if individuals practice Latino customs each were associated with 2 points or higher on the ISI per unit increase.
Conclusion: The study shows that acculturative stress is significantly associated with insomnia severity scores among Spanish speaking populations living in Florida. In these populations, increased acculturation stress may help explain the etiology of insomnia. Future research may investigate modifiers of this association, such as by age or sex or native English or Spanish speaker.

INSOMNIA SEVERITY, SLEEP RELATED IMPAIRMENT, AND DIET QUALITY AMONG BLACK ADULTS IN THE US

Velarie Ansu Baidoo[1], Astrid Zamora[2], Michelle G. Thompson[1], Carolina Scaramutti[3], Michael Grandner[4], Azizi Seixas[1], Girardin Jean-Louis[1]

[1] University of Miami Miller School of Medicine, [2] Stanford University School of Medicine, [3] University of Miami, [4] University of Arizona College of Medicine

Introduction: Adequate sleep and a healthy diet are known to play beneficial roles in cardiometabolic health. However, there is limited epidemiological evidence of this relationship among Black adults, potentially contributing to higher rates of cardiometabolic diseases. This study investigated the associations between 1) diet quality and insomnia severity and 2) diet quality and sleep-related impairment (SRI).
Methods: Baseline data was obtained from 534 Black participants (females 64%; age range 18-75 years) who were enrolled in the NIH-funded study, ESSENTIAL. The Insomnia Severity Index (ISI) and the Patient-Reported Outcomes Measurement Information System-SRI (PROMIS-SRI) were used. Diet quality was assessed via the Rapid Eating Assessment for Participants–Short Form (REAP-S); higher scores indicated a healthier diet quality. Using the REAP-S, we also calculated separate categories for healthy and unhealthy diet quality; lower scores indicating lower vs. higher consumption, respectively. Multivariate linear regression models were used to evaluate the associations between diet quality (predictor variable) with insomnia symptoms and SRI (outcome variables). Adjusted covariates included age, sex, education, body mass index, and marital status.
Results: Mean (SD) scores for ISI and SRI were 16.97 (7.03) and 53.64 (8.72), respectively. The total mean REAP-S score was 26.22 (5.03), indicating a lower average score compared with the United States mean of 32. Multivariate regression analysis revealed that higher ISI scores were associated with lower total diet quality (β = -0.20, p = 0.002) and a lower unhealthy diet score (β = -0.43, p = 0.002), indicating increased intake of unhealthy foods. Similarly, higher SRI scores were associated with lower total diet quality (β = -0.30, p = 0.0002), lower unhealthy diet scores (β = -0.58, p = 0.001), and lower healthy diet consumption (β = -0.70, p = 0.003).
Conclusion: Inverse relationships were observed between diet quality and both insomnia and sleep-related impairment among Black adults. Future studies should examine dietary patterns and metabolic outcomes among larger, more diverse populations.

MENTAL HEALTH SYMPTOMS AND INSOMNIA IN APPALACHIA: DEPRESSION AS A KEY MEDIATOR OF SOCIAL SUPPORT EFFECTS

Mairead Moloney[1], Emily Slade[2], Heier Kory[2], Joon Chung[3], Daniela Moga[2]

[1] University of Miami Miller School of Medicine, Department of Informatics and Health Data Science, [2] University of Kentucky, [3] University of Miami

Introduction: Appalachian Kentucky experiences disproportionate rates of both sleep and mental health disorders. While the relationship between mental health and sleep is well-documented, the complex interplay between social support, mental health symptoms, and insomnia severity remains poorly understood, particularly in rural populations facing multiple health disparities. This study examined associations between mental health symptoms (i.e., anxiety, depression, perceived stress) and insomnia severity in Appalachian adults. Given the well-established associations between depression, social support, and insomnia, we additionally investigated depression as a key mediator between social support and insomnia.
Methods: Data were collected from the Researching Equitable Sleep Time in Kentucky Communities (REST-KY) study, a longitudinal study of sleep and health disparities in Appalachian

Kentucky. In Wave 1, data were collected from 306 adults across 12 Appalachian Kentucky counties via REDCap surveys. Measures included the following well-validated scales: Insomnia Severity Index (ISI), Patient Health Questionnaire-9 (PHQ-9), Generalized Anxiety Disorder-7 (GAD-7), Perceived Stress Scale (PSS), and modified Medical Outcomes Study Social Support Survey (mMOS-SS). Analyses adjusted for living alone, age, sex, income, use of sleep medications (yes/no), polypharmacy (i.e., 5+ medications [yes/no]).

Results: Of the 270 participants who completed the ISI (Mage 46.0 [range = 18-81]), most were white (97.4%) women (79.9%) Higher symptoms of depression (r=0.63, p< 0.001), anxiety (r=0.51, p< 0.001), and perceived stress (r=0.48, p< 0.001) were strongly associated with greater insomnia severity. After covariate adjustment, each one-point increase in PHQ-9, GAD-7, and PSS scores was associated with 0.6, 0.5, and 0.3-point increases in the insomnia severity index, respectively. Mediation analysis revealed that depressive symptoms mediated 62% of the total effect of social support on insomnia severity (p=0.007).

Conclusion: In this sample of Appalachian Kentucky adults, symptoms of depression, anxiety, and perceived stress were all significantly associated with greater insomnia severity. Depression, known to be highly prevalent in this population, significantly mediated the relationship between social support and insomnia severity. These findings suggest that addressing mental health symptoms, particularly depression, may be crucial for improving sleep outcomes in this underserved region and culturally tailored interventions that simultaneously target both social support and depression may be particularly effective.

EVERYDAY DISCRIMINATION EXPERIENCES AND INSOMNIA SEVERITY, STRATIFIED BY SEX, AMONG BLACK INDIVIDUALS LIVING IN NEW YORK CITY AND MIAMI

Michelle Thompson[1], Joon Chung[2], Velarie Ansu Baidoo[1], Sadeaqua Scott[2], Azizi Seixas[2], Michael Grandner[3], Girardin Jean-Louis[1]

[1] University of Miami Miller School of Medicine, [2] University of Miami, [3] Department of Psychiatry, College of Medicine, University of Arizona

Introduction: Although emergent research has explored relationships between everyday discrimination (EDS) and insomnia severity (ISI), little is known about whether discrimination impacts sleep differently across diverse demographic groups such as sex. Biological males and females tend to have differing insomnia severity, and discrimination may impact this relationship in unique ways. By sex, this study investigates the associations of EDS experiences with insomnia among Blacks living in two urban cities, New York and Miami.

Methods: Cross-sectional survey data were extracted for 382 Blacks, ages 18 to 75 years, who were enrolled in the NIH-funded study ESSENTIAL, which investigates psychosocial and environmental determinants of insufficient sleep and associations with adverse health outcomes. Ordinary Least Squares (OLS) linear regression analyses examined sex-stratified associations between EDS and ISI. Adjustment covariates included age, Body Mass Index, education, income, marital status, employment, and ethnicity. Post-hoc regression analyses assessed non-linear relationships between spline-modeled EDS and ISI. Nine sex-stratified linear regressions were conducted as follow up to assess associations in each EDS item. Results were evaluated qualitatively.

Results: in the sample, 68% were female (Meanage = 39.0±12.7[Meanage for males was 42.4±13.3]). Among females, greater everyday discrimination was significantly associated with greater insomnia severity (β=0.115, 95% CI [0.039, 0.191], p = 0.003). However, among males, analyses revealed that greater everyday discrimination was not significantly associated with greater insomnia severity (β=.075, 95% CI [-0.035, 0.184], p = 0.178). In subsequent analyses, we further observed a potential non-linear relationship between EDS and ISI among females. Qualitative assessment of the EDS items on ISI suggested that seven of the nine point components may have a greater association in females than males.

Conclusion: Discrimination may be a contributing factor to sleep disparities among Blacks, potentially moderated by sex. For females (but not for males), every unit increase in EDS was associated with a unit increase in ISI. Understanding how Black males and females differentially conceptualize insomnia and/or their experiences with discrimination is imperative for the development of tailored interventions to reduce sleep health disparities among these groups. Future investigations should explore the gendered experience of discrimination and insomnia which may differ by sex.

LIVING ARRANGEMENTS AND INSOMNIA IN RURAL APPALACHIA: THE ROLE OF SOCIAL SUPPORT

Mairead Moloney[1], Emily Slade[2], Kory Heier[2], Joon Chung[1], Daniela Moga[2]

[1] University of Miami, [2] University of Kentucky

Introduction: Appalachian Kentucky faces significant sleep health disparities, including higher rates of insomnia. In this region, where family connections and multigenerational households are culturally valued, living alone may contribute to sleep difficulties. However, the mechanisms linking living arrangements to sleep health in this population remain understudied. This study examined the association between living alone and insomnia severity and investigated whether social support mediates this relationship in a region already experiencing substantial health disparities.

Methods: Data were collected from the Researching Equitable Sleep Time in Kentucky Communities (REST-KY) study, a longitudinal study of sleep and health disparities in Appalachian Kentucky. In Wave 1, 306 adults from 12 counties completed REDCap surveys containing numerous validated scales including the Insomnia Severity Index (ISI) and modified Medical Outcomes Study Social Support Survey (mMOS-SS). Living situation was self-reported. Multiple linear regression models adjusted for age, sex, income, sleep medication use, and polypharmacy (5+ medications). Mediation analysis examined social support as a mediator between living alone and insomnia severity.

Results: 270 participants completed the ISI; most were middle-aged (MAge=46.0 range = 18-81]) white (97.4%) women (79.9%). Participants living alone (n=52) reported significantly

higher insomnia severity compared to those not living alone (mean ISI: 14.6 vs 11.1, p< 0.001). Living alone was also associated with lower overall social support (mean: 3.35 vs 4.16, p< 0.001). After covariate adjustment, living alone remained significantly associated with higher insomnia severity (p< 0.001). Mediation analysis indicated that living alone had a significant total effect on insomnia severity (p=0.017), with living alone leading to higher insomnia severity. A significant proportion of this effect (approximately 32%) was mediated through social support (p=0.027).
Conclusion: Living alone is associated with higher insomnia severity in this sample of Appalachian adults, with social support playing a significant mediating role. Findings highlight the importance of social connections for sleep health in a region where family ties are culturally central and sleep disparities are overrepresented. Interventions targeting social support, particularly for those living alone, may help address sleep disparities in Appalachian Kentucky. Future research should explore culturally-tailored approaches to enhance social support and improve sleep health in this underserved population.

"SINGLE-SHOT" COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA (CBT-I) IS RELATED TO IMPROVEMENTS IN SLEEP ONSET AND MAINTENANCE PROBLEMS

Jamie Walker[1], Rebecca Campbell[2], Ana Bridges[1], Carlos Acosta[1], Daniel Taylor[3], Jason Ellis[4], Ivan Vargas[5]
[1] University of Arkansas, [2] University of Arizona, [3] The University of Arizona, [4] Northumbria University, [5] University of Notre Dame

Introduction: Although more than half of primary care patients endorse insomnia symptoms, few options are available to manage their sleep continuity disturbance. CBT-I is the first line treatment for insomnia, but a standard course of at least 6 sessions is typically not feasible in primary care settings. The present RCT investigated a "single shot" version of CBT-I in primary care patients suffering from clinically elevated insomnia symptoms.
Methods: Forty-one primary care patients (Mage = 26.2, SDage = 9.4; 70.7% women, 73.2% White) at an integrated behavioral health center were enrolled in the current study and randomly assigned to either one session of CBT-I or one session of an attentional control condition. Daily sleep diaries were used to assess changes in total wake time (TWT = SL+WASO+EMA) and sleep efficiency (%SE) at (1) baseline, (2) one-week post-treatment, and (3) one-month post-treatment. Insomnia symptoms (ISI) and depression symptoms (PHQ-8) were also assessed at baseline and one-month post-treatment.
Results: The final analyses included data from 37 patients (CBT-I = 17, control = 20), after 4 patients were lost to follow-up. Compared to the control group, patients who received one-session of CBT-I reported greater improvements in TWT (t(33) = -2.54, p<.01; mean difference = -42.64; Cohen's d = -0.86) and %SE (t(33) = 1.80, p<.05; mean difference = 0.05; Cohen's d=0.61) from baseline to post-treatment. The CBT-I patients continued to show greater improvements through the 1-month follow-up in TWT (t(30) = -4.11, p <.001; mean difference = -73.28; Cohen's d = -1.46) and %SE (t(30) = 3.18, p<.01; mean difference = 0.12; Cohen's d = 1.13). There was also greater improvement for patients in the CBT-I group on ISI scores (t(30) = -1.85, p<.05; mean difference = -2.65; Cohen's d = -0.66) and PHQ-8 scores (t(29) = -2.29, p<.05; mean difference = -3.70; Cohen's d = -0.83) from baseline to 1 month follow-up.
Conclusion: The present study provides preliminary data to support the use of "single-shot" CBT-I in primary care settings. Furthermore, results suggest that this one-session version of CBT-I may provide a potential benefit beyond sleep by also having meaningful effects on depression symptoms.

A RANDOMIZED CONTROLLED TRIAL OF CBT-I IN VETERANS IN EARLY RECOVERY FROM ALCOHOL USE DISORDER

Subhajit Chakravorty[1], Knashawn Morales[2], Daniel Taylor[3], Samuel Kuna[4], Sean He[5], David Oslin[6], J. Todd Arnedt[7], Henry Kranzler[8]
[1] Crescenz VAMC - Perelman School of Medicine, [2] University of Pennsylvania, [3] The University of Arizona, [4] Cpl. Michael J. Crescenz VA Medical Center, Philadelphia, PA, [5] University of Hawaii Psychiatry Residency Programs, [6] Cpl. Michael J. Crescenz VA Medical Center - Perelman School of Medicine, [7] Michigan Medicine, University of Michigan, [8] Perelman School of Medicine

Introduction: Although insomnia increases relapse risk in early recovery from Alcohol Use Disorder (AUD), no adequately powered clinical trial has evaluated the efficacy of Cognitive Behavioral Therapy for Insomnia (CBT-I) on either insomnia or alcohol outcomes in a largely African-American sample. Objectives: 1) To determine the efficacy of CBT-I for improving insomnia, alcohol-related outcomes, and daytime functioning at post-treatment and at 3- and 6-month follow-up; 2) Evaluate whether improvement in insomnia is associated with a reduction in alcohol-related outcomes post-treatment.
Methods: Design: A randomized, controlled clinical trial of CBT-I compared to Quasi-Desensitization therapy (QDT), conducted between 2015 and 2020, with assessments at baseline, end of treatment (8 weeks), and 3- and 6-month post-treatment (Clinicaltrials.gov # NCT01987089). Setting: Outpatient addiction psychiatry clinic at an urban VA Medical Center. Participants: 63 veterans (51.6±9.6 years, 58 men (92.1%), 52 African-Americans (82.54%) with insomnia and past-year AUD. Intervention(s): Eight weekly in-person sessions of either CBT-I (n=31) or QDT (n=32). Main Outcome(s) and Measure(s): Primary outcomes were the Insomnia Severity Index score (ISI), and Percent Days Abstinent (PDA, from the Timeline Follow Back interview). Secondary outcomes were sleep diary variables, drinks per day, percent non-heavy drinking days, Penn Alcohol Craving Scale score, and scores from the 12-item Short Form scale (SF-12), Beck Depression Inventory and Trait subscale from the State-Trait Anxiety Inventory.
Results: Post-treatment data were obtained from 88.9% of participants. Although CBT-I was efficacious in improving insomnia with effect sizes (E.S.) larger than the meta-analytic estimates, QDT was equally efficacious in improving insomnia (E.S.=-1.63 vs. -1.50), improving abstinence (E.S.=1.54 vs. 1.91) and next-day functioning (E.S.=-0.26 vs. -0.17). Across treatment groups, remission from insomnia was associated with a lower post-treatment alcohol craving score at 8 weeks (2.8, 95% CI=1.1, 4.4 vs.

9.5, 95% CI=6.1, 13.0 in non-responders), an effect that persisted for 6 months after treatment.
Conclusion: CBT-I and QDT are equally effective for treating insomnia during early recovery from AUD. Reduced alcohol craving may be a mechanism by which a remission from insomnia improves drinking outcomes.

COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA IN VETERANS WITH MILD TRAUMATIC BRAIN INJURY

Ansgar Furst[1], Rayma Williams[1], Halee Staggs[1], Jessica Dietch[2], Gloria Maramba[1], Gladys Veltkamp[1], Donn Posner[3], Odette Harris[1], Jamie Zeitzer[4], Rachel Manber[4], Jerome Yesavage[4]
[1] VA Palo Alto HCS, [2] Oregon State University, [3] Sleepwell Consultants, [4] Stanford University

Introduction: Recent meta-analyses show that 30-70% of individuals with a history of traumatic brain injury (TBI) suffer from persistent sleep disturbances. Further, more than 80% of all TBI cases are mild (mTBI) and report more insomnia than those with moderate-to-severe TBI. Given the positive track record of Cognitive Behavioral Therapy for Insomnia (CBT-I) in other conditions, CBT-I could also be an effective treatment for insomnia in those with mTBI, despite common comorbidities.
Methods: In this RCT (NCT03261674) veterans (n=110, 29.1 % female, 51.2±11.5 years old) were randomized to either CBT-I or an active control involving pseudo desensitization. During the treatment, participants had access to a therapist for six 60-minute sessions, once per week, for six consecutive weeks. Treatment was remotely delivered nationwide via telehealth. Independently living veterans with chronic (>3 months since injury) mTBI and insomnia were included in the trial. Comorbid post-traumatic stress disorder (PTSD) was permitted. Central nervous system-active medications were allowed as long as the dose, timing, and formulation were stable (≥ 3 weeks pre-treatment). All sleep measures were based on self-report. The primary outcome measure was the Insomnia Severity Index (ISI) and treatment effects were tested using intent-to-treat analyses based on linear mixed effects models with data derived from multiple imputations.
Results: CBT-I was associated with significantly greater improvement in ISI (p <.001, Beta=0.59) compared to controls. At post treatment, CBT-I had > 8-point reduction of ISI from 16.4±3.6 to 7.4±5.3; controls only improved moderately from 15.6±4.6 to 10.2±6.2. Pre-post improvements in CBT-I were accompanied with improved (p's <.001) sleep efficiency (+12.1±12.0 %), mental health (SF-36 mental component score, -4.8±12.3), depression (PHQ-8, -4.2±5.2), and reduced time in bed (-1.0±1.3 h), wake after sleep onset (-32.6±33.6 min), sleep onset latency (-30.4±42.1 min), early morning awakenings (-28.2±42.2 min) while total sleep time remained virtually unchanged (+0.1±1.3 h).
Conclusion: Despite high rates of co-morbid PTSD and cognitive difficulties associated with mTBI, CBT-I remains a robust treatment for insomnia in this group. Future efforts should focus on increasing accessibility of CBT-I for individuals who have recently sustained a mTBI.

COMPARATIVE EFFECTIVENESS OF MEDICATION, DIGITAL CBT-I (DCBT-I), AND COMBINED THERAPY FOR INSOMNIA IN RURAL ADULTS

Katie Stone[1], Eileen Johnson[1], Sairam Parthasarathy[2], Jerry Krishnan[3], Lee Ritterband[4], Stephen Thomas[5], Julio Fernandez-Mendoza[6], Eric Davis[4], Daniel Taylor[2], Richelle Koopman[7], Christina McCrae[8], Asha Singh[9], Andrew Krystal[10], Daniel Buysse[11]

Introduction: Cognitive Behavioral Therapy for Insomnia (CBT-I) is the recommended first-line treatment for insomnia, but medications remain widely used. Limited evidence suggests combination treatment may capitalize on the advantages of each treatment. However, CBT-I, medication, and combination treatment are rarely compared, and empirical evidence to support best clinical practice with these modalities remains sparse. The COZI study addressed these evidence gaps.
Methods: COZI was a multi-center 3-arm randomized comparative effectiveness trial conducted in primary care settings. Participants were 155 rural U.S. adults aged 23-80 years old with chronic insomnia, randomized to: 1) medication (patient/provider preference of trazodone or zolpidem); 2) digital CBT-I (dCBT-I); or 3) combination of medication+dCBT-I. Treatment outcomes were measured at 9 weeks, 6 and 12 months. The primary outcome was the Insomnia Severity Index (ISI) score. Secondary outcomes included treatment response (defined as □6-point decrease in ISI score) and the Pittsburgh Sleep Quality Index (PSQI) score.
Results: All groups experienced significant, large reductions in ISI scores at all time points. At 6 months, combination therapy (ΔISI=10.2) showed a significant advantage over dCBT-I (ΔISI=7.8) or medication (ΔISI=8.0) alone (both pairwise comparisons Ps< 0.05). These comparisons were not statistically significant after correction for multiple comparisons. Combination therapy showed significantly higher treatment response rates (81.3%) compared to medication alone (57.4%). Combination therapy also showed significantly larger reductions in PSQI scores at all time-points compared to medication alone. Among the 79.4% of participants whose pre-randomization preferred medication was trazodone, both trazodone alone and combined trazodone+dCBT-I were effective in reducing ISI. Side effects were minimal in all groups.
Conclusion: All three treatments showed robust effectiveness for chronic insomnia in primary care practices. Medication and dCBT-I were effective for the treatment of chronic insomnia, but their combination may result in significantly greater effectiveness.
Support (if any): This work was supported through a Patient-Centered Outcomes Research Institute (PCORI) Award (CER-2018C2-13262: "Comparative Effectiveness of Zolpidem/Trazodone and Cognitive Behavioral Therapy for Insomnia in Rural Adults" (COZI). Introduction: Digital CBT-I offers a scalable solution for insomnia treatment, but evidence of its real-world adoption and impact in U.S. clinical settings is limited. This study evaluates the implementation and effects of digital CBT-I within a U.S. healthcare system, utilizing Normalization Process Theory to integrate it into clinical workflows. We compare healthcare utilization between patients who engaged with digital CBT-I and those who were offered but did not use it.

Methods: Patients with insomnia were offered digital CBT-I via electronic and clinical workflows at the Internal Medicine and Sleep clinics within Henry Ford Health, Detroit, Michigan. Normalization Process Theory guided implementation. Electronic order rates and patient sign-ups assessed implementation success and workflow acceptability. Clinician training sessions and educational materials supported uptake. A propensity-matched case-control design compared healthcare utilization rates between 340 digital CBT-I users and 340 matched controls, who were offered digital CBT-I but did not use it. We analyzed patient chart data and standardized time across patients. We evaluated the odds of medication fills and visits before and after.

Results: A total of 340 patients utilizing digital CBT-I from treating practitioners were matched with 340 controls who did not. Digital CBT-I patients exhibited a 64% reduction in medication fills (for any condition) during the post-treatment period relative to before ($p < 0.001$), and were 53% less likely to fill insomnia-specific prescriptions compared to pre-treatment ($p=0.013$). Controls showed no significant changes. Time-varied logistic regression indicated that digital CBT-I patients had 37% higher odds of using outpatient services within the initial 30-60 days ($p=0.048$), but subsequently showed 28% lower odds at 120-150 days ($p=0.041$), and 41% lower odds at 150-180 days ($p=0.039$).

Conclusion: Normalization Process Theory effectively facilitated the integration of digital CBT-I into clinical workflows, providing immediate access with minimal workflow disruptions. Training sessions and ongoing clinician reminders promoted patient uptake of standard care for insomnia management. Findings indicate that digital CBT-I is associated with reduced medication fills and decreased odds of outpatient visits over time, suggesting its potential as an effective, scalable treatment for insomnia in clinical settings.

EARLY FINDINGS FROM A NON-INFERIORITY TRIAL COMPARING TRADITIONAL VS. PROVIDER-GUIDED ASYNCHRONOUS DIGITAL CBTI

Anne Germain[1], Brian O'Reilly[2], Megan Wolfson[3], Sem Chan[4], Matthew Brock[5], Hunter Hearn[6], Shelley Knowles[7], Vincent Mysliwiec[8], Meredith Wallace[9]

[1] NOCTEM Health Inc., [2] Madigan Army Medical Center, [3] Noctem, [4] Knowesis, Inc., [5] San Antonio Uniformed Services Health Education Consortium, [6] NF/SG Veterans Affairs Medical Center, [7] Carl R. Darnall Army Medical Center, [8] The University of Texas Health Science Center, [9] University of Pittsburgh

Introduction: CBTI is the first-line recommended treatment for insomnia. However, the impracticability of CBTI protocols in real-world clinical settings and the scarcity of trained providers create significant CBTI capability gaps. This ongoing non-inferiority trial aims to compare CBTI as usual (CAU) and provider-guided asynchronous CBTI (PGAC) delivered via a clinical decision support platform in service members (SMs) diagnosed with insomnia who are receiving sleep care in a military treatment facility. Here, we report early observations on the primary outcomes of interest: the magnitude of improvements in insomnia severity, depression, and anxiety after 6 weeks of initiating treatment relative to baseline in CAU and PGAC.

Methods: Participating SMs were randomized to CAU (n = 38) or PGAC (n = 38). Clinical psychologists delivered CBTI in both groups. The CAU group received in-person CBTI, whereas PGAC was delivered via the COAST clinical decision support platform. At baseline and post-treatment, all participants completed the Insomnia Severity Index (ISI), the PHQ2 (depression), and the GAD2 (anxiety).

Results: All 38 PGAC patients (10 women; mean age = 32.9 + 8.5; baseline ISI:19 + 4.6; 20 endorsing current shift work) and 33/38 CAU patients (8 women; mean age 31.3 + 7.3; baseline ISI 18.7 + 4.7; 13 endorsing current shift work) initiated treatment. Six-week data was available for 94% of CAU participants and 87% of PGAC participants. At 6 weeks, the PGAC group showed greater improvements in insomnia (4.1 + 4.1) relative to CAU (1.7 + 5.7; Cohen's d = 0.48; 95% C.I: 0.01 - 0.96). At baseline both groups endorsed subclinical levels of depression and anxiety; and there was no significant change in depression and anxiety at the 6-week timepoint.

Conclusion: These preliminary findings suggest that PGAC delivered via a clinical decision support platform may be non-inferior to traditional CBTI. Tech-enabled PGAC could address current CBTI capabilities gaps in military and civilian healthcare settings and offer an additional option in an insomnia stepped care model. Ongoing follow-up data collection will ascertain non-inferiority, and the durability of benefits observed with PGAC and CAU over time.

HEALTH AND SLEEP OUTCOMES IN TRIAGED STEPPED-CARE FOR INSOMNIA: SECONDARY OUTCOMES FROM THE RESTING STUDY

Nicole Gumport[1], Isabelle Tully[2], Bohye Kim[1], Jane Kim[1], Norah Simpson[1], Jessica Dietch[3], Rachel Manber[1]

[1] Stanford University, [2] Case Western Reserve University, [3] Oregon State University

Introduction: Given the worldwide shortage of providers trained to deliver cognitive behavior therapy for insomnia (CBT-I), digital CBT-I (dCBT-I) may increase access to CBT-I. Determining how best to allocate digital and therapist-led resources is needed. Encouragingly, the parent study established the validity of a

Triage Checklist to classify patients projected to do better if they start treatment with a therapist (tCBT-I) compared to dCBT-I. The goal of the present study was to examine the impact of this triaged stepped-care approach on mental health, physical health, and sleep outcomes from baseline to 12-month follow-up.
Methods: 245 middle aged and older adults with insomnia were classified via the Triage Checklist (Manber et al., 2024). Those projected to do better starting treatment with tCBT-I versus dCBT-I constituted the YES stratum (n=137); the rest constituted the NO stratum (n=108). Participants were randomized within stratum to a strategy using dCBT-I only (ONLN) or a stepped-care strategy (STEP). The STEP strategy prospectively allocated the first step of care to dCBT-I or tCBT-I based on the Triage Checklist. Physical and mental health outcomes were measured via the PROMIS Global Health (physical and mental health subscales), Patient Health Questionnaire-4 (PHQ-4), Generalized Anxiety Disorder-7 (GAD-7), and Geriatric Depression Scale (GDS). Sleep was measured via the Epworth Sleepiness Scale (ESS), PROMIS Sleep-Related Impairment (PROMIS-SRI), and sleep diary- and actigraphy-derived sleep duration, total wake time, sleep efficiency, and sleep quality. Mixed effects models evaluated the effects of arm (STEP vs. ONLN) from baseline to 12 months.
Results: Compared to ONLN, STEP was associated with greater improvement on PROMIS mental health (Beta=0.13, p=.02), GAD-7 (Beta=-0.11, p=.002), GDS (Beta=-0.06, p=.01), PROMIS-SRI (Beta=-0.24, p=.0005), and sleep quality (Beta=0.01, p=.003). Within the YES stratum, compared to ONLN, STEP was associated with greater improvement on PROMIS mental health (Beta=0.17, p=.03), PHQ-4 (Beta=-0.07, p=.03), GAD-7 (Beta=-0.15, p=.003), GDS (Beta=-0.08, p=.01), PROMIS-SRI (Beta=-0.29, p=.002), ESS (Beta=-0.11, p=.03), and sleep diary-derived sleep quality (Beta=0.02, p=.02).
Conclusion: STEP was associated with greater improvements in mental health outcomes and select self-reported sleep outcomes compared to ONLN, offering further support for using a triaged stepped care approach.

TRAJECTORIES OF HYPNOTIC MEDICATION USE IN A TRIAGED STEPPED-CARE CBT-I TRIAL FOR INSOMNIA: RESULTS FROM THE RESTING STUDY

Norah Simpson[1], Isabelle Tully[1], Jessica Dietch[2], Nicole Gumport[1], Joshua Tutek[3], Bohye Kim[1], Jane Kim[1], Rachel Manber[1]
[1] Stanford University, [2] Oregon State University, [3] MUSC

Introduction: Previous research has demonstrated that patients with insomnia disorder who use hypnotic medication and engage in cognitive behavioral therapy for insomnia (CBT-I) decrease or eliminate prescription hypnotic medication use in the short-term. However, significant reductions of hypnotic use are not maintained long-term (> 3 months post-treatment). Little is known about longer-term trajectories of hypnotic medication use following CBT-I, and which patient or treatment-related factors may be associated with these trajectories. The current study utilized data from the RESTING trial (Manber et al., 2023), which tested use of a triaged stepped-care algorithm, to explore this question.
Methods: 245 middle-aged and older adults with insomnia received access to CBT-I for 12 months, either digitally or with a therapist, or both (sequentially). Therapist-led CBT-I included treatment components to support hypnotic tapering if this was a treatment goal. Latent class linear mixed model analyses were used to identify patterns of change in the amount of prescription hypnotic medications used over time among participants who used prescription hypnotics at baseline. Six potential baseline predictors were examined: age, gender, insomnia severity, sleep-impairment, and physical health and mental health at baseline.
Results: A three-class model was chosen based on Akaike Information Criterion, Bayesian Information Criterion, log-likelihood values and the size of the classes. The first class had low use at baseline with gradual decreasing use over time (LOW; n=60). The second and third classes had higher use at baseline; the second had decreasing use over time (DECR; n=31) and the third had increasing use (INCR; n=6). 148 participants never used prescription hypnotics. There were no significant differences between potential predictor variables (p-values >.05). Five out of the six participants in INCR had access only to digital CBT-I.
Conclusion: 94% of middle-to-older aged adults enrolling in a CBT-I trial who were using hypnotic medication at baseline were in sub-classes that were characterized by reduced medication use over the 12-month study period. Future research is needed to evaluate the value of including treatment components to support hypnotic tapering in CBT-I.

LONG-TERM SURVIVAL OF SLEEP MEDICATIONS IN PATIENTS WITH HEART FAILURE AND INSOMNIA: A RETROSPECTIVE ANALYSIS

Syed Imran Ahmed[1], Salvatore Carbone[1]
[1] Virginia Commonwealth University

Introduction: Insomnia is highly prevalent in patients with heart failure (HF). Pharmacological therapy is commonly used in the management of insomnia. The long-term effects of insomnia medications in patients with HF and concomitant insomnia have been largely understudied. Particularly, whether differences in long-term survival exist between these medications is unknown. To compare survival in patients with HF and insomnia treated with different insomnia medications: benzodiazepine derivatives (BNZ), melatonin-agonists (MLT), tricyclic antidepressants (TCA), Z-drugs (zaleplon, zolpidem, and eszopiclone), orexin receptor-antagonists (OX), and control (no drugs).
Methods: Retrospective cohort study using TriNetX, a global network of medical records from healthcare organizations worldwide. Adults with HF (ICD10:I50) and insomnia (ICD10:G47.0) receiving insomnia medications were included. The propensity score was matched (1:1) using demographic variables and HF-related disease severity (i.e., NtproBNP). The outcome was all-cause mortality within 6 years from initiation of any of the sleep medication groups. Hazard ratios (HRs) and 95% Confidence intervals (CIs) were calculated using the Kaplan-Meier test between groups.
Results: Among 3,767,049 patients with HF, 249,571 had insomnia. After propensity score matching, OX was associated with lower mortality compared to TCA [HR=0.73, 95%CI=0.65,0.83; p< 0.0001], Z-drugs [HR=0.69, 95%CI=0.61, 0.78; p< 0.0001], MLT [HR=0.51, 95%CI=0.45,0.57; p< 0.0001], BNZ [HR=0.60,

95%CI=0.53,0.68; p< 0.0001], and control [HR=0.68, 95%CI=0.60,0.77; p< 0.0001]. Similarly, TCA was associated with lower mortality risk compared to Z-drugs [HR=0.90, 95%CI=0.88,0.93; p< 0.0001], MLT [HR=0.71, 95%CI=0.69, 0.73; p< 0.0001], BNZ [HR=0.86, 95%CI=0.83, 0.88; p< 0.0001], and control [HR=0.86, 95%CI=0.84,0.88; p< 0.0001]. Z-drugs were associated with lower mortality risk compared to MLT [HR=0.77, 95%CI=0.74, 0.77; p< 0.0001], and BNZ [HR=0.93, 95%CI=0.92,0.95; p< 0.0001] but no difference to control [HR=0.99, 95%CI=0.98, 1.02; p=0.915]. However, treatment with MLT or BNZ was associated with an increased mortality risk compared to control [HR=1.27, 95%CI=1.25,1.29; p< 0.0001], [HR=1.06, 95%CI= 1.05,1.08; p< 0.0001], respectively. MLT was associated with higher mortality risk compared to BNZ [HR=1.19, 95%CI=1.18,1.21; p< 0.0001].

Conclusion: In this retrospective study, treatment with orexin receptor agonists was associated with a more favorable survival compared to other insomnia medications in patients with HF and insomnia. Future randomized controlled studies are warranted to confirm these findings.

Introduction: Evidence regarding the potential adverse impact of sleep medications on hearing is inconsistent and limited. Potential mechanisms include decreased input from the auditory nerve and disturbed organization and integration of sensory information. This study aims to investigate the associations between trajectories of sleep medication use over nearly 30 years and late-life hearing among community-dwelling adults.

Methods: Participants in the Atherosclerosis Risk in Communities (ARIC) Study underwent hearing evaluations at visit 6 (2016-17) and provided medications used in the past four weeks for each visit from visits 1 (1987-89) to 6. Hearing outcomes included: (1) Peripheral auditory function: better-ear four-frequency (0.5, 1, 2, 4 kHz) pure-tone average (PTA, higher=worse) assessed by pure-tone audiometry in decibels (dB); (2) Central auditory function: Quick Speech-in-noise (QuickSIN) test measures the ability to understand speech in noise, with score ranging from 0-30 (higher=better). Sleep medication included barbiturates, benzodiazepine derivatives, non-selective serotonin reuptake inhibitor antidepressants, and hypnotics. Sleep medication use was considered as any vs. none at each visit and group-based trajectory modeling identified three trajectory groups: non-users (N=2,398), increasing users (N=449), and continuous users (N=255). Linear regression models were used to estimate differences in hearing associated with sleep medication use trajectory groups. Models adjusted for demographics, lifestyle, and cardiovascular factors. We further conducted stratification analysis by visit 2 (1990-92) self-reported insomnia symptoms, including having trouble falling asleep and waking up repeatedly (yes vs. no).

Results: Among 3,102 participants (mean visit 1 age=50.7 years, 59% female, 21% Black), when compared to non-users, increasing users had 1.61 dB (95% confidence interval [CI]: 0.38, 2.84) significantly worse PTA; no differences were observed in QuickSIN. The association was significant among participants without trouble falling asleep (1.93 dB, 95% CI: 0.53, 3.34), but not among those with the symptom (0.53 dB, 95% CI: -2.22, 3.28). However, for waking up repeatedly, the association was stronger among those with the symptom (Yes: 2.35 dB, 95% CI: 0.41, 4.29; No: 1.29 dB, 95% CI: -0.36, 2.94).

Conclusion: This study provides initial evidence linking sleep medication use from midlife to late life with worse late-life hearing, and the association might differ by sleep symptoms.

BZRA HYPNOTIC RECEPTOR SPECIFICITY AND REBOUND INSOMNIA

Timothy Roehrs[1], Thomas Roth[2]

[1] Henry Ford Health, [2] Sleep Disorders and Research Center, Henry Ford Health System

Introduction: Discontinuing hypnotics after chronic use remains a concern, which has never been directly tested in a controlled, blinded, prospective study using self-administration choice procedures. We report on discontinuation predictors in a clinical trial in which persons with insomnia were instructed to stop taking medication after 6 months of nightly use.

Methods:: Insomnia participants aged 23-61 yrs, (n=41, 36 females), with no other sleep disorders, unstable medical or psychiatric diseases or drug dependency completed the trial. Following a NPSG participants were randomized to zolpidem XR (12.5 mg), eszopiclone (3 mg), or placebo nightly for 6 months. After 6 months nightly use, over a 2-week discontinuation, they were instructed to discontinue their hypnotic use, but if necessary, to self-administer either 1, 2, or 3 capsules of their assigned "blinded" medication (zolpidem XR 6.25 mg, 6.25 mg, placebo; eszopiclone 2 mg, 1 mg, placebo as capsules 1, 2 and 3 respectively; or 3 placebos). Sleep was recorded by actigraphy on a baseline week and during the two discontinuation weeks and scored for latency to sleep (LAT min), wake during sleep (WASO min), and sleep efficiency (SE %). Rebound insomnia was tested by comparing baseline nt 1 to discontinuation nts 1 & 2.

Results: Over the 14 nights 21 participants took zero (51%) capsules and among the 20 taking capsules the median total number chosen was 3. During the two-week discontinuation the BzRA receptor non-specific hypnotic, eszopiclone, was associated with a significantly greater (p<.005) number of capsule choices than the placebo group with the zolpidem group (BzRA receptor

specific) not different than placebo. Compared to baseline, on discontinuation night 1 the eszopiclone group had greater WASO (i.e. rebound insomnia +10.2 +/-8.4 min), differing ($p < .05$) from the placebo (-9.3 +/-6.3 min) and zolpidem (-12.2+/8.5 min) groups which did not experience rebound insomnia. No rebound insomnia on discontinuation nt 2 in any of the three groups.
Conclusion: Fifty-one percent discontinued 6-months of nightly hypnotic use. The BzRA receptor non-specific hypnotic group, eszopiclone, self-administered a greater number of capsules during the two-week discontinuation and experienced rebound insomnia on discontinuation night 1.

INSOMNIA SEVERITY FOLLOWING BENZODIAZEPINE RECEPTOR AGONIST DEPRESCRIBING AND CBTI: DOES SLEEP APNEA RISK MATTER?

Constance Fung[1], Cathy Alessi[2], Jennifer Martin[3], Karen Josephson[4], Lara Kierlin[5], Joseph Dzierzewski[6], Alison Moore[7], M. Safwan Badr[8], Michelle Zeidler[9], Andrew Guzman[10], Austin Grinberg[11], Jason Smith[12], Ian Cook[13], Monica Kelly[14], Michael Mitchell[4]

Introduction: Benzodiazepine receptor agonist (BZRA) deprescribing and cognitive behavioral therapy for insomnia (CBTI) are recommended for older adults with chronic insomnia, who often have co-occurring obstructive sleep apnea (OSA) symptoms or diagnosis (COMISA). Prioritization of OSA management may delay BZRA deprescribing and CBTI initiation. We hypothesized that Insomnia Severity Index (ISI) would improve with BZRA deprescribing and CBTI irrespective of OSA risk or monitoring of OSA treatment.
Methods: We pooled data from two arms of a randomized clinical trial that enrolled adults aged ≥55 years who chronically use BZRAs for insomnia (Mage 69.2 years, 34.6% female, 73.4% discontinued BZRA 1-week post-treatment [PTX] and 61.7% at 6 months [6M]). STOP-Bang, OSA diagnosis status, Epworth Sleepiness Scale (ESS), and ISI were collected at baseline (BL). Sleep testing was conducted if STOP-Bang was 5+ ("high risk"). Event index (apnea-hypopnea index [AHI] or respiratory event index [REI]) from prior sleep test reports was abstracted. All participants underwent CBTI and a gradual BZRA taper. Although participants continued to receive usual primary care and sleep care, OSA therapy was not monitored during intervention and only a prescription for therapy (e.g., positive airway pressure) for OSA was required for individuals with AHI≥30 or AHI≥15 plus ESS>10 to be eligible to receive CBTI. Follow-up ISI was administered at PTX and 6M. Linear mixed models examined changes in ISI from BL to PTX and 6M in participants at 1) "high risk"/any OSA (STOP-Bang 5+ or AHI or REI ≥5) and 2) moderate-severe OSA (AHI or REI ≥15).
Results: In participants at high risk for OSA based on STOP-Bang or with known AHI/REI >5 (n=87, 47%, BL MISI 14.8), ISI significantly improved at PTX (MISI 7.6, Δ-7.1, $p<.001$) and 6M (MISI 8.3, Δ-6.6, $p<.001$). In participants with moderate-severe OSA (n=23, 13%, BL MISI 15.7), ISI significantly improved at PTX (MISI 8.7, Δ-7.0, $p<.001$) and 6M (MISI 8.8, Δ-6.8, $p<.001$).
Conclusion: Insomnia severity improved with BZRA deprescribing and CBTI even in the context of unmonitored OSA symptoms and treatment. These results suggest that OSA status should not preclude BZRA deprescribing or CBTI initiation.

PATIENT-REPORTED OUTCOMES FOR LEMBOREXANT TREATMENT IN CHINESE PATIENTS WITH INSOMNIA (PROEM): A REAL-WORLD STUDY

Xueli Li#[1], Shuqiong Zheng#[2], Weiying Jian[3], Yamei Tang[4], Yongqiang Lin[5], Fujun Jia[1], Bin Zhang*[2],*
[1] Guangdong Provincial People's Hospital, [2] Nanfang Hospital, Southern Medical University, [3] Guangzhou United Family Hospital, [4] Sun Yat-sen Memorial Hospital, Sun Yat-sen University, [5] Clifford Hospital

Introduction: Lemborexant (LEM) is a novel dual orexin receptor antagonist approved for treating adults with insomnia in the United States, Canada, Japan and some other countries. Except for one case report, there has been no published study of LEM treatment for patients with insomnia in China. This study assessed LEM treatment for patients with insomnia in routine clinical practice in China.
Methods: This multicenter, prospective, 12-week, real-world observational study (NCT06225947) plans to enroll 200 adult patients with insomnia who visited 1 of the 5 participating hospitals in China from Feburary2024. All patients were treated with LEM as per routine clinical practice. For the interim analysis, the primary endpoint was remitter rate after 4 weeks of treatment (patients with a post-treatment Insomnia Severity Index [ISI] score of < 8.). Treatment-emergent adverse events (TEAEs) were recorded.
Results: By the cut-off date of the interim analysis, 100 patients had been taking LEM for at ≥4 weeks (79) or withdrew from the study (21). They had a mean age of 45.18±13.17 years, mean insomnia duration of 6.35±7.71 years, and a mean baseline ISI score of 17.13±4.12 points. Sixty-four (64.00%) patients were female. Twenty-three (23.00%), 6 (6.00%) and 71 (71.00%) patients received LEM as initial monotherapy, transitioned to LEM, or added LEM to existing hypnotic therapy, respectively. The remitter rate was 33.00% (33/100) after 4 weeks of treatment, and the responder rates (ISI score decreased ≥6 points from baseline) after 1, 2 and 4weeks of treatment were 40.00% (40/100), 52.00% (52/100) and 54.00% (54/100), respectively. Mean ISI and Patient Health Questionnaire-9 scores decreased significantly after 1 week of treatment (-4.79±5.68, -1.03±4.04, respectively,

both P< 0.001) and continued to decrease (-8.10±5.21, -2.71±3.51 after 4 weeks of treatment, respectively). Mean General Anxiety Disorder-7 score decreased significantly after 2 weeks of treatment and continued to decrease during the study. Hence, LEM treatment improved their mood as well. Twenty-two (22.00%) patients experienced mild (21) or moderate (1) treatment-related TEAEs. The most common TEAE was somnolence (11.00%).
Conclusion: This first real-world observational study of LEM treatment in China demonstrated that LEM treatment was effective and safe in treating Chinese adult patients with insomnia.

LEMBOREXANT'S EFFECTS ON RAPID EYE MOVEMENT (REM) SLEEP ARCHITECTURE IN ASIAN AND NON-ASIAN ADULTS WITH INSOMNIA: COMPARATIVE ANALYSIS FROM 3 STUDIES

Yong Won Cho[1], Michael Mak[2], Jocelyn Y. Cheng[3], Naoto Yamakawa[4], Dinesh Kumar[3], Kisaki Onishi[4], Takao Takase[4], Margaret Moline[3]

[1] Keimyung University School of Medicine, Daegu, Korea, [2] Centre for Addiction & Mental Health, Toronto, Ontario, Canada, [3] Eisai Inc., Nutley, New Jersey, United States, [4] Eisai Co., Ltd., Tokyo, Japan

Introduction: Sleep architecture is altered in insomnia, including reduced rapid eye movement (REM) sleep. As REM sleep supports cognition and emotional regulation, its preservation has potentially important clinical implications. Treatment with lemborexant (LEM), a dual orexin-receptor antagonist, led to increased REM sleep compared with placebo (PBO) in adults with insomnia. This investigation evaluated the comparative effects of LEM on REM sleep parameters between Asian and non-Asian adults with insomnia, thereby evaluating potential effects of race.
Methods: This analysis incorporated data from 3 independent, 1-month, randomized, double-blind, PBO-controlled, parallel-group studies. E2006-J086-311 (Study 311; NCT04549168) included Chinese participants ≥18y. E2006-J082-204 (Study 204; NCT05594589) included Korean participants 19–80y. E2006-G000-304 (Study 304; NCT02783729) enrolled participants ≥55y (females)/≥65y (males) of any race; only non-Asian participants are presented here. Polysomnographic assessment of REM sleep and REM latency (REML) was conducted at baseline (during single-blind PBO run-in) and following 1 month of treatment with LEM 10mg (LEM10) or PBO.
Results: Mean (SD) baseline REM for LEM10 and PBO was 68.65(19.167) and 69.85(17.091) min, 67.37(28.695) and 58.96(36.077) min, and 61.58(20.409) and 65.32(19.591) min for Study 311 (LEM10, n=93; PBO, n=100), Study 204 (LEM10, n=26; PBO, n=13), and Study 304 (LEM10, n=264; PBO, n=206), respectively. At 1 month, least squares mean (LSM) (SE) CFB in REM for LEM10 and PBO was 24.05(3.451) and 8.59(3.176) min (P< 0.0001), 28.06(5.325) and 12.77(7.529) min (P=0.1035), and 21.82(1.368) and 5.10(1.528) min (P< 0.0001) for Study 311, Study 204, and Study 304, respectively. Mean (SD) baseline REML for LEM10 and PBO was 98.26(41.392) and 95.59(33.729) min, 125.63(68.727) and 131.42(91.967) min, and 100.14(54.320) and 99.60(51.803) min for Study 311, Study 204, and Study 304, respectively. Mean (SD) CFB in REML for LEM10 and PBO was −38.47(45.677) and −7.20(37.393) min (P< 0.0001), −42.15(73.471) and −0.83(59.514) min (P=0.0709), and −38.16(56.103) and −7.28(62.479) min (P< 0.0001) for Study 311, Study 204, and Study 304, respectively.
Conclusion: The magnitude of changes in REM sleep and REML was comparable between Asian and non-Asian participants, demonstrating LEM's consistent therapeutic effect across diverse patient populations. Given REM sleep's established role in cognition and emotional regulation, these findings suggest potentially significant clinical implications warranting further evaluation.

CONSISTENCY OF OBJECTIVE RESULTS ON SLEEP ONSET AND SLEEP MAINTENANCE PARAMETERS FROM GLOBAL STUDIES OF LEMBOREXANT

Alan Lowe[1], Naoto Yamakawa[2], Takao Takase[2], Kenya Nakai[3], Dinesh Kumar[4], Kisaki Onishi[2], Margaret Moline[4]

[1] University of Toronto, [2] Eisai Co., Ltd., Tokyo, Japan, [3] Eisai Co., Ltd., [4] Eisai Inc., Nutley, New Jersey, United States

Introduction: When selecting a hypnotic for patients, it is important to know whether there are differences in response based on age, sex, and/or race. To increase patient diversity across the clinical development program for lemborexant (LEM), a dual orexin-receptor antagonist approved to treat adults with insomnia, 2 additional studies were conducted beyond the original Phase 3 studies that enrolled patients in North America, Europe, and Japan, but few from South Korea and none from China. Since studies have now completed in these latter countries, it is possible to compare results on polysomnography (PSG) from the 3 studies conducted globally with South Korea or China.
Methods: Each study was 1-month, multiple-site, randomized, and placebo-controlled enrolling participants with insomnia disorder. Study E2006-G000-304 (Study 304) included females ≥55 years/males ≥65 years with confirmed sleep maintenance insomnia. Studies E2006-J086-311 (Study 311) and E2006-J082-204 (Study 204) enrolled adults ≥18 and 19–80 years, respectively, with confirmed sleep onset and/or maintenance insomnia. PSGs were obtained during the placebo run-in (baseline) and at end-of-treatment. Each study included LEM 10 mg (LEM10) and placebo. Study 304 also included zolpidem extended-release, and Studies 204 and 304 included LEM 5 mg (not discussed here). Change from baseline to Day 30 in latency-to-persistent-sleep (LPS), sleep efficiency (SE), and wake-after-sleep-onset (WASO) were calculated. Safety and pharmacokinetics (PKs) were assessed.
Results: Results from the 3 PSG studies (204, 304, and 311) were compared using 95% confidence intervals (CIs). LEM10 led to larger changes from baseline in LPS, SE, and WASO compared to placebo. The CIs overlapped, demonstrating that the direction and magnitude of effect were similar. LEM PKs from Studies 204 and 311 were comparable to Study 304. Based on the totality of LEM data from clinical trials, analyses show that oral clearance was not affected by race. In Studies 204 and 311, like global Study 304, overall incidence of LEM10 treatment-emergent adverse events was similar to placebo. In all studies, most TEAEs were mild/moderate.
Conclusion: These data support the view that LEM is an effective and well-tolerated treatment for patients with insomnia without influence by race/national origin.

PRAZOSIN IMPROVES INSOMNIA AND LINKS SLEEP IMPROVEMENTS TO REDUCED HEADACHE SEVERITY IN POSTTRAUMATIC HEADACHES

Maria-Efstratia Tsimpanouli[1], Yeilim Cho[1], Cynthia L. Mayer[2], Elaine R. Peskind[1], Murray A. Raskind[3], Jeffrey J. Iliff[4]

[1] University of Washington, School of Medicine, Department of Psychiatry and Behavioral Sciences, [2] University of Washington, School of Medicine, Department of Radiology, [3] University of Washington, School of Medicine Department of Psychiatry and Behavioral Sciences, [4] VISN [20] Mental Illness Research, Education, and Clinical Center

Introduction: Sleep disturbances, including poor sleep quality and insomnia, are critical factors affecting well-being and quality of life, particularly in individuals with posttraumatic headaches (PTH) following mild traumatic brain injury (mTBI). These issues are prevalent in military veterans and active-duty service members, contributing to significant impairment. This secondary analysis of a randomized controlled trial evaluating prazosin, an alpha-1 adrenergic receptor antagonist, for PTH prophylaxis aimed to assess changes in sleep quality and insomnia severity, as measured by the Pittsburgh Sleep Quality Index (PSQI) and Insomnia Severity Index (ISI), and their relationship with changes in headache impact, measured by the Headache Impact Test (HIT).

Methods: Participants were randomized to prazosin (n=26) or placebo (n=52). This analysis focused on changes in PSQI and ISI total and domain scores, collected at baseline and end-of-study to evaluate total sleep quality and insomnia severity. Correlations between changes in sleep measures and changes in HIT scores were also examined within each group. Comparisons and correlations were considered significant at $p < 0.05$.

Results: There were no significant differences between prazosin (age 40.6 ±11.9 years, 8.3% female) and placebo (age 39.2 ±9 years, 15.4% female) groups for changes in total PSQI score. However, the prazosin and placebo groups were significantly different in terms of changes in HIT (-5.04 vs -0.5, p=0.004) and total ISI (-3.46 vs -0.69, p=0.003) scores. Multiple ISI domains were also improved by prazosin, including falling asleep, staying asleep, and waking up too early, reflecting reduced insomnia severity. Additionally, changes in total PSQI (r=0.42, p=0.003), total ISI (r=0.31, p=0.03) and other ISI domains were significantly correlated with changes in HIT scores only in the prazosin group, indicating that sleep improvements were associated with reduced headache impact.

Conclusion: Prazosin improved insomnia severity and specific aspects of sleep initiation and maintenance, although overall sleep quality remained unchanged. The correlation between improved sleep outcomes and reduced headache impact in the prazosin group highlights its potential to address both sleep disturbances and headache-related disability in military personnel with mTBI-related PTH. Further research is needed to confirm these findings.

BEHAVIOUR, ATTITUDES, AND EXPERIENCES OF LONG-TERM BENZODIAZEPINE USERS DURING COVID-19: AN EXPLORATORY ANALYSIS

Kristien Coteur[1], Ellen Lambrecht[1], Zoa Rooms[1], Birgitte Schoenmakers[1]

[1] KU Leuven, Belgium

Introduction: The COVID-19 pandemic disrupted daily routines and exacerbated stress, significantly affecting sleep and substance use behaviors. Benzodiazepine receptor agonists (BZRAs) are commonly prescribed for sleep disorders, yet their long-term use carries risks such as dependency, cognitive and psychomotor impairment. This study explores how the pandemic influenced the attitudes, behaviors, and experiences of long-term BZRA users in Belgium, focusing on substance use patterns, sleep management strategies, and psychosocial impacts.

Methods: Data from 723 unique long-term BZRA users about changes in hypnotics or sedatives, alcohol, tobacco, and pain medication use, and the impact of psychosocial symptoms was analyzed. The data were collected as part of a cluster randomized controlled trial in Belgian general practices, which started in 2019 and continued until 2021. The trial aimed to assess the effectiveness of blended care for discontinuing long-term BZRA use in patients with insomnia. Changes and symptoms were mapped using a specific COVID-19 questionnaire from June 2020 onwards. Descriptive analyses were performed, including prevalence rates and central tendency measures, along with thematic synthesis of qualitative data.

Results: At one year follow-up, 79 participants (10.9%) reported an increase in BZRA use and 70 (9.7%) a decrease, while most (n=426; 58.9%) reported no change. Common symptoms such as sleep problems, stress, and feeling anxious, impacted substance use in respectively 169 (23.4%), 162 (22.4%), and 136 (18.8%) participants. Coping strategies commonly included digital social interactions and new hobbies. While the contact limitations created an opportunity for some to taper BZRA, they resulted in social isolation for others. Findings particularly highlight the complex interplay between dependence, psychological distress, and social isolation, with significant variation in individual experiences.

Conclusion: The intricate interplay between lifestyle, social factors, and substance use during crisis periods was highlighted. Findings underscore the need for personalized, holistic interventions to manage sleep disorders and reduce long-term BZRA dependency, particularly during times of heightened stress.

Support (if any): The Big Bird trial, registered at clinicaltrials.gov (NCT03937180), was independent research (KCE-17016) funded by Belgian Health Care Knowledge Centre under the KCE Trials Programme.

NATIONAL PRESCRIBING TRENDS FOR INSOMNIA MEDICATIONS IN MEDICAID PATIENTS

Nicholas Shaffer[1], Telyn Peterson[1], Karen Hentschel-Franks[1]

[1] UT Health San Antonio

Introduction: Insomnia is a common condition among Medicaid recipients, with a prevalence of 74.3 per 1,000 recipients reported in a study analyzing state Medicaid fee-for-service claims. As a joint state-federal program, Medicaid significantly shapes treatment access and affordability for vulnerable populations. This study examines prescribing practices for insomnia medications across the United States, identifies regional variations, and evaluates implications for equitable care. Understanding these patterns is crucial for developing policies that enhance access

to effective, affordable, and equitable treatments for Medicaid beneficiaries.
Methods: Medicaid drug utilization data from 2023, spanning all 50 states and the District of Columbia, were analyzed to evaluate prescribing patterns for 10 insomnia medications: doxepin, eszopiclone, ramelteon, suvorexant, temazepam, tiagabine, trazodone, triazolam, zaleplon, and zolpidem. Average prescription rates per 1,000 enrollees and Medicaid reimbursement rates were compared. State-level variations were assessed using Kruskal-Wallis and PERMANOVA tests to identify statistical significance.
Results: Trazodone and zolpidem were the most prescribed medications, with average prescription rates of 130.9 (SD = 44.5) and 27.3 (SD = 13.3) per 1,000 enrollees, respectively. Ramelteon and eszopiclone had lower rates, at 0.9 (SD = 1.2) and 4.0 (SD = 3.2) per 1,000 enrollees. Moderate rates were observed for doxepin (mean = 9.1, SD = 5.7) and temazepam (mean = 3.2, SD = 2.3). Rarely prescribed medications included tiagabine (mean = 0.031, SD = 0.047) and triazolam (mean = 0.565, SD = 0.717). Medicaid reimbursement rates were highest for trazodone ($1.36 per enrollee), followed by zolpidem ($0.23) and doxepin ($0.26), while zaleplon had the lowest reimbursement ($0.01). Kruskal-Wallis and PERMANOVA tests (p = 0.336) found no significant state-level differences.
Conclusion: Although no significant regional differences in prescribing patterns were observed, variability in medication use and reimbursement highlights potential disparities in access to insomnia treatments. Trazodone's dominant use underscores the need for further research into its efficacy and optimal role in insomnia management. These findings raise questions about whether prescribing patterns reflect clinical appropriateness or broader systemic factors, such as cost, prescriber familiarity, or Medicaid policies. This study provides a foundation for future research and policy initiatives to address treatment disparities and improve insomnia care for Medicaid beneficiaries nationwide.

INSOMNIA MEDICATION PRESCRIBING PATTERNS AMONG MEDICARE SLEEP PHYSICIANS

Nicholas Shaffer[1], Telyn Peterson[1], Adeel Meraj[2]
[1] UT Health San Antonio, [2] Audie L. Murphy Memorial Veterans Hospital Sleep Disorders Center

Introduction: Insomnia affects up to two-thirds of adults, often requiring medical intervention from a sleep specialist. While cognitive behavioral therapy for insomnia (CBT-I) is the gold standard, pharmacotherapy remains common due to limited access to trained CBT-I providers and other barriers. Despite the widespread use of insomnia medications, prescribing patterns among sleep medicine physicians remain underexplored. This study examines how physician demographics, training, and practice location influence prescribing practices, with the goal of identifying trends, regional variations, and opportunities for improving evidence-based care.
Methods: Data were collected on 10/16/2024 from 531 Medicare Part D sleep medicine physicians listed by CMS for 2022. Prescribing patterns for 10 insomnia medications—doxepin, eszopiclone, ramelteon, suvorexant, temazepam, tiagabine, trazodone, triazolam, zaleplon, and zolpidem—were analyzed. Comparisons by gender, degree type (MD, DO), specialty, graduation year (pre- and post-2011, marking the start of sleep medicine fellowship requirements), and geographic region (per the Electronic Residency Application Service map) were conducted using Mann-Whitney U, Kruskal-Wallis, and PERMANOVA tests.
Results: Zolpidem was the most prescribed insomnia medication (median: 23 prescriptions/physician) across all specialties except psychiatry, where trazodone was most frequently prescribed (median: 41 prescriptions, p=0.00185). Geographic factors significantly influenced prescribing practices (PERMANOVA, p=0.026). Physicians in the West South Central region favored trazodone over zolpidem compared to the Pacific (p=0.021) and South Atlantic (p=0.041) regions. Subgroup analyses revealed additional findings: MDs prescribed more ramelteon than DOs (p=0.000074). Zolpidem and ramelteon prescriptions decreased with graduation year, with zolpidem declining from a median of 24 to 14 prescriptions/physician (p=0.021) and ramelteon decreasing from 17 to 12 (p=0.045). Despite this decline, zolpidem remained the most prescribed medication across all groups.
Conclusion: This study highlights variations in prescribing practices for insomnia medications among sleep physicians. Zolpidem remains the most widely prescribed drug, followed by trazodone. Regional factors significantly influence prescribing trends, while physician demographics, degree type, and training appear to have limited impact. These findings emphasize the need to address regional variations and better align prescribing practices with evidence-based standards. Further research is needed to explore the drivers of these trends and assess the impact of educational initiatives promoting consistent, high-quality insomnia care.

ESTIMATES OF CANNABIS USE AS A SLEEP AID: RESULTS FROM A NATIONAL SLEEP FOUNDATION POPULATION SURVEY

Joseph Dzierzewski[1], Alysa Miller[1], Spencer Nielson[1], John Lopos[1]
[1] National Sleep Foundation

Introduction: National Sleep Foundation population research indicates that the majority of adults are not getting enough sleep and are dissatisfied with their sleep. Numerous potential solutions for sleep difficulties continue to be introduced to the public, ranging from digital therapeutics to prescription and over-the-counter medicines, to nutritional supplements and cannabis-based products. Among consumers, use of products generalized as cannabis (i.e., CBD, CBN, THC) represents a growing paradigm in sleep aids. Given the lack of established guidelines on cannabis use and sleep, it is important to monitor the public's current use and willingness to use cannabis-based products to promote sleep.
Methods: Data were drawn from an online, national survey utilizing a probability-based, random sample of 1,372 U.S. adults, oversampled for both Black and Hispanic individuals. The survey was administered in English or Spanish, and included demographic information, questions probing sleep duration and quality, and three items asking about (a) current, (b) past, and (c) future likelihood of cannabis use to help sleep. Descriptive statistics were used to summarize rates of cannabis use to help sleep. Sleep differences between individuals who did and did not endorse current or past use or a willingness to try cannabis to help sleep were examined via t-tests.

Results: Current and past use of cannabis to help with sleep was reported at 9% and 17%, respectively. Twenty-three percent of adults said they were likely to consider use of a cannabis product to help them sleep. Adults who currently use, have used, or are willing to use cannabis to help with sleep had significantly shorter sleep durations and lower sleep quality than their counterparts ($p<.05$ for all comparisons).
Conclusion: Over 23 million US adults currently use cannabis-based products to help them sleep, while nearly twice that number have previously tried cannabis-based products for sleep. Over 60 million adults are likely to consider cannabis products in attempts to improve their sleep. Unfortunately, there is a dearth of evidence-based guidelines on the use of cannabis for sleep. Much more work is needed to determine the short-term and long-term effects of cannabis products on sleep health to best inform public recommendations.

EFFECTS OF A CANNABIDIOL/TERPENE FORMULATION ON SLEEP IN INDIVIDUALS WITH INSOMNIA: A DOUBLE-BLIND, PLACEBO-CONTROLLED, RANDOMIZED, CROSSOVER STUDY

Paul Muchowski[1], Michael Wang[1], Marcus Faust[1], Scott Abbott[1], Vikrant Patel[1], Eric Chang[1], John Clark[2], Nephi Stella[3]
[1] Defined Research Institute, [2] University of Washington, [3] Stella Consulting LLC

Introduction: Cannabidiol (CBD) is increasingly used as a health supplement, though few clinical studies have demonstrated benefits. The primary objective of this study was to evaluate the effects of an oral CBD-terpene formulation on sleep physiology in individuals with insomnia.
Methods: In this double-blind, placebo-controlled, randomized clinical trial, 125 individuals with insomnia received an oral administration of CBD (300 mg) and terpenes (1 mg each of linalool, myrcene, phytol, limonene, α-terpinene, α-terpineol, α-pinene, and β-caryophyllene) for ≥ 4 days/week over 4 weeks using a crossover design. The study medication was devoid of β9-tetrahydrocannabinol. The primary outcome measure was the percentage of time participants spent in the combination of slow-wave sleep (SWS) and rapid eye movement (REM) sleep stages, as measured by a wrist-worn sleep-tracking device.
Results: This CBD-terpene regimen marginally increased the mean nightly percentage of time participants spent in SWS + REM sleep compared to the placebo (mean [standard error], 1.3% [0.60%]; 95% confidence interval, 0.1–2.5%; P =.03). More robust increases were observed in participants with low baseline SWS + REM sleep, as well as in day sleepers. For select participants, the increase in SWS + REM sleep averaged as much as 48 minutes/night over a 4-week treatment period. This treatment had no effect on total sleep time, resting heart rate, or heart rate variability, and no adverse events were reported.
Conclusion: Select CBD-terpene ratios may increase SWS + REM sleep in some individuals with insomnia and may have the potential to provide a safe and efficacious alternative to over-the-counter sleep aids and commonly prescribed sleep medications.

TRANSCRANIAL ALTERNATING ELECTRICAL STIMULATION IN SUBJECTS WITH INSOMNIA SYMPTOMS: A RANDOMIZED CONTROLLED STUDY

Minji Lee[1], Jung Kyung Hong[2], Yeaeun Lee[2], In-Young Yoon[2]
[1] Soonchunhyang University Seoul Hospital, [2] Seoul National University Bundang Hospital

Introduction: Transcranial alternating electrical stimulation (tACS) is non-invasive brain stimulation technique that delivers alternating microcurrent via electrodes. This study aimed to evaluate whether tACS could effectively improve symptoms of insomnia.
Methods: Participants with insomnia symptoms without meeting the criteria of insomnia disorder were recruited and randomized to 0.5 Hz, 100 Hz, or a sham group. In order to maximize the delivery of intracranial stimulation, a frequency of 10 kHz was used as the carrier frequency. Participants were required to use the device for 30 minutes, twice a day for 6 weeks. The Pittsburgh Sleep Quality Index (PSQI), the Insomnia Severity Index, sleep diary, and actigraphy were administered before and after the intervention.
Results: Eighty-seven participants (74 females, mean age = 54.15 ± 0.73 years) were randomized and finished the trial. The PSQI score showed significant improvement across all three groups without significant difference between groups (Sham: 9.93 to 6.72, $p < 0.001$; 0.5 Hz: 9.24 to 6.62, $p < 0.001$; 100 Hz: 9.34 to 6.93, $p = 0.001$). In the average sleep diary over four days, sleep latency (SL) and wake after sleep onset (WASO) decreased in all three groups (sham, 0.5 Hz, 100 Hz) without significant group by visit interaction (SL: -5.74 min, -8.94 min, and -16.53 min, respectively, $p = 0.345$; WASO: -10.74 min, -23.62 min, and -16.73 min, respectively, $p = 0.431$). No significant improvement in objective sleep measurements was observed in any group.
Conclusion: The tACS was not more effective than the sham treatment in reducing insomnia symptoms. Future study design should consider the strong placebo effect on sleep and the possibility that high carrier frequencies may confound the original frequencies.

CONTINUOUS THETA BURST STIMULATION AND PRE-SLEEP WORRY

Katelyn Rohlwing[1], Alisa Huskey[1], Salma Patel[1], William Killgore[1]
[1] The University of Arizona

Introduction: Continuous theta burst stimulation (cTBS), a type of repetitive transcranial magnetic stimulation (rTMS), has been shown to reduce the severity of insomnia and anxiety in participants with insomnia. This study examined whether pre-sleep rumination impacts sleep onset latency (SOL) and whether these effects would be ameliorated following cTBS targeted to the default mode network (DMN), a brain system involved in self-focused cognition and ruminative thinking.
Methods: Twenty participants (12 female, 8 male) with insomnia symptoms completed two overnight in-lab sessions including the administration of either active or sham cTBS in a counterbalanced, cross-over, double-blind clinical trial. Participants

completed the Glasgow Content of Thoughts Inventory (GCTI) before and after cTBS administration, followed by eight hours of sleep in-lab monitored by polysomnography. The GCTI items assessed pre-sleep thought types (i.e., problem-solving, worries, and thoughts about sleep) and frequency. A paired samples t-test compared pre-cTBS and post-cTBS GCTI scores in the sham and active conditions. Another t-test examined SOL from sham to active cTBS. Two simple linear regressions examined the effect of the change in GCTI from pre-cTBS to post-cTBS on SOL during the sham and active visits, separately.

Results: There were no differences in SOL by treatment condition (p>0.05). GCTI scores post-cTBS (M=51.95, SD=10.95) were significantly higher than pre-cTBS (M=48.75, SD=10.99) in the sham condition (p=0.047); however, GCTI scores post-cTBS (M=49.85, SD=10.83) were not significantly different than pre-cTBS (M=48.20, SD=12.73) in the active condition (p=0.271). Two simple linear regressions showed that the change in GCTI from pre to post-cTBS administration had no significant effect on SOL in the sham condition (F(1,18)=3.677, B=2.154 p=0.071, R2=0.123) or active condition (F(1,18)=2.474, B=-1.593, p=0.133, R2=0.072).

Conclusion: There were no direct treatment-condition effects on pre-sleep rumination or SOL. However, pre-sleep rumination increased following sham cTBS only, suggesting that this increase may have been ameliorated in the active condition. However, the small sample size of this pilot study and single administration presents a limitation to statistical power. Future work should examine the effect of active cTBS for reducing pre-sleep rumination in larger clinical trials with multiple administrations.

PRE-SLEEP RUMINATION AND RESTING-STATE CONNECTIVITY WITH THE BED NUCLEUS OF STRIA TERMINALIS IN INDIVIDUALS WITH INSOMNIA SYMPTOMS

Alisa Huskey[1], Jungwon Cha[1], Kymberly Henderson-Arredondo[2], Lindsey Hildebrand[2], Kathryn Kennedy[1], David Negelspach[1], William Killgore[1]

[1] The University of Arizona, [2] University of Arizona

Introduction: Projections from the central amygdala to the bed nucleus of the stria terminalis (BNST) are implicated in slower, longer-lasting perseverative anxiety symptoms. The BNST's role in sustained hyperarousal may delay sleep by promoting rumination prior to sleep onset, as is common in insomnia disorder. We hypothesized that BNST connectivity to regions of the default mode network (DMN) at baseline would be associated with elevated pre-sleep ruminations. Furthermore, we hypothesize that reductions in pre-sleep rumination following active continuous theta-burst stimulation (cTBS) will be associated with decreased, or no, BNST functional connectivity (FC).

Methods: Participants were 20 individuals (12 women; 19 to 39 years old) with self-reported insomnia (i.e., ISI≥15, PSQI≥6, and/or ESS≥11). To assess pre-sleep rumination, participants filled out the Glasgow Content of Thought Inventory (GCTI) prior to coming to the laboratory for cTBS overnight visits counterbalanced between one sham and the other active 40-second cTBS. The target region was the left inferior parietal lobule, a posterior region the DMN. MRI scans were conducted before and after each stimulation type.

Results: Seed-to-voxel connectivity with a seed placed in the BNST shows that higher baseline GCTI severity is associated with positive BNST FC to a precuneus cluster with center at +10 -40 + 06 (r =.701, p<.001, T =7.05, p-FDR < 0.001) and negative BNST FC connectivity to a left frontal pole cluster with center at -14 + 58 + 34 (r =-.657, p<.001; T = -6.25, p-FDR = 0.045). Reductions in GCTI following active cTBS, compared to pre-active and sham conditions, is associated with negative FC of the BNST with a cluster including the posterior cingulate gyrus and the precuneus with center at -02 -40 42 (r =-.736, p<.05, T = -5.48, p-FDR < 0.001).

Conclusion: BNST connectivity with the precuneus was associated with baseline levels of pre-sleep rumination and this effect was modulated only following active cTBS. Specifically, individuals with steeper reductions in pre-sleep rumination severity following cTBS exhibit more negative connectivity between the BNST and this posterior region of the DMN. As hypothesized, BNST connectivity to regions of the DMN predicts pre-sleep rumination and this connectivity reverses following cTBS.

INSOMNIA TREATMENT FOR ANTI-SUICIDAL RESPONSE IS ASSOCIATED WITH LOWER PERCEIVED STIGMA AND POSTTREATMENT IMPROVEMENTS IN HOPE: AN OPEN-LABEL TRIAL

Rebecca Bernert[1], Savannah Pham[2], Shamsi Soltani[2], Melanie Hom[2], Anne Germain[3], Alan Schatzberg[2], Michael Rudd[4], Amanda Hilberg[2], Lauren Murphy[2], Megan Chavez Tomlinson[2]

[1] Resiliency Systems, LLC, [2] Stanford Suicide Prevention Research Laboratory, Stanford University School of Medicine, [3] NOCTEM Health Inc., [4] University of Memphis

Introduction: Suicide has emerged as a public health emergency, but selective treatments remain scarce and unacceptable to those high in need. Perceived stigma represents a central barrier to treatment and thus prevention, but has yet to be evaluated in association with sleep, anti-suicidal treatment response, and other resiliency outcomes.

Methods: Comprehensive screening (n=310 participants screened, n=59 completed a full-battery eligibility assessment) for current suicide risk (CSSRS>1), DSM-V-defined MDD, and clinically-significant insomnia (ISI>10, PSQI>5) supported inclusion in an open-label suicide prevention clinical trial (iSleep: Insomnia Treatment for Improved Well-Being). A multi-component, non-pharmacological (5-week) treatment (integrating CBTi, IRT, and SRT interventions) was manualized according to session-by-session powerpoints, handouts, and therapist guide sheets. Measures: The Columbia Suicide Severity Rating Scale (CSSRS), Beck Scale for Suicide (BSS), Quick Inventory of Depressive Symptomatology (QIDS-SR), Insomnia Severity Index (ISI), Pittsburgh Sleep Quality Index (PSQI), Disturbing Dream and Nightmare Severity Index (DDNSI), Perceived Stigma Scale (PSS), and Rudd Hope Scale (RHS). Assessments occurred at Baseline, Treatment, and Posttreatment (2 weeks, 1,3 mos). Data and safety monitoring procedures supported risk assessment, triage, and outpatient safety planning.

Results: Thirty-five participants (aged 20-70; M=41 years) were allocated treatment. Perceived Stigma: Significant mean differences were observed in PSS scores at pretreatment among

participants, indicating lower perceived stigma ratings toward sleep treatment (PSS-SLP) relative to mental health treatment (PSS-MH) [M=10.0, SD=4.4; M=13.3, SD=6.35, respectively]: t(34)=3.94, p<.001; CI=1.60-5.02. Hope Measures: Paired t-tests revealed significant improvements in RHS scores from pre- to posttreatment phases [M=13.23, SD=4.03; M=16.03, SD=4.4, respectively]: t(30)=-3.03, p<.01; CI=-4.69—0.91. This paralleled large, posttreatment reductions (87%) in suicidal ideation, alongside depression, insomnia, sleep-quality, and nightmare improvements (p<.001).

Conclusion: Lower perceived stigma was associated with sleep treatment compared to psychological treatment, further supporting the utility of sleep as a modifiable, non-stigmatizing therapeutic target for suicidal behaviors. In addition, use of a rapid-action insomnia intervention (iSleep Treatment) resulted in significant posttreatment improvements in hope and overall well-being. This is the first known report testing perceived stigma in the context of a suicide prevention clinical trial, while demonstrating therapeutic impact to hope and resiliency measures underlying anti-suicidal response.

EFFECT OF AN ONLINE MEDITATION PROGRAM IN WOMEN WITH INSOMNIA: A RANDOMIZED CLINICAL TRIAL

Maria José Morais[1], Andréia Bezerra[2], Carolina Banzoli[3], Leandro Lucena[2], Marcia Prieto[4], Sergio Tufik[5], Helena Hachul[1]

[1] Universidade Federal de São Paulo, [2] Universidade Federal de Sao Paulo, [3] Hospital Santa Marcelina, [4] Hospital Israelita Alberta Einstein, [5] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: An epidemiological study conducted by the Sleep Institute in 2007 revealed that 44.8% of the population in São Paulo exhibited symptoms of insomnia, with women being disproportionately affected (32%). Considering a global adaptation towards utilizing technology for health services, the present study evaluated the effects of an online meditation program on women with insomnia.

Methods: The study was a longitudinal, randomized and controlled trial. Participants include women aged 18 to 47 years with insomnia diagnosed by a sleep specialist. The sample was distributed into two groups: Intervention and Control. Both groups received an initial lecture about sleep hygiene. The Intervention group was invited to participate in eight virtual weekly sessions. During these sessions, participants received guidance to engage in meditation practice using the Anapana technique, which focuses on breath regulation to calm the mind. The Control group remained on a waitlist. The Insomnia Severity Index (ISI) was used to evaluate the main outcome. Measurements were taken at the baseline and at the end of the program. General Mixed Model (GMM) with within-subject random factor was utilized to assess the effects of meditation on ISI, comparing the Control and Intervention groups.

Results: A total of 307 women registered for the project, of which 120 were included. Of these, 62 completed the protocol. The overall sample had a mean age of 35.8 years, with a normal BMI and a high level of education. Results from the GMM indicated a significant effect of time, group, and the interaction of time*group. The intervention showed a decrease of 10.29 points in ISI at the end of protocol, with a mean score of 8.29 points on this instrument. The participants' results varied by 37.7% among them. Of the 34 participants who received intervention, 70.6% responded to treatment, and of those who responded, 66.7% had remission of ISI symptoms.

Conclusion: Online meditation appears to be a promising therapy for improving insomnia symptoms in women of reproductive age.

COGNITIVE TRAINING IN MILD COGNITIVE IMPAIRMENT AND INSOMNIA (TRAIN-MCI): PRELIMINARY EFFECTS ON COGNITION AND SLEEP

Ashley Curtis[1], Amy Costa[1], Madison Musich[2], Lauren Nowakowski[2], Kobe Young[2], Kenda Eberhardt[2], David Beversdorf[2], Nelson Cowan[2], Christina McCrae[1]

[1] University of South Florida, [2] University of Missouri

Introduction: Nearly half of older adults with mild cognitive impairment (MCI) experience comorbid insomnia, which worsens cognitive symptoms. There are no pharmacological treatments for cognition and behavioral insomnia treatments require trained therapists, while sleep medications are associated with adverse side effects such as increased fall risk and cognitive disturbance. This study evaluated preliminary effects of computerized cognitive training for improving cognition and sleep in older adults with MCI and insomnia.

Methods: Older Adults (N=27, Mage=67.63±5.90, 21 women) with MCI (MoCA score of 18-26/30 or 1.5 SD below norms on 1+ cognitive task, intact activities of daily living) and insomnia [DSM-5 criteria plus sleep diaries showing >30 mins sleep onset latency or wake time after sleep onset (WASO) on 3+ nights/7] were randomized (2:1) to 8 weeks of cognitive training (n=19; Cognifit) or trivia control (n=8; answering questions online) for 45 mins, 3x per week. Cognition (Cambridge Brain Sciences battery), subjective sleep (Insomnia Severity Index, average 7-day diary-reported sleep onset latency, WASO, sleep efficiency, #awakenings, total sleep time) and objective sleep [WatchPAT; same metrics and %lighter, %deep, %Rapid Eye Movement (REM) sleep] were assessed at baseline and post-intervention. Planned baseline vs. post-intervention comparisons and effect size estimation across outcomes were conducted for cognitive training versus trivia control.

Results: Cognitive training significantly improved spatial planning (p=.028; hedges g=.54, moderate effect), and showed trends for improved visuospatial (p=.08; hedges g=.53) and verbal (p=.08; hedges g=.50) working memory, with no changes in controls (ps ranged from.27-.94). Cognitive training also significantly reduced diary-#awakenings (p=.007, hedges g=.46), improved objective sleep efficiency (p=.05, hedges g=.47), and trended towards reduced diary-WASO (p=.067, hedges g=.53), with no changes in controls (ps ranged from.29-.80). Objective REM% increased for trivia control (p=.02, hedges g=1.00), but not cognitive training (p=.23).

Conclusion: Preliminary findings suggest in older adults with MCI, at home computerized multimodal cognitive training leads to near transfer effects for non-trained cognition and far transfer effects for sleep maintenance and efficiency symptoms. Larger randomized controlled trials with longer follow-up and

evaluation of mechanisms underlying cognitive training transfer effects are warranted.

TRAIT MINDFULNESS PROTECTS AGAINST THE HARMFUL EFFECTS OF NOCTURNAL COGNITIVE AROUSAL ON INSOMNIA AND DEPRESSION SYMPTOMS IN PREGNANCY AND POSTPARTUM

Mika Hirata[1], Heba Afaneh[2], Ishana Kapoor[1], David Kalmbach[1], Anthony Reffi[3], Matthew Jennings[2], Philip Cheng[4], Jason Ong[5], Christopher Drake[3]

[1] Henry Ford Sleep Research, [2] Henry Ford Health, [3] Henry Ford Health System, [4] Henry Ford Health + Michigan State University Health Sciences, [5] Nox Health

Introduction: Perinatal women are highly vulnerable to insomnia and depression. High cognitive arousal (e.g., worry, rumination) at night is a key risk factor for developing insomnia and depression during this period. However, mindfulness skills have been proposed to reduce risk for negative health outcomes by protecting individuals against the harmful effects of cognitive arousal. This prospective study tested whether trait mindfulness protects perinatal women against the harmful effects nocturnal cognitive arousal on insomnia and depression.
Methods: Nine women (Age: 29.9±4.4y; Gestation at enrollment: 26.7±1.0w) completed weekly health surveys for 4 months across late pregnancy and early postpartum. Study outcomes included the revised cognitive and affective mindfulness scale (CAMS-R), pre-sleep arousal scale's cognitive factor (PSASC), insomnia severity index (ISI), and Edinburgh postnatal depression scale (EPDS). Linear mixed modeling was used to account for repeated measures and to test trait effects (between-person differences) and state effects (within-person changes) while controlling for relevant covariates.
Results: Lagged linear mixed modeling showed that women with high trait mindfulness reported lower levels of ISI (b=-5.37, p=.032) and EPDS (b=-14.25, p<.001) across the next four months. However, within-person analyses showed higher state PSASC predicted higher levels of next-week ISI (b=1.95, p.030) and EPDS (b=1.28, p=.047). Mixed modeling also revealed significant moderation effects for CAMS-R*PSASC on future ISI (b=.01, p<.001) and EPDS (b=.002, p=.012) such that the magnitude of PSASC's effects on ISI and EPDS were smaller for women with high trait mindfulness. Indeed, insomnia- and depression-risk were lowest when women endorsed high CAMS-R and low PSASC (3.9% insomnia, 9.8% depression), whereas disease-risk was highest when women endorsed low CAMS-R and high PSASC (62.2% insomnia, 83.8% depression).
Conclusion: Perinatal women with high trait mindfulness are protected against the harmful effects of high cognitive arousal on insomnia and depression, whereas women with low mindfulness are at higher risk for insomnia and depression when experiencing high cognitive arousal. These prospective data support trait mindfulness as a critical protective factor against the development of insomnia and depression during pregnancy and postpartum. Interventions promoting mindfulness skills may help expecting moms sleep and feel better.

BEHAVIORAL INSOMNIA TREATMENT ACCESSIBILITY IN THE US: A REAL-WORLD ASSESSMENT OF COST, LOCATION, AND AVAILABILITY

Matthew Jennings[1], Marleigh Treger[1], Eric Zhou[2], Philip Cheng[3]

[1] Henry Ford Health, [2] Harvard Medical School, [3] Henry Ford Health + Michigan State University Health Sciences

Introduction: Cognitive Behavioral Therapy for Insomnia (CBT-I) is the gold-standard treatment for insomnia disorder. There have been consistent calls to increase patient accessibility to CBT-I. However, there have been few studies of what the experience is for patients who are recommended CBT-I and seek community-based care. Even less attention has been paid to this experience in patients and communities with lower incomes and poorer insurance coverage. We sought to examine the real-world access to providers with CBT-I expertise.
Methods: We contacted all clinicians listed on the Society of Behavioral Sleep Medicine's provider registry who met the following inclusion criteria: (1) US-based, (2) master's degree or above, and (3) eligible for state licensure. Initial data on treatment modality, insurance coverage, session costs, waitlist times, and practice locations were collected through internet searches, and were supplemented by contacting providers as potential patients through a maximum of three emails, with follow-up phone calls used as needed. Practice addresses were used to generate census-tract income data to compare to the 2022 family-of-four poverty line.
Results: Data from N=240 CBT-I providers were collected, spanning 42 states. Of these, 92.1% (n=221) were accepting new patients, but only 56.3% (n=135) accepted insurance. Among CBT-I providers accepting new patients, initial session costs averaged $260.71 (SD=$91.81, mode=$250.00, range=$100.00-$530.00); subsequent session costs averaged $227.74 (SD=$76.50, mode=$250.00, range=$75.00-$500.00), and wait times averaged 51.1 days (SD=61.9, range=0-300, mode=7). Average household income in practice areas was $95,246 (SD=$52,622). Only 5.0% (n=12) of CBT-I providers accepting new patients operated in communities at or below the poverty line, and just 3.3% (n=8) accepted insurance. Among these providers, only one accepted Medicaid.
Conclusion: This study underscores significant access disparities for behavioral insomnia treatment in the US, highlighting how high treatment costs and limited availability of CBT-I providers have disproportionate and negative impacts on lower-income populations and those with inadequate insurance coverage. A large proportion of CBT-I providers do not accept insurance, leaving 135 behavioral sleep providers to treat those millions of Americans with insomnia unable to afford private pay. Even with insurance, logistical barriers like provider location and nearly two-month wait times exacerbate insomnia care disparities.

REDUCING BURNOUT IN FACULTY PHYSICIANS WITH SLEEP COACHING

Nayeli Nunez Cruz[1], Philip Gehrman[1], Jennifer Goldshmeid[1], Hannah Wang[1], Indira Gurubhagavatula[1], Ilene Rosen[1]

[1] University of Pennsylvania

Introduction: Health workers are experiencing record rates of occupational burnout. A significant proportion of faculty physicians have impaired sleep that may affect wellbeing and contribute to burnout. Fortunately, there are simple, behavioral strategies that improve sleep, but their impact on burnout is unknown. We identified faculty physicians with mild sleep impairment and assessed the impact of a brief sleep coaching intervention on self-reported burnout using validated scales.
Methods: We delivered 30-minute educational presentations to Department of Medicine (DOM) faculty at an academic medical center. Using Research Electronic Data Capture (REDCap) we asked attendees to complete a Sleep Health Survey which included the Epworth Sleepiness Scale (ESS), Insomnia Severity Index (ISI), shiftwork, and the Maslach Burnout Inventory (MBI). Respondents were offered a single session of sleep coaching with a psychologist if they met one or more of the following criteria: ISI between 7-13 or yes to current shiftwork. We conducted post-intervention surveys one month after their appointment and compared pre-post changes in the ISI, ESS, and MBI using paired-samples t-tests.
Results: A total of N=226 faculty completed the REDCap survey and 79 (35%) met criteria for sleep coaching. N=63 had ISI between 7-13, N=9 said yes to shiftwork, and N=7 had both ISI between 7-13 and shiftwork. N=24 participants completed both a single session of sleep coaching and the post-intervention survey at 1 month. These faculty were 62.5% female and 75% White with an average age of 45.8 (8.9) years. There were significant improvements on the ISI (9.6 (1.8) to 5.3 (3.6); $p < 0.01$), and on the MBI Emotional Exhaustion (20.2 (9.7) to 15.3 (9.1); $p < 0.01$), Depersonalization (11.8 (8) to 9.3 (6.8); $p = 0.03$), and Personal Achievement (39.2 (5.8) to 41.5 (5.5); $p = 0.02$) subscales.
Conclusion: These exploratory data show how a simple targeted intervention can have significant benefits in terms of improving sleep and reducing burnout among faculty physicians. Larger scale studies are needed to examine scalability and effectiveness of delivering sleep coaching to address occupational burnout in physicians.

ACCEPTABILITY OF SLEEP INTERVENTIONS AMONG FIREFIGHTERS

Siyuan Huang[1], Dana Epstein[2], Hannah Miller[1], Daniel Taylor[3], Michael Grandner[4], David Glickenstein[5], Matthew Lujan[6], Patricia Haynes[3]

[1] Department of Health Promotion Sciences, University of Arizona, [2] College of Health Solutions, Arizona State University, [3] University of Arizona, [4] Department of Psychiatry, College of Medicine, University of Arizona, [5] Department of Mathematics, University of Arizona, [6] Mel and Enid Zuckerman College of Public Health, University of Arizona

Introduction: Insufficient sleep disproportionately imposes significant health risks to firefighters. However, access to evidence-based sleep interventions, such as cognitive behavioral therapy for insomnia (CBTi), remains limited in this population. To build a foundation for the implementation of worksite sleep health coaching in fire departments, this study assessed firefighters' acceptability of nine CBTi-informed sleep interventions.
Methods: The Patient-Reported Outcomes Measurement Information System–Sleep Disturbance–Short Form 8b was used to screen for firefighters working 24-hour+ shifts who presented sleep disorder symptoms (T score ≥ 55). Eligible participants included 232 firefighters from 20 Arizona fire agencies who completed a cross-sectional online survey, which incorporated the Theoretical Framework of Acceptability measure to assess their perceived sleep intervention acceptability.
Results: Over half of the firefighters agreed or strongly agreed that the CBTi-informed sleep interventions were likable (percentage: 53%-74%), acceptable (61%-88%), and anticipated to be effective (54%-66%), except for timed exposure to ambient light and darkness, which only 35% liked and 42% perceived as effective. The top three interventions with the highest percentage of firefighters rating them as likable, acceptable, and being anticipated as effective were sleep education (64%, 88%, 58%), sleep extension (69%, 76%, 63%), and recovery sleep enhancement (74%, 80%, 66%). Interestingly, a higher percentage of firefighters also perceived sleep education (34%) and sleep extension (35%) as very effortful compared to other interventions (average: 23%). Firefighters with greater sleep symptoms were less likely to like sleep extension (Odds Ratio = 0.92, 95% CI = 0.87-0.98, p =.017) and recovery sleep enhancement (OR = 0.93, 95% CI = 0.87-0.99, p =.025) whereas more likely to perceive sleep education as effort-intensive (OR = 1.08, 95% CI = 1.02-1.14, p =.018).
Conclusion: A moderate to high percentage of firefighters demonstrated acceptability of the sleep interventions, with sleep education, sleep extension, and recovery sleep enhancement ranking the highest. Interestingly, sleep education and sleep extension were frequently viewed as acceptable despite being effort-intensive, highlighting the importance of assessing different dimensions of acceptability of sleep interventions. These findings suggest promise in translating these evidence-based interventions to the workplace to improve firefighter sleep health.

RACIAL/ETHNIC DIFFERENCES IN SLEEP OUTCOMES AFTER A BRIEF SLEEP INTERVENTION IN USAF TECHNICAL TRAINING STUDENTS

Faith Luyster[1], Xin-Qun Wang[2], Chase Aycock[3], Rosemary Estevez Burns[4], Trevin Glasgow[2], Jenny Halbert[2], Kara Wiseman[2], Jordan Ellis[5]

[1] University of Pittsburgh School of Nursing, [2] University of Virginia, [3] San Antonio-Lackland Air Force Base, [4] San Antonio – Lackland Air Force Base, [5] 316th Medical Group-Joint Base Andr ews

Introduction: Racial and ethnic minorities in the military experience shorter sleep durations and higher rates of sleep problems compared to their Non-Hispanic White (NHW) counterparts. A group-based, single-session Brief Sleep Intervention (BSI) for United States Air Force Technical Training (USAFTT) students improved sleep duration, sleep quality, and sleep behavior. Sleep health disparities are well documented, thus this secondary analysis examined racial/ethnic differences in sleep outcomes and behavior change engagement following the BSI.

Methods: Non-randomized intervention assignment included a 2:1 allocation ratio (BSI:active control [brief tobacco] intervention). Participants completed the Self-Assessment of Sleep Survey-Split at baseline and 2-week follow-up for assessment of weekday sleep duration (< 6 vs. ≥6 hours), sleep quality (very poor/poor/fair vs. good/very good), and weekend catch-up sleep duration. At 2-week follow-up, BSI participants reported whether they engaged in their self-selected "Action Step' during the intervention. Propensity score-adjusted logistic/linear regression models were used to assess the intervention effects among different racial/ethnic groups in the outcomes of interest.
Results: The sample included 321 USAFTT students (mean age 20.9 ± 3.6; 81.9% men; 51.7% NHW; 24.3% Hispanic; 23.4% non-Hispanic People of Color). Among Hispanic students at follow-up, those in the BSI group were more likely to have a weekday sleep duration ≥6 hours (aOR 12.43, 95%CI, 8.70-17.76) and report good/very good weekend sleep quality (aOR 3.10, 95%CI, 2.48-3.87) compared to those in the active control group. Among those who received the BSI, Hispanic students at follow-up were more likely to have a weekday sleep duration ≥6 hours (aOR 6.28, 95%CI, 5.36-7.37; aOR 9.56, 95%CI, 3.02-30.27) and good/very good weekday sleep duration (aOR 1.83, 95%CI, 1.52-2.19; aOR 2.37, 95%CI, 1.60-3.52) compared to NHW or non-Hispanic People of Color, and have engaged in the 'Action Step' chosen during the intervention than NHW (aOR 1.54, 95%CI, 1.25-1.89). No group differences were found in weekend catchup sleep duration after Bonferroni multiple comparison adjustment.
Conclusion: Within the BSI group, Hispanic students exhibited better sleep outcomes and greater behavior change engagement than other racial/ethnic groups. Further research should explore the mechanisms underlying these differences and identify BSI features that promote treatment success among Hispanic USAFTT students.

CHARACTERISTICS OF TREATMENT RESPONDERS IN A TRIAL OF BRIEF BEHAVIORAL THERAPY FOR CANCER-RELATED INSOMNIA

Nicole Carmona[1], Chelsey McGill, PhD[2], Arnethea Sutton[3], James Burch[3], Susan Hong[4], Sarah Braun[3], Ruth Nyagaka[5], Priyanka Patel[3], Oxana Palesh[6]
[1] Department of Psychology, York University, [2] Virginia Commonwealth University Massey Cancer Center, [3] Virginia Commonwealth University, [4] VCU Massey Cancer Center, [5] Stanford University, [6] Massey Cancer Center

Introduction: Nearly 80% of cancer patients undergoing treatment experience insomnia symptoms and disrupted sleep. Brief Behavioral Therapy for Cancer-Related Insomnia (BBT-CI) has shown to be efficacious for patients with breast cancer undergoing treatment. Few studies have characterized treatment responders from non-responders in oncology settings, which can help facilitate precision-based medicine. In this secondary analysis of breast cancer patients, we analyzed how baseline characteristics differ between treatment responders and non-responders to BBT-CI.
Methods: Patients with breast cancer (N=73, 51% stage II, M age=50.7 years) completed measures of insomnia severity (ISI), dysfunctional beliefs about sleep (DBAS), emotion regulation (DERS), fatigue (BFI), chronotype (OWL-Lark), and domains of health-related quality of life (HRQoL; EORTC-30) and 93.2% (Msession=5.82, SD=.78) completed all 6 sessions of BBT-CI. Given lack of consensus in the literature, we defined treatment response as either an 8- or 6-point change on the ISI from baseline to endpoint.
Results: Scores on the ISI reduced, on average, by 4.76 points. Treatment response rates varied widely based on the definition selected; 27% of participants achieved an 8-point reduction on the ISI, whereas 43% achieved a 6-point reduction. At baseline, both levels of responders were more fatigued and reported worse insomnia and sleep quality, had more eveningness tendencies, more unhelpful beliefs about sleep, and poorer social functioning. An 8-point reduction was uniquely associated with worse dyspnea and self-reported cognitive functioning as measured by EORTC-30 scales, whereas a 6-point reduction was associated with younger age and surgical status. Responders did not differ on other demographic or clinical characteristics (e.g., cancer stage or treatment with chemotherapy, hormone therapy, or radiotherapy).
Conclusion: Treatment responders to BBT-CI had more severe baseline sleep and fatigue symptoms and poorer self-reported HRQoL. Surgical history was associated with more limited treatment response. While regression to the mean remains possible, it may also be that those with more severe baseline symptomatology are more motivated to engage in BBT-CI, and therefore more likely to benefit. These preliminary findings may support the use of stepped care to match higher-intensity interventions to those who need them most.

EFFICACY OF BRIEF BEHAVIORAL THERAPY FOR INSOMNIA FOR VETERANS WITH PTSD VERSUS BBTI WITH ESZOPICLONE

Erin Gould[1], Parveen Attai[1], Keziah Aibangbee[1], Ali El Solh[1]
[1] University at Buffalo

Introduction: In veterans with posttraumatic stress disorder (PTSD), comorbid insomnia and obstructive sleep apnea (COMISA) are responsible for detrimental effects on sleep and quality of life. In this investigation, we assessed the augmentation of brief behavioral therapy for insomnia (BBTI) with eszopiclone over BBTI alone for the treatment of chronic insomnia on sleep quality in veterans with PTSD experiencing COMISA.
Methods: Fifty-three PTSD patients aged 18 to 65 years old with COMISA were randomized to four sessions of BBTI over 6 weeks plus 2 weeks of eszopiclone (2 mg/d) or BBTI alone with follow-up visits conducted at 6 and 24 weeks. Study outcomes included the Pittsburgh Sleep Quality Index (PSQI) [primary], Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS), Beck Depression Inventory-II (BDI-II), and PTSD Checklist (PCL) [secondary]. Actigraphy-derived sleep indices and CPAP adherence were also collected.
Results: A significant and comparable improvement in sleep quality was observed between baseline and 24 weeks for combination therapy (PSQI mean score change, -5.25; 95% CI, -6.59, -3.91) and BBTI (PSQI mean score change -5.45; 95%CI, -6.78, -4.12). Similar improvements were recorded for ISI, ESS, BDI, and PCL. Compared to BBTI alone, combination therapy showed higher reduction in insomnia symptoms (ISI mean score

difference -2.3; 95% CI, -4.95, 0.28) concomitantly with a drop in sleep latency (SL) (SL mean difference -8.21 minutes; 95% CI, -16.13, -0.29) at 6 weeks. The combination of BBTI plus eszopiclone produced a higher remission rate of insomnia at 6 weeks than BBTI (31% versus 7%, p=0.03), with both interventions achieving comparable rates at 24 weeks. Patients receiving combination therapy used on average CPAP 75.8 minutes/night (95% CI, 17.18,134.72) more than BBTI by week 6. However, CPAP adherence was no more different between the groups by week 24.
Conclusion: Veterans with PTSD and COMISA had comparable improvement in sleep quality of life with the combination of eszopiclone with BBTI to that achieved with BBTI-only therapy. Although the addition of eszopiclone to BBTI conferred an early benefit in the remission rate of insomnia and in CPAP usage relative to BBTI, both modalities achieved similar outcomes at long-term follow-up.

COGNITIVE BEHAVIORAL THERAPY FOR MENOPAUSAL INSOMNIA (CBT-MI) IMPROVES INSOMNIA SEVERITY AND VASOMOTOR SYMPTOMS IN PERI- AND POSTMENOPAUSAL WOMEN

Emily Arentson-Lantz[1], Manasa Kokonda[2], Jessica Meers[2], Rachel Manber[3], Alexandria Muench[4], Michael Perlis[5], Julia Boyle[6], Maria Swartz[7], Michael Grandner[8], Sara Nowakowski[2]
[1] Department of Nutrition Sciences and Health Behavior, University of Texas Medical Branch, Galveston, TX, USA, [2] Department of Medicine, Baylor College of Medicine, Houston, TX, USA, [3] Stanford University, [4] University of Pennsylvania, [5] Department of Psychiatry, University of Pennsylvania, [6] Office of Research and Development & New England GRECC, VA Boston Healthcare System, [7] Department of Pediatrics-Research UT MD Anderson Cancer Center, [8] Department of Psychiatry, College of Medicine, University of Arizona

Introduction: Approximately 20-60% of peri- and postmenopausal women in the US have insomnia symptoms that can be exacerbated by vasomotor symptoms [VMS], including nocturnal hot flashes (nHF). While cognitive behavioral therapy for insomnia (CBT-I) has been shown to be effective in decreasing insomnia in this population, it is unclear how nighttime (e.g., difficulty falling asleep) versus daytime (e.g., daytime sleepiness) symptoms are impacted. This study examined the effect of CBT for menopausal insomnia (CBT-MI) on insomnia severity and symptoms as well as VMS in a randomized clinical trial.
Methods: Peri-and postmenopausal participants with insomnia and nHF (53.6y) were assigned to receive CBT-MI (n=18) or Menopause Education Control (MEC; n=25). The Insomnia Severity Index (ISI) and Hot Flash Related Daily Interference Scale (HFDRIS) were administered at baseline and post-intervention. Three factor analysis was used to look at changes in insomnia symptom types including Factor 1–ISI Sleep Symptoms (items 1,2,3), Factor 2–ISI Daytime Symptoms related to Insomnia (items 5,6), and Factor 3–ISI Perception of Symptoms (items 4,7). Generalized linear regression was performed to find the differences from baseline to post-treatment between the treatment groups.
Results: At baseline, total ISI score was not significantly different between the groups (15.1±3.5 vs. 15.0±4.4; P=0.34). Following the intervention period, ISI scores were significantly lower in the CBTI-MI group than the MEC group (4.9±1.1 vs. 8.8±1.1; P=0.01). With respect to VMS, there were significant differences between treatment group ratings of hot flash interference (HFDRIS) at post-treatment (P=0.01). The changes from baseline in ISI Sleep Symptoms (P=0.005) and ISI Perception Symptoms (p=0.002) was significantly greater in the CBT-MI group compared to MEC, while the change from baseline of ISI Daytime Symptoms was not significantly different (P=0.1).
Conclusion: CBT-MI significantly decreases menopause insomnia severity and improves vasomotor symptoms in midlife women primarily due to attenuating sleep symptoms and perceptions of insomnia symptoms. CBT-MI did not significantly improve daytime symptoms associated with insomnia.
Support (if any): This work is supported by NIH Grant #s K23NR014008 (Nowakowski). Additional support was provided by the Center for Innovations in Quality, Effectiveness and Safety (CIN 13-413).

PRELIMINARY INVESTIGATION INTO THE EFFECTS OF CBT-I ON SUBJECTIVE INSOMNIA AND CIRCADIAN REST/ACTIVITY RHYTHMS IN PERSONS WITH TBI

Hannah Maybrier[1], Heather Altier[1], Eunyeong Joo[1], Claudia Campbell[1], Michael Smith[2], Adam Spira[3], Luis Buenaver[2]
[1] Johns Hopkins School of Medicine, [2] Johns Hopkins University, [3] Johns Hopkins Bloomberg School of Public Health

Introduction: Disordered circadian rest/activity rhythms (RARs) and insomnia frequently co-occur. Aspects of cognitive behavioral therapy for insomnia (CBTI) aim at improving circadian RARs by establishing regular sleep times and consolidating sleep periods. Timing of sleep periods has also been associated with insomnia, wherein evening chronotype has been linked to greater sleep disturbance. However, there is limited research exploring whether CBTI improves insomnia via improved structure and timing of circadian RARs. We examined whether CBTI reduces insomnia severity via improved RAR structure or shifted RAR timing.
Methods: Our community sample of persons with a history of traumatic brain injury (TBI) and comorbid insomnia (N=38, Mage=38+/-12, 37% female) were randomized to a 4-session treatment group: CBTI or sleep education. Circadian RARs were continually estimated with actigraphy. Variables estimating RAR structure included interdaily stability (IS), intradaily variability (IV), and relative amplitude (RA). RAR timing was estimated as the sleep period midpoint. Effects of CBTI on RAR variables were estimated as the group difference in change in RAR variables from baseline to treatment end. Effect of CBTI on insomnia severity was estimated as the group difference in Insomnia Severity Index (ISI) score change from baseline to 12-weeks post-treatment. Secondary analyses explored whether RAR change moderated effects of treatment group on ISI change.
Results: Compared to controls, participants randomized to CBTI had improved long-term ISI scores (β= -0.851, SE=0.322, p=0.008). CBTI had no effect on change in sleep midpoint, IV, RA, or IS. However, a significant IV by group interaction suggested that individuals with greater reduction in sleep-wake rhythm fragmentation during CBTI experienced greater reduction in insomnia severity (β= -0.894, SE=0.401, p=0.026).

Conclusion: Results show that CBTI reduced insomnia severity. While CBTI did not affect IV, RA, IS, or the sleep midpoint, CBTI-induced reductions in insomnia severity were stronger in those who exhibited greater reductions in IV. This suggests that benefits of CBTI may be influenced by changes in RARs in those with TBI. Future analyses will explore factors associated with changes in circadian rhythm and insomnia severity, and examine CBTI effects on circadian rhythm and sleep phase in a larger sample.

TREATMENT ENGAGEMENT OF COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA IN ADOLESCENTS: A QUALITATIVE ANALYSIS

Hao Fong Sit[1], Rachel Ran Wang[1], Forrest Tin Wai Cheung[2], Ngan-yin Chan[3], Joey Chan[3], Jihui Zhang[3], Albert Martin Li[4], Yun-Kwok Wing[3], Colin A. Espie[2], Shirley Li[1]

[1] Sleep Research Clinic and Laboratory, Department of Psychology, The University of Hong Kong, Hong Kong SAR, [2] Sir Jules Thorn Sleep and Circadian Neuroscience Institute, Nuffield Department of Clinical Neurosciences, University of Oxford, [3] Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, [4] Department of Paediatrics, Faculty of Medicine, The Chinese University of Hong Kong

Introduction: Insomnia is common in adolescents, with a prevalence of 10-30%. Despite its high prevalence, many did not received treatment, and treatment engagement is suboptimal in the young population. Although there is a consensus on the importance of identifying potential barriers to treatment for insomnia, understanding on treatment engagement in adolescents is limited. The present qualitative study aimed to identify the factors related to the continued treatment engagement of cognitive behavioral therapy for insomnia (CBT-I) in adolescents.
Methods: Thirty-seven adolescents (age = 18.38 ± 1.64, 15-20; female: 70.3%) with DSM-5 insomnia disorder, as ascertained by the clinical interview, participated in individual semi-structured qualitative interviews. All participants received 6-session CBT-I, either delivered in a group or digital format. Interviews were conducted by trained interviewers for about 60 minutes via videoconferencing after the treatment. The interview asked about individual experiences and feedback about the treatment. All the interviews were audio-recorded and transcribed verbatim. Thematic analysis was used to identify themes related to continued treatment engagement in CBT-I.
Results: Six major themes were identified to understand factors that affect continued treatment engagement during the intervention period: drive to achieve treatment goal (e.g., wanting to improve sleep), personal strengths (e.g., sense of commitment), perceived benefits (e.g., symptom improvement during treatment), intervention/study design (e.g., time/place convenient), and social influence (e.g., peer influence), changes in life (e.g., busy personal schedule).
Conclusion: The current study enhanced our understanding of the factors related to continued treatment engagement among adolescents who received CBT-I. The themes cover individual, treatment-related, and environmental factors. The findings may inform clinical practice on how to better engage adolescents during sleep intervention to optimize treatment outcomes.

THE EFFECT OF COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA (CBTI) ON BURNOUT SYMPTOMS

Philippe Stenstrom[1], Maude Bouchard[1], Taís Araújo[1], Cherie La Rocque[1], Régine Denesle[1]

[1] HALEO Preventive Health Solutions

Introduction: Insomnia is increasingly recognized as both a contributing factor to burnout and a predictor of future disability leave. Despite this, little research has investigated whether treating insomnia can alleviate burnout symptoms. This study aimed to examine the impact of videoconference-delivered Cognitive Behavioral Therapy for Insomnia (CBTi) on burnout symptoms in a working adult population.
Methods: Thirty adult workers (mean age = 42.6) experiencing insomnia participated in HALEO's CBTi program, which consisted of five weekly, 30-minute video sessions with licensed therapists, supported by a digital platform. Insomnia severity was assessed using the Insomnia Severity Index (ISI), and burnout symptoms were measured with the Burnout Assessment Tool (BAT). Participants completed both measures at baseline and three months post-therapy. Data were analyzed using one-tailed paired t-tests to assess changes in ISI and BAT scores, and Pearson correlations to examine associations between changes in insomnia and burnout symptoms.
Results: ISI scores significantly decreased from baseline (M = 15.93, SD = 4.36) to post-therapy (M = 7.30, SD = 5.72; $t(29) = 7.68$, $p < .001$, $d = 1.40$). Similarly, BAT scores were significantly lower post-therapy (M = 2.03, SD = 0.54) compared to baseline (M = 2.54, SD = 0.48; $t(29) = 5.57$, $p < .001$, $d = 1.02$). A significant positive correlation was found between improvements in ISI and BAT scores ($r = 0.519$, $p = .003$), indicating that reductions in insomnia severity were associated with reductions in burnout symptoms.
Conclusion: The findings suggest that, beyond its established effectiveness in reducing insomnia symptoms, videoconference-delivered CBTi may also contribute to significant reductions in burnout symptoms among working adults. The observed correlation between reductions in insomnia and burnout symptoms highlights a potential interaction that warrants further exploration.

Introduction: Insomnia symptoms are associated with increased pain intensity preceding or immediately following surgery. The present clinical trial (NCT04269239) examined the efficacy of cognitive behavioral therapy for insomnia (CBT-I) to reduce insomnia severity and explored the relationship between insomnia and pain in patients with insomnia recovering from hip or knee joint arthroplasty.
Methods: Participants (N=70; 68% Females; Mean age=67.3 years) were randomly assigned to receive CBT-I (n=35) or Health Education Control (HEC; n=35). The Insomnia Severity Index (ISI), PROMIS Pain, and Hip/Knee Osteoarthritis Outcome Score (HOOS/KOOS) were administered pre- and post-intervention. Three factors of ISI, including Factor1-Sleep Symptoms, Factor2–Daytime Symptoms, and Factor3–Perception Symptoms were also assessed.
Results: At baseline, ISI scores were not significantly different between groups (13.3±1.0 vs. 12.3±1.1; P=0.34). Post-intervention, ISI scores were significantly lower in the CBT-I group than the HEC group (7.2±1.5 vs. 2.7±2.1; P=0.03). Changes from baseline in ISI Sleep Symptoms (P=0.04) and Perception Symptoms (P=0.02) were significantly greater in the CBT-I group compared to HEC, while changes in Daytime Symptoms were not significant (P=0.3). There were no significant differences between treatment groups for measures of joint pain (PROMIS) and functioning (HOOS/KOOS). However, significant associations were found for change scores from pre- versus post-intervention for ISI and PROMIS Pain Intensity (P=0.03) and Pain Interference (P=0.006) and HOOS/KOOS Pain (P=0.03), Symptoms (P=0.03), Activities of Daily Living (P=0.01), and Quality of Life (P=0.002) for all participants combined.
Conclusion: The study demonstrates that CBT-I decreases insomnia severity in patients recovering from knee or hip joint arthroplasty primarily due to attenuating sleep symptoms and perceptions of insomnia. CBT-I did not significantly improve daytime symptoms associated with insomnia, pain, or functioning. Improvements in insomnia severity were associated with improvements pain intensity and interference, hip/knee pain, symptoms, activities of daily living, and quality of life independent of treatment group.

SEX DISPARITIES IN CBT-I TREATMENT RESPONSE IN PATIENTS RECOVERING FROM HIP OR KNEE JOINT ARTHROPLASTY

Sara Nowakowski[1], Manasa Kokonda[1], Emily Arentson-Lantz[2], Jessica Meers[1], Doris Escobedo[1], Julia Boyle[3], Zbigniew Gugala[4], Michael Smith[5], Jennifer Martin[6]

[1] Department of Medicine, Baylor College of Medicine, Houston, TX, USA, [2] Department of Nutrition Sciences and Health Behavior, University of Texas Medical Branch, Galveston, TX, USA, [3] Office of Research and Development & New England GRECC, VA Boston Healthcare System, [4] Department of Orthopedic Surgery and Rehabilitation, University of Texas Medical Branch, Galveston, TX, USA, [5] Johns Hopkins University, [6] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System

Introduction: Sex disparities in both insomnia and perceived pain have been demonstrated, where female patients tend to report greater insomnia symptoms, pain sensitivity and higher prevalence to insomnia disorder and chronic pain conditions compared to male patients. The present trial examined the sex differences in response to cognitive behavioral therapy for insomnia (CBT-I) in patients with insomnia disorder undergoing hip or knee joint arthroplasty.
Methods: Participants (N=69; 68% Female; Mean age=67.3 years) were randomly assigned to receive CBT-I (n=23 female; n=11 male) or Health Education Control (HEC; n=24 female, n=11 Male). The Insomnia Severity Index (ISI), PROMIS Pain, and Hip/Knee Osteoarthritis Outcome Score (HOOS/KOOS) were administered at baseline and post-intervention. Generalized linear models were performed to detect sex and treatment group differences and sub-group analysis by sex.
Results: There were no significant differences between male versus female participants for pre-post intervention changes in ISI, PROMIS pain intensity or pain interference. In female participants, change in ISI from baseline to post-treatment was significantly lower in the CBTI group than the HEC group (-8.5±6.4 vs -2.1±7.6; P=0.02), but not in male participants (P=0.21). In female participants, there was a significant correlation in pre-post change in ISI with pre-post change in PROMIS pain intensity (r=0.5, P=0.03), pain interference (r=0.6, P=0.01), HOOS/KOOS activities of daily living (r=-0.4, P=0.04) and quality of life (r=-0.5, P=0.01). No significant associations between insomnia and pain were observed in male participants.
Conclusion: Among individuals with insomnia recovering from hip or knee joint arthroplasty, there was a greater decrease in insomnia severity following CBT-I compared to HEC in female participants but not male participants. Pain outcomes improved across both treatment conditions for male and female participants and no significant group differences were found. Regardless of treatment group of the female participants, improvements in insomnia severity were associated with improvements in pain intensity, pain interference, activities of daily living, and quality of life.

COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA IMPROVES PAIN SEQUELAE IN TRAUMATIC BRAIN INJURY: PRELIMINARY SUBGROUP ANALYSES

Heather Altier[1], Eunyeong Joo[1], Hannah Maybrier[1], Anirudh Sharma[1], Jeannie Leoutsakos[1], Vani Rao[2], Charlene Gamaldo[2], Rachel Salas[2], Luu Pham[3], Matthew Peters[2], Durga Roy[2], Claudia Campbell[1], Michael Smith[4], Luis Buenaver[4]

Introduction: Persistent pain is a prevalent consequence of traumatic brain injury (TBI), with an estimated 51.5% of civilian populations experiencing chronic pain comorbidly. Sleep disturbance and pain are interrelated and share cognitive-emotional contributors. Their relationship is believed to be reciprocal, whereby pain disrupts sleep, and disturbed sleep exacerbates clinical pain via impaired functioning of endogenous pain modulatory systems. This cycle suggests that integrating sleep management strategies into chronic pain treatment could improve pain-related psychological outcomes (e.g., anxiety, depression). This study evaluates the effects of cognitive behavioral therapy for insomnia (CBT-I) on pain-related variables in individuals with TBI.
Methods: This cohort consisted of a community sample of TBI patients (N=49) participating in a parent randomized trial comparing 4-session CBT-I to 4-session sleep science and hygiene education. Participants completed sleep diaries and psychological measures before, during, and 3-months after treatment. Outcomes included anxiety and depressive symptoms, pain catastrophizing, cognitive pre-sleep arousal, and sleep quality. Linear mixed-effects models were analyzed to assess whether CBT-I improved pain sequelae in participants with Brief Pain Inventory (BPI) severity scores ≥3 at baseline (N=13).
Results: TBI participants randomized to CBT-I (N=6; Mage=42.0±14.2 years; MBPI=5.7±2.3; Range=3.3-8.5) were mostly female (66.7%) and equally white (50%) and black (50%). Sleep education participants (N=7; Mage=47.7±10.5 years; MBPI=4.2±1.4; Range=3.3-7.0) were predominantly female (71.4%) and white (71.4%). Analyses demonstrated a statistically significant group-by-time interaction for anxiety (b=-0.550[-0.870, -0.229], p=0.001), depression (b=-0.416[-0.686, -0.146], p=0.003), pain catastrophizing (b=-0.809[-1.529, -0.089], p=0.03), cognitive pre-sleep arousal (b=-0.680[-1.111, -0.249], p=0.002), sleep quality (b=-0.302[-0.494, -0.110], p=0.002), and sleep diary sleep efficiency (b=0.013, SE=.006, p=0.04) such that outcomes improved over time following CBT-I. No significant group differences emerged for pain severity.
Conclusion: In individuals with TBI, CBT-I significantly improved key correlates of pain, including anxiety, depressive symptoms, and sleep quality. While pain severity was not affected, alleviating psychological distress and improving sleep quality enhanced the quality of life for individuals with persistent pain. Given the limited research on nonpharmacological treatments for chronic pain in TBI and the preliminary nature of our findings, further research explicitly incorporating sleep interventions into pain management strategies is needed with larger samples.

COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA OUTCOMES: INSOMNIA IDENTITY AND INSOMNIA SEVERITY

Sarah Emert[1], Alisa Huskey[2], Samantha Nagy[3], Kelly Kim[3], Jacqueline Leete[3], Nicole Lopez[3], Ethan Olson[3], Hatty Lara[3], Rebecca Campbell[3], Daniel Taylor[3]

[1] Idaho State University, [2] The University of Arizona, [3] University of Arizona

Introduction: Insomnia is defined as difficulty falling or staying asleep or waking earlier than desired with inability to return to sleep. Insomnia Identity is described as one's identification as "an insomniac," which can be measured independently of other sleep parameters or a diagnosis of insomnia disorder. This study investigated whether pathologizing sleep concerns through endorsement of Insomnia Identity may alter treatment outcomes.
Methods: Participants (N=87, 71 females, Mage=57.69±4.88 years) completed questionnaires about Insomnia Identity (InsID) and insomnia severity (ISI) pre- and post-cognitive behavioral therapy for insomnia (CBTi) in a 4-arm, randomized clinical trial with a 3:3:3:1 allocation ratio: in-person, telehealth, SHUTi, and waitlist. Change in InsID ratings after treatment and the relationships between baseline InsID and post-treatment ISI were examined.
Results: ANOVA results indicated participants did not differ between group on pre-treatment (BL) ISI or InsID ratings (p's>.05). There were significant differences between groups for ISI at post-treatment (PT), F (3,72)=4.09, p=.010, specifically between waitlist (mISI=14.57), in-person (mISI=7.22), and telehealth (mISI=7.17), but not SHUTi (mISI=8.52). There were significant differences between groups for PT InsID, F (3,72) = 3.52, p=.019, specifically between waitlist (mInsID=5.14), in-person (mInsID=2.91), telehealth (mInsID=2.96), and SHUTi (mInsID=2.90). The three treatment groups did not significantly differ for either analysis. Linear regression was used to determine if InsID ratings pre-treatment predicted post-treatment ISI and ISI pre-post change scores within the treatment groups only. Elevated pre-treatment InsID predicted higher posttreatment-ISI scores, F (1,65)=8.17, p=.006, R^2=.11, β=.34, but did not differ between groups (p=.14). InsID did not predict ISI change scores (p=.82).
Conclusion: Results indicate that Insomnia Identity is modifiable with CBTi treatment and appears to be related to the overall outcome of insomnia severity. Future treatment focused on reducing Insomnia Identity may lead to improved treatment outcomes.

CHANGES IN NEURAL ACTIVATION UNDERLYING COGNITIVE CONTROL IN PATIENTS WITH CHRONIC INSOMNIA DISORDER AFTER CBT-I

Sun-Young Kim[1], Jeong Eun Jeon[2], Ha Young Lee[2], Jin Hyuk Yoo[2], Minah Kim[2], Seung Hyun Kim[3], Jiyoon Shin[4], Mincheol Seo[5], Kyung Hwa Lee[2], Yu Jin Lee[2]

[1] Ewha Womans University Hospital, [2] Seoul National University Hospital, [3] Seoul National University Hospital, [4] Uijeongbu Eulji Medical Center, [5] Veteran Health Service Medical Center

Introduction: This study investigated whether CBT-I alters neural activation during an emotional Stroop task in chronic insomnia disorder (CID). It also examined how changes in brain activation after CBT-I are linked to sleep or emotional-related symptom changes in CID.
Methods: This study included 23 CID patients and 11 controls who completed self-reported questionnaires, sleep diaries, actigraphy, and fMRI at both baseline and at the 5-week follow-up. CID patients received individualized face-to-face CBT-I once a week for 5 weeks. During fMRI, participants performed the emotional Stroop task with negative, sleep-related, and neutral words. Brain activation changes were compared pre- to post-CBT-I in the CID group and baseline to 5-week follow-up in the

control group, using a repeated measures ANOVA. Correlations neural activation changes and sleep or emotional-related symptom changes after CBT-I in the CID group were also analyzed.
Results: After CBT-I, scores on ISI, PSQI, and DBAS was significantly decreased. In addition, SOL and SE on sleep diary and WASO measured by actigraphy were significantly improved. Regarding psychiatric symptoms, scores on BAI and BDI were also reduced after CBT-I. CID patients showed increased activation in the right supratemporal gyrus (STG), right visual association area (VAA), and left supramarginal gyrus (SMG) during the emotional Stroop task with negative words (vs. neutral words) after CBT-I (STG, $p = 0.001$; VAA, $p < 0.001$; SMG, $p < 0.001$). However, no changes in these brain regions were observed in the control group. Neural activation changes in STG were negatively correlated with DBAS, and in VAA, they were negatively correlated with PSQI and ISI. Neural activation changes in STG and VAA were negatively correlated with BDI scores.
Conclusion: CBT-I enhanced activation in the right STG, VAA, and left SMG, which are known to be dorsal attentional networks, under the negative word condition. These findings may reflect improved attentional and cognitive processing of negative emotional stimuli, potentially linked to improved insomnia and depressive symptoms.

DETERMINANTS OF TREATMENT RESPONSE TO CBT-I IN VETERANS PRESENTING WITH COMORBID INSOMNIA AND SLEEP APNEA

Keziah Aibangbee[1], Erin Gould[1], Amber Martinson[2], Ali El Solh[1]
[1] University at Buffalo, [2] VA Salt Lake City Healthcare System

Introduction: Cognitive behavioral therapy for insomnia (CBT-I) is considered the preferred treatment for insomnia in patients with comorbid insomnia and obstructive sleep apnea (COMISA). The remission rates with CBT-I are generally considered lower than in insomnia-only populations and there is variability in individual treatment responses. In this study, we sought to identify specific clinical attributes that predict benefit from CBT-I in patients with COMISA.
Methods: We conducted a retrospective analysis of the national Veterans Health Administration (VHA) electronic medical records covering veterans with the diagnosis of COMISA between January 2021 and December 2023. A total of 131 eligible cases received brief behavioral therapy for insomnia (BBTI) over 6 weeks, 56 (43%) of whom did not achieve remission.
Results: Fifty-six patients (43%) did not meet ISI criteria for BBTI response. Patients who did not respond to BBTI had a higher sleep propensity at baseline than those who did respond to BBTI ($p=0.02$), however, both groups had comparable degree of insomnia severity ($p=0.78$). Prior to BBTI, there was no significant difference in the CPAP usage between BBTI responders (84.7±53.9 minutes) and BBTI nonresponders (78.9±77.5 minutes) (difference 5.7 minutes, 95% CI [-18.3, 29.7]; $p=0.62$). Post BBTI, patients in BBTI responders used CPAP for a longer duration compared with baseline (difference 63.6 minutes, 95% CI [51.1, 76.3]; $p< 0.001$] but not for BBTI nonresponders (difference 9.1 minutes, 95% CI [-10.2, 28.4]; $p=0.35$). Moreover, BBTI responders achieved higher CPAP use (148.3±84.4 minutes) than BBTI nonresponders (84.6β β 53.9 minutes), with a statistically significant difference between the two groups (60.3 minutes, 95%CI [30.3, 90.2]; $p< 0.001$) (Figure 2).Non-whites (OR 3.5, 95% CI [1.4, 8.8]) and shorter sleep time (OR 0.98, 95% CI [0.98, 0.99] were independent predictors of blunted response to BBTI. These findings remained true even when depression and AHI were forced into the regression model. Patients with a total sleep duration < 4.1 hours were at greatest risk for BBTI failure.
Conclusion: These findings buttress the need that identifying insomnia phenotypes in patients with COMISA would help deliver personalized care while maximizing CBT-I treatment resources.

PREDICTORS OF INSOMNIA SEVERITY IN A VETERAN POPULATION REFERRED FOR CBT-I

Isabella Soreca[1], Adam Bramoweth[1], Mark Thomas[2]
[1] VA Pittsburgh Healthcare System, [2] Pittsburgh VA Healthcare System

Introduction: The Insomnia Severity Index (ISI) is a widely used measure assessing the subjective severity of insomnia symptoms. While sleep behaviors such as total sleep time (TST) and sleep efficiency (SE) contribute to the perception of insomnia severity, the role of patient-level characteristics in predicting ISI scores above and beyond these variables has not been fully elucidated. This study explores the relationship between common comorbidities, such as Obstructive sleep apnea (OSA), post-traumatic stress disorder (PTSD) and major depressive disorder (MDD) and insomnia severity in Veterans referred for CBT-I.
Methods: Data were obtained from the VA's Corporate Data Warehouse, a repository of clinical and administrative Veteran data aggregated from VA electronic health records. Our sample consisted of Veterans who had an outpatient cognitive behavioral therapy for insomnia (CBT-I) encounter, between 10/01/2015 and 06/15/2023. A regression model was built to test the contribution of age, sex, race, TST and SE (sleep diary), presence of OSA, PTSD, and MDD to baseline CBT-I session ISI score.
Results: A total of 7046 veterans had complete data, including TST, SE, ISI and OSA/PTSD/MDD diagnoses. Patients with PTSD were younger, had worse baseline ISI scores, shorter TST, and poorer SE. The regression results showed a small but significant negative relationship with age ($\beta = -0.032$, $p < 0.001$), notable racial differences, with "Hispanic" and "Other" Veterans reporting lower ISI scores ($\beta = -0.561$, $p = 0.030$; $\beta = -1.037$, $p < 0.001$ respectively), a negative association with TST ($\beta = -0.006$, $p < 0.001$), and SE ($\beta = -13.795$, $p < 0.001$). A diagnosis of OSA ($\beta = 0.827$, $p < 0.001$), PTSD ($\beta = 0.435$, $p = 0.002$) and MDD ($\beta = 0.345$, $p = 0.013$) were positive predictors of higher ISI scores. The model accounted for 22.1% of the variance in ISI scores ($R^2 = 0.221$).
Conclusion: Psychiatric and medical comorbidities significantly influence insomnia severity among Veterans. These relationships persist even when controlling for other variables, including TST and SE, suggesting a unique contribution of other patient-level factors, such as OSA, PTSD and MDD to the subjective insomnia-related distress and impairment.

CBT-0601 0601 0601 0601 I FOR VETERANS WITH PSYCHOSIS: EVALUATING ADHERENCE AND FUNCTIONAL OUTCOMES

Elizabeth Klingaman[1], Julia Russell[1], Clayton Brown[2], Lan Li[2]
[1] U.S. Department of Veterans Affairs, [2] University of Maryland School of Medicine

Introduction: Veterans with psychosis experience environmental, psychological, and systemic barriers to receiving and benefiting from CBT-I. To promote delivery and adherence, we developed a 10-session guide (CBT-I for Psychosis) for tailoring CBT-I to address these barriers. We delivered CBT-I for Psychosis compared to an active control Health and Wellness (HW) intervention and assessed (1) functional outcomes, (2) characteristics of CBT-I adherence, and (3) the relationship between adherence and post-CBT-I outcomes.
Methods: The sample was N=47 Veterans with psychosis; 26 randomized to CBT-I for Psychosis and 21 to HW. Measures assessed at baseline, post-treatment, and 3-month follow-up included the Insomnia Severity Index (ISI), Functional Outcomes of Sleep Questionnaire-10 (FOSQ-10), and World Health Organization Disability Assessment Schedule 2.0 (WHODAS2.0). Adherence measures were 14-day standard deviation (SD) of out of bed-time (OBT) derived from participant-completed Consensus Sleep Log-Core (CSD-C) diaries at each timepoint, and therapist-rated Treatment Components Adherence Scales (TCAS) at final CBT-I session.
Results: A general linear model with correlated errors was used to test differences on outcome measures. Regression terms in the model included time, and intervention-by-time interactions. At post but not follow-up, CBT-I yielded greater ISI reductions (t[46]=-2.07, p=.044, d=-.70), and FOSQ-10 improvements (t[46]=2.21, p=.032, d=.46), whereas HW yielded FOSQ-10 deteriorations. There was a greater increase in participation in community activities in HW relative to CBT-I at post (t[46]=2.39, p=.021, d=.48) and follow-up (t[46]=2.33, p=.024, d=.52) as measured by WHODAS2.0. For OBT, there was a trend for larger SD decreases in CBT-I relative to HW at post (t[44]=-1.77, p=0.08, d=-0.55) but not follow-up. Scores on the TCAS were not associated with the FOSQ-10 at any timepoint, but were moderately correlated with the ISI at 3-month follow-up, (r[16]=-.57; p=.02).
Conclusion: CBT-I for Psychosis yielded substantial benefits to insomnia severity and sleep-related functioning, but not community engagement. Therapist-rated adherence may predict longer-term insomnia outcomes. Results demonstrated a trend with a medium effect size of CBT-I in reducing diary-derived OBT SDs, suggesting adherence to consistent rise times. Larger trials should use multimethod assessments to examine OBT variability and its relation to sleep-related functioning for Veterans with psychosis.

Introduction: Acceptance and Behavioral Changes to Treat Insomnia (ABC-I) is a promising acceptance- and behavioral-based intervention for the treatment of chronic insomnia disorder, with previously demonstrated non-inferiority to Cognitive Behavioral Therapy for Insomnia (CBT-I) for symptom reduction and superior adherence to behavioral treatment recommendations among women veterans. Comorbid posttraumatic stress disorder (PTSD) is a common clinical presentation that can hinder insomnia treatment engagement and outcomes. This analysis sought to determine whether ABC-I led to greater PTSD symptom improvement, compared to CBT-I, in women veterans.
Methods: We analyzed data from a subset of participants in a randomized comparative effectiveness trial of ABC-I vs CBT-I in women veterans with probable PTSD (NCT02076165). Analysis 1 included 30 participants who received ABC-I. Analysis 2 also included 23 participants who received CBT-I. PTSD symptoms were measured via PTSD Checklist (PCL-5) total and cluster scores (i.e., B: intrusion, C: avoidance, D: negative cognitions/mood, E: hyperarousal). Probable PTSD was defined by PCL-5 total score ≥ 33. For analysis 1 we used paired-groups t-tests, and for analysis 2 we used independent groups t-tests (comparing improvement for the ABC-I vs. CBT-I group). Effect sizes were computed for both analyses (Cohen's d). We employed 1-tailed testing and alpha =.20 as the a-priori threshold given the exploratory nature of these analyses.
Results: In Analysis 1, veterans who received ABC-I demonstrated a significant reduction in PCL-5 total and cluster (B-E) scores at both post-treatment and 3-month follow-up (ds = -0.71—1.50, ps < 0.01). In Analysis 2, ABC-I demonstrated greater PTSD symptom reductions (i.e., change-scores) than CBT-I at the 3-month follow-up (but not post-treatment) for PCL-5 total (Δd = -6.8, p = 0.08) and cluster C and D scores (Δd = -1.1, p = 0.10, Δd = -4.2, p = 0.03).
Conclusion: ABC-I holds promise for addressing insomnia and PTSD symptoms in trauma-exposed individuals, a population that has historically demonstrated sub-optimal responses to CBT-I. Further work should explore potential mechanisms by which ABC-I may confer ancillary treatment benefits.

DEVELOPMENT OF A TAILORED DIGITAL CBT-I PILOT INTERVENTION IN OLDER U.S. LATINO SURGICAL PATIENTS

Andrea Castillo Suárez[1], Chenlu Gao[2], Mili Jimenez Gallardo[1], Anaëlle Charles[1], Peng Li[2], Kun Hu[2], John Winkelman[3], Lei Gao[2]

[1] Massachusetts General Hospital/Harvard Medical School, [2] Massachusetts General Hospital/ Harvard Medical school, [3] Harvard Medical School

Introduction: Insomnia and sleep-related disturbances affect over one-third of older adults undergoing surgery. Insomnia increases the vulnerability to postoperative delirium (POD) and cognitive decline, impairing postoperative recovery. U.S. Latino/Hispanic older adults are disproportionately affected by these sleep-related disturbances, with over half reporting mild-to-severe insomnia symptoms. Cognitive Behavioral Therapy for Insomnia (CBT-I) is the first-line treatment for insomnia, but nearly all current digital versions are in English, making it endemically underutilized by minority groups due to linguistic and cultural barriers. This AASM-funded (352-DS-24) pilot study aims to culturally tailor a digital CBT-I intervention for older Latino/Hispanic surgical patients to evaluate its 1) feasibility and 2) preliminary efficacy.
Methods: Up to ten stakeholders (patients, caregivers/family, and healthcare professionals, including primary care, anesthesia, surgery, and behavioral sleep physicians) will be recruited to participate in two focus group sessions. Both groups will test the intervention and provide feedback on cultural and linguistic needs. After incorporating their feedback, we will recruit ten older U.S. Latino/Hispanic surgical patients (≥65 years old) with insomnia (Insomnia Severity Index≥8) to undergo a tailored digital CBT-I intervention comprising one in-person baseline session and three virtual sessions over four weeks. We will assess the feasibility, acceptability, and preliminary efficacy of the culturally tailored CBT-I intervention through adherence tracking, utility and satisfaction surveys, sleep diaries, preoperative anxiety, and postoperative cognitive and physical recovery.
Results: We will present our experiences and qualitative learning from the focus group sessions, such as cultural differences and barriers identified and any adaptations to the translated intervention. We also anticipate reporting our experiences with and preliminary findings from the first participants' adherence, satisfaction, and sleep efficiency results. Potential challenges include recruiting and retaining older Latino/Hispanic participants, technical literacy, and access to digital tools, which will be mitigated through technical support and simplified intervention designs.
Conclusion: This pilot study aims to adapt a well-established digital insomnia intervention for an underserved population, addressing critical gaps in perioperative care for older U.S. Latino/Hispanic surgical patients. If successful, this approach may reduce the burden of insomnia and postoperative cognitive decline, advancing equitable healthcare practices.

A SOUND APPROACH: IS DIGITAL BEHAVIORAL INSOMNIA THERAPY ACCESSIBLE FOR THE DEAF COMMUNITY?

Veronica Van Rossen[1], Marleigh Treger[2], Ishana Kapoor[1], Cynthia Fellman-Couture[1], Christopher Drake[3], Philip Cheng[4]
[1] Henry Ford Sleep Research, [2] Henry Ford Health, [3] Henry Ford Health System, [4] Henry Ford Health + Michigan State University Health Sciences

Introduction: Prior research has demonstrated that digitally delivered CBT for Insomnia (dCBT-I) is highly effective for those who can access and complete treatment. However, there are significant accessibility challenges for many vulnerable populations. Extant studies have focused on those with low socioeconomic (SES) resources and/or low digital health literacy; however, the accessibility of dCBT-I for people with hearing disabilities has not been well-established. This study conducted qualitative interviews with dCBT-I patients from various backgrounds about treatment adherence and the addition of a nurse coach.
Methods: Patients (n=263) had an initial telehealth consultation with the coach, then completed six consecutive weeks dCBT-I sessions via a mobile health application alongside sleep diaries which tracked sleep efficiency, sleep restriction, and time in bed. Patients received personalized feedback from the coach after each session and had the option of booking additional telehealth coaching sessions. Qualitative interviews were conducted with a subsample of patients to assess adherence across ability, SES, and treatment completion barriers and facilitators using the NIMHD framework. Results specifically pertinent to those with hearing disability are presented here.
Results: While patients with hearing disabilities were able to successfully complete the treatment, there were several barriers and facilitators named. Patients found that specific digital tools that are usually not available (e.g., chat box, live closed captioning) were integral to their ability to fully participate in the treatment. Patients with a hearing disability often relied on their own tools and strategies (e.g., translation services, microphones) to make the treatment recommendations feasible. Patients also noted that having a coach aided in treatment adherence, specifically referencing the importance of receiving encouragement as an important factor in their own treatment continuation.
Conclusion: This feedback highlights the importance of augmenting dCBT-I with relevant tools and technology to increase accessibility to those with a hearing disability. Though the digital administration of CBT-I already has tools that increase accessibility compared to in-person treatment, those were not sufficient. Future research should further examine how implementation of dCBT-I can have greater equitable access for disabled communities.

EFFECTS OF DIGITAL CBT-I ON SELF-REPORTED SLEEP MEASURES: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Ingrid Leite[1], Viviane Kakazu[1], Sergio Tufik[2], Gabriel Pires[3],
[1] Universidade Federal de São Paulo, [2] Departamento de Psicobiologia, Universidade Federal de São Paulo, [3] Universidade de Federal de São Paulo

Introduction: Cognitive Behavioral Therapy for Insomnia (CBT-I) is the gold-standard treatment for this sleep disorder, but its implementation is limited due to the reduced number of trained professionals and high costs. Digital CBT-I (dCBT-I) has emerged as a viable alternative, and previous meta-analyses demonstrated its efficacy on insomnia outcomes. However, a gap remains in evaluating the effects of dCBT-I on sleep macroarchitecture. This study aimed to investigate it through meta-analyses of randomized clinical trials (RCTs).
Methods: Systematic searches were conducted in PubMed and Web of Science for RCTs evaluating dCBT-I in adults with

chronic insomnia. Studies were included if they assessed Total Sleep Time (TST), Sleep Onset Latency (SOL), Sleep Efficiency (SE), Wake After Sleep Onset (WASO), and Number of Awakenings (NWAK) either as self-reported information or polysomnography (PSG). Meta-analyses were conducted for active (in-person CBT-I or telehealth) and inactive (no treatment or minimal intervention) control groups. Effect size was calculated using raw mean differences and meta-analyses were performed using random-effects models.
Results: A total of fifteen RCTs were included, comprising sixteen analyses. They were conducted with data from sleep diaries only, as none of the included studies provided PSG data. When comparing dCBT-I with active control, no significant differences were detected. In comparison to inactive controls, statistically significant effects were observed. TST increased by 0.21 hours, SOL decreased by 15.52 minutes, SE improved by 10.51%, WASO reduced by 16.43 minutes, and NWAK decreased by 0.53.
Conclusion: DCBT-I was associated with improvements in sleep macroarchitecture parameters when compared to inactive control groups, but no significant differences were identified when compared to active control groups. This denotes that dCBT-I is as effective as in-person CBT-I. Future research should include objective sleep measures to enhance these findings.

EVALUATING PARTICIPATION IN COGNITIVE-BEHAVIORAL THERAPY FOR INSOMNIA IN VETERANS USING ELECTRONIC HEALTH RECORDS

Mark Thomas[1], Adam Bramoweth[2], Yeon-Jung Seo[3], Daniel Buysse[4], Isabella Soreca[2]

[1] Pittsburgh VA Healthcare System, [2] VA Pittsburgh Healthcare System, [3] University of Pittsburgh, [4] University of Pittsburgh School of Medicine

Introduction: Insomnia disorder is a chronic, debilitating disorder that is highly prevalent in US Veterans. Cognitive-Behavioral Therapy for Insomnia (CBT-I) is an effective, first-line treatment for insomnia across the Veterans Health Administration (VHA). However, early discontinuation of CBT-I is common, with estimates of 25-40% of Veterans discontinuing after one session in smaller samples of Veterans. Retention barriers may be experienced differently for Veteran subgroups at risk for health inequities, like people of color or those with serious mental illness. The current study leverages electronic health records across all CBT-I encounters in VHA to identify sociodemographic and clinical factors associated with CBT-I discontinuation and completion.
Methods: Data were obtained from VA Corporate Data Warehouse in Veterans with at least one CBT-I outpatient progress note between FY2015-FY2023. Extracted predictors include total sessions, age, sex, race, medical comorbidities, baseline insomnia symptom severity, concurrent sleep medication use, and mental health diagnoses. A series of chi-square tests were performed to evaluate differences in these predictors for two variables: a) discontinuation after 1 session, and b) completion of treatment (defined as achieving the minimally-recommended 4 sessions).
Results: Of the 82,214 Veterans (82.8% Male, mean age = 50.9 years, 46.3% non-White) who initiated CBT-I, 69.9% of Veterans discontinued CBT-I after the first session, and only 16.0% completed the minimally-recommended 4 sessions. Veterans of color, younger (< 45 years), and with a diagnosis of psychosis, substance use disorder, and alcohol use disorder completed fewer sessions and had lower rates of treatment completion (all p-values <.02). Female Veterans and Veterans with a diagnosis of anxiety disorders, depression, and PTSD completed more sessions and had higher rates of treatment completion (all p-values <.001).
Conclusion: Despite its effectiveness, most Veterans do not complete CBT-I. This study identified sociodemographic and clinical factors that contributed to engagement and discontinuation in CBT-I. These data suggest that greater efforts at patient retention may be needed for younger Veterans and those with psychosis or substance use problems. Further research is necessary to understand these facilitators and barriers to improve treatment engagement and outcomes for Veterans with insomnia.

CLIENT EXPECTATIONS OF DIFFERENT COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA MODALITIES AND RELATED TREATMENT OUTCOMES

Cordell Stover[1], Sarah Emert[1], Emme Tucker[1], Lauren Elmore[1], Alisa Huskey[2], Samantha Nagy[3], Kelly Kim[3], Jacqueline Leete[3], Nicole Lopez[3], Ethan Olson[3], Hatty Lara[3], Rebecca Campbell[3], Daniel Taylor[3]

[1] Idaho State University, [2] The University of Arizona, [3] University of Arizona

Introduction: Cognitive behavioral therapy for insomnia (CBTi) is considered the first-line treatment for insomnia, but access to this treatment is limited. Telehealth- or Internet-delivered CBTi are potential strategies for increasing access. This study investigated the perceived credibility and expectancy of treatment success across three CBTi modalities and explored the effects of credibility and expectancy has on treatment outcomes.
Methods: Sixty-two participants (84% Females, Mage=57.90 years; SD=4.75) between the ages of 50-65 who reported complaints of insomnia were recruited for this study. Participants completed the Credibility Expectancy Scale (CEQ) at the first session and the Insomnia Severity Index (ISI) pre- and post-treatment. Participants were randomly assigned into one of the three CBTi modalities: In-Person (n=21), Telehealth (n=22), and Internet (SHUTi; n=19) delivered CBTi. CEQ variables were separated into a credibility score, expectations based on feelings score, and expectations based on thoughts score.
Results: Differences between CEQ scores of credibility and expectations were compared across CBTi modalities, using one-way analyses of variance. Credibility scores were significantly higher for In-Person (M=7.59, SD=1.10) and Telehealth (M=7.36, SD=1.23) when compared to Internet-delivered CBTi (M=5.86, SD=1.74, p's <.05). Expectancy (thought-based) scores were significantly higher for Telehealth CBTi (M=6.41, SD=1.59) when compared to Internet-delivered CBTi (M=4.89, SD=2.31, p's <.05). All other comparisons did not meet statistical significance. A multiple linear regression analysis resulted in a significant model, R2=.23, F(1, 60)=18.18, p <.001. Further analysis revealed that the measure of

expectancy based on feeling was the only significant predictor of posttreatment ISI scores, β=-.48, p <.001.
Conclusion: Results reveal that patients expect more improvements from CBTi modes that involve a clinician. The pre-treatment expectancy predicts post-treatment ISI only with expectancy based on feelings, which indicates that expectations of CBTi outcomes based on thoughts and feelings are different, this may be affecting the overall treatment outcomes. Future research could explore this further. Results suggest that Telehealth CBTi may be an effective strategy to increase the accessibility of treatment for insomnia.

STEPPED-CARE MANAGEMENT OF INSOMNIA: PATIENT TREATMENT CHOICES IN A PRAGMATIC CLINICAL TRIAL SETTING

Janet Cheung[1], Lee Ritterband[2], Si-Jing Chen[3], Hans Ivers[3], Charles Morin[3]
[1] The University of Sydney, [2] University of Virginia, [3] Université Laval

Introduction: Informing patients about prospective options for managing insomnia remains challenging in practice given the competing risk-benefit profiles between options. This study evaluated patient treatment choices for insomnia as part of a pragmatic clinical trial for a two-phase cognitive behavioral therapy for insomnia (CBT-I) intervention.
Methods: Upon enrollment, participants (N=154, 73% women, mean age: 51.8 ± 14.2 years) were guided by a patient decision aid (PtDA), outlining the risk-benefit profiles of in-person CBT-I, digital CBT-I (dCBT-I), and medication. In phase-1, participants were offered a choice between dCBT-I, dCBT-I + medication or medication only. Non-remitters were enrolled into phase-2 (N=69), choosing between in-person CBT-I, medication, or no further treatment. A secondary analysis was conducted evaluating patient treatment choices and the acceptability of the PtDA. The presence of decisional conflict with treatment choice(s) was screened using the 4-item SURE (Sure of myself; Understand information; Risk-benefit ratio; Encouragement) checklist.
Results: In phase-1, 47.4% (n= 73) of participants chose dCBT-I, followed by dCBT-I + medication (42.3% n=66) and medication (9.74%; n=15). The dCBT-I group were less likely to use medications compared to the other two treatment groups (p < 0.001). Men (p = 0.032) and individuals less motivated to change sleep habits (p=0.014) were more likely to choose medication only in phase-1. In phase-2, 60.9% (n=42) of non-remitters chose in-person CBT-I, followed by no further treatment (23.6%; n=16) and medication (15.9%; n=11). Non-remitters from the medication group were more likely to choose medication again in phase-2 (p< 0.001). Decisional conflict (i.e., SURE score < 4) was only observed in 6% (n=9/154) and 3% (n=2/59) of participants across phase-1 and phase-2, respectively. With respect to acceptability, over 90% of participants (n=145/154; n=57/59) endorsed the PtDA as easy to understand, easy to read, clarified their treatment preferences, and facilitated decision-making.
Conclusion: The PtDA was endorsed as acceptable and appeared to address the decisional conflict that often arises when choosing between insomnia treatments. This may explain the higher-than-expected uptake of dCBT-I and CBT-I, warranting further research on the impact of PtDAs on insomnia treatment outcomes.
Support (if any): This study was funded by the Canadian Institutes for Health Research (Grant #353509).

EFFECT OF A PRESCRIPTION DIGITAL THERAPEUTIC FOR CHRONIC INSOMNIA ON DAYTIME SLEEPINESS: RESULTS FROM THE REAL-WORLD DREAM STUDY

Candi Holyfield[1], Rebecca Hankla[1], Samantha Edington[1], Frances Thorndike[1], Robert Gerwien[2], Lee Ritterband[3]
[1] Nox Health, [2] Statistical Consulting, [3] University of Virginia

Introduction: Digital Cognitive Behavioral Therapy for Insomnia (dCBT-I) delivers gold-standard treatment for chronic insomnia. Concerns about increased sleepiness during the sleep restriction phase of dCBT-I have limited its use, especially in safety-sensitive occupations like those regulated by the Department of Transportation (DOT); however, its impact on real-world populations has been underexplored. The Epworth Sleepiness Scale (ESS), a validated measure of daytime sleepiness, allows us to evaluate sleepiness throughout dCBT-I treatment. This study investigates the impact of dCBT-I on ESS-measured sleepiness.
Methods: Real-world data was derived from a prospective, single-arm, pragmatic clinical study (DREAM [USA; N=1565, aged 22-75]). The intervention was a dCBT-I program delivered through the FDA-cleared Somryst® mobile application. The program delivered 6 interactive treatment Cores over 6-9 weeks covering key CBT-I principles, with sleep restriction implemented between Cores 2-3. Participants completed the ESS and Insomnia Severity Index (ISI) at the beginning of each Core and entered daily sleep diaries used to tailor sleep restriction windows.
Results: Contrary to concerns about sleepiness post-sleep restriction implementation, ESS scores did not increase at Core 3. Instead, ESS scores demonstrated significant reductions from Core 1 to Cores 3-6, indicating decreased daytime sleepiness throughout the intervention. ESS scores decreased from a mean of 9.14 at Core 1 to 7.30 at Core 6. Relative to Core 1, the mean differences for each core were: Core 3 (-0.66, p < 0.001), Core 4 (-0.81, p < 0.001), Core 5 (-1.37, p < 0.001), and Core 6 (-1.84, p < 0.001). ISI scores decreased from a mean of 18.83 in Core 1 to 9.87 at Core 6; the mean difference from Core 1 to 6 was -8.96, p < 0.001.
Conclusion: Evaluation of ESS scores throughout dCBT-I treatment revealed no increase in subjective sleepiness, even during sleep restriction. In fact, real-world participants demonstrated resilience and adaptation to the intervention, reflected by significant progressive reductions in ESS scores across cores. These findings support further discussion on utilizing dCBT-I programs for safety-sensitive populations.
Support (if any): Funding provided by Pear Therapeutics, Inc., with additional support from Nox Health, Inc. (NCT04325464).

APPLICATION OF DECENTRALIZED CLINICAL TRIAL TO VALIDATE THE EFFICACY OF DIGITAL THERAPEUTICS FOR INSOMNIA

Kyungmee Park[1], Suonaa Lee[2], Yujin Lee[3], Daa Un Moon[4], Eun Lee[2]
[1] Department of Hospital Medicine, Yongin Severance Hospital, Yonsei University College of Medicine, Yongin, Republic of Korea, [2] Department of Psychiatry and the Institute of Behavioral

Science in Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, [3] College of Pharmacy, Yonsei Institiute of Pharmaceutical Sciences, Yonsei University, Incheon, Republic of Korea, [4] Department of Psychiatry and Neurosciences, CCM, Charité Universitätsmedizin Berlin, Corporate Member of Freie Universität and Humboldt-Universität zu Berlin, Berlin, Germany.

Introduction: Cognitive behavioral therapy for insomnia (CBT-I) has proven to be an effective treatment, however, its accessibility is limited. To address this issue, digital therapeutics for insomnia (DTx-I) have emerged as potential solution to enhance access. We have opted to conduct a decentralized clinical trial (DCT) which can minimize the necessity for participants to in-person hospital visits. This study aimed to evaluate the clinical efficacy of a proprietary DTx-I, "WELT-I", and assess the feasibility and utility of DCTs for validating DTx-I.
Methods: A double-blind, sham-controlled randomized DCT was conducted with 68 participants meeting DSM-5 criteria for insomnia (n=33 for WELT-I group, n=35 for control group). Sleep metrics and self-reported psychiatric questionnaires, including dysfunctional beliefs and attitudes about sleep (DBAS-16), were measured over 7 weeks. All trial procedures except one on-site visit for written consent were conducted remotely. The primary outcome for efficacy was sleep efficiency. For the utility of DCTs, time to reach recruitment goal, retention rates, and participants' satisfaction were evaluated.
Results: WELT-I significantly improved sleep efficiency compared to the sham app (least square difference=8.28, p value=0.04) and DBAS-16 score (least square difference=-1.03, p value=0.01). Recruitment was completed within 73 days, with a retention rate of 82.14% and a mean satisfaction score of 7.21 out of 10.
Conclusion: This study provides evidence that WELT-I, a CBT-I-based digital therapeutics, is a safe and effective approach to managing insomnia disorder. The DCT approach enabled rapid recruitment, high retention, and strong participant satisfaction, highlighting its potential as a scalable and efficient method for validating DTx-I.
Support (if any): The present study was supported by the National Research Foundation of Korea, funded by the Ministry of Science, ICT & Future Planning, Republic of Korea, under grant number 2022R1A2B5B03002611 (Eun Lee); the Daegu-Gyeongbuk Medical Innovation Foundation under grant number B0081115000708 (Eun Lee); the Korea Health Industry Development Institute under grant number RS-2023-00266002 (Eun Lee); and Korea Medical Device Development fund, under grant number RS-2023-00255005 (Kyung Mee Park). SPONSORSHIP BIAS AND METHODOLOGICAL QUALITY IN RANDOMIZED CONTROLLED TRIALS ABOUT DIGITAL CBT FOR INSOMNIA

Viviane Kakazu[1], Ingrid Porto Araújo Leite[2], Ygor de Matos Luciano[2], Sergio Tufik[2], Gabriel Pires[2]
[1] Universidade Federal de São Paulo, [2] Universidade de Federal de São Paulo

Introduction: Industry sponsorship bias refers to distortions that can occur at any point in a study to favor its sponsor. Digital cognitive behavioral therapy for insomnia (CBT-I) is a nonpharmacological treatment whose studies are often sponsored by the developer companies. The aim of this study was to assess whether sponsorship bias in digital CBT-I studies predicts more favorable outcomes on randomized controlled trials (RCTs).
Methods: A systematic review of PubMed and Web of Science databases was conducted to identify RCTs on digital CBT-I in adults. Information was collected on the type of publication, methodological quality, and involvement of the authors with the company developing the digital CBT-I studied. Industry sponsorship bias was measured on a 0 to 4 scale, based on the number of authors primarily affiliated to the companies developing the digital CBT-I interventions, or to mentions of sponsorship or funding received from these companies. The methodological quality of the RCTs was evaluated using the van Tulder scale
Results: Twenty-eight RCT analyses were included. The most frequent intervention was SHUTi (39.28%), followed by non-specified digital interventions for insomnia. The mean insomnia severity index (ISI) scores were 15.04±4.89 in the control group, 10.75±5.06 in the experimental group, and the mean effect size was 1.06±1.66. There was no correlation between the sponsorship bias level and the ISI effect size (ρ=1.000; p=0.198). The ISI effect size was equivalent among studies with and without sponsorship bias (p=0.405). The presence of sponsorship bias was associated with both open access publication (p=0.022) and lower methodological quality (p=0.027).
Conclusion: Sponsorship bias did not favor the results of digital CBT-I interventions, as no correlation was found between industry sponsorship bias and the ISI score. However, sponsorship bias was significantly associated with both open access publication and with lower methodological quality.
Support (if any): This work was supported by the Associação Fundo de Incentivo à Pesquisa (AFIP), São Paulo, Brazil. INVESTIGATING BEHAVIOR CHANGE IN THERAPIST-LED VERSUS DIGITAL CBT-I AND ITS MEDIATING ROLE ON CLINICAL OUTCOMES

Parky Lau[1], Norah Simpson[1], Isabelle Tully[1], Bohye Kim[1], Jane Kim[1], Jessica Dietch[2], Joshua Tutek[3], Rachel Manber[1]
[1] Stanford University, [2] Oregon State University, [3] MUSC

Introduction: This study analyzed data from a subset of participants from the RESTING Study who were previously shown have differential reduction in insomnia severity (ISI) following digital CBT-I (dCBT-I) or therapist delivered CBT-I (tCBT-I). Given the centrality of behavioral change in sleep interventions, we examined whether the changes in time awake during the period allocated for sleep and lingering in bed differed by treatment modality, and whether these changes mediated the differential reductions in insomnia severity between the two arms.

Methods: Adults 50 years or older identified as likely to derive better benefit from tCBT-I were randomized to dCBT-I (n=69) or tCBT-I (n=68) (M age=63.26 years [SD=7.79], 69% female). Time awake during the period allocated for sleep (Total Wakefulness) was computed as the average difference between the number of hours from 'lights out' until 'rise time' and 'total sleep time'; lingering (Linger) was average of hours between 'into bed' and 'lights out' plus hours between 'wake time' and 'rise time', both derived from the consensus sleep diary. Participants were assessed at baseline, 2,4,6,9, and 12 months. Quadratic mixed effects models were tested, one per behavioral variable of interest. MacArthur mediation model was used to examine whether changes in these variables at 2 months predicted subsequent trajectory of change in insomnia severity index (ISI).
Results: Participants who received tCBT-I had significantly greater reduction in Linger than those receiving dCBT-I (B=-0.013, p=0.047, partial η2=0.003) but not in Total Wakefulness (p=0.053). The mediation model revealed that early change in Linger (from baseline to two months) predicted subsequent change (slope) in ISI from 2 to 12 months (B=-0.28, p=.046 for the three-way interaction between treatment arm, time, and early change in excessive lingering).
Conclusion: Findings indicated that tCBT-I may support greater changes in using bed only for sleep than dCBT-I. These findings may be unique for a subset of individuals with insomnia disorder predicted to have a better response to tCBT-I and may not be generalized to individuals who were predicted to respond equally as well from the two treatment modalities.

EFFECTS OF A TRIAGED CBTI APPROACH USING DIGITAL OR THERAPIST DELIVERY ON PRESCRIPTION HYPNOTIC USE: RESULTS FROM THE RESTING STUDY

Rachel Manber[1], Isabelle Tully[1], Jessica Dietch[2], Joshua Tutek[3], Nicole Gumport[1], Bohye Kim[1], Jane Kim[1], Norah Simpson[1]
[1] Stanford University, [2] Oregon State University, [3] MUSC

Introduction: Use of prescription hypnotic medications and the negative impacts of their use increase in older age. This study aimed to compare the effects of two delivery strategies for CBT-I on prescription medication use among adults aged 50 and older with insomnia disorder.
Methods: Participants (N=245) were classified at baseline by a Triage-Checklist. Those projected to do better if they were to start treatment with therapist versus digitally delivered CBT-I (tCBTI versus dCBTI) constituted the YES stratum (n=137); the rest constituted the NO stratum (n=108). The YES stratum included individuals with one of the following: high daytime sleepiness, high psychological distress, use of prescription sleep medication on most nights, very short sleep durations, or extreme sleep schedules. Access to CBT-I was available for 12 months. tCBTI included the same components as dCBTI plus a module to promote circadian alignment of sleep schedules and another to offer support for medication taper (when identified as a treatment goal). Participants were randomized within stratum to a strategy that utilized only dCBTI (ONLN) or to a stepped-care strategy that prospectively allocated the first step of care to dCBTI or tCBTI based on the Triage-Checklist and switched dCBTI-non-responders at 2-months to tCBTI (STEP). The average nightly amount of prescription hypnotic medications used (MEDS) was computed by first converting each dose to the number of minimal available doses, thus accounting for the variability in type of medication both across and within participants. Mixed effects models with experimental arm, time (0,2,4,6,9, and 12 months), and their interaction were tested.
Results: Compared to ONLN, participants in STEP had greater reductions in MEDS (p=0.019). Within the YES stratum, compared to ONLN, those in STEP had greater reductions in MEDS (p=0.018). Within the NO stratum MEDS was low and did not change differentially between STEP and ONLN (p =.91). Within the ONLN arm, change in MEDS was minimal and did not differ between strata. Results did not change with treatment-dose covariate adjustment.
Conclusion: A triaged-stepped care approach to CBT-I can help reduce prescription medication use among middle age and older adults, particularly among those with complex presentations.

FACTOR ANALYSIS OF FEAR OF SLEEP AND EXPERIENTIAL AVOIDANCE IN TRAUMA-RELATED INSOMNIA

Xi Yang[1], Shay Kelly[2], Melynda Casement[3]
[1] University of Pittsburgh Medical Center, [2] Portland Psychotherapy, [3] University of Oregon

Introduction: Fear of sleep (FoS) often develops following trauma exposure and may play a key role in maintaining insomnia symptoms. While fear of sleep has been operationalized within the Fear of Sleep Inventory - Short Form, prior studies have reported inconsistent factor structures. Experiential avoidance (EA), a trait-based measure of avoidance behavior, is associated with post-traumatic stress disorder (PTSD) and insomnia, and further shares conceptual overlap with FoS and may help clarify its unique contributions to trauma-induced insomnia.
Methods: This study evaluated the psychometric properties of the FoSI-SF in a sample of college students (N = 197), examining its factor structure, convergent validity with EA, and discriminant validity with sleep hygiene, a sleep-related factor linked to insomnia. A subset of participants (n = 50) with clinically-significant PTSD symptoms and sub-threshold insomnia was analyzed to test a conceptual model of FoS.
Results: Exploratory factor analysis revealed a three-factor structure for the FoSI-SF: 1. Fear of loss of control/vulnerability; 2. Fear of darkness; and 3. Fear of re-experiencing traumatic nightmares. The FoSI-SF demonstrated convergent validity with EA, but lacked discriminant validity with sleep hygiene. In the subset sample, trauma-related hypervigilance significantly predicted fear of loss of control/vulnerability, while nightmares significantly predicted fear of re-experiencing traumatic nightmares.
Conclusion: This study identified a three-factor structure of the FoSI-SF and highlighted the construct's relationship with EA and trauma-related processes (i.e., hypervigilance and nightmares). While FoS appears to overlap conceptually with EA, its distinct role in insomnia warrants further exploration, particularly in trauma-exposed populations.

FINANCIAL TOXICITY, RACIAL DISPARITIES, AND HEALTHCARE ACCESS IN PREGNANT WOMEN WITH INSOMNIA

Heba Afaneh[1], Mika Hirata[2], David Kalmbach[2], Philip Cheng[3], D'Angela Pitts[1]

[1] Henry Ford Health, [2] Henry Ford Sleep Research, [3] Henry Ford Health + Michigan State University Health Sciences

Introduction: Insomnia affects half of women during pregnancy, which reduces quality of life and harms maternal health. As awareness of prenatal insomnia increases, more pregnant women are seeking help for their sleep. However, little is known about real-world barriers pregnant women face when seeking insomnia treatment. The present study explored associations of race and financial toxicity with clinical morbidity and care access among pregnant women seeking insomnia care.

Methods: Three-hundred-and-ninety-three pregnant women (Age: 30.7±4.9yrs; Gestation: 25.7±3.4wks) seeking treatment for insomnia in a large health system completed an online survey. Outcomes included sociodemographics, the Comprehensive Score of financial Toxicity survey, Edinburgh Postnatal Depression Scale, and Perinatal Rumination Scale-Night. We employed chi-square analyses and multivariate linear and logistic regression.

Results: Half of treatment-seeking patients identified racially as white (52.7%), whereas 21.7% identified as Black (most well-represented groups). Nearly half of the sample reported no/mild financial toxicity, whereas 39.2% endorsed moderate financial toxicity and 13.9% endorsed severe financial toxicity. Regarding health insurance, 29.9% of patients had public insurance. Relative to white patients, non-white patients reported higher levels of moderate-to-severe financial toxicity (62.4% vs 45.0%) and greater utilization of public insurance (40.9% vs 20.1%). Multivariate regression showed that financial toxicity was independently associated with depression (b=-.252, p<.001), perinatal rumination (b=-.491, p<.001), and suicidal ideation (SI; OR=1.07, p<.001), whereas race was not. Indeed, more severe financial toxicity was associated with greater disease burden as indicated by higher rates of comorbid depression (Severe toxicity: 80.0%; Moderate: 61.9%; No/Mild: 29.7%), perinatal rumination (Severe: 80.0%; Moderate: 56.8%; No/Mild: 28.1%), and SI (Severe: 23.6%; Moderate: 16.8%; No/Mild: 5.4%). Unfortunately, patients with greater financial toxicity were less likely to be able to afford copays for psychotherapy services (Severe toxicity: 69.1% cannot afford copays; Moderate: 57.1%, No/Mild: 27.2%).

Conclusion: Pregnant women seeking insomnia treatment present with high rates of depression, perinatal rumination, and SI. Non-white women are over-represented among those with moderate-to-severe financial toxicity, and greater financial toxicity is associated with greater clinical morbidity. Despite this greater disease burden, patients with greater financial toxicity are disproportionately unable to afford care, thereby severely limiting treatment access for those with highest need.

RATES OF COMORBID INSOMNIA AND SLEEP APNEA (COMISA) IN TWO DIFFERENT TRAUMATIC BRAIN INJURY POPULATIONS: MILITARY AND CIVILIAN

Eunyeong Joo[1], Heather Altier[1], Hannah Maybrier[1], Frank Sgambati[1], Luu Pham[2], Elsa Ermer[3], Stacey Harcum[3], Seyi Gbade-Alabi[3], Paul Pasquina[3], Una McCann[1], Michael Smith[4], Renan Castillo[5], Lauren Allen[5], Douglas Wallace[6], Luis Buenaver[4]

[1] Johns Hopkins School of Medicine, [2] Division of Pulmonary and Critical Care, Johns Hopkins University School of Medicine, [3] Uniformed Services University of the Health Sciences, [4] Johns Hopkins University, [5] Johns Hopkins School of Public Health, [6] University of Miami

Introduction: Insomnia and sleep apnea (SA) are common sleep disorders, with approximately 11-13% of the global population experiencing comorbid insomnia and sleep apnea (COMISA). COMISA substantially increases risk for both medical and psychiatric morbidity relative to having either disorder alone. Moreover, sleep disorders are notably common in those with a traumatic brain injury (TBI; insomnia rates of 71% and SA of 25%). This study explored COMISA rates in military and civilian TBI populations.

Methods: Data came from two different randomized trials of cognitive behavioral therapy for insomnia in persons with TBI and comorbid insomnia symptoms. One trial is ongoing in military personnel while the other trial was completed in civilians. Participants completed self-report measures of insomnia severity, sleepiness, and sleep quality. Participants also underwent a structured interview for sleep disorders to establish diagnostic criteria, and cognitive and home sleep apnea testing.

Results: The cohort consisted of 19 military personnel (Mage=35.0 [SD=± 11.14]) and 49 civilians (Mage=39.6 [SD=± 12.84]). The military sample was mostly male (68%) and white (74%), whereas the civilian sample was mostly female (63%) and white (69%). Average cognitive testing scores were 25.7 (SD=± 2.12) for military and 25.3 (SD=± 3.07) for civilians. Both samples endorsed moderate insomnia (M=18.6 [SD=± 4.30] military; M=19.1 [SD=± 5.43] civilians), poor sleep quality (M=10.5 [SD=± 3.15] military; M=12.3 [SD=± 3.45] civilians), and daytime sleepiness (M=9.7 [SD=± 6.65] military; M=6.2 [SD=± 4.60] civilians). Comorbid SA (Apnea-Hypopnea Index [AHI] ≥ 5) was prevalent, with approximately, 86% of military (AHI: M=12.1 [SD=± 8.96]; range: 5.8-34.3) and 45% of civilians (AHI: M=6.1 [SD=± 6.09]; range: 5.0-26.5) experiencing COMISA. Body mass index (BMI) was similar in both groups (M=26.5 [SD=± 3.38] military; M=29.3 [SD=± 5.67] civilians).

Conclusion: COMISA and poor sleep quality were prevalent in military and civilian TBI populations, with military personnel exhibiting nearly double the rate of COMISA despite a lower BMI. However, the optimal treatment sequence for managing insomnia and SA in these patients remains unclear. Future research should focus on identifying the most effective treatment approach and consider patient subgroups to better inform clinical practice.

MEASURES OF SLEEP, PSYCHIATRIC, AND NEUROBEHAVIORAL SYMPTOMS IN POST-9/11 VETERANS WITH HISTORY OF MILD TRAUMATIC BRAIN INJURY AND INSOMNIA

Abigail Mack[1], Jennifer Salamat[1], Elizabeth Twamley[1], Amy Jak[1], Philip Gehrman[2], Henry Orff[1]

[1] VA San Diego Healthcare System, [2] University of Pennsylvania

Introduction: Traumatic brain injury (TBI) has been deemed the "signature wound" of the Iraq and Afghanistan conflicts and continues to be a common occurrence for active-duty personnel. For many Veterans, mild traumatic brain injury (mTBI) is associated with persistent post-concussive symptoms, of which sleep, and psychiatric disturbances are among the most common. In this investigation we describe and evaluate baseline sleep and clinical symptomatology in a sample of post-9/11 Veterans with mTBI who participated in a clinical trial for insomnia.

Methods: 67 Veterans completed baseline assessment measures. Each participant was assessed on a battery of self-report questionnaires evaluating sleep (Insomnia Severity Index [ISI]; Pittsburgh Quality Sleep Index [PSQI]), psychiatric (Patient Health Questionnaire [PHQ-9]; Generalized Anxiety Disorder Scale [GAD-7]); PTSD (PTSD Checklist for DSM 5 [PCL-5]), and neurobehavioral symptoms (Neurobehavioral Symptom Inventory [NSI]). Veterans also completed a one-week baseline sleep diary and underwent two nights of polysomnography (PSG; data from second night analyzed).

Results: Veterans (55M/12F; age=35.8+/-7.3) showed moderately elevated insomnia severity (ISI=20.2+/-4.3) and general sleep disturbance (PSQI=14.6+/-2.7). Psychiatric and post-concussive measures also indicated clinically meaningful impairment (PHQ-9=14.5+/-5.3; GAD-7=11.3+/-5.2); PCL=40.1+/-18.5; NSI=42.8+/-16.3). On prospective sleep diaries (one-week averaged data) Veterans reported sleep latencies (SL) of 43.9+/-32.0 mins, wake after sleep onset times (WASO) of 39.4+/-34.9 mins, total sleep times (TST) of 308+/-126 mins, and sleep efficiencies (SE) of 75.1+/-13.7 percent. On PSG Veterans exhibited better sleep relative to sleep diaries (SL=16.4+/-13.7mins, WASO=31.9+/-19.8mins, TST=391.8+/-45.2mins, SE=87.9+/-6.3%). Pearson correlations were conducted to examine the relationship between NSI scores and objective/subjective sleep measures. Results found that post-concussive symptoms were positively corelated with insomnia severity (ISI:r=0.56, p<.001) and general sleep disturbance (PSQI:r=0.54,p<.001) and negatively correlated with sleep efficiency on PSG (r=-0.47,p=.009).

Conclusion: In this investigation, post-9/11 Veterans with history of mTBI showed clinically relevant self-reported sleep disturbance (retrospectively and prospectively) and elevated psychiatric and neurobehavioral symptomatology. Whether observed discrepancies in subjective vs objective sleep measures reflect bias in reporting, reactivity to laboratory testing, or other factors warrants further investigation. Understanding the reasons for such discrepancies could help inform interventions designed to assist Veterans with mTBI and sleep disturbance.

REAL-WORLD DATA ON PATIENTS WITH INSOMNIA, OBSTRUCTIVE SLEEP APNEA (OSA), OR BOTH (COMISA)

Kate Cole[1], Anita Malik[2], Caleb Woodford[2], Naomi Alpert[2], Will McConnell[2], Kimberly Sterling[2]

[1] ResMed, [2] ResMed Science Center

Introduction: Insomnia and OSA, comorbidly known as COMISA, are the two most common sleep disorders. There is limited real world evidence comparing these patient groups and understanding their burden on the US healthcare system. This study compares real world data from patients with COMISA to those with OSA or insomnia alone from a US national sample.

Methods: This retrospective study used insurance claims data (commercial, Medicare Advantage, Medicaid) from patients with insomnia and patients with OSA. COMISA patients were identified from the OSA patients that had evidence of insomnia (ICD-9/10 diagnosis code or insomnia prescription fill) in the year prior to and year post OSA diagnosis. The index date for patients with insomnia was the first evidence of insomnia. The index date for patients with OSA and COMISA was the sleep test with an OSA diagnosis. Demographics, comorbid conditions, and healthcare costs were described for each patient group.

Results: Overall, 14.5% of patients with insomnia also had a diagnosis of OSA, and 23.0% of patients with OSA also had a diagnosis of insomnia. After applying inclusion/exclusion criteria, the study had 1,075,339 patients with insomnia only, 1,272,333 patients with OSA only, and 157,894 with COMISA. Patients with insomnia were more commonly female (64%), OSA more commonly male (59%), and COMISA more evenly split (53% female/47% male). Patients with COMISA had a higher number of conditions (aside from OSA and insomnia) than patients with OSA or insomnia alone (mean number of conditions: 3.3 vs OSA: 2.6, insomnia: 2.1). Patients with OSA or COMISA had a markedly higher prevalence of cardiac conditions, respiratory conditions, and hyperlipidemia. Those with insomnia or COMISA had a markedly higher prevalence of depression and anxiety. COMISA patients were the most expensive to the healthcare system with total annual costs averaging $12,492 per patient (insomnia: $9,672, OSA: $9,589), stemming from increased costs in outpatient hospitalizations, office visits, and prescription medications.

Conclusion: Patients with COMISA have more conditions and cost the healthcare system more than patients with OSA or insomnia alone. Further research and treatment innovation is needed to support sustainable treatment options to mitigate this cost burden.

ASSOCIATIONS BETWEEN REM OSA, WHITE MATTER MICROSTRUCTURE, AND COGNITION IN COMMUNITY-DWELLING COGNITIVELY UNIMPAIRED OLDER ADULTS

Joshua Gills[1], Shrestha Shah[2], Anthony Briggs[1], Mark Bernard[1], Joanna Dominguez[1], Rachel McCray[1], Elena Valkanova[3], Luisa F. Figueredo[4], Korey Kam[5], Anna Mullins[6], Ankit Parekh[5], Girardin Jean-Louis[7], Andrew Varga[5], Ricardo Osorio[4], Omonigho Michael Bubu[4]

Introduction: Obstructive sleep apnea (OSA) severity increases Alzheimer's disease (AD) and cognitive decline risks. OSA during rapid eye movement (REM) sleep is sometimes more severe than non-REM OSA, however the relationship between REM-OSA severity and cognition is not well characterized. Emerging evidence also suggests that white matter microstructure alterations may contribute to cognitive deficits in patients with OSA. We examined associations between white matter tract integrity, cognition, and REM-OSA severity in cognitively unimpaired older adults.

Methods: This cross-sectional study included 70 community-dwelling cognitively unimpaired older adults (35 non-OSA,35 REM-OSA; mean±SD: age=66.3±4.9y) participating in NYU studies of sleep, aging, and memory. Participants had diffusion-weighted imaging, neuropsychological battery tests, overnight polysomnography, and clinical data. REM-OSA was characterized as REM AHI4% (>15 events/hour). Neuropsychiatric testing included processing speed, working memory, and visuospatial ability measures. Cingulum, uncinate fasciculus (UF), and fornix microstructure properties were estimated using diffusional tensor imaging metrics. Multivariable linear regression models examined associations of white matter microstructure (exposure) on cognitive measures (outcome measure) between OSA and non-OSA, and white matter microstructure by REM-OSA severity on cognition. Models were adjusted for age, race, education, sex.

Results: Of the 70 participants (35 non-OSA, and 35 REM-OSA),68.8% and 62.9% were female, respectively. Mean±SD education was 16.5±2.4y REM-OSA (vs. 16.3±2.5y controls). Participants with REM-OSA had lower attention (β[REM AHI4%]=-1.07[-2.1 - -0.04],p< 0.050) and slower processing speeds (β[REM AHI4%]=0.29[0.05 – 0.54],p< 0.050) compared to controls. REM-OSA was associated with white matter microstructure alterations within both hemispheres of the cingulum(p=0.01) and fornix(p=0.040). Furthermore, decrements in the UF were associated with worse working memory β[UF] = -0.25 [-0.45 - -0.05], p < 0.050) and slower processing speed β[UF] = 0.26 [0.04 – 0.50], p < 0.050). Moreover, REM-OSA severity interaction with white matter microstructure demonstrated lower working memory β[REM AHI4% x cingulum, right]=-0.20[-0.37- -0.03],p < 0.050; β[REM AHI4% x cingulum, left]=-0.23 [-0.44 - -0.02], p< 0.050) and reduced visuospatial ability β[REM AHI4% x fornix]=-0.23 [-0.44 - -0.01], p< 0.050).

Conclusion: Our findings demonstrate the critical role of white matter microstructure in the relationship between REM-OSA and cognition. Longitudinal studies are needed to investigate the mediating role of white matter microstructure alterations between REM-OSA and cognitive decline.

ASSOCIATIONS BETWEEN LIMBIC WHITE MATTER TRACK INTEGRITY AND COGNITION IN OBSTRUCTIVE SLEEP APNEA

Rachel McCray[1], Joshua Gills[1], Shrestha Shah[2], Anthony Briggs[1], Mark Bernard[1], Anamarie Sogade[1], Elizabeth Weisgerber[1], Julian McBride[1], Hakyoung Kim[1], Chinonye Nnajiofor[1], Elena Valkanova[1], Arlener D. Turner[3], Omonigho Michael Bubu[4]

[1] NYU Grossman School of Medicine, [2] Georgia Institute of Technology, [3] Miami Dade College, [4] Department of Psychiatry, New York University Grossman School of Medicine

Introduction: Obstructive Sleep Apnea (OSA) severity raises the risk of Alzheimer's disease (AD) and cognitive decline. Recent data suggest white matter integrity alterations may contribute to cognitive deficits in OSA patients. We examined the association between white matter integrity and cognition in cognitively unimpaired older adults.

Methods: This cross-sectional study involved 133 cognitively normal adults average age 66.6 [5.2] years) from NYU sleep, aging, and memory studies. Participants underwent diffusion tensor imaging (DTI), neuropsychological tests, overnight polysomnography, and clinical assessments. OSA was defined by an Apnea-Hypopnea Index (AHI) >15 events/hour. Cognitive tests assessed processing speed, working memory, and visuospatial ability. DTI metrics estimated white matter microstructure (WMM) in the cingulum, uncinate fasciculus (UF), and fornix. Multivariable linear regression analyzed WMM's impact on cognition, adjusting for age, race, education, sex, and time between polysomnography and MRI.

Results: Of the 133 participants, 69.9% were female 52.6% were Black and mean [SD] for education was 16.5±2.4y. OSA severity was associated with poorer visual-spatial scores (β[AHI4%]=-0.27 [-0.48 - -0.06],p< 0.050), working memory (β[AHI4%]=-0.24 [-0.48 - -0.0004],p< 0.050), and processing speed (β[AHI4%]=0.28[0.01 – 0.55],p< 0.050) than controls. OSA severity was associated with WMM alterations within the fornix (p=0.038). Furthermore, UF decrements were associated with poorer working memory (β[UF] = -0.24 [-0.44 - -0.05], p < 0.050) and processing speed (β[UF] = 0.28 [0.04 – 0.50], p < 0.050). OSA severity interaction with WMM demonstrated worse visuospatial ability (β[AHI4% x cingulum, right] = 0.25 [0.03- 0.47], p < 0.050; β[AHI4% x UF, Left] = -0.22 [-0.43 - -0.02], p < 0.050; β[AHI4% x fornix}=-0.34 [0.08- 0.60],p< 0.050) and processing speed (β[AHI4% x cingulum, left] = 0.33 [0.03 – 0.63], p < 0.050; β[AHI4% x UF, left]=0.26 [0.03 -0.49],p< 0.050).

Conclusion: OSA severity was associated with greater WMM alterations. Both OSA severity and WMM alterations were independently associated with poorer cognitive outcomes. OSA severity and WMM alteration interacted in a synergistic manner on specific cognitive domains, thus demonstrating the critical role of white matter integrity in the relationship between OSA and cognition. Longitudinal studies are needed to investigate the role of OSA severity on WMM alterations and cognitive decline.

NONINVASIVE MRI-BASED PARENCHYMAL CSF (PCSF) MAPPING SHOWS INCREASED GLYMPHATIC FLUID VOLUME IN UNTREATED OSA

Samantha Keil[1], Liangdong Zhou[1], Xiuyuan H. Wang[1], Thanh D. Nguyen[1], Gloria C. Chiang[1], Yi Li[1], Tracy A. Butler[1]

[1] Weill Cornell Medicine

Introduction: Obstructive sleep apnea (OSA) is one of the most prevalent sleep disorders, affecting an estimated 936 million adults globally. When left untreated, OSA increases the risk for co-morbidities including cardiovascular and metabolic disease, mood disorders, cognitive impairment, and neurodegenerative diseases including Alzheimer's disease. Moreover, while continuous positive airway pressure (CPAP) therapy presents an effective treatment option, ameliorating sleep apnea and reducing downstream risk of co-morbidities, non-compliance occurs in 30-80% of patients. Therefore, defining the mechanism by which CPAP therapy proves effective may identify alternative therapeutic interventions. Recent studies highlight the glymphatic system, a brain-wide network of CSF-filled perivascular spaces (PVS), in facilitating the clearance of metabolic waste from the brain during sleep. Due to the dynamic and microscopic nature of PVS, evaluating the glymphatic system clinically has proved difficult. Parenchymal CSF (pCSF) mapping, a non-invasive MRI-based approach, offers a novel clinically feasible modality for evaluating parenchymal perivascular glymphatic fluid volume. This study aims to assess differences in pCSF mapping among normal healthy controls (HC) and age matched subjects with either CPAP treated or untreated OSA.

Methods: Our cross-sectional analysis involved three groups (n=32): HC, CPAP-treated OSA, and untreated OSA participants. Neuroimaging included 3T-derived T1W, multi-echo FAST-T2 for pCSF, and T2-FLAIR sequences. Image processing was performed with FreeSurfer for ROI parcellation and an in-house MATLAB code for pCSF mapping.

Results: Across multiple regions individuals with untreated OSA exhibit a significantly higher burden of pCSF compared to both CPAP-treated OSA and HC participants. In the temporal lobe, for example, untreated OSA participants exhibited 6.01% pCSF compared to 5.26% in CPAP-treated (p=0.011) and 5.32% in HC (p=0.0013). Whereas CPAP treatment appeared to mitigate this pCSF increase, aligning closely with HC. No difference in cortical volumes was observed across groups, suggesting these pCSF findings are not related to brain atrophy. Together these findings support a role of glymphatic impairment in OSA.

Conclusion: These findings underscore the impact of OSA on the brain's glymphatic system, highlighting glymphatic dysfunction as a potential contributor to the downstream effect of untreated OSA. Further research is necessary to substantiate these findings in a longitudinal within subject cohort before and after CPAP treatment.

HYPOXIC BURDEN IN OSA IS CORRELATED WITH THE GAMMA BAND SPECTRAL SLOPE DURING AROUSALS

Junjie Liu[1]

[1] University of Iowa

Introduction: Obstructive sleep apnea (OSA) causes intermittent hypoxia during sleep, which in turn is associated with increased risks of cognitive impairment. However, the mechanism by which intermittent hypoxia impairs the brain is unclear, since there is no salient neurophysiological change during the hypoxia. Recent studies established the gamma-band (30-45 Hz) spectral slope as a novel electroencephalography (EEG) marker of the arousal level (Lendner et al, PubMed ID 32720644). Here we use this EEG marker to study whether intermittent hypoxia increases the arousal level in OSA.
Methods: We analyzed the dataset of Cleveland Family Study, which was obtained from the National Sleep Research Resources database, and comprised of single-night polysomnography studies for 730 subjects (age: 41 +/- 19 years), along with denotations of sleep stages and respiratory events (apneas and hypopneas). We pooled together 60175 respiratory events during non-REM sleep for analysis. Using a shifting temporal window of 5 s, EEG power spectral density was computed using Welch's method, and spectral slope was computed from linear fitting of logarithm of power to logarithm of frequency over 30-45 Hz range. The severity of intermittent hypoxia was quantified as the hypoxic burden (Azarbarzin et al, PubMed ID 30376054).
Results: Across all respiratory events, hypoxic burden was strongly correlated with the increase of 30-45 Hz spectral slope during the 10 seconds after the end of respiratory events (Spearman's correlation coefficient r = 0.14). The averaged increase of spectral slope was 0.52 for events with >= 4% hypoxic burden, vs. 0.26 for events with <= 2% hypoxic burden. Hypoxic burden was also strongly correlated (r = 0.21) with the increase of gamma-band EEG power, but critically was only weakly correlated (r = 0.03) with the increase of alpha-band (8-13 Hz) EEG power. Thus, our findings cannot be explained as electromyographic artifacts in EEG.
Conclusion: Previous studies showed that gamma-band spectral slope reflects the neuronal excitation-inhibition balance, and acute hypoxia generally inhibits synaptic activity. Thus, our findings support the hypothesis that intermittent hypoxia in OSA impairs the brain by disrupting the neuronal excitation-inhibition balance, intensifying neural inhibition during apnea/hypopnea and intensifying neural excitation during the arousal immediately after apnea/hypopnea.

AROUSAL THRESHOLD ESTIMATED BY PHENOTYPING USING POLYSOMNOGRAPHY IS LOWER USING AUTOMATED AROUSAL SCORING COMPARED TO MANUAL AROUSAL SCORING

Thomas Tolbert[1]*, Anna Mullins*[1]*, Ankit Parekh*[2]*, Adriana De Resende*[3]*, Alicia Legard*[4]*, Justin De La Fuente*[4]*, Jag Sunderram*[4]*, David Rapoport*[1]*, Indu Ayappa*[5]

[1] Icahn School of Medicine at Mount Sinai, [2] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [3] Rutgers - Environmental and Occupational Health Sciences Institute, [4] Rutgers Robert Wood Johnson Medical School, [5] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Phenotyping using polysomnography (PUP) is a computer-based method for "endotyping" obstructive sleep apnea (OSA) using clinical sleep study data. PUP provides estimates of mechanisms causing upper airway collapse in sleep: arousal threshold (ArTH), loop gain, and upper airway collapsibility and muscle response. PUP analyses have typically depended on manual scoring of sleep stages, respiratory events, and arousals. However, PUP has an automated arousal scoring capability based on electroencephalography (EEG) power analysis. We hypothesized that automated arousal scoring may produce systematic differences in ArTH estimates compared to manual arousal scoring.
Methods: Three methods of arousal scoring were separately conducted before full PUP analysis: 1) traditional manual scoring; 2) fully automated scoring using PUP's internal methodology; 3) a hybrid manual-automated method, also built into PUP, which "touches up" manually-scored arousals using automated analysis. ArTH was estimated from non-rapid eye movement (NREM) sleep. ArTH estimated in the context of manually scored arousals (ManArTH) was compared to ArTH estimated under fully automated arousal scoring (AutoArTH) and to ArTH estimated under hybrid arousal scoring (HybridArTH).
Results: PUP analysis was completed in 99 individuals (age 56.4±7.5 years; 10 female; BMI 31.3±4.9 kg/m2) with OSA (apnea-hypopnea index, AHI3A 31.77±19.1, range 10.6—104.3 events/hr) according to in-lab diagnostic (n = 80) or split-night (n = 19) sleep studies. Arousal index (ArI) was higher using automated scoring (median 42.7 [25th—75th percentile 37.8—56.2] arousals/hr) compared to manual scoring (23.2 [19.0—37.3] arousals/hr, $p < 0.001$ for difference). AutoArTH (106.2 [101.6—111.6] %Veupnea) and HybridArTH (111.1 [104.6—120.3] %Veupnea) were both significantly lower than ManArTH (111.3 [105.9—120.7] %Veupnea, $p< 0.05$ for both comparisons). Intraindividual differences between ManArTH and AutoArTH (7.4±13.4 %Veupnea) were larger than that between ManArTH and HybridArTH (1.5±6.1 %Veupnea). In separate univariate regression analyses, neither age, sex, BMI, AHI3A, study type (diagnostic verse split-night), nor intraindividual difference in ArI were associated with intraindividual difference in ArTH.
Conclusion: In a cohort of predominantly middle-aged men with OSA of varying severity, PUP-estimated ArTH was systematically lower using automated scoring compared to manual scoring. Hybrid manual-automated arousal scoring produced ArTH estimates very similar to manual scoring, though also systematically lower.

LOW AROUSAL THRESHOLD REDUCES HYPOGLOSSAL NERVE STIMULATION USAGE IN OBSTRUCTIVE SLEEP APNEA PATIENTS

Atqiya Aishah[1]*, Sara Op de Beeck*[2]*, Ali Azarbarzin*[3]*, Joao Monteiro*[4]*, Olivier Vanderveken*[2]*, Andrew Wellman*[3]*, Scott Sands*[3]*, Daniel Vena*[4]

[1] Harvard Medical School and Brigham and Women's Hospital, [2] University of Antwerp, [3] Brigham and Women's Hospital and

Harvard Medical School, [4] Brigham and Womens Hospital and Harvard Medical School

Introduction: Hypoglossal nerve stimulation (HGNS) is an effective alternative to continuous positive airway pressure (CPAP) for obstructive sleep apnea. Although adherence to HGNS is generally high, approximately 15-27% of patients exhibit suboptimal adherence, limiting effectiveness. Adherence is particularly important for HGNS, as it involves a surgical procedure with inherent risks and significant costs. Low arousal threshold has been identified as a predictor of non-adherence to CPAP. Similarly, this study tests the hypothesis that a low arousal threshold is associated with decreased HGNS usage.
Methods: We performed a secondary analysis of the Stimulation Therapy for Apnea Reduction (STAR) Trial. Arousal threshold and pharyngeal collapsibility (i.e., endotype traits) were estimated from baseline polysomnography studies. HGNS usage was calculated from cumulative hours of stimulation pulse duration recorded by the device and downloaded at the 12-month follow-up. Since this value reflects the hours of active stimulation during inspiration, it was divided by 40%, assuming a respiratory duty cycle of 40%, to estimate total HGNS on time (i.e., usage). To test our hypothesis, we used multiple linear regression to quantify the association between arousal threshold and HGNS usage, adjusting for age, sex, neck circumference, and total sleep time. Sensitivity analysis evaluated the effect of adjusting for collapsibility. The mediating effect of HGNS efficacy (%reduction in AHI from baseline) was also studied.
Results: HGNS usage data was available from 64 patients at the 12-month follow-up, among whom 50 had a baseline PSG to compute the endotype traits (median[IQR] Age: 53[45,60] years, 43 men, BMI: 27.8[26.0,30.0] kg/m2, AHI: 33.8[25.1,40.0], Usage: 6.2[4.2,8.4] hours). As hypothesized, a lower arousal threshold by 1SD (25.8 %eupneic ventilation), was associated with >1 hour less of HGNS usage (Beta [95%CI]: 1.1[0.17,2.0] hours, p=0.011). Including collapsibility in the model increased the effect of arousal threshold on usage (Beta [95%CI]: 1.2[0.26,2.2] hours). Including HGNS efficacy in the model did not mediate the effect of arousal threshold on usage (1.1[0.17,1.9]).
Conclusion: Patients with a lower arousal threshold—those who wake from sleep more easily—show significantly reduced HGNS usage, an effect that is independent of HGNS efficacy. These findings uncover a critical mechanism driving suboptimal adherence to HGNS therapy.

DEMOGRAPHIC DIFFERENCES IN THE PHYSIOLOGICAL BURDENS OF SLEEP APNEA

Sarah Chu[1], Sajila Wickramaratne[1], Pavel Boulgakov[1], Korey Kam[2], Andrew Varga[2], Indu Ayappa[3], Anna Mullins[1], Thomas Tolbert[1], David Rapoport[1], Ankit Parekh[2]
[1] Icahn School of Medicine at Mount Sinai, [2] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [3] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Diagnosis of obstructive sleep apnea (OSA) depends on the Apnea-Hypopnea Index (AHI), a metric with acknowledged limitations, but known variation across demographic groups. Novel methodologies may better quantify OSA pathophysiology, but differences in these metrics across age, sex, and race/ethnicity remain yet to be explored. Leveraging data from the Sleep Heart Health Study (SHHS) and the Multi-Ethnic Study of Atherosclerosis (MESA), we investigated potential variations in the emerging physiological metrics of OSA across participant demographics.
Methods: High-quality signals of participants from SHHS (n=5407) and MESA (n=1544) were analyzed for four physiological metrics: 1) Hypoxic Burden (area under oxygen desaturation ≥ 3% dips), 2) Ventilatory Burden (proportion of breaths with < 50% normalized amplitude), Autonomic Burden (increase in heart rate by ≥ 3 beats/min, independent of respiratory events), and Arousal Burden measured by ΔSWAK (change in delta power across K-complexes in N2 sleep). We only assessed participants with Ventilatory Burden > 25% to examine only those exhibiting some degree of abnormal overnight breathing. Each metric was regressed against age, sex, and race/ethnicity in separate univariate analyses. Multivariate analyses were adjusted for AHI3A or AHI4. A significance level of 0.05 was used and statistical analyses were done with RStudio v.4.4.2.
Results: Within the study population, participants were predominantly female (n=3635/6951, 52.3%), with a mean age of 64.4 ± 11.0 years. Most participants were self-reported as White (n=5143/6951, 74.0%). Sex differences were observed across all the physiological domains with males showing significantly higher Hypoxic, Ventilatory, Autonomic, and Arousal Burdens ($p < 0.05$). All physiological burden values increased with age, with the highest severity observed in the ≥80 years age group. Differences were also found significant among the race/ethnicity groups ($p < 0.05$). After adjusting for AHI3A and AHI4 separately, there was no change in the findings or significance of the analyses.
Conclusion: There were significant differences in OSA-related physiological burdens with variations across age, sex, and race/ethnicity, independent of AHI severity. These findings appear to be in addition to known differences in OSA severity and may offer insight into varying pathophysiologies across demographic groups.

VISCERAL ADIPOSITY PREDICTS INCIDENT OBSTRUCTIVE SLEEP APNEA: A 9-YEAR FOLLOW-UP OF WISCONSIN SLEEP COHORT

Yun Li[1], Alexandros Vgontzas[2], Dandan Zheng[1], Yanyuan Dai[1]
[1] Shantou University Mental Health Center, [2] Sleep Research and Treatment Center, Penn State College of Medicine

Introduction: It has been reported that visceral adiposity is associated with obstructive sleep apnea (OSA). However, no longitudinal study has examined the association between visceral adiposity and OSA in adults. The aim of this study was to examine the association between visceral adiposity and incident OSA in the Wisconsin Sleep Cohort (WSC).
Methods: In this study, we included 311 subjects without OSA at baseline with a median follow-up duration of 9 years. OSA was defined based on apnea-hypopnea index (AHI) ≥ 5/hour. Body roundness index (BRI) was used to assess visceral adiposity. BRI is an anthropometric index that combines height and waist circumference and reflects both visceral adipose tissue and body fat percentage. Higher BRI indicates more visceral adiposity. Visceral obesity was defined as BRI level higher than the 75th percentile of the overall sample. Linear and logistic regression models were used to examine the association between visceral adiposity and incident OSA after adjusting for age, gender, race, baseline AHI, change of

BMI, and overweight at baseline. We stratified the sample based on the median age of the overall sample (55 years) to examine whether age influences the association between visceral adiposity and OSA.
Results: Baseline greater BRI values predicted higher AHI levels at follow-up after adjusting for confounding factors (β=0.194, p=0.004). In a sensitivity analysis, we found that baseline visceral obesity was associated with 1.9-fold increased risk of incident OSA compared to those without visceral obesity (odds ratio [OR]=1.888, 95% confidence interval [95%CI]= 1.05- 3.41). Interestingly, we found this association was influenced by age (interaction-p< 0.05). The association between baseline visceral adiposity and incident OSA was only observed in adults < 55 years old (β=0.382, p< 0.001), but not in adults ≥55 years old (β=-0.005, p=0.964).
Conclusion: Visceral adiposity is a significant risk factor for the development of OSA. These data suggest that visceral adiposity, a central etiologic factor of metabolic syndrome, is the primary mechanism leading to OSA in young/middle aged individuals and should be the target in our preventative and treatment strategies for this prevalent sleep disorder.

VISCERAL ADIPOSITY INDEX IS ASSOCIATED WITH HYPERTENSION RISK IN PATIENTS WITH MILD-TO-MODERATE OBSTRUCTIVE SLEEP APNEA: AGE AND SEX EFFECT

Nikolaos Athanasiou[1], Slobodanka Pejovic[1], Julio Fernandez-Mendoza[2], Yun Li[3], Alexandros Vgontzas[1]
[1] Sleep Research and Treatment Center, Penn State College of Medicine, [2] Penn State College of Medicine, [3] Shantou University Medical College

Introduction: It has been shown that mild-to-moderate obstructive sleep apnea (mmOSA) is associated with cardiometabolic risks. Although visceral adiposity has been suggested as a primary pathophysiologic factor leading to OSA, the predictive value of visceral adiposity for cardiovascular problems in OSA has not been examined. The aim of this study is to assess the utility of visceral adiposity index (VAI), in identifying the risk of hypertension across a wide age range of patients with mmOSA.
Methods: Adults (n =216, 56% men) of a wide age range (28–90 years old, mean age 52.64 ± 12.74) with mmOSA (5 ≤ AHI < 30) completed in-lab polysomnography or home testing, medical history and complete physical examination, and a blood draw for lipid profile. VAI, a sex-specific mathematical index type based on waist circumference, Body Mass Index (BMI), triglycerides and HDL cholesterol levels, was used to assess visceral adiposity. Hypertension was defined based on blood pressure ≥140/90 mmHg. Since there was a significant sex and age effect, binary logistic regression analysis was performed separately for men vs women to investigate the association between VAI and risk of hypertension, while controlling for BMI, AHI, diabetes and antihypertensive medication.
Results: In men < 60 years, lnVAI but not AHI or BMI were associated with greater odds for hypertension (odds ratio [OR] =3.043, 95% CI =1.012-9.152, p =0.048; OR =0.98, 95% CI =0.887-1.098, p =0.807; OR =0.388, 95% CI =0.91-1.65, p =0.2, respectively). In contrast, in men ≥ 60 years neither lnVAI, AHI nor BMI were associated with increased odds for hypertension. In women, a trend was observed in the association of BMI ([OR] =1.143, 95% CI =0.98-1.330, p =0.083), but not of lnVAI or AHI with hypertension risk.
Conclusion: Visceral adiposity based on routinely obtained clinical measures, improves the ability to detect hypertension risk in young and middle-aged, but not older men with mmOSA, suggesting that our therapeutic goal should be the reduction of visceral adiposity and its metabolic correlates. In contrast, in women it appears that global adiposity is the stronger predictor of hypertension and weight loss may be sufficient.

CARDIOVASCULAR DISEASE RISK FACTORS IN FORMER NATIONAL FOOTBALL LEAGUE PLAYERS: IMPACT OF OBSTRUCTIVE SLEEP APNEA

Ian Greenlund[1], Marc Forgione[2], Jonathan Perryman[2], David Gergen[3], Rodolfo Martinez-Ferrate[3], Joshua Bock[1], Naima Covassin[1], Jan Bukartyk[1], Arthur Roberts[3], Virend Somers[1]
[1] Mayo Clinic, [2] Massachusetts General Brigham, [3] Living Heart Foundation

Introduction: Cardiovascular disease (CVD) remains the leading cause of death in the United States. We previously showed a high prevalence of obstructive sleep apnea (OSA) among former National Football League (NFL) players. Further, we hypothesized that post-career OSA impacts CVD risk among retired professional athletes, even though these former NFL players are often near peak physical fitness for a significant portion of their lifespan. The Living Heart Foundation Heart-Obesity-Prevention-Education Group aimed to provide an in-depth health assessment for CVD risk factors among former NFL players to examine the role of OSA on blood pressure (BP) and echocardiographic measurements.
Methods: Forty-three former NFL players completed an at-home sleep study and outpatient health assessment to determine CVD risk including office BP and transthoracic echocardiogram (TTE) measurements. Seated BP readings were made in triplicate, TTE measurements, including ejection fraction, left atrial size, left ventricular size and thickness, and ascending aortic diameter, were obtained in 17 former NFL players without OSA (age: 46±10 years, BMI: 32±5 kg/m2, apnea-hypopnea index: 3±1 events/hour) and 26 with OSA (age: 51±9 years, BMI: 33±5 kg/m2, apnea-hypopnea index: 17±12 events/hour). Independent sample t-tests were utilized to determine differences in blood pressure and TTE measurements between OSA and non-OSA groups (α=0.05).
Results: Systolic BP was similar in non-OSA vs. OSA groups (131±12 vs. 135±16 mmHg, p=0.443), while diastolic BP was higher in former NFL players with OSA (78±8 vs. 86±9 mmHg, p=0.007). Ejection fraction, left atrial size, left ventricular size, and left ventricular thickness were similar between groups (p>0.05 for all). However, ascending aortic diameter was modestly larger in former NFL players with OSA (3.3±0.19 vs. 3.5±0.40 cm, p=0.048).
Conclusion: These findings suggest OSA may be a primary driver of increased BP and increased aortic diameter in former NFL players, and impact cardiac structural health, suggesting augmented CVD risk in former NFL players. Future work is warranted to investigate impact of race and player position on OSA-mediated CVD risk in retired NFL players.

DIFFUSION IMAGING MARKERS OF RESIDUAL EXCESSIVE DAYTIME SLEEPINESS IN TREATED OBSTRUCTIVE SLEEP APNEA

Barbara Junco[1], Ashley Schafer[1], Elena Ruiz Perez[1], Christian Agudelo[1], Sonya Kaur[1], Salim Dib[1], Douglas Wallace[1], Roger McIntosh[1], Alberto Ramos[1]

[1] University of Miami

Introduction: OSA-related hypoxemia and sleep fragmentation disrupt arousal and attention, processes largely facilitated by interhemispheric communication via the corpus callosum (CC), the brain's largest white matter (WM) pathway. The Psychomotor Vigilance Test (PVT) objectively measures attention and is a useful assay for excessive daytime sleepiness (EDS). Altered WM integrity and microstructure has been previously reported in OSA, however whether these metrics vary as a function of CC cross-section or severity of EDS is unclear. We hypothesize that the Neurite Orientation Dispersion and Density Imaging (NODDI) model of white matter will be more sensitive than traditional diffusion, but both metrics will predict the severity of EDS.
Methods: This cross-sectional study included 54 OSA patients treated with PAP therapy for ≥6 hours mean nightly use (mean age 60.7; 35% female). Residual EDS was measured via PVT, defined as lapses ≥500ms. We used multi-modal imaging to acquire diffusion weighted WM metrics. The NODDI metric of Fractional Isotropic Volume (FISO), a marker of neuroinflammation, assessed WM microstructure. DTI pre-processing and WMI metrics (Fractional Anisotropy (FA), Mean Diffusivity (MD), Radial Diffusivity (RD), Axial Diffusivity (AD)) were extracted for the CC and subregions (body, genu, splenium) using automated tractography. FISO was derived for the body, genu and splenium. Multiple regression analyses tested PVT associations and WM metrics, controlling for AHI, BMI, and age.
Results: Increases in PVT lapses was associated with greater AD (β =.30, p =.037) in the CC. Subregional analyses revealed that PVT showed the strongest associations with diffusivity metrics (AD, MD, RD) in the splenium (β's =.31 -.33), then genu (β's =.22 -.28), then the body (β's = -.03 -.09). PVT correlations with FISO were highest in the splenium (β =.35), then the body (β =.26) and genu (β =.18).
Conclusion: Residual EDS in PAP-adherent OSA patients is linked to persistent white matter damage in the corpus callosum, particularly the splenium. The observed differences between FISO and traditional diffusion metrics underscore the utility of advanced imaging models like NODDI in identifying microstructural changes associated with EDS.

SLEEP-DISORDERED BREATHING DURING RAPID EYE MOVEMENT SLEEP IS ASSOCIATED WITH SUBJECTIVE COGNITIVE DECLINE

YUE DONG[1], Kristine Wilckens[2], Faith Luyster[3], Matthew Gratton[4], Diego Mazzotti[4], Paul scott[1], Jennifer Lingler[5], Meghan Fissore[5], Jonna Morris[5]

[1] University of Pittsburgh, [2] University of Pittsburgh School of Medicine, [3] University of Pittsburgh School of Nursing, [4] University of Kansas Medical Center, [5] University of Pittsburgh

Introduction: The relationship between sleep-disordered breathing (SDB) and cognition in the aging population remains a subject of debate. While research has linked non-rapid eye movement (NREM) sleep to cognition, fewer studies have explored the impact of rapid eye movement (REM) sleep. Preliminary evidence reveals different impact of REM and NREM respiratory events on cognition. Hence, this study aims to 1) examine the relationship between REM sleep and perceived cognitive decline (PCD), and 2) compare the impact of respiratory severity in REM vs. NREM on PCD.
Methods: Cross-sectional analysis was conducted with 46 participants balanced by sex (mean age= 56.0, SD=18.7) with untreated obstructive sleep apnea (mean sAHI3%= 20.6, SD=14.3) who were asked to wear a sleep wearable device that measured respiratory metrics for 15 consecutive nights. Respiratory metrics included cyclic variation of heart rate and apnea hypopnea index. Cardiopulmonary coupling characterized sleep stages were divided into unstable NREM, stable NREM, and REM. Respiratory and sleep metrics were aggregated the across 15 nights as means and standard deviations. The Everyday Measurement of Cognition, administered at baseline, measured perceived cognitive decline in the past 20 years in memory, language, visual-spatial and perceptual, as well as executive function (planning, organization, and divided attention). Partial correlation was used to analyze PCD and REM% and duration with control of age and education, and Steiger's Z to compare the association between respiratory metrics and PCD in NREM vs. REM.
Results: After controlling for age and education, there is positive association between executive organization decline (EOD) and variability in REM% (r=.327, p=.030) and variability in REM duration (r=.389, p=.009). Additionally, there is positive association between average AHI in REM and EOD (r=.348, p=.020) after controlling for age and education. The association between AHI in REM and EOD was significantly stronger than the corresponding association with NREM (Z=-1.92, p=.027).
Conclusion: Greater variability in REM% or duration is linked to greater PCD, highlighting the role of REM-related respiratory severity on cognition. Recruitment is ongoing to strengthen findings.

OSA INFLUENCES LOCUS COERULEUS STRUCTURAL INTEGRITY ON 7T MRI IN COGNITIVELY NORMAL OLDER ADULTS

Korey Kam[1], Naomi Gaggi[2], Daphne Valencia[3], Sara Hishinuma[3], Ankit Parekh[3], Dan Iosifescu[2], Esther Blessing[2], Omonigho Michael Bubu[4], Ricardo Osorio[4], Laurel Morris[3], Andrew Varga[1]

[1] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [2] NYU Grossman School of Medicine, [3] Icahn School of Medicine at Mount Sinai, [4] Department of Psychiatry, New York University Grossman School of Medicine

Introduction: The locus coeruleus (LC), an important sleep/wake regulating structure and site of early change in neurodegenerative

disease, is best measured in humans with ultra-high field 7-Tesla MRI due to its small size. We hypothesized that obstructive sleep apnea (OSA) would negatively influence LC structural integrity and volume in cognitively normal elderly individuals.
Methods: We examined the LC using 7T MRI with a computational LC localization and segmentation algorithm in 30 cognitively normal older subjects: 17 with a new OSA clinical diagnosis and 13 from the community without sleep complaints. Obstructive sleep apnea was assessed by WatchPAT home sleep study or in-lab polysomnography. We evaluated associations between OSA severity/hypoxic burden and LC structural metrics: absolute volume, volume normalized to brainstem or whole brain volume, and LC integrity, a relative measure of MRI contrast enhanced neuromelanin.
Results: Of the 30 subjects, mean age was 66 years and 53% were women. The cohort was dichotomized using an OSA cutoff of AHI4%>=5 (OSA+, n=22, OSA-, n = 8). Total sleep time was not significantly different between the OSA- and OSA+ groups. As expected, AHI4%, REM AHI4%, and min. oxygen saturation during sleep were all significantly different in the OSA- and OSA+ groups, though time below 90% oxygen saturation (T90) was not. We observed a significant negative association between LC integrity and T90 [R=-0.45, p=0.035] in the OSA+ group, but not the OSA- group [R=0.58, p=0.132]. We did not observe differences between the OSA+ and OSA- groups for the absolute LC volume [OSA-: 145± 63mm3, OSA+: 132± 74, p=0.44], LC volume normalized to brainstem volume [OSA-: 0.0052± 0.0032, OSA+: 0.0055± 0.0032, p=0.83], LC volume normalized to whole brain volume [OSA-: 8.0e-05± 4.8e-05, OSA+: 7.6-05± 4.7e-05, p=0.83], or LC integrity [OSA-: 1.60± 0.09, OSA+: 1.58± 0.14, =0.94].
Conclusion: This study presents some of the first evidence that greater hypoxic burden as assessed by T90 is associated with reduced LC integrity in older adults, potentially implicating a role for nocturnal hypoxemia in the pathological decline of the LC with aging.

THE ROLE OF SEROTONERGIC SIGNALING IN LIFE QUALITY, DEPRESSION, AND INSOMNIA AMONG OBSTRUCTIVE SLEEP APNEA PATIENTS

Marcin Sochal[1], Marta Ditmer[1], Szymon Turkiewicz[1], Piotr Białasiewicz[1], Adrian Gajewski[1], Maciej Chałubiński[1], Agata Gabryelska[1]
[1] Medical University of Lodz, Poland

Introduction: The serotonergic system, including serotonin and serotonin transporter (SERT), might play a complex, yet still elusive role in obstructive sleep apnea (OSA) and its psychiatric comorbidities.
Methods: This study recruited 76 participants at the Department of Sleep and Metabolic Disorders, Medical University of Lodz. Polysomnography (PSG) assessed sleep-related parameters, participants with apnea/hypopnea index (AHI)>30 were assigned to the OSA group (n=36), and those with AHI< 5 to the healthy controls (HC, n=40). Venous blood was collected in the evening before PSG and in the morning after. Serum levels of serotonin and SERT were measured using enzyme-linked immunosorbent assay (ELISA). SERT mRNA expression analysis from peripheral blood leukocytes was performed with qRT-PCR (reference gene: β-actin) following RNA isolation and cDNA synthesis. Participants were evaluated for depressive symptoms (Beck Depression Inventory, BDI), insomnia severity (Insomnia Severity Index, ISI), and quality of life (QoL, Short Form 36, SF-36) with the cut-off points: ISI>14 for insomnia, BDI>13 for presence of depression symptoms, and SF-36< 64 for low QoL.
Results: This study found no significant differences in any of the studied laboratory variables between OSA and HC (all p > 0.05). Depressive symptoms were unrelated to serotonergic parameters in the OSA group but in HC individuals without mood disorders had higher baseline SERT level and evening/morning SERT ratio than their depressed counterparts (p=0.044, p=0.005, respectively). Among OSA participants, those with a good QoL showed elevated serotonin levels in both the evening (p=0.028) and morning (p=0.043) than those with lower QoL. In the insomnia group, baseline SERT protein levels were significantly greater in the HC group compared to the OSA group (p=0.045). Baseline SERT mRNA expression (insomnia group) was higher in the OSA than in the HC (p=0.032).
Conclusion: Serotonergic signalling might be related to the QoL, depression, and insomnia in OSA patients. Stratifying this group of patients into different phenotypes based on subjective and objective, might open new avenues for treatment and allow for more personalized approach.
Support (if any): The study was financed by the Ministry of Science and Higher Education, Poland (SKN/SP/602313/2024).

METABOLIC EFFECTS OF ACUTE SUSTAINED HYPOXIA IN HEALTHY VOLUNTEERS

Luu Pham[1], Alan Schwartz[2], Daisy Duan[3], Vsevolod Polotsky[4], Jonathan Jun[1]
[1] Johns Hopkins University, [2] University of Pennsylvania Perelman School of Medicine, [3] Johns Hopkins University School of Medicine, [4] The George Washington University

Introduction: Obstructive sleep apnea (OSA) causes recurrent periods of hypoxia during sleep and is associated with disorders of glucose homeostasis including glucose intolerance and diabetes. In OSA patients, CPAP withdrawal increased glucose, insulin and free fatty acids (FFA). In healthy volunteers, hypoxia during wakefulness reduced insulin sensitivity, suggesting that hypoxia causes metabolic abnormalities in OSA patients. In this study, we exposed healthy volunteers to hypoxia during sleep to examine the effects of hypoxia on nocturnal plasma glucose and FFA.
Methods: We conducted a randomized cross-over study in healthy volunteers of 1 night each of breathing room air (RA) vs. hypoxic gas (HG) (Hypoxico, Ltd) while undergoing polysomnography. Each study night before sleep, participants ate a standardized iso-caloric meal. On hypoxia nights, FiO2 was titrated to maintain oxyhemoglobin saturation (SPO2) of approximately 83 ± 2% during sleep. We measured venous glucose, insulin and free fatty acids (FFA) every 30 minutes between 22:00 and 06:00. Mean plasma metabolite levels compared between using Wilcoxon rank-sum tests.
Results: 12 participants (8 male, mean age 29.8 ± SD 5.6 of years and mean BMI 25.4 ± 4.5 kg/m2) completed both nights of the study. On RA, participants slept for 368 minutes and had a mean apnea hypopnea index (AHI) of 4.0 ± 2.7 events/hr with mean SPO2 of 96.2 ± 1.1%. On HG, mean SPO2 fell to 85.4 ± 1.1% and AHI increased to 29.3 ± 29.4/hr (almost exclusively

central apneas). Nevertheless, mean glucose (86 ± 7 on RA, vs. 85 ± 7 mg/dL on HG), insulin (5.3 ± 2.2 vs. 5.3 ± 2.4 µU/mL) or FFA (323 ± 132, vs. 322 ± 131 mmol/L) did not differ between RA and HG.
Conclusion: In healthy volunteers, one night of hypoxia was insufficient to stimulate glucose, insulin or FFA elevations. These findings are in contrast to glucose and/or FFA found in other experiments in sleep apnea patients, suggesting that factors including hypoxia patterns, exposure duration, sleep fragmentation, sex or body composition may account for sleep-apnea-related nocturnal metabolic abnormalities.

BREATHING CONTROL ALTERATIONS AND SLEEP APNEA IN PATIENTS WITH IDIOPATHIC PULMONARY FIBROSIS

Claudia Loppnow[1], Andrea Peterson[1], Ailiang Xie[1], Isabella Marquetti[1], Daniel Morris[1], Braden Ellis[1], Mihaela Teodorescu[1]
[1] School of Medicine and Public Health, University of Wisconsin-Madison

Introduction: Obstructive Sleep Apnea (OSA) is highly common among patients with Idiopathic Pulmonary Fibrosis (IPF), but data on mechanisms whereby IPF-related features impact OSA pathogenesis are lacking. We hypothesized that IPF patients experience more disturbances in control of breathing (COB) because of poor lung function, contributing to OSA.
Methods: Pulmonary function tests (PFTs) were performed on IPF patients, followed by overnight polysomnography. Standard PFT and sleep-disordered breathing (SDB) measures, along with segments of quiet breathing (≥2 minutes) during stable N2/N3 sleep were extracted, the latter for analysis of ventilatory parameters (respiratory frequency [f], tidal volume [Vt] and minute ventilation [Ve], and inspiratory duty cycle [inspiratory/ breath time, Ti/Ttot]) using custom software. Spearman's Rank test was used to test correlations between variables of interest.
Results: Data from 7 patients (6 males) aged (mean±SD) 68±6.3 years were available. Lower FVC (%predicted) correlated with lower respiratory frequency (p-value=0.023), higher Forced Expiratory Volume in the first second (FEV1) of forced vital capacity (FVC) maneuver expressed relative to FVC (FEV1/FVC) correlated with lower Ti/Ttot (p-value=0.0234), and lower lung diffusing capacity corrected for hemoglobin (%predicted) with higher respiratory frequency (p-value< 0.0001). Higher Ve correlated with higher AHI (p-value=0.0005) and ODI (p-value=0.007).
Conclusion: In this initial dataset, IPF-associated pulmonary dysfunction increased breathing frequency and Ve, and prevented the increase in the duty cycle during sleep. These breathing alterations may promote instability and limit compensatory mechanisms for preserving ventilation under conditions of inspiratory flow limitation during sleep, setting the stage for OSA. Larger samples are needed to consolidate these preliminary results.

CONCURRENT DYSFUNCTIONAL COGNITIONS ABOUT SLEEP AND EXCESSIVE DAYTIME SLEEPINESS TYPICAL IN COMORBID INSOMNIA AND SLEEP APNEA: A JAPANESE PSG DATABANK

Tomohiro Utsumi[1], Takuya Yoshiike[1], Kentaro Matsui[2], Aoi Kawamura[1], Shinobu Okamura[1], Kentaro Nagao[1], Megumi Hazumi[1], Kenichi Kuriyama[1]
[1] Department of Sleep-Wake Disorders, National Institute of Mental Health, National Center of Neurology and Psychiatry, [2] Department of Laboratory Medicine, National Center Hospital, National Center of Neurology and Psychiatry

Introduction: Comorbid Insomnia and Sleep Apnea (COMISA), the co-occurrence of Chronic Insomnia Disorder (CID) and Obstructive Sleep Apnea (OSA), often has worse clinical symptoms and poorer treatment outcomes than either condition alone. Despite their importance, dysfunctional cognitions about sleep are not necessarily prominent in CID. Similarly, excessive daytime sleepiness is not always prominent in OSA, despite potential sleep debt. However, given the possible mechanism by which CID and OSA mutually deteriorate, poor clinical outcomes of COMISA could be simultaneously influenced by these psychobehavioral hallmarks. This study examined associations of dysfunctional cognitions about sleep and excessive daytime sleepiness to a unique characteristic of COMISA, potentially its challenging clinical manifestations.
Methods: We analyzed data from 346 patients, consisting of CID alone (n = 55, median age: 44.0), OSA alone (n = 195, median age: 52.0), and COMISA (n = 96, median age: 65.0) using the National Center Hospital of NCNP database, which is part of a polysomnography databank for sleep disorders in Japan. Participants were classified into 4 groups based on the combinations of high/low Dysfunctional Beliefs and Attitudes about Sleep Scale (DBAS) and Epworth Sleepiness Scale (ESS) scores, each dichotomized by median split. The relationship between DBAS/ESS combinations and COMISA was examined using two separate logistic regression analyses: one predicting COMISA vs. CID and another predicting COMISA vs. OSA, with DBAS/ESS combinations as independent variables, and age and sex as covariates.
Results: In unadjusted analyses, compared to the low DBAS/low ESS combination, the high DBAS/high ESS combination was associated with a higher probability of having COMISA vs. OSA, but not vs. CID. After adjusting for age, we found significant associations between the high DBAS/high ESS combination and COMISA for both comparisons: COMISA vs. CID (adjusted odds ratio [AOR] = 5.14; p= 0.007) and COMISA vs. OSA (AOR = 3.29; p = 0.004). These associations remained significant after sex adjustment.
Conclusion: Results suggest a concurrent worsening of sleep cognition and daytime sleepiness in COMISA. These findings highlight the need for comprehensive assessment and treatment approaches that address both cognitive and physiological aspects of COMISA.

INVESTIGATION OF THE INTERPLAY OF HYPOXIA-INDUCIBLE FACTOR AND CIRCADIAN CLOCK SIGNALING IN OBSTRUCTIVE SLEEP APNEA PATIENTS

Agata Gabryelska[1], Szymon Turkiewicz[1], Adrian Gajewski[2], Piotr Białasiewicz[2], Dominik Strzelecki[1], Marta Ditmer[1], Maciej Chałubiński[2], Marcin Sochal[1]

[1] Medical University of Lodz, [2] Medical University of Lodz, Poland

Introduction: Obstructive sleep apnea (OSA) due to recurrent episodes of hypoxia is characterized by changes in the Hypoxia-inducible factor 1 (HIF-1) signaling pathway and thus may affect the expression of circadian clock genes and proteins in this group of patients. This relationship may have a bidirectional relationship with circadian mechanisms. This study aimed to investigate the relationship between the circadian clock and HIF-1 in OSA patients versus controls.
Methods: The study included 70 participants, who underwent polysomnography (PSG) and were assigned into OSA (apnea-hypopnea index (AHI)≥5, n=54) or control (AHI< 5, n=16) groups. BMAL1, CLOCK, PER1, CRY1, HIF-1α, and HIF-1β gene expressions and protein levels were measured in evening and morning samples, collected respectively before and after PSG. This study was funded by the National Science Centre, grant number 2018/31/N/NZ5/03931.
Results: The OSA group was characterized by increased protein levels of CLOCK, CRY1, PER1, and HIF-1a, both in the morning and evening (all $p < 0.05$), and decreased morning gene expression of BMAL1 ($p=0.02$) compared to the control group. No statistically significant correlations between gene expression and protein levels were observed either in the morning or in the evening in the case of all evaluated circadian clocks (all $p > 0.20$). Associations between almost all circadian clock gene expressions and both HIF-1 subunits were observed in the OSA group at both time points (all $p < 0.05$), with the exception of the association between PER1 and HIF-1α in the morning ($R=0.050$, $p=0.73$). In the control group, only a correlation between HIF-1α levels and CRY1 expression in the morning ($R=0.588$, $p=0.02$) was found.
Conclusion: OSA appears to affect the circadian clock and HIF-1 signaling pathway, with increased CLOCK, CRY1, PER1, and HIF-1α protein levels observed in OSA patients. Results suggest that the interplay between these signaling pathways may involve complex posttranscriptional and posttranslational mechanisms.

HYPOXIA AND METABOLIC DYSREGULATION IN OBSTRUCTIVE SLEEP APNEA: INSIGHTS INTO HIF-1 SIGNALING AND INSULIN RESISTANCE

Szymon Turkiewicz[1], Marcin Sochal[1], Adrian Gajewski[2], Piotr Białasiewicz[2], Dominik Strzelecki[1], Marta Ditmer[1], Maciej Chałubiński[2], Piotr Kaczmarski[1], Michalina Bawor-Mostowa[1], Agata Gabryelska[1]

[1] Medical University of Lodz, [2] Medical University of Lodz, Poland

Introduction: Obstructive sleep apnea (OSA) is a prevalent disorder associated with intermittent hypoxia, disrupted sleep architecture, and metabolic dysfunction, contributing to increased cardiovascular risk. Hypoxia-inducible factor 1 (HIF-1) and its downstream targets, glucose transporter 1 (GLUT1) and insulin receptor (INSR), play a crucial role in cellular adaptation to hypoxia and glucose metabolism. This study investigated the expression of HIF-1 subunits, GLUT1, and INSR at the genetic and protein levels in individuals with OSA and their associations with insulin resistance markers, including the homeostasis model assessment of insulin resistance (HOMA-IR).
Methods: 89 participants underwent overnight polysomnography (PSG) and were classified into two groups based on their apnea-hypopnea index (AHI): OSA (AHI≥5, n=47) and control (AHI< 5, n=42) groups. Morning blood samples were analyzed for HIF-1α, HIF-1β, GLUT1, and INSR gene expression levels, as well as serum protein levels, insulin, and glucose concentrations. HOMA-IR was calculated as a marker of insulin resistance. This study was supported by the Ministry of Science and Higher Education under the "Diamond Grant" program (grant no. 0067/DIA/2018/47).
Results: The OSA group exhibited significantly lower expression levels of HIF-1α and GLUT1 ($p = 0.046$ and $p = 0.007$, respectively) and a decreased protein level of INSR ($p < 0.001$) compared to the control group. No statistically significant correlations were observed between gene expression levels and their respective protein products. The OSA group also demonstrated elevated serum insulin and glucose concentrations alongside increased HOMA-IR values ($p < 0.001$ for all). Additionally, in the OSA group, AHI was positively correlated with insulin ($R=0.303$, $p=0.041$), glucose ($R=0.327$, $p=0.026$), and HOMA-IR ($R=0.378$, $p=0.01$). Significant associations between the expression of HIF-1α, HIF-1β, INSR, and GLUT1 were observed in both groups, except for the relationship between HIF-1α and INSR ($p=0.089$), which was absent in the OSA group.
Conclusion: OSA is associated with reduced HIF-1α and GLUT1 expression, decreased INSR protein levels, and elevated markers of insulin resistance. These findings suggest a potential role for HIF-1 signaling in metabolic dysfunction in OSA and highlight the need for further research into targeted therapeutic strategies.
Support (if any): The Ministry of Science and Higher Education "Diamond Grant" (no. 0067/DIA/2018/47; to AG) funded the study.

SHALLOWER SLEEP BY ODDS RATIO PRODUCT IS ASSOCIATED WITH LOW AROUSAL THRESHOLD WHEN ADJUSTED FOR CONFOUNDING OBSTRUCTIVE SLEEP APNEA SEVERITY

Thomas Tolbert[1], Sri Saranya Ravi[1], Anna Mullins[1], Ankit Parekh[2], Adriana De Resende[3], Alicia Legard[4], Justin De La Fuente[4], Jag Sunderram[4], David Rapoport[1], Indu Ayappa[5]

[1] Icahn School of Medicine at Mount Sinai, [2] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [3] Rutgers - Environmental and Occupational Health Sciences Institute, [4] Rutgers Robert Wood Johnson Medical School, [5] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Odds ratio product (ORP) is an electroencephalography-based method for capturing sleep depth. Higher ORP

indicates greater probability of sleep interruption by wakefulness ("shallower sleep"). A potential source of sleep interruption is arousal in response to respiratory events due to obstructive sleep apnea (OSA). Phenotyping using polysomnography (PUP) is a computer-based method to estimate the mechanisms contributing to OSA from routine sleep study data. We hypothesized that shallower sleep (higher ORP) would be associated with easier arousal by respiratory events (low PUP-estimated ArTH).
Methods: Automated ORP analyses were conducted for in-lab sleep studies using the Cerebra Sleep System. Separately, studies were manually scored for sleep, arousals, and respiratory events prior to PUP analyses. As PUP estimates ArTH from non-rapid eye movement (NREM) sleep, mean ORP during NREM sleep was used as the representative ORP metric for each study. Individuals with PUP-estimated ArTH in the lowest tertile were considered to have low ArTH. Associations between ORP and low ArTH were examined using univariate and multivariate logistic regression analyses.
Results: Full ORP and PUP analyses were completed for 54 individuals (age 54.8±7.7 years; 6 female; BMI 31.9±4.9 kg/m2) with untreated OSA (AHI3A 30.1±19.7 events/hr). Mean ORP in NREM sleep was 0.82±0.23. Low PUP-estimated ArTH was present in 17 individuals. Univariate logistic regression did not demonstrate a significant association between low ArTH and ORP (OR for 1 SD increase in ORP = 1.59 [0.89—3.03], p = 0.127). However, with adjustment for OSA severity according to AHI3A, low ArTH was associated with rise in ORP (OR = 2.58 [1.24—6.47], p =0.021). The association remained with further adjustment for age, sex, and BMI (OR = 2.73 [1.17—7.98], p = 0.034).
Conclusion: ORP and PUP-estimated ArTH did not have a clear relationship in a cohort of predominantly male, middle-aged individuals with OSA. However, with adjustment for OSA severity, rising ORP was associated with greater odds of low ArTH, suggesting complex relationships among ORP, ArTH, and OSA. Further investigation should determine whether OSA confounds the relationship between ORP and ArTH by both disrupting sleep (raising ORP) and producing resistance to sleep disruption (raising ArTH).

BASELINE PATHOPHYSIOLOGIC TRAITS OF PEDIATRIC OBSTRUCTIVE SLEEP APNEA TO ASSESS RESPONSE TO ADENOTONSILLECTOMY

Po-Yang Tsou[1], Raichel Alex[2], Susan Redline[3], Scott Sands[2]
[1] Boston Children's Hospital, [2] Brigham and Women's Hospital and Harvard Medical School, [3] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Adenotonsillectomy is the first-line treatment for pediatric obstructive sleep apnea (pOSA) as adenotonsillar hypertrophy is a major risk factor for pOSA. However, the response rate to adenotonsillectomy varies from 20% to 70%. Pathophysiological determinants of OSA (endotypes), including greater pharyngeal collapsibility, reduced dilator muscle compensation, elevated chemoreflex loop gain, and altered arousal threshold, have shown promise in predicting responses to OSA treatment in adults. We aimed to determine whether the characterization of pOSA pathophysiologic traits estimated from polysomnography could predict response to adenotonsillectomy.
Methods: Endotypes were estimated during REM and NREM sleep from baseline polysomnography in children with OSA who received adenotonsillectomy in the Childhood Adenotonsillectomy Trial (CHAT; N=194; mean age:6.56 years; Black:54.12%; Asian:2.58%; female:58.25%; obese:34.54%). The primary outcome was the difference between baseline and follow-up REM-AHI (events/hour). Secondary outcomes were changes in NREM-AHI, and AHI reduction ≥50% (estimated for both REM- and NREM-sleep) and pOSA resolution (AHI < 2 events/hr) (estimated for both REM- and NREM- sleep). Multivariable regression models assessed associations of REM and NREM endotypes (per standard deviation) with primary and secondary outcomes derived from REM and NREM sleep.
Results: The sample had a baseline total AHI of 6.92 ± 5.73 (events/hr)(mean ± SD); REM-AHI of 16.43 ± 19.02; NREM-AHI of 4.76 ± 4.33, and a follow-up AHI of 1.59 ± 3.01; REM-AHI of 3.93 ± 8.50; NREM-AHI of 1.02 ± 2.00. Univariable analyses showed that higher REM-collapsibility at baseline was associated with greater REM-AHI reduction (REM: β:-6.39[95% CI:-9.47, -3.30] events/hr), and improvement in REM-AHI≥50% (odds ratio:1.63[95% CI:1.01, 2.65]). Multivariable analyses adjusting for other endotypes yielded similar results - greater collapsibility at baseline associated with a greater reduction in REM-AHI (β^adj:-9.66[95% CI:-18.82, -0.51]) and the association persisted after additional adjustment for age, sex, BMI-z, and Black race (β^adj:-10.52[95% CI:-19.68, -1.37]). No significant associations between endotypes and secondary outcomes were observed in multivariable analyses.
Conclusion: Quantifying pOSA traits using clinical polysomnography can identify an endotype-based subgroup of patients with increased pharyngeal collapsibility who are more responsive to adenotonsillectomy. These results suggest opportunities for targeting mechanistic traits to improve the outcomes of surgical therapies for pOSA.

Introduction: Obesity is an important risk factor for obstructive sleep apnea (OSA) development. Likewise, obesity management is an important component of OSA treatment. We evaluated the impact of sleeve gastrectomy on OSA endotypes in prospective and retrospective cohorts.
Methods: The SLIM-OSA trial (NCT04793334; IRB#191948) seeks to elucidate the mechanisms for why weight loss improves OSA in some but not all individuals. Participants underwent baseline polysomnography. Six months following sleeve gastrectomy, polysomnography was repeated. A separate cohort with a history of sleeve gastrectomy and polysomnography received updated polysomnography. We pooled these cohorts for comparison.
Results: Of 55 individuals undergoing baseline studies, 20 received surgery and repeated polysomnography; 15 had baseline

OSA with follow-up data. In the retrospective cohort, 19 had baseline OSA and post-op data. Across 34 individuals with paired data, the cohort was 82% female, 52% Hispanic, with a median age of 44 years. Pre-op BMI was 42 kg/m², decreasing to 34 kg/m² post-op ($p < 0.0001$). AHI decreased from 18/h to 15/h ($p = 0.12$). VpassiveT improved (72% to 80% Veupnea, $p < 0.001$), Vmin increased (67% to 76% Veupnea, $p < 0.001$), and chemoreflex delay rose (9.7 to 11.7 seconds, $p = 0.018$). No significant changes were seen in Vactive (101% to 102%, $p = 0.5$), upper airway gain (1.42 to 1.73, $p = 0.08$), Lg1 (0.52 to 0.47, $p = 0.15$), or hypoxic burden (34% to 24%min/h, $p = 0.2$). ArthresT decreased from 149 to 133 ($p = 0.007$). Linear models revealed significant associations between ΔAHI and ΔBMI ($r = 0.33$, $p = 0.052$), ΔVpassiveT ($r = -0.35$, $p = 0.045$), ΔVactive ($r = -0.34$, $p = 0.049$), Δupper airway gain ($r = -0.54$, $p = 0.0026$), and Δhypoxic burden ($r = 0.64$, $p = 0.0001$). Similar trends were observed with ΔBMI as the independent variable.

Conclusion: Passive collapsibility and chemoreflex delay tended to improve after sleeve gastrectomy. Some participants with obesity did not have OSA, and there are sex differences with respect to how obesity impacts OSA. The mechanisms for weight loss improving OSA are complex.

ANALYSIS OF POLYSOMNOGRAPHY IN PATIENTS WITH SLEEP DISORDERS ACCOMPANIED BY TINNITUS

Woo Yong Bae[1], Dong Won Jung[1], In Bum Park[1], Young Bin Youn[1]

[1] Dong-A University Hospital

Introduction: Tinnitus is a symptom characterized by the perception of sound generated within the body, specifically by the spontaneous depolarization of auditory nerve fibers, without any external auditory stimulus. Although the exact etiology of tinnitus remains unknown, there is a strong electrophysiological hypothesis suggesting that functional changes in the limbic system's amygdala and the cerebral cortex, as well as the subcortical structures, lead to tinnitus through autonomic nervous system dysfunction. Sleep disorders are also known to be influenced by and to influence the complex interactions among the ascending reticular system, central arousal system, cognitive system, and emotional regulating system in the central nervous system. Therefore, based on these theoretical foundations, we aimed to analyze the relationship between tinnitus and sleep by examining the association between tinnitus and polysomnography (PSG) results using the Tinnitus Handicap Inventory (THI).

Methods: A retrospective analysis was conducted on patients who visited the clinic and underwent both PSG and the Korean version of the THI. The clinical characteristics, PSG results, and scores from psychiatric symptom questionnaires were compared between the group with tinnitus and the group without tinnitus. Additionally, the PSG results and questionnaire scores were compared based on the THI scores.

Results: There were statistically significant differences in the Periodic Limb Movement (PLM) index, sleep latency, and lowest SpO2 between the group with tinnitus and the group without tinnitus. The tinnitus group exhibited lower PLM index, higher sleep latency, and higher lowest SpO2 compared to the group without tinnitus. When analyzing the PSG results based on THI scores, a significant negative correlation was found between THI and REM latency. There were no significant differences in the average scores of questionnaires between the group with tinnitus and the group without tinnitus. Multiple regression analysis also did not reveal any significant correlations between THI scores and questionnaire scores.

Conclusion: Tinnitus, sleep disorders, and depression are associated with autonomic nervous system overactivity through the limbic system. Studies that examine the relationship between tinnitus, sleep disorders, depression, anxiety, and stress using PSG and questionnaires can provide a better understanding of sleep patterns, autonomic nervous system function, and electrophysiological models.

DIFFERENCES IN SLEEP QUALITY IN INDIVIDUALS RECEIVING OPIOID MEDICATION FOR OPIOID USE DISORDER VERSUS CHRONIC PAIN

Myles Finlay[1], Poppy Gardiner[2], Marian Wilson[3], Devon Hansen[1], Matthew Layton[2]

[1] Washington State University, [2] Elson S. Floyd College of Medicine, Washington State University, Spokane, Washington, USA, [3] Washington State University: College of Nursing

Introduction: Chronic pain is a prevalent condition often treated with opioid medication. Opioids, such as methadone, are also used to treat opioid use disorder (OUD). As central nervous system depressants, opioids can exacerbate sleep problems, particularly those due to respiratory issues. This study investigates sleep quality and respiratory distress measures in adults with Chronic Pain (CP) receiving opioid medication and those with OUD receiving methadone.

Methods: Adults (18years+) in the CP group had a "moderate" daily level of pain (≥5 on a 0-10 Numeric Pain Scale [NPS]) and were prescribed opioids. Adults (18years+) in the OUD group were enrolled in an opioid treatment program and taking methadone daily. All participants rated their pain intensity and interference scales using the PROMIS. NightOwl mini disposable home sleep tests (Ectosence, Leuven, Belgium) were used to record total sleep time (TST), time in bed (TIB), sleep efficiency (SE), and apnea-hypopnea index (AHI) for all participants.

Results: In total, N= 17 (12 women) provided data, N=9 (6 women 60y±12y [Mean ± SD]) in the CP group and N=8 (6 women 45.5y±12.3y) in the OUD group. Average pain intensity and interference T-scores were 69.4±8.1 and 69.72±6.5 for CP and 59.6±7.9 and 58.4±9.1 for OUD ($t>-2.45$, $p< 0.02$). CP participants spent 8.6±2.8h TIB and 5.08±2.3h asleep, resulting in an SE of 61.4±24.9% and a predicted AHI of 6.6±6.4, indicative of mild sleep apnea. OUD participants spent 8.27±2.93h TIB and 4.19±2.03 hours asleep, resulting in an SE of 54.86±19.35% and a predicted AHI of 21.4±27.7, indicative of moderate sleep apnea (all $p>0.05$).

Conclusion: Although the CP group reported significantly higher pain intensity and interference scores, objective sleep data showed the OUD group had higher measures of sleep apnea and worse sleep efficiency. This preliminary data warrants further exploration of sleep quality and respiratory status among adults with chronic pain and OUD receiving maintenance treatment with opioids.

EFFECT OF ACETAZOLAMIDE ON BREATHING STABILITY IN OPIOID-ASSOCIATED SLEEP-DISORDERED BREATHING

Danny Greig[1], Ruchi Rastogi[2], Chandra Miryala[2], M Badr[2], Lili Zhao[2], Susmita Chowdhuri[2]

[1] John D. Dingell VAMC, [2] JDDVAMC

Introduction: The mechanisms of opioid-induced sleep disordered breathing (SDB) are unclear. Reduced cerebral vascular responsiveness to CO2 may increase breathing instability. Whether acetazolamide (ACZ) can enhance breathing stability in opioid-SDB by reducing loop gain and/or enhancing cerebrovascular responsiveness to CO2 (CVR) has not been studied. We hypothesized that in patients with opioid-SDB, ingestion of ACZ will alleviate breathing instability during NREM sleep by reducing the apneic threshold (AT) and plant gain, and/or by increasing CVR

Methods: Seven participants with opioid-associated SDB (age 48.4±15.8 yr, BMI 32.1±6.9 kg/m2, 4 male, 2 female, 1 transgender, apnea-hypopnea index 39.2±21.8/hr, central apnea index 3.2±5.2/hr, morphine equivalent dose: 29.8±9.2 mg) were randomized to oral ACZ 500 mg vs. placebo twice a day for 6 days. On day-4, while on the drug, middle cerebral artery velocity (MCAV) was measured while awake using transcranial doppler ultrasound. Multiple trials with hyperoxia hypercapnic breathing determined cerebrovascular conductance (CVC): ΔMCAV/Δmean arterial pressure, where Δ=trial minus baseline values, and slope of CVR: ΔCVC/ΔPETCO2. This was followed by measurement of AT using noninvasive mechanical ventilation during NREM sleep, and PSG on a subsequent night while still on the drug. Plant gain (PG) and controller gain (CG), components of loop gain, were determined using published methods. Average data from multiple CVR trials and AT trials are reported. Serum opioid levels were measured on experimental nights. Serum bicarbonate levels: ACZ: 19.7±2.6 mEq/L vs. placebo: 27.2±3.3 mEq/L.

Results: Four participants have completed both arms of the study. Data are presented as ACZ vs. placebo (n=4): CVC 68.1±16.3 vs. 72.9±21.1 units, CVR 1.9±0.4 vs. 2.0±0.6 unit/mmHg; AT trials: eupneic PETCO2 33.3±4.4 mmHg vs 41.1±3.4 mmHg ($p< 0.001$), eupneic minute ventilation 11.8±3.6 L/min vs. 7.4±1.5 L/min ($p=0.08$), AT-PETCO2 29.8±4.7 mmHg vs 38.0±3.4 mmHg ($p=0.002$), PG 3.1±0.7 vs. 5.8±0.7 mmHg/L/min ($p=0.02$), CG 2.6±0.8 vs. 2.0±0.9 L/min/mmHg.

Conclusion: In participants with opioid-associated SDB, compared with placebo, ACZ significantly decreased the AT during NREM sleep, indicating increased breathing stability related to a significantly reduced PG, with reduced eupneic PETCO2. However, there was no change in CVR with ACZ. Additional studies will determine the role of ACZ therapy in opioid-associated SDB.

A BREATHLESS PUZZLE: CENTRAL SLEEP APNEA AND SUBCLINICAL BRAINSTEM COMPRESSION

Jose Rodriguez Velez[1], Pedro Baez Gutierrez[1], Patricia Fernandez Hawa[1], Lissette Jimenez Davila[1]

[1] VA Caribbean Health Care System

Introduction: Sleep breathing disorders (SBDs) are characterized by recurrent episodes of apnea (cessation of breathing) or hypopnea (reduced breathing) during sleep, arising from overlapping pathophysiological mechanisms. Central sleep apnea is not a singular disorder but can occur independently or as part of other clinical syndromes. It is primarily caused by a transient loss of output from the pontomedullary pacemaker, affecting respiratory muscles such as the diaphragm, thorax, and abdomen. Various pathophysiological classifications exist, including high loop gain associated with conditions like heart failure, and rhythm generation failure due to brainstem disorders. Among the latter, Chiari malformation is well-documented, though data are limited. The exact mechanism remains unclear, but it is hypothesized that central apneas may result from dysfunction of the respiratory center due to medulla oblongata compression or vascular compression causing ischemia. Brainstem compression may also affect the reticular activating system, and compression or stretching of the glossopharyngeal nerve could impair afferent input from the carotid bodies, affecting the chemoreflex. Damaged chemoreceptors may reduce responsiveness to CO2, leading to central apneas.

Methods: Case presentation

Results: We present a case of a 40-year-old male with predominantly central sleep apnea, evaluated for Chiari malformation. MRI revealed a 3mm tonsillar herniation, which did not meet the criteria for Chiari malformation Type I but suggests a potential cause for the central sleep apnea.

Conclusion: This case highlights the need for further investigation into the pathophysiology of central sleep apnea, particularly regarding the severity of anatomical brainstem disorders that might trigger such apneas.

ELEVEN-YEAR PREVALENCE OF SLEEP-DISORDERED BREATHING IN COMMUNITY-BASED HEALTH CENTERS ACROSS THE UNITED STATES

Rupsha Singh[1], Symielle Gaston[1], Jacqueline Barkoski[2], Frankie LaPorte[2], Dayna Neo[2], Paul Juarez[3], Robert Voss[4], Anna Steeves-Reece[4], Chandra Jackson[1]

[1] National Institute of Environmental Health Sciences, [2] DLH, LLC, [3] Wilberforce University, [4] OCHIN

Introduction: Sleep-disordered breathing (SDB) disproportionately affects socioeconomically disadvantaged populations, including minoritized racial and ethnic groups and rural communities. Community-based health centers (CBHCs) are critical to help address structural healthcare inequities by providing care to socioeconomically disadvantaged populations. However, little is known about the prevalence of SDB in CBHCs, although these data can inform resource allocation and intervention by identifying high-need populations and prioritizing areas with the greatest burden of SDB.

Methods: We investigated the prevalence of SDB among adults seeking care at CBHCs between 2012 and 2022 using electronic health record data from the OCHIN network of community health organizations, comprised of >34,500 providers at >2,000 healthcare delivery sites across 40 states. SDB cases were identified using ICD-9-CM/ICD-10-CM and CPT/HCPCS codes. Central sleep apnea (CSA), obstructive sleep apnea (OSA), or other/unspecified sleep apnea subtypes were identified using ICD-9-CM/

ICD-10-CM codes. Demographic data were obtained from patient's initial encounter during the study period. Comorbidities were identified using ICD-9-CM/ICD-10-CM codes, vital measures (i.e., blood pressure, height, weight), and medications. We used descriptive statistics to obtain frequencies and percentages.
Results: Among 4,167,921 adults, the median age at first encounter was 39 [IQR: 27-54] years. Most (57%) were women, White (60%), non-Hispanic (NH, 62%), non-Veteran (57%), and resided in the Western region (59%). Additionally, 30% reported incomes < 25% of the federal poverty level, and 36% had Medicaid. SDB was diagnosed in 168,937 (4%) patients. The OSA subtype was most prevalent (3%), followed by other/unspecified apnea (2%), and CSA (0.1%). Among OSA patients, 42% were aged 50–65 years, 54% were NH-White, 52% were men, and 45% never smoked. Hypertension (74%), obesity [BMI ≥30 kg/m2] (65%), and diabetes (38%) were prevalent comorbidities among individuals diagnosed with OSA. The prevalence of SDB increased among patients aged 18-34 years (9% to 15%), NH-Black patients (12% to 16%), and Hispanic patients (9% to 20%), while in other groups the prevalence either decreased or remained stable between 2012 and 2022.
Conclusion: At 4%, SDB is prevalent among patients seeking care in CBHCs, especially among those with comorbidities. Expanding adequate and high-quality sleep medicine services through CBHCs may advance sleep health equity.

SOCIAL RISK FACTORS, SLEEP APNEA AND CARDIOVASCULAR RISK: CLINICAL PREDICTORS IN COMMUNITY HEALTH CENTERS

Diego Mazzotti[1], Ryan Urbanowicz[2], Marta Jankowska[3]
[1] University of Kansas Medical Center, [2] Cedars Sinai Medical Center, [3] Beckman Research Institute, City of Hope

Introduction: Racial, ethnic and socioeconomically disadvantaged minorities are more likely to experience insufficient sleep, sleep disorders, and negative cardiovascular (CV) outcomes. However, pathways linking health disparities to sleep disturbances and CV outcomes are largely underexplored. We leveraged electronic health record (EHR) data from the Accelerating Data Value Across a National Community Health Center Network (ADVANCE) Clinical Research Network (CRN) to identify social risk factor clusters, assess their association with obstructive sleep apnea (OSA), and determine relevant clinical predictors of cardiovascular (CV) outcomes among those experiencing OSA.
Methods: Geographically informed social indicators were used to define social risk factor clusters via latent class analysis. EHR-wide diagnoses were used as predictors of 5-year incidence of major adverse CV events (MACE) using STREAMLINE, an end-to-end rigorous and interpretable automated machine learning pipeline.
Results: Analyses among over 1.4 million individuals revealed three major social risk factor clusters: lowest (35.7%), average (43.6%) and highest (22.7%) social burden. In adjusted analyses, those experiencing highest social burden were less likely to have received a diagnosis of OSA when compared to those experiencing lowest social burden (OR [95%CI]=0.85[0.82-0.88]). Among those with OSA and free of prior CV diseases (N=4,405), performance of predicting incident MACE reached a AUC of 0.70 overall but varied when assessed within each social risk factor cluster. Feature importance also revealed that different clinical factors might explain predictions among each cluster.
Conclusion: Results suggest relevant health disparities in the diagnosis of OSA and across clinical predictors of CV diseases among those with OSA, across social risk factor clusters, indicating that tailored interventions geared toward minimizing these disparities are warranted.

DISTRIBUTION OF CARDIOMETABOLIC COMPLICATIONS IN U. S. VETERANS BEFORE AND AFTER SLEEP TESTING

Destinee Morrow[1], Silvia Crivelli[1], Rafael Zamora-Resendiz[1], Michael Mooney[2], Connor Smith[2], Carrie Puckett[3], Alexander Gomez[4], Taylor Anderson[2], Matthew Hudkins[2], Ritchie Verma[2], Amrish Pipalia[2], Da Jin[2], Patrick Finley[5], Drew Levin[5], Eilis Boudreau[2]
[1] Lawrence Berkeley National Laboratory, [2] Oregon Health & Science University, [3] VA Portland Health Care System, [4] VA San Francisco Health Care System, [5] Sandia National Laboratories

Introduction: Obstructive sleep apnea (OSA) is a prevalent condition among Veterans affecting 24% and ranking among the top five most common diagnoses in the Veterans Health Administration (VHA). Epidemiologic studies demonstrate a strong association between OSA and cardiometabolic disease. This study describes the temporal distribution of common cardiometabolic comorbidities in relationship to the first sleep test within VHA.
Methods: This study is a sub-analysis of data from a larger project leveraging Artificial Intelligence (AI) to predict which Veterans with OSA are most likely to develop cardiometabolic comorbidities. Data from 24 million Veteran records collected between 1999 and 2022 were analyzed using Current Procedural Terminology for diagnostic sleep testing, and International Classification of Disease 9 and 10 codes for OSA and cardiometabolic comorbidities. Prevalence of comorbidities was documented within two years prior to the first sleep study (T0) and for up to 22 years afterwards. A preliminary logistic regression model was used to predict the likelihood of developing an additional comorbidity after T0.
Results: The analysis identified 1.3 million Veterans who underwent sleep testing within VHA, with 939,954 having at least one comorbidity. Within two years prior to T0 the following comorbidities were observed: hypertension 54%, diabetes mellitus 29%, coronary artery disease 22%, heart failure 8.5%, stroke 8.9%, and atrial fibrillation 7.4%. After T0 the number of Veterans with these comorbidities increased: hypertension 60%, diabetes mellitus 42%, coronary artery disease 33%, heart failure 18%, stroke 16%, and atrial fibrillation 15%. At T0 44% had at least two comorbidities, 21% had at least three comorbidities, 9% had at least four comorbidities. An initial logistic regression predictive model has an AUROC of 0.74 with OSA having an odds ratio of 2.13 for developing a new comorbidity after T0.
Conclusion: These findings suggest many Veterans have already developed significant cardiometabolic comorbidities by the time of OSA diagnoses, with additional diagnoses occurring subsequently. This may reflect increased healthcare engagement

leading to the diagnosis of comorbidities or potentially indicate a causal relationship. Additional research is needed to better define the relationship between OSA and incident comorbidities.

SLEEP APNEA PATHOPHYSIOLOGICAL TRAITS AND CARDIOVASCULAR OUTCOMES: THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS

Raichel Alex[1], Ali Azarbarzin[1], Susan Redline[2], Scott Sands[1]
[1] Brigham and Women's Hospital and Harvard Medical School, [2] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Identifying which patients with obstructive sleep apnea (OSA) are at elevated risk for major adverse cardiovascular events (MACE) may help target treatment to those most likely to benefit. Here we evaluated whether OSA-related MACE risk differs by underlying pathophysiology. Since augmented cardiopulmonary responsiveness to respiratory events may contribute to adverse cardiovascular outcomes of OSA, we tested the hypothesis that OSA patients with increased loop gain (OSAHighLG) are at increased MACE risk, whereas those without elevated loop gain (OSALowLG) are not.
Methods: At-home polysomnography from Multi-Ethnic Study of Atherosclerosis provided measures of pathophysiological traits (loop gain, collapsibility, muscle compensation, and arousal threshold). MACE was defined as incident myocardial infarction, resuscitated cardiac arrest, stroke, or cardiovascular mortality. Cox proportional hazard modeling evaluated the association between MACE and OSAHighLG (apnea-hypopnea index [AHI]≥15 events/hr and loop gain>median) and OSALowLG compared to non-OSA controls (AHI< 15) adjusting for age, sex, body mass index, race, hypertension, diabetes, and smoking. Sensitivity analyses assessed severe OSA (AHI>30) separately. Secondary analyses 1) redefined OSA severity subgroups using hypoxic burden >32 %min/hr (i.e. HBHighLG, HBLowLG), 2) examined other endotypic traits, and 3) evaluated a simplified biomarker of loop gain (periodicity per event cycle length variability).
Results: In the sample (N=1968, age:68.5±9.1 years, AHI:24.3±19.4 events/hr, follow-up:8.3±1.9 years), 11.4% exhibited MACE events. Increased MACE risk was observed in OSAHighLG (hazard ratio [95%CI] vs controls: 1.79[1.17-2.73], N=586) but was less evident in OSALowLG (1.46[0.94-2.27], N=586; difference ratio:1.23[0.83-1.82]). MACE risk was markedly increased in severe OSAHighLG (2.23[1.40-3.54], N=333) but not in severe OSALowLG (1.32[0.74-2.35], N=252). Defining OSA severity using hypoxic burden yielded similar results (HBHighLG:1.82[1.19-2.78] vs. HBLowLG:1.35[0.86-2.12]). OSA-related MACE risk also tended to be higher with greater vs. milder collapsibility (1.81 vs. 1.47) and good vs. poor compensation (1.80 vs. 1.48), but not with high vs low arousal threshold (1.68 vs. 1.57). MACE risk was higher in OSAHighLG compared to OSALowLG based on periodicity (2.15[1.42-3.26] vs. 1.15[0.72-1.82]; difference ratio: 1.87[1.25-2.80]).
Conclusion: Elevated MACE risk in OSA is particularly evident in patients with elevated loop gain. Pathophysiological trait measures may improve identification of OSA patients who are at elevated risk of adverse cardiovascular outcomes.

COMPARING ACCURACY, SENSITIVITY, AND SPECIFICITY OF ACTIGRAPHY TO POLYSOMNOGRAPHY IN COGNITIVELY NORMAL OLDER ADULTS WITH OBSTRUCTIVE SLEEP APNEA

Mark Bernard[1], Joshua Gills[1], Shrestha Shah[2], Anthony Briggs[1], Toluwalase Akinluyi[1], Nia Ojemen[1], Luisa F. Figueredo[3], Julian McBride[1], Elena Valkanova[4], Andrew Varga[5], Girardin Jean-Louis[6], Ricardo Osorio[3], Omonigho Michael Bubu[3]
[1] NYU Grossman School of Medicine, [2] Georgia Institute of Technology, [3] Department of Psychiatry, New York University Grossman School of Medicine, [4] University of South Florida, [5] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [6] University of Miami Miller School of Medicine

Introduction: There is continued research interest in determining the concordance between polysomnography (PSG) and actigraphy, particularly in individuals with Obstructive Sleep Apnea (OSA). We investigated the accuracy, sensitivity, and specificity of actigraphy-measured sleep vs. PSG in a cohort of older adults with and without OSA.
Methods: PSG for each participant was recorded overnight at bedside. During a separate period of seven consecutive nights, actigraphy was collected for each participant at home using wrist-worn actigraphs on the non-dominant hand. Sleep time was validated with participant-provided sleep logs. Statistical analyses, including t-tests, chi-square tests, and sensitivity-specificity assessments, were performed. Lin's concordance correlation coefficient (CCC) and reduced major axis regression (RMAR) were utilized as measures of agreement and proportional bias, respectively.
Results: The study included 151 community-dwelling older adults (ages 47-84) evaluated at the NYU Alzheimer's Disease Research Center and enrolled in studies investigating sleep health and aging. Of the 151 participants, 108 (71.5%) were white, 43 (28.5%) were Black/African American, and 71 (47.0%) had OSA (defined as apnea hypopnea index [AHI] > 5%). Among mean PSG-measured sleep parameters, Sleep Efficiency was 81.2% (SD 11.81%), Total Sleep Time (TST) 373.4 (76.06) minutes, Sleep Latency 12.4 (22.34) minutes, and Wake Time 72.6 (45.4) minutes. Sensitivity, specificity, and accuracy of actigraphy compared to PSG were low: 0.646, 0.220, and 0.500, respectively. Among participants with OSA, sensitivity was slightly lower (0.634), and specificity slightly higher (0.234), with similar accuracy (0.500). The largest difference among measures was in TST in both OSA and non-OSA participants: actigraphy overestimated TST by 26.23 (100.13) minutes overall, and 16.47 (102.47) minutes in OSA participants. Lin's CCC was low (< 0.9) for all actigraphy-measured parameters compared to PSG, regardless of OSA status. In addition, RMAR slopes (≠ 1) suggest proportional bias across all measures, while RMAR intercepts (≠ 0) for all measures show fixed bias, regardless of participant OSA status.
Conclusion: In this study population, there was low accuracy and concordance of actigraphy measured sleep parameters compared to PSG, with both proportional and fixed bias across measures, regardless of OSA status. This suggests that OSA status is not a factor in PSG/Actigraphy concordance.

APPLICATION OF REDUCED TIDAL VOLUME INDEX AND VENTILATION LOSS DERIVED FROM EIT FOR DIAGNOSING AND ASSESSING SEVERITY OF OSA

Sung Wan Kim[1], Jeon Gang Doo[2]

[1] Kyung Hee Medical Center, Kyung Hee University, [2] Nowon Eulji Medical Center, Eulji University

Introduction: Overnight polysomnography (PSG) is an old standard study used to diagnose obstructive sleep apnea (OSA), and apnea- hypopnea index (AHI) is usually used to define the severity of OSA. However, the severity of OSA may be too complex to be accurately defined solely based on the AHI. We aimed to explore new parameters (reduced tidal volume index and ventilation loss) for measuring respiratory events during sleep and assessing the individual severity of OSA using electrical impedance tomography (EIT) technology.
Methods: PSG and EIT were simultaneously performed on 30 adult male subjects with snoring and sleep apnea symptoms. The outcome parameters of PSG were AHI, oxygen desaturation index (ODI), and mean and lowest SpO2. The outcome parameters of EIT were the detection of low tidal volume (LTV) or very low tidal volume (VLTV), reduced tidal volume index (RTI), and ventilation loss (VL). LTV and VLTV were defined as respiratory events measured by EIT, characterized by abnormally reduced tidal volume during sleep. The RTI was defined as the average number of LTV and VLTV events per hour of sleep. The VL was calculated as the percentage of ventilation depleted by all detected LTV and VLTV events. The agreement of detected respiratory events between PSG and EIT was compared. And the relationship between AHI and RTI was evaluated. Finally, the correlation between the outcome parameters of PSG and EIT was assessed.
Results: Respiratory events detected between PSG and EIT in the Bland-Altman plot were in good agreement. Linear regression analysis demonstrated a statistically significant correlation between AHI and RTI ($R2 = 0.798$; $p < 0.001$). RTI showed a statistically significant correlation with AHI ($r = 0.893$), ODI ($r=0.894$), lowest SpO2 ($r = -0.815$), and mean SpO2 ($r = -0.711$) (all $p< 0.001$). VL varied considerably between subjects. However, VL also showed a significant statistical correlation with AHI ($r=0.819$), ODI ($r=0.830$), lowest SpO2 ($r = -0.720$), and mean SpO2 ($r = -0.618$) (all $p< 0.001$).
Conclusion: The combination of RTI and VL in EIT might be a promising tool for supplementing PSG limitations in diagnosing OSA and understanding its individual severity.

A MACHINE LEARNING APPROACH FOR TARGETED OBSTRUCTIVE SLEEP APNEA CASE-FINDING IN OUTPATIENT CLINICS

Zachary Oatley[1]

[1] Northeast Ohio Medical School

Introduction: OSA is a disease characterized by repeated apnea, oxygen desaturation, and fragmented sleep, with an estimated population prevalence of 12%. Most OSA patients are undiagnosed, contributing to a substantial health and economic burden; however, no standardized screening protocol has been recommended. This study proposes a novel two-step, machine learning-enabled approach to OSA case-finding in outpatient settings.
Methods: Two models were developed using data from 5,761 patients in the Sleep Heart Health Study. The first step leverages routinely available electronic health record (EHR) data, enabling automatic risk score generation in the EHR user interface. High-risk patients are flagged for further evaluation to identify unrecognized symptoms and refine the risk prediction. This process enables targeted use of clinical resources while identifying patients at elevated OSA risk. Available features included demographic information, hypertension incidence, body size measurements, and engineered indices. OSA was defined using AHI>15, measured by 4% oxygen desaturation with or without arousal. Feature selection was conducted using lasso regularization and recursive feature elimination with repeated 5-fold cross-validation, retaining features selected by both models. The final model employed XGBoost with monotonic constraints and shapely additive values for interpretability. Hyperparameters were tuned using Bayesian optimization with repeated cross-validation at each iteration before testing on a hold-out dataset to measure model performance.
Results: The first and second steps of the approach achieved AUROC scores of 0.721 and 0.793, respectively. The performance was analyzed sequentially to simulate a low-cost case-finding workflow. Using only EHR data, 40.2% of patients had significant OSA risk (>12%). Following sleep-specific data collection, 72.7% of flagged patients had a predicted OSA risk of >25%. At these risk thresholds, the combined approach yielded a positive predictive value of 39.8%, a sensitivity of 68.7%, and a specificity of 77.8%, successfully identifying over two-thirds of OSA cases.
Conclusion: This study demonstrates the feasibility of a machine learning approach for efficient and targeted OSA case-finding in outpatient settings. Viewing personalized risk scores, clinicians can decide whether to pursue further action according to clinical judgment, care priorities, and time constraints.
Support (if any): Data used was from the Sleep Heart Health Study, supported by NHLBI funding grants.

A COMPARISON OF HOME SLEEP APNEA TESTING ORDERED BY PRIMARY CARE PROVIDERS AND SLEEP SPECIALISTS

Loretta Colvin[1]

[1] SSM Health - St. Louis

Introduction: United States (U.S.) sleep centers face workforce shortages, declining reimbursement, and growth in value-based care payment models. Thus, alternative options for obstructive sleep apnea (OSA) care that reduce cost and better utilize resources are needed. Expanded primary care provider (PCP) roles in OSA care lower costs and achieve similar clinical outcomes to specialists, but are less common in the U.S. This study compared performance metrics and OSA diagnosis for PCP and specialists utilizing home sleep apnea testing (HSAT).
Methods: A retrospective cohort study compared PCP referrals for specialist consultation or HSAT; Group 1 was referred for consultation with subsequent HSAT ordered by the specialist

while Group 2 had PCP-ordered HSAT before specialty clinic consultation. Full pathway completion included encounters for both clinic and HSAT. Electronic health record data were extracted and analyzed using Pearson χ^2 for completion and proportion diagnosed or Mann Whitney U independent samples test for wait times.
Results: Of the 1,535 referrals placed, completion rates for Groups 1 and 2 were similar for first encounter (36% vs. 42%, p =.10) and second encounter (23% vs. 22%, p =.95), respectively. For the 565 completed first encounters, referral rates were similar for the second encounter for Groups 1 and 2 (78% vs. 79%, p =.77). Diagnosis rates were lower in Group 1 compared to Group 2 (21% vs. 37%, p <.001). Full pathway was completed by 347, median days to pathway completion were longer for Group 1 compared to Group 2 (84 [IQR: 50-99] vs. 40 [27-56], p <.001). Respective OSA diagnosis rates were similar (94% vs. 100%, p =.10). For these groups (n=347), demographic and disease characteristics did not differ, including age 45 years [27-38], 55% male, BMI 32 kg/m2, respiratory event index (3% criteria) 21/hr [10-39], and nadir oxygen saturation 78% [74-82%], with all p >.05.
Conclusion: Similar or better diagnosis rates and performance metrics were achieved by HSAT ordered by PCP compared to sleep specialists for uncomplicated OSA. Expanding PCP roles in ordering HSAT prior to referral for specialist consultation appears to be a feasible alternative to specialist consult prior to HSAT.

A REMOTE-PATIENT-MONITORING (RPM) SYSTEM USING FDA CLEARED WEARABLE TECHNOLOGY FOR OSA MANAGEMENT OVERCOMES DEFICIENCIES FOUND IN PAP AHI RPM DATA

Jerald Simmons[1], Maggie Lavender[1], Stormy Lopez[1], Sam Sadeghian[2]

[1] Comprehensive Sleep Medicine Associates, [2] REST Technologies, Inc.

Introduction: Advancements in OSA treatment monitoring now include nightly Remote Patient Monitoring (RPM), typically from PAP machines (PAP-RPM). Recognizing PAP-RPM's limitations, we present practical examples of a superior approach implemented at CSMA using the REST-Tracker RPM (RT-RPM) system for capturing nightly OSA-metrics.
Methods: The REST-Tracker employs a Ring-Oximeter with Cardiopulmonary Coupling (CPC) analysis through SleepImage™, an FDA-cleared cloud-computing system. It provides OSA metrics at two sensitivity levels (sAHI_3% and sAHI_4%) with longitudinal viewing and automated data surveillance for workflow optimization.
Results: From about 300 RT-RPM patients with OSA, managed by a variety of treatment methods, ranging from PAP, Inspire-HGNS, Oral-Appliance-Therapy to orthodontics, we present three cases, all on PAP in whom PAP data, available from ResMed Airview platform, demonstrating RT-RPM's ability to capture treatment deficiencies not observed by PAP-RPM: Case 1: A 74-year-old male with OSA, using Inspire and PAP therapy, showed increased sAHI on RT-RPM (sAHI_3% 14.7/SD 5.7, sAHI_4% 8.4/SD 4.1) despite normal PAP-RPM data (pAHI 3.7/SD 2). Investigation revealed correlation with intermittent alcohol use, detected only through RT-RPM. Case 2: A 76-year-old female's RT-RPM detected elevated sAHI (sAHI_3% 27.5/SD 12.9, sAHI_4% 16.4/SD 7.8) while PAP-RPM remained normal (pAHI 3.4/SD 1.8). Investigation revealed high-altitude vacation effects, leading to PAP pressure adjustments and oxygen supplementation. Case 3: A 78-year-old female with severe OSA on combination therapy showed normal PAP-RPM data (pAHI 0.8/SD 1.4) but elevated RT-RPM readings (sAHI_3% 26.2/SD 6.7, sAHI_4% 15.9/SD 5.9), matching persistent symptoms and necessitating treatment modifications.
Conclusion: These cases demonstrate PAP data's inadequacy in identifying intermittent OSA exacerbations. Our group has demonstrated a clear distinction between the pAHI and sAHI sensitivities, reported in a separate abstract. Besides the significantly lower sensitivity identifying residual OSA by the pAHI, PAP-RPM is limited to only provide OSA metrics while the patient is on therapy, were as RT-RPM provides metrics regardless of therapy type or usage, giving a more significant indication of morbidity impact from OSA status. We conclude that relying solely on PAP data for OSA patient monitoring is not sufficient to be deemed a standard of care goal since better methods are now becoming available with advanced wearable technologies.

UNMASKING OBSTRUCTIVE SLEEP APNEA: ESTIMATED PREVALENCE AND IMPACT IN THE UNITED STATES

Ibrahim Sönmez[1], Alexandre Vo Dupuy[1], Kristina Yu[2], John Cronin[2], John Yee[2], Ali Azarbarzin[3]

[1] Clarivate Analytics, [2] Apnimed Inc., [3] Brigham and Women's Hospital and Harvard Medical School

Introduction: Obstructive sleep apnea (OSA) is a serious, chronic sleep-related breathing disease, characterized by repeated upper airway obstructions during sleep, leading to episodes of disrupted breathing, sleep fragmentation, and reduced oxygen saturation. Adjusting for obesity as a major risk factor, we aimed to estimate the up-to-date prevalence of OSA in United States (US) adults in 2024.
Methods: We conducted a literature-based analysis to identify studies of OSA prevalence in the general or community adult population, using the AHI4 criteria (all apneas plus hypopneas with ≥ 4% oxygen desaturation) from polysomnography or home sleep apnea test. OSA was defined as having an AHI4 ≥ 5 events/hour. For the total prevalence, we estimated age- and gender-specific rates based on eligible studies and extrapolated missing data (e.g., age-group) from studies where data were available. The base-year estimation for 2004 was calculated by averaging age-specific total OSA prevalence data from these studies, accounting for methodological and population differences, to establish a foundational baseline for further adjustments. We calculated the obesity population attributable fraction (PAF) which was applied to base year estimates to project OSA prevalence in year 2024 adjusting for obesity and extrapolated to the US Census population data. The AHI distribution of mild (5-< 15), moderate (15-< 30) and severe (>30 events/h) were also estimated.
Results: Total of 80.6 million individuals were estimated to be living with OSA in the US in 2024, of whom 47,623,848 (59%) were males and 32,967,117 (41%) females. This translates to

32.2% overall prevalence in the US among adults aged 20 years and older, with 39% males and 25.8% females, adjusting for obesity. The AHI severity distribution was estimated to be 61% mild, 24% moderate, and 15% severe.
Conclusion: Our findings indicate that OSA is highly prevalent among US adults. Despite its substantial prevalence, OSA remains largely undiagnosed, highlighting the urgent need for improved screening and diagnosis as well as greater awareness about the chronic and serious complications of untreated OSA.

ESTIMATING UNDERDIAGNOSIS OF OBSTRUCTIVE SLEEP APNEA IN MEDICARE CLAIMS DATA

Zachary Marcum[1], Dominic Nunag[1], Saif Rathore[2], Matthew Davis[1]
[1] Medicus Economics, [2] Sandbar Life Sciences

Introduction: Claims-based measurement often underestimates the prevalence of chronic diseases, such as obstructive sleep apnea (OSA), due to the underreporting of diagnosis codes on billing records. Despite this limitation, claims data remain a valuable source for understanding disease burden due to their large sample sizes and patient-level, longitudinal follow-up capabilities. To address the underestimation of chronic disease prevalence in claims data, a mathematical framework can be applied to leverage the longitudinal diagnosis information and adjust the estimates for undiagnosed cases.
Methods: We applied the method described by Stocking et al (2023), which identifies latent individuals—those likely to have the condition but not yet diagnosed—to estimate the corrected prevalence of OSA in 2023. This study used a 100% sample of Medicare fee-for-service (FFS) beneficiaries ≥65 years who were continuously enrolled between January 1, 2018, and December 31, 2023 (1-year baseline and 5 years of follow-up). OSA was defined as ≥1 inpatient claim or ≥2 outpatient claims with relevant diagnosis codes in any position (ICD-10: G47.30, G47.33, or G47.39). Using 2019 as the first follow-up year and assuming patients first diagnosed with OSA in 2020 or later also had the condition in 2019, we calculated the ratio of latent to diagnosed prevalence for 2019. This ratio was then applied to a separate cohort of beneficiaries continuously enrolled in 2023 to estimate the corrected prevalence of OSA for that year.
Results: The 5-year cohort included 14,939,076 beneficiaries, of whom 2,371,642 were identified as having OSA between 2019 and 2023, with approximately 49% initially diagnosed in 2019. Applying the ratio of latent to diagnosed prevalence to the 2023 cohort (N=22,121,159), the prevalence estimate of OSA increased from a diagnosed prevalence of 9.2% to a corrected prevalence of 18.9%.
Conclusion: By using a cohort of Medicare FFS beneficiaries and applying a mathematical approach to correct for underdiagnosis, the corrected prevalence of OSA in 2023 (18.9%) was estimated to be approximately 2.1-times higher than the diagnosed prevalence derived from cross-sectional claims data alone. This corrected epidemiologic estimate can help decision-makers better assess the budget impact of emerging therapeutics for OSA.

PREVALENCE AND UNMET NEED OF OBSTRUCTIVE SLEEP APNEA IN THE UNITED STATES

Nathaniel Watson[1], Kristina Yu[2], David Campbell[3], Lisa Bloudek[3], John Yee[2], John Cronin[2], Ana Sanchez Azofra[2], Nikolina Boskovic[3]
[1] Department of Neurology, University of Washington School of Medicine, [2] Apnimed Inc., [3] Curta Inc.

Introduction: Obstructive sleep apnea (OSA) is a serious, chronic sleep-related breathing disease characterized by repeated upper airway obstructions during sleep, leading to disrupted breathing, sleep fragmentation, impaired sleep quality, and reduced oxygenation. Despite growing awareness, OSA remains underdiagnosed and undertreated, especially in mild to moderate cases and among non-obese individuals with the disease. Positive airway pressure (PAP) is the standard treatment, but its use is limited by patient satisfaction, convenience, comfort, and OSA underdiagnosis.
Methods: An epidemiologic model was developed to estimate the number of adults aged ≥18 with OSA in the United States with a current unmet need for OSA treatment due to intolerance or refusal of PAP, or lack of PAP treatment being offered. The prevalence of OSA was calculated from U.S. Census and published age, sex, and BMI-based prevalence rates from the Wisconsin Sleep Cohort Study (AASM 2007 criteria) adjusted to AASM 2012 scoring criteria and a published model predicting change in OSA incidence up to year 2025. Diagnosis rate was obtained from the 2016 AASM study on the clinical and economic burden of OSA in the U.S which utilized data from the Wisconsin Sleep Cohort Study. Treatment rates were obtained from analyses of real-world data from commercial, Medicare and Medicaid medical and pharmacy claims, and clinical practice settings.
Results: With prevalence estimates ranging from 24% to 33%, up to ~85.6M adults in the U.S. have OSA, of whom 68.5M (80%) are undiagnosed. Among the 1 in 5 individuals with OSA who are diagnosed (~17.1M), up to 4.5M (26%) remain untreated. Additionally, of those who initiate PAP therapy, more than half (63%; ~10.8M) discontinue treatment or fail to meet Medicare treatment adherence criteria. Overall, among the 20% of patients who are diagnosed, between 9M and 12.5M adults in the U.S. may not be adequately managed with PAP.
Conclusion: OSA in the U.S. poses a substantial challenge, with millions of diagnosed OSA patients potentially not receiving adequate treatment. Additionally, a significant portion of OSA cases remain undiagnosed. The variability in published OSA prevalence rates underscores the need for more accurate estimates to better understand and address the true unmet need.

OBESITY HYPOVENTILATION SYNDROME IN A HISPANIC POPULATION: NEED TO ACT

William Rodriguez[1], Jose Rodriguez Velez[1], Lissette Jimenez Davila[2]

[1] VACHS, [2] VA Caribbean Health Care System

Introduction: Obesity hypoventilation syndrome (OHS), is characterized by obesity, sleep-disordered breathing such as obstructive sleep apnea (OSA), and chronic daytime hypercapnia. Its prevalence is increasing in parallel with obesity rates, yet epidemiological data on OHS remain limited, particularly among minority groups like Latinos, who are disproportionately affected by obesity. This study aims to address the gap in characterizing obese patients with and without OHS admitted to the Medical Intensive Care Unit (MICU) at the VA Caribbean Health Care System (VACHS).
Methods: A retrospective record review of electronic health records from the VACHS which included obese patients admitted to the MICU between January 1, 2019, and December 31, 2022 was done. Demographics, body mass index (BMI), diagnosis of OHS, comorbidities, and other health parameters was collected.. Quantitative data was analyzed for central tendency, dispersion, and association, while qualitative data was assessed for frequency distribution. The aim was to characterize epidemiological differences between patients with and without OHS in order to address future healthcare strategies.
Results: 378 obese patients admitted to the MICU were evaluated. 15 met the criteria for OHS, approximately 4% of the total sample. None of these patients had been previously diagnosed with OHS, highlighting a critical gap in clinical awareness and diagnosis. This underdiagnosis is particularly concerning given the high mortality rate of 73.3% observed in the OHS group. The study also identified a trend toward non-compliance with CPAP therapy, which, combined with changes in pCO2 levels from baseline to acute settings, suggests that improved adherence to CPAP could potentially enhance patient outcomes.
Conclusion: This study underscores the critical need for increased awareness and early diagnosis of OHS in the ICU setting of this predominant Hispanic population. The high mortality rate among these patients suggests that OHS is a significant contributor to poor outcomes, potentially exacerbated by non-compliance with CPAP therapy. Although the study did not find statistically significant differences in pCO2 levels upon admission, the observed trends warrant further investigation. Future research should focus on larger sample sizes and explore strategies to improve diagnosis and treatment adherence, potentially reducing mortality and improving the quality of care in patients with OHS.

DEMOGRAPHIC, CLINICAL, AND TREATMENT CHARACTERISTICS IN A LARGE COHORT OF PATIENTS EVALUATED FOR SLEEP APNEA

Karolina Perez[1], Sabrina Seifert[1], Misty Shah[2], Imran Patel[2], Salma Patel[3]

[1] University of Arizona COM Tucson, [2] University of Arizona, [3] The University of Arizona

Introduction: Sleep apnea is a sleep-related breathing disorder characterized by repeated interruptions in breathing, encompassing two main types: obstructive sleep apnea (OSA), caused by airway obstruction, and central sleep apnea (CSA), resulting from diminished respiratory effort. Sleep apnea is associated with significant health risks, including cardiovascular disease, metabolic dysfunction, and reduced quality of life. Polysomnography (PSG) is the diagnostic gold standard, with positive airway pressure (PAP) therapy as the primary treatment. This study evaluates the demographic, clinical, and treatment characteristics of patients assessed for sleep apnea in a large cohort.
Methods: A retrospective chart review was conducted for patients referred for sleep studies for evaluation of sleep apnea from November 2020 to March 2024 at an academic medical center. Diagnoses were determined using PSG or home sleep apnea testing (HSAT) and categorized as OSA, CSA, a combination of OSA and CSA, or no sleep apnea. Heart failure comorbidities were identified through transthoracic echocardiograms (TTE) and medical records.
Results: Of 1,103 patients evaluated (mean age: 54 ± 16 years; mean BMI: 34.2; 49% male; 61% Caucasian), 76% were diagnosed with OSA, 4% with combined OSA and CSA, and 0.7% with CSA alone. Nineteen percent had no sleep apnea. The mean apnea-hypopnea index (AHI) for patients with available PSG results was 43.9 ± 33.9, indicating severe disease. PAP therapy was prescribed to 69% of patients, including 49% on CPAP, 18% on BiPAP, 1.5% on adaptive servo-ventilation (ASV), and 0.5% on oral appliances. Heart failure was observed in 13.3% of patients, with 9.7% presenting with heart failure with preserved ejection fraction (HFpEF) and 3.6% with heart failure with reduced ejection fraction (HFrEF).
Conclusion: This study demonstrates the high prevalence of OSA and its significant association with comorbidities, such as heart failure. These findings highlight the need for early diagnosis and individualized treatment strategies to improve patient outcomes and mitigate the broader health impacts of sleep apnea.

RACIAL AND ETHNIC DISPARITIES IN THE DIAGNOSIS AND TREATMENT OF OBSTRUCTIVE SLEEP APNEA IN MIDDLE-AGED AND OLDER ADULTS

Marc Kaizi-Lutu[1], Chunyu Liu[1], Emerson Wickwire[2], Jennifer Albrecht[2], Atul Malhotra[3], Alden Gross[4], Halima Amjad[5], Chien-Yu Tseng[6], Xiaowen Chen[4], Vishaldeep Sekhon[4], Marcela Blinka[4], Adam Spira[4], Christopher Kaufmann[6]

[1] Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, [2] University of Maryland Baltimore, [3] University of California, San Diego, [4] Johns Hopkins Bloomberg School of Public Health, [5] Johns Hopkins University School of Medicine, [6] University of Florida

Introduction: Racial and ethnic disparities exist in the prevalence of obstructive sleep apnea (OSA); however, research on racial and ethnic differences in the diagnosis and treatment of OSA in older populations is limited. We examined whether the likelihood of being undiagnosed or untreated for OSA differed by race/ethnicity among middle-aged and older adults with probable OSA or self-reported OSA diagnosis.

Methods: Data came from the 2016 wave of the Health and Retirement Study (HRS), a nationally representative study of middle-aged and older adults in the United States. We categorized participants as: "probable OSA" based on a modified STOP-Bang measure; self-reported diagnosis of OSA; or self-reported OSA treatment (i.e., CPAP, oral appliance, surgery). We further classified participants as probable-undiagnosed OSA, diagnosed-untreated OSA, or diagnosed-treated OSA. Participants without a self-reported diagnosis who had a total score of ≥4 on the modified STOP-Bang measure or who had a score ≥3 and endorsed 2 items from the STOP portion of the scale were considered probable-undiagnosed OSA.
Results: Among 5,007 participants (mean 63.5 ± 9.16 years; 46.2% female), 39% of non-Hispanic White (NHW), 53% of non-Hispanic Black (NHB), and 66% of Hispanic participants had undiagnosed OSA. After adjustment for factors related to demographics, health, and insurance, compared to NHWs, NHBs had 42% higher odds of probable-undiagnosed OSA (AOR=1.42, 95% CI [1.15, 1.74], p< 0.001) and Hispanics had 95% higher odds of probable-undiagnosed OSA (AOR=1.95, 95% CI [1.50, 2.54], p< 0.001). Among those reporting OSA diagnosis, compared to NHWs, Hispanic participants had 50% higher odds of being untreated (AOR=1.50, 95% CI [1.02, 2.19], p=0.038); odds of treatment did not differ between NHBs and NHWs.
Conclusion: Among middle-aged and older adults, Hispanics are markedly more likely to be undiagnosed than NHWs and NHBs. Moreover, when diagnosed, Hispanics are the most likely to be untreated. If replicated, these findings indicate a critical sleep health disparity.

SLEEP APNEA RISK IN PATIENTS WITH PULMONARY HYPERTENSION AND INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SCLERODERMA

Elizabeth Han[1], Aarti Grover[1], Harrison Farber[1]
[1] Tufts Medical Center

Introduction: Scleroderma (SSc) is a rare, chronic, multi-system connective tissue disorder characterized by excessive collagen deposition in the skin and internal organs. SSc is associated with interstitial lung disease (SSc-ILD) and pulmonary hypertension (SSc-PH). SSc, ILD, and PH have each been individually associated with an increased risk of obstructive sleep apnea (OSA). However, the relationships between SSc-ILD, SSc-PH, and SSc-ILD-PH and sleep apnea remain unclear. SSc is also associated with malnutrition and a low average BMI, decreasing the presence of typical sleep apnea symptoms. The objectives of this study are to better characterize the risk of sleep apnea in this cohort and to identify an effective screening tool.
Methods: We retrospectively reviewed records of 78 patients seen in the Pulmonary Clinic at Tufts Medical Center from May 1, 2020 through February 1, 2024 for scleroderma. We used right heart catheterizations (RHC), pulmonary function tests, computed tomography, and sleep studies from their electronic medical records.
Results: Of 78 patients with SSc (83.3% female), 22 (28.2%) had SSc-PH, 13 (16.7%) had SSc-ILD, and 43 (55.5%) had SSc-PH-ILD. The diagnosis of PH was made by RHC for all patients. Of the 78 patients, 18 (23.1%) were tested for OSA and 14 (77.8%) had positive sleep studies. There was no statistically significant difference in the rate of positive sleep studies among the 3 groups. Of the 78 patients, 27 (34.6%) reported chronic insomnia. Patients with SSc-PH-ILD had statistically higher rates of chronic insomnia compared to patients with SSc-PH (p = 0.021). 10 of the 27 patients who reported chronic insomnia completed sleep studies – all 10 (100%) tested positive for sleep apnea.
Conclusion: Although only a fifth of patients were tested for OSA, the majority had positive sleep tests. Among those with chronic insomnia, all who were tested had positive sleep studies. Patients with SSc-ILD-PH had concomitant chronic insomnia more often than those with SSc-PH alone, bringing into question the impact of having all three disease processes simultaneously. Future prospective studies are needed to examine the relationship of SSc with sleep apnea and to understand chronic insomnia as a screening tool for patients with SSc.

RISK FACTORS FOR SLEEP DISORDERED BREATHING AMONG HISPANICS AND NON-HISPANICS – A RETROSPECTIVE STUDY

Masood Azhar[1], Wendy Cardenas[1], Anshul Saxena[1], Md Ahmed[1], John Rankin[1], Harneet Walia[1]
[1] Baptist Health South Florida, Inc

Introduction: Sleep Disordered Breathing (SDB) is highly prevalent in the Hispanic population. However, limited research exists on the risk factors associated with SDB. This study examines the risk factors among SDB patients in Hispanic and non-Hispanic (NH) populations.
Methods: Retrospective data from Baptist Health's sleep study database (September 2020–September 2022) were analyzed. Adult patients diagnosed with SDB via polysomnogram, split-night polysomnogram, or home sleep apnea testing were included. SDB was classified based on apnea-hypopnea index (AHI), as negative/mild (AHI < 15) or moderate/severe (AHI ≥ 15). AHI category, age, sex, BMI, ethnicity, average and minimum blood oxygen saturation (SpO2), and secondary diagnoses were compared between Hispanic and NH patients. Multivariate logistic regression analyses were used to calculate the odds ratio (OR) for moderate/severe SDB.
Results: Of 9,111 patients, 5,816 (63.8%) were Hispanic, and 3,295 (36.2%) were NH. Males comprised 53% of Hispanic and 57.4% of NH (P< 0.001). Obesity was observed in 59.4% of Hispanic vs. 57.4% of NH (P< 0.001). Among Hispanic patients, 47.8% had moderate/severe SDB vs. 45.6% NH patients (P=0.04). Median AHI was 14.2 among Hispanic and 13.5 among NH patients (P=0.01). Similarly, average SpO2 was 94.1% in Hispanic vs. 93.9% in NH patients (P=0.03). Overall, Hispanic ethnicity (OR 1.20 [CI 1.09–1.31]), male sex (OR 2.07 [CI 1.89–2.28]), obesity (OR 3.81 [CI 3.24–4.49]), hypertension (OR 1.22 [CI 1.10–1.36]), and respiratory illnesses (OR 1.28 [CI 1.15–1.42]) were associated with moderate/severe SBD. Among Hispanic patients, male sex (OR 2.00 [CI 1.78–2.25]), obesity (OR 4.70 [CI 3.78–5.84]), hypertension (OR 1.22 [CI 1.06–1.39]), and respiratory illnesses (OR 1.35 [CI 1.18–1.54]) were the key risk factors for moderate/severe SDB, whereas in NH patients, male sex (OR 2.39 [CI 2.04–2.80]), obesity (OR 2.94 [CI 2.29–3.77]), and diabetes (OR 1.29 [CI 1.06–1.58]) were significant risk factors for moderate/severe SDB.

Conclusion: Overall, Hispanic ethnicity, male sex, obesity, and hypertension were significantly associated with moderate/severe SDB category. In addition, respiratory illness was a risk factor among Hispanic patients, while diabetes was more significant in NH patients.

DIFFERENCES IN CLINICAL PRESENTATION OF OBSTRUCTIVE SLEEP APNEA IN NATIVE HAWAIIAN AND PACIFIC ISLANDER PATIENTS

Nicholas Anderson[1], Tamlyn Sasaki[2], Cierra Nakamura[3], Julia Jahansooz[3], Enrique Carrazana[4], Kore Liow[1], Meliza Roman[5], Hyeong Jun Ahn[3]

[1] Sleep and Insomnia Center, Hawaii Pacific Neuroscience, [2] University of Hawaii John A. Burns School of Medicine, [3] University of Hawaii John A Burns School of Medicine, [4] John A. Burns School of Medicine, University of Hawaii, [5] JABSOM Biostatistics Core Facility, University of Hawaii John A Burns School of Medicine

Introduction: Obstructive sleep apnea (OSA) is the most common sleep-related breathing disorder in the U.S. Disparities in OSA severity have been identified in minority groups, but little is known about its impact on Native Hawaiian and Pacific Islander (NHPI) populations. NHPIs are disproportionately affected by obesity, a significant risk factor for OSA morbidity. However, no studies have compared OSA clinical presentations in NHPIs to other racial groups. This study evaluates OSA severity in NHPIs relative to Whites in Hawaii, aiming to better understand its effects on this understudied population.
Methods: This study was conducted at a single-center outpatient neurology clinic and included White or NHPI patients, based on self-reported race, diagnosed with OSA between January 1st, 2013, and June 1st, 2023. Pearson's Chi-squared and Fisher's exact tests were used to identify associations between apnea-hypopnea index (AHI), race, and clinical characteristics such as body mass index and Mallampati score. Logistic regression models were utilized to estimate associations between OSA severity and race.
Results: The study included 91 NHPI and 129 White OSA patients. Among NHPIs, 78.0% were obese compared to 48.8% of Whites ($p< 0.001$). Moderate or severe OSA was present in 72.5% of NHPIs compared to 52.7% of Whites ($p< 0.001$). No significant differences in Mallampati scores or retrognathia were found. After adjusting for BMI, STOP-BANG scores, neck circumference, and history of MI, NHPIs were 3 times more likely to have moderate to severe OSA than Whites (adjusted OR = 3.01 [95% CI: 1.31, 7.23]).
Conclusion: This study demonstrated increased severity of OSA in NHPIs compared to Whites. Although obesity was more prevalent among NHPIs and likely contributed to OSA severity, differences persisted after adjusting for BMI, suggesting other contributing variables. Socioeconomic barriers, including limited healthcare access, low CPAP adherence, and delayed diagnoses, are potential contributors to OSA severity in minority groups. Future studies should explore late detection, management gaps, and craniofacial differences in NHPIs. This is the first study to compare the severity of OSA in NHPIs with that of other racial groups, highlighting the need for more inclusivity of this population in sleep medicine research to improve clinical outcomes.

PREVALENCE AND RISK FACTORS OF SLEEP-DISORDERED BREATHING IN THE SECOND TRIMESTER OF PREGNANCY

Valentina Poletti[1], Sandra Hackethal[2], Silvia Riccardi[2], Corrado Garbazza[2], Mauro Manconi[2]

[1] Università Cattolica del Sacro Cuore, [2] Neurocenter of Southern Switzerland, Regional Hospital of Lugano

Introduction: Sleep-disordered breathing (SDB) encompasses abnormal respiratory patterns during sleep which can negatively affect maternal and fetal health. While late pregnancy is known to carry a heightened risk for SDB, less research focuses on the second trimester, a critical period for maternal physiological changes. This study aims to estimate the prevalence of SDB in the second trimester and explore their relationship with demographic and sleep-related factors.
Methods: This study is a secondary analysis of the LifeON Study, which recruited pregnant women aged 18-55. A total of 353 women underwent home-based polysomnography at 23-25 weeks of gestation and completed sleep assessments (ESS, ISI and PSQI). Women were categorized with SDB if their respiratory disturbance index (RDI) was ≥5, and OSA was defined as RDI ≥5 plus ESS ≥10.
Results: Fifteen women (4.2%) were diagnosed with SDB (mean AHI = 8.61 ± 3.44), mostly mild cases except for one moderate; of these, 4 (1.1%) were classified as OSA. Women with SDB had higher BMI (28.39 ± 3.15 vs. 24.49 ± 3.67, $p < 0.001$) and neck circumference (34.46 ± 1.81 cm vs. 33.18 ± 4.19 cm, $p = 0.006$) than those without. No significant differences emerged in subjective sleep scores. ODI 3% correlated with BMI ($\rho = 0.364$, $p < 0.01$) and neck circumference ($\rho = 0.159$, $p < 0.01$); similar correlations were observed for AHI. BMI predicted ODI 3% ($\beta = 0.275$, $p < 0.001$), while neck ($\beta = 0.151$, $p = 0.01$) and abdominal circumference ($\beta = 0.27$, $p < 0.001$) predicted AHI. Furthermore, supine AHI was higher compared to the non-supine position and greater in women who spent more time in the supine position.
Conclusion: Although lower than in late pregnancy, the prevalence of SDB in the second trimester highlights the importance of identifying pregnant women at risk, particularly those with higher BMI or neck circumference. These anthropometric measures, along with the supine position, emerged as significant predictors and could serve as simple, non-invasive tools for early screening. Timely identification and management of SDB during pregnancy may help reduce maternal and fetal complications, emphasizing the need for routine evaluation in clinical practice.

REAL-WORLD INCREMENTAL ECONOMIC BURDEN OF FATIGUE AMONG PATIENTS WITH OBSTRUCTIVE SLEEP APNEA IN THE MEDICARE FEE-FOR-SERVICE POPULATION

Kristina Yu[1], Nathaniel Watson[2], Brian Cade[3], John Yee[1], Bret Zeldow[4], Ronald Farkas[1], John Cronin[1], Junhui Zhao[4], Tracy Yee[4], Anran Tan[4], Susan Redline[3]

[1] Apnimed Inc., [2] Department of Neurology, University of Washington School of Medicine, [3] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [4] Genesis Research Inc.

Introduction: Fatigue, distinct from sleepiness, is one of the most common obstructive sleep apnea (OSA) symptoms, and is associated with diminished quality of life, poor psychological and physical functioning and increased risk of occupational and motor vehicle accidents. The aim of this study was to estimate the incremental healthcare cost burden of fatigue among patients with OSA in the Medicare fee-for-service (FFS) population.
Methods: Retrospective observational claims analysis was conducted comparing newly diagnosed OSA patients with fatigue to matched OSA patients without fatigue. Medical and pharmacy claims from the 2017-2022 Medicare FFS database were used to identify incident cases of fatigue among newly diagnosed OSA patients who met the following criteria: ≥1 inpatient or ≥2 outpatient claims (with ≥7 days apart) with an ICD-10-CM diagnosis code of OSA (G47.33, G47.30, G47.39); ≥1 procedure code for polysomnography or home sleep apnea test in 12 months prior to OSA diagnosis index date; continuous insurance coverage ≥12 months before OSA diagnosis index (baseline period) and ≥12 months after fatigue index date (follow-up period). Fatigue cases had ≥1 claim for fatigue (R53.1, R53.81, R53.82, R53.83) after the OSA diagnosis index date. Controls had no diagnosis of fatigue and were propensity score matched to fatigue cases.
Results: Total of 71,710 newly diagnosed OSA patients met eligibility criteria, of whom ~36% had ≥1 diagnosis claim for fatigue. Mean (SD) age was 72.8 years (5.3), 51% male, and 88% White. After OSA diagnosis, all-cause healthcare costs were significantly higher (all $p< 0.001$) for patients with fatigue vs. matched controls: Per-patient-per-year (PPPY) all-cause hospitalization ($7,721 vs $1,998); outpatient visits ($5,225 vs $3,004); emergency department visits ($882 vs $291); other medical visits ($11,005 vs $5,455); and pharmacy costs ($5,192 vs $3,643). Overall, the PPPY all-cause total costs ($30,025 vs $14,390, $p< 0.001$) in OSA patients with fatigue were significantly higher than those without fatigue.
Conclusion: Fatigue is significantly associated with an increase in all-cause total healthcare costs in newly diagnosed OSA patients as compared with matched patients without fatigue. Addressing fatigue may be useful as part of OSA screening, diagnosis and treatment due to the incremental humanistic and economic burden.

ESTIMATED PREVALENCE OF OSA WITH SLEEPINESS BY OCCUPATIONS AND INDUSTRIES IN ENGLAND: A DESCRIPTIVE STUDY

Ryohei Kinoshita[1], Jennifer Quint[1], Constantinos Kallis[1], Michael Polkey[1]
[1] Imperial College London

Introduction: Sleepiness due to Obstructive sleep apnea (OSA) may cause work-related injuries and low productivity. Because most such individuals are undiagnosed, workplace screening would allow identification and treatment with CPAP to improve both health and productivity. Screening in occupations/industries with a higher prevalence of disease would identify more people with OSA at a lower cost per head. Although prior studies focused on drivers, our previous study (Sleep Advances 2024 18;5(1):zpae069) showed a relatively higher prevalence of OSA in other occupations/industries in England. However, the prevalence of OSA with sleepiness (OSA+S) by occupations/industries remains unknown. This study aimed to estimate the prevalence of OSA+S by occupations and industries in England.
Methods: To estimate OSA+S in the English population aged 40-64, we applied multiple imputation to a dataset that combined the Health Survey for England 2019 dataset (n=21791) and Sleep Heart Health Study dataset (n=5804). The analysis was validated against the Wisconsin Sleep Cohort dataset (n=1123). OSA with sleepiness: AHI≥15 + sleep latency < 8 min or ESS >10. Covariates were: age, sex, ethnicity, BMI, alcohol, smoking, hypertension, diabetes, Standard Occupation Classification (SOC), and Standard Industry Classification (SIC). Separating samples by SOC and SIC, we estimated the pooled prevalence of OSA+S by occupations and industries with 95% CIs. Survey weights were incorporated throughout the analysis.
Results: The overall estimated prevalence of OSA+S in individuals aged 40-64 was 11.9% (95%CI: 10.3%-13.6%). The estimated prevalence by industries and occupations varied widely. Descriptively, relatively higher prevalences were estimated in occupations of Protective Service (14.5%: 4.6%-37.1%), Construction Trades (14.4%: 8.5%-23.3%), Crafts & Printing (13.6%: 6.0%-28.0%), Machine operatives (13.4%: 7.0%-24.1%), and Transport & Drivers (13.3%: 6.5%-25.4%). Among industries, Accommodation & Food (14.5%: 7.0%-27.4%), Agriculture, Mining, Energy, Utilities & Waste (13.6%: 6.7%-25.7%), Transportation & Storage (12.9%: 7.4%-21.6%), Public Services (12.7%: 7.0%-22.1%), and Financial Activities (12.7%: 5.8%-25.4%) showed relatively higher prevalences.
Conclusion: Our data show that is possible to estimate the prevalence of OSA+S, although the confidence intervals were wide, especially in groups with smaller numbers. Relatively higher prevalences were estimated in some safety-sensitive occupations, suggesting that those occupations may be suitable target populations for workplace screening.

A PROSPECTIVE PILOT STUDY OF OBSTRUCTIVE SLEEP APNEA AMONG GREEK AMERICANS IN THE UPPER MIDWEST

Dimitrios Kantas[1], Essa Mohamed[1], Shahid Karim[1], Jingen Li[1], Ian Greenlund[2], Erik StLouis[2], Virend Somers[2]
[1] Mayo Clinic Rochester, [2] Mayo Clinic

Introduction: Obstructive sleep apnea (OSA) has been linked to metabolic syndrome, heart failure, atrial fibrillation, and hypertension. Although ethnic differences related to OSA have been reported, no studies have evaluated the impact of OSA among Greek-Americans.
Methods: This prospective cross-sectional study, in partnership with the Greek-American community, employed a community-based participatory research framework. Individuals who were of Greek descent and ≥18 years of age were recruited. Anthropometric measurements, Mallampati score, BMI, and adiposity (DEXA scan) were determined. All subjects were administered the Epworth Sleepiness Scale (ESS) and underwent home sleep apnea test (WatchPAT ONE), using a desaturation

threshold of 4% as diagnostic. Descriptive statistics were computed to describe the study population and data were analyzed using the student t-test and chi-squared test.
Results: A 76 Greeks, 34 males (44.8%) and 42 females (55.2%), were enrolled in this study with a mean ± SD age and BMI of 42.6±17.5 years (p< 0.01) and 27±6 kg/m2, respectively. A total of 22 (29%; 14 males and 8 females) individuals were diagnosed with OSA, of whom 13 (59.1%) had mild, 5 (22.7%) had moderate and 4 (18.2%) had severe OSA. Subjects with OSA were older (58.8±11.9 vs 36.0±15.1 years, p< 0.01), had higher BMI (32±7 vs 25±4 kg/m2, p< 0.01), larger neck circumference (40±4 vs 35±4 cm, p< 0.01) and higher waist-to-hip ratio (0.94±0.08 vs 0.84±0.07, p< 0.01). Body fat percentage was significantly higher among those with versus without OSA (38.8±9.6 vs 34.0±9.2%; p=0.04) while Mallampati and ESS scores were similar.
Conclusion: This is the first study to assess sleep metrics of Greek-Americans suffering from OSA. Characteristics of those with OSA are similar to other populations. However, the commonly used ESS screening appears to have limited application in this cohort of subjects. Greek-Americans with elevated body fat percentage when associated with concurrent OSA, may be at higher risk of developing cardiometabolic adverse events. Additional studies are required to further elucidate the effect of sleep physiology, cardiometabolic dysfunction and health outcomes.
Support (if any): This work was supported by a grant from Sleep Number Corporation to Mayo Clinic, by WatchPATs provided by Zoll Itamar, and by the National Institutes of Health HL160619.

SOCIAL FACTORS AND DISPARITIES IN OBSTRUCTIVE SLEEP APNEA SELF-REPORTING AND CLINICAL DOCUMENTATION: THE ALL OF US RESEARCH PROGRAM

Soniya Mishra[1], Jess Meyer[1], Carla Keirns[1], Diego Mazzotti[1]
[1] University of Kansas Medical Center

Introduction: Obstructive sleep apnea (OSA) is a prevalent condition, but a significant proportion of cases remain undiagnosed and untreated, likely due to disparities in access to care. Identifying factors contributing to these disparities is fundamental. This study aims to understand social domains that explain disparities between self-reported and clinically diagnosed cases of OSA among participants in the All of Us Research Program.
Methods: We used the All of Us Research Program electronic health records (EHR) data, self-report of sleep apnea ("Have you ever been diagnosed with the following conditions? – Sleep Apnea"), and social determinants of health survey responses. We identified 93 unique questions assessing healthcare access, social connectedness, neighborhood characteristics, and individual socioeconomic factors. Latent class analysis was applied to identify distinct clusters within social domains based on these questions. The associations between social domain clusters and self-reported or EHR-derived OSA were evaluated using logistic regression adjusted for age, sex, race, and ethnicity.
Results: A total of 24,493 adults with available data were included in the analysis (63.7% women, mean [SD] age 54.5 [16.7], 76.1% White, 8.2% Black, 2.8% Asian, 12.9% other). The prevalence of self-reported OSA was 18.2%, while EHR-based diagnoses were reported in 13.2% of participants. Disparities in the odds of self-reporting OSA (OR [95%CI] = 2.3 [2.0-2.7]) and EHR-derived OSA (1.5 [1.3-1.8]) were observed among those with highest burden of healthcare access and quality, as compared to those with lowest. Similar trends were observed among those with overall lower social connectedness and higher community burden (2.2 [2.0-2.6] and 1.8 [1.6-2.1]), and overall higher economic instability (2.1 [1.8-2.4] and 1.6 [1.4-1.9]).
Conclusion: All of Us participants experiencing higher social risk are more likely to self-report a diagnosis of OSA than they are to have documented diagnoses of OSA in the EHR. These findings underscore the influence of social and healthcare access factors on the likelihood of reporting of OSA but having no clinical record of OSA diagnosis and therefore no treatment for this common, high-risk condition.

THE RELATIONSHIP BETWEEN MARITAL STATUS AND OSA IN BLACK/AFRICAN AMERICANS

Nina L'Houtellier[1], Elizabeth Mirabal[2], Matthew Coppello[2], Aisha Severe[2], Sadeaqua Scott[1], April Rogers[3], Yolette Williams[2], Azizi Seixas[4], Girardin Jean-Louis[4]
[1] University of Miami, [2] University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, [3] St. John's University, [4] University of Miami Miller School of Medicine

Introduction: Obstructive sleep apnea (OSA) has become increasingly prevalent since the COVID-19 pandemic, highlighting the risks associated with impaired breathing. Social and interpersonal factors, such as marital status or co-sleeping, may influence health-related outcomes, including severity of OSA symptoms. This study aims to fill that gap by investigating whether marital status influences the frequency of apnea events (oxygen desaturation ≥3% and 4%) in Black/African American (AA) populations.
Methods: Data collected from the MOSAIC and ESSENTIAL studies were used in this analysis. These studies examine sleep in Black/AA populations in South Florida and include baseline surveys, seven days of sleep monitoring using the Sleep Image Ring, and a blood draw. A total of 316 participants were included in the analysis from varying marital statuses: married/cohabitating, separated, widowed, never married, divorced, and single. Oxygen desaturation counts and other sleep parameters were analyzed.
Results: Analyses showed that marital status was significantly associated with sleep parameters. Compared to married participants, separated participants had lower quality sleep (r2 =.02 95% CI: [-17.82, -0.66]), widowed participants had longer total sleep times (r2 =.01, 95% CI: [851.76, 6511.82]) and durations (r2 = <.01, 95% CI: [283.27, 8142.92]), and divorced individuals had more total 3% (r2 =.02, 95% CI: [10.05, 69.03]) and 4% apnea desaturation counts (r2 =.03, 95% CI: [7.81, 52.21]).
Conclusion: Marital status impacts sleep health with separated, widowed, and divorced individuals showing notable differences compared to married/cohabitating participants. The higher apnea-related desaturation events observed in divorced individuals underscore the influence of marital status on OSA severity. These findings emphasize the need to consider social and interpersonal factors in sleep health research and interventions in Black/AA.

TRENDS IN OBSTRUCTIVE SLEEP APNEA DIAGNOSTICS IN BRAZIL

Sofia Furlan[1], Gabriel Cordovil[1], Douglas Silva[1], Vinicius Pafume[1], Fatima Sert-Kuniyoshi[1]

[1] ResMed

Introduction: Obstructive Sleep Apnea (OSA) is a global health concern, with Brazil ranking third worldwide in the number of affected individuals. Despite an estimated 25 million Brazilians having OSA, recent data revealed significant disparities in access to OSA diagnosis and treatment in Brazil. Type III home sleep apnea testing (HSAT) offers a scalable alternative to address diagnostic gaps. This study aims to map trends in OSA diagnostic growth in Brazil.

Methods: Data on polysomnography (PSG) procedures were extracted from public health records (DATASUS), and HSAT data were sourced from anonymized ApneaLink Air test records in a cloud-based platform (AirView). The analysis covered the period from January 2018 to June 2024 across public and private healthcare settings, assessing diagnostic volumes, growth rates, density per 100,000 inhabitants, and modality-specific trends.

Results: From 2018 to mid-2024, 77,764 PSG tests (38.35 tests per 100,000 inhabitants), and 154,407 HSAT exams, (76.14 tests per 100,000 inhabitants) were performed in Brazil. While PSG diagnostics showed a 67% growth, HSAT experienced a dramatic 2,502% increase potentially driven by its adaptability and scalability. Regional analysis revealed that 87% of HSAT diagnostics were concentrated in the Southeast and South macro-regions, whereas the North and Central-West regions remained underserved, highlighting significant inequities in diagnostic access.

Conclusion: The exponential growth of HSAT underscores its transformative potential in addressing diagnostic barriers for OSA in Brazil. Cloud-based platforms may have played a pivotal role, facilitating remote interpretation by experts. The COVID-19 pandemic likely accelerated HSAT adoption by emphasizing the need for decentralized, remote diagnostic solutions. While HSAT represents a significant advance in diagnostic accessibility, achieving equitable diagnostic coverage will require continued investments in infrastructure, professional training, and public awareness. This study highlights the importance of leveraging technology-enabled solutions to address OSA diagnosis gaps in Brazil and other underserved regions.

Support (if any): Anonymized data hosted on the cloud-based platform were made available by ResMed for the purposes of this study.

ASSOCIATION BETWEEN RACE, ETHNICITY, AND NEIGHBORHOOD SOCIOECONOMIC DISADVANTAGE WITH CONTINUOUS POSITIVE AIRWAY PRESSURE ADHERENCE

Carla Obeid[1], Yadi Li[2], Jarrod Dalton[2], Alex Milinovich[2], Brittany Lapin[2], Reena Mehra[3], Cinthya Pena-Orbea[4]

[1] Central Michigan University School of Medicine, [2] Quantitative Health Sciences, Lerner Research, Cleveland Clinic, [3] Division of Pulmonary, Critical Care and Sleep Medicine, University of Washington, [4] Sleep Disorders Center, Neurological Institute, Cleveland Clinic

Introduction: Racial and ethnic differences in continuous positive airway pressure (CPAP) therapy are well documented, yet the influence of neighborhood socioeconomic disadvantage on these disparities remains unclear. We investigated the extent to which area deprivation index (ADI) relates to racial/ethnic differences in CPAP usage while adjusting for basic demographics and sleep apnea severity.

Methods: A retrospective cohort of adult patients who initiated CPAP therapy at a large health system between January 2017 and January 2024 was analyzed. Adherence was defined as CPAP usage ≥4 hours for ≥70% of nights with average nightly usage in minutes analyzed over 90, 183, and 365-day periods after setup. ADI was analyzed in national rank quintiles (Q1-Q5). Multivariable logistic regression models were conducted to assess the association between race/ethnicity and ADI with CPAP adherence, adjusting for age, sex, insurance, marital status, apnea hypopnea index (AHI) and Epworth sleepiness scale (ESS). Statistical interaction effects between ADI and race/ethnicity was assessed.

Results: The study sample included 7,556 adults with average age 53.0 ± 13.8, 45% female, 15% non-Hispanic Black (NHB), and 4% Hispanic. NHB were more likely to live in areas of greatest deprivation compared to non-Hispanic Whites (NHW) (63.4%vs12.6%, p< 0.001). The average CPAP usage in minutes was lower among NHB vs NHW at 3-month (with similar results at 6- and 12-month): [median 295.6, interquartile range (208.4-363.6) vs 353.5 (274.4, 420.2), p< 0.001]. In adjusted models, NHB patients were less likely to be adherent to CPAP therapy compared to NHW patients at 3-, 6-, and 12-month independent of ADI (3-month: adjusted odds ratio (aOR)=0.64,95%CI:0.54-0.76, p< 0.001; 6-month: aOR=0.62,95% CI: 0.53-0.73, p< 0.001; 12-month: aOR=0.66,95%CI:0.55-0.78, p< 0.001). Likewise, living in the most disadvantaged neighborhoods was associated with reduced CPAP therapy adherence at all 3 time points independent of race/ethnicity (3-month: aOR=0.59,95%CI:0.44-0.80, p< 0.001; 6-month: aOR=0.60,95% CI:0.46-0.79, p< 0.001; 12-month: aOR=0.63,95%CI:0.48-0.83, p=0.001). Interactions of race/ethnicity and ADI were not statistically significant (p>0.46).

Conclusion: CPAP adherence is lower in NHB patients independent of neighborhood socioeconomic disadvantage. This highlights the need to better understand individual-level clinical and psychosocial factors that are driving these disparities in OSA treatment.

ENVIRONMENTAL BURDEN AND SLEEP-DISORDERED BREATHING PREVALENCE AMONG PATIENTS OF COMMUNITY-BASED HEALTH CENTERS

Wensu Zhou[1], Symielle Gaston[1], Ian Buller[2], Frankie LaPorte[3], Dayna Neo[3], Robert Voss[4], Anna Steeves-Reece[4], Paul Juarez[5], Chandra Jackson[1]

[1] National Institute of Environmental Health Sciences, [2] DLH Corporation, [3] DLH, LLC, [4] OCHIN, [5] Wilberforce University

Introduction: Environmental conditions can impact sleep-disordered breathing (SDB), through, for instance, pollutants

contributing to inflammation in the respiratory tract. However, limited research has comprehensively examined environmental features in relation to sleep disorders, especially among underserved populations who are more vulnerable to facing environmental injustices.

Methods: We assessed associations between cumulative environmental injustice and SDB using 2022 electronic health record data (EHRD) from socioeconomically disadvantaged patients in the OCHIN network of community-based health centers (CBHCs). We linked the census tract-level Environmental Justice Index (EJI) comprised of the submodules- Social Vulnerability Module [SVM] (e.g., poverty), Health Vulnerability Module [HVM] (e.g., pre-existing chronic disease), and Environmental Burden Module [EBM] (e.g., toxic sites; air pollution)- to the EHRD patients' geocoded census tracts at their first 2022 visit. Percentile ranks for the EJI, SVM, HVM, and EBM ranged from 0-1, higher ranks represented increased burden/vulnerability. SDB and subtypes, including obstructive sleep apnea (OSA), central sleep apnea (CSA), and other/unspecified sleep apnea (OUSA), were defined using ICD-9/10-CM and CPT/HCPCS codes. Adjusted for age, sex, gender identity, race, and ethnicity, log-binomial models were used to estimate prevalence ratios and 95% confidence intervals (PR[CI]).

Results: Among 1,957,775 patients, median age was 43.0 [IQR=30.0-58.0] years. There were more males than females in the study. The prevalence of SDB was 5.5% and 3.8% for OSA, 0.1% for CSA, and 2.2% for OUSA. Higher EJI rank was associated with a higher prevalence of SDB (PR=1.05 [1.02–1.07]) and OUSA (PR=1.06 [1.03–1.10]). Higher SVM and HVM were associated with a higher prevalence of SDB (PR-SVM=1.15 [1.13-1.18]; PR-HVM=1.22 [1.19-1.24]) and its subtypes (ranges: CSA PR=1.09 [1.05-1.13] to OUSA PR=1.39 [1.10-1.74]). Higher EBM was associated with a lower prevalence of SDB (PR=0.73 [0.72-0.75]) and its subtypes (range: CSA PR=0.44 [0.33-0.55] to OUSA PR=0.75 [0.73-0.78]).

Conclusion: Patients of CBHCs living in communities more affected by socioeconomic and health burdens had a higher prevalence of SDB. However, higher environmental burden was associated with lower SDB prevalence, which may be due to systematic underdiagnoses of SDB even in CBHCs, meriting further investigation. These findings inform future interventions designed to reduce SDB among socioeconomically disadvantaged populations.

HIGH INCIDENCE OF UNDIAGNOSED OBSTRUCTIVE SLEEP APNEA IN HOSPITALIZED PATIENTS WITH CONGESTIVE HEART FAILURE

Mayuri Mudgal[1], Kassandra Olgers[2], Scott Knollinger[3], Robert Stansbury[4], Edward Rojas[2], Vishal Deepak[5], Sunil Sharma[2]

[1] Camden Clark Medical Center, [2] West Virginia University, [3] WVU Medicine, [4] West Virginia University School of Medicine, [5] WVU

Introduction: Sleep-disordered breathing (SDB) is highly prevalent in hospitalized patients. This is also true for patients with congestive heart failure (CHF) who get hospitalized with either stable or decompensated CHF. We aim to understand the prevalence, and severity of obstructive sleep apnea (OSA) in the various subtypes of CHF namely heart failure with reduced ejection fraction (HFrEF) and heart failure with preserved ejection fraction (HFpEF) in the hospital setting.

Methods: Through a retrospective review of 2251 patients from 09/2019-12/2023 in a hospital-based sleep medicine program registry, 1023 patients were noted to have a history of CHF. From these, patients were divided into HFrEF and HFpEF subtypes. Patient underwent portable sleep study or high resolution pulse-oximetry testing during their hospital stay. Data on AHI, ODI, time spent less than 88% as well as incidence and severity of OSA was obtained and compared between the two groups.

Results: Of the 1023 CHF patients, 482 patients (47%) had HFrEF and 541(53%)had HFpEF. The mean age was 60.9± 13.9 and 63.4±12.5 yrs respectively with 70% and 51.1% males in the 2 groups. HFrEF had a slightly lower BMI at 34.4± 10.5 compared to 40.2± 12.7 Kg/m2. HTN, DM, HLD and coronary artery disease were highly prevalent in both the groups (55-89%). In the HFrEF group, Apnea link was performed in 361 pts(78.8%) and HRPO in 97 (21.2%). In the HFpEF group, Apnea link was performed in 308 (62.5%) and HRPO only in 185 (37.5%). Interestingly, 75.9% HFrEF pts were diagnosed with OSA and 60.8% in the HFpEF group. These were predominantly, moderate- severe OSA in HFrEF compared to HFpEF group (60.35% vs 52.67%) with mean AHI 19.9± 19.5 vs 14.6± 16.8. Also noted was the time spent < 88% (T88) on HRPO which was shorter in the HFrEF group compared to the HFpEF group (47.7± 68.8 vs 77.3 ± 303.2 minutes).

Conclusion: There is a high incidence of undiagnosed obstructive sleep apnea in patients hospitalized with congestive heart failure. It was severe in the HFrEF group compared to the HFpEF group. It is recommended that patients admitted to the hospital with underlying CHF be screened for sleep apnea.

SLEEP APNEA IN HOSPITALIZED PATIENTS WITH SYSTOLIC HEART FAILURE (SLEEP-HEART STUDY)

Mayuri Mudgal[1], Kassandra Olgers[2], Scott Knollinger[3], Robert Stansbury[4], Edward Rojas[2], Vishal Deepak[5], Sunil Sharma[2]

[1] Camden Clark Medical Center, [2] West Virginia University, [3] WVU Medicine, [4] West Virginia University School of Medicine, [5] WVU

Introduction: Sleep disordered breathing(SDB) is common in patients with heart failure(CHF) and is subtyped into obstructive (OSA) and central sleep apnea(CSA). Based on prior studies,CSA occurs in 25-40% of patients with CHF with reduced ejection fraction (HFrEF). With the implementation of quadruple therapy for management of HFrEF in the recent years, we aim to understand the current prevalence of CSA in our hospitalized patients both with stable and decompensated HFrEF as well as compare outcomes data.

Methods: Through a retrospective review of patients from 09/2019-12/2023 in a hospital-based sleep medicine program registry. patients admitted with a history of HFrEF, who underwent inpatient Apnea link followed by outpatient polysomnography (PSG) were reviewed. Patients were subdivided into those admitted with stable HFrEF and decompensated HFrEF. Data on in-hospital AHI, time spent< 88% (T88), PSG AHI, sleep apnea type, medications and outcomes data were compared.

Results: Of the 77 HFrEF pts on whom complete data on inpatient screening and post-discharge PSG was available, 50 had decompensated and 27 were stable HFrEF. Mean BMI was 35.3 ±11.8 vs 35.2 ± 9.2 while mean EF was 27 ± 11 vs 32.5 ± 9.7. Interestingly, apnea link AHI was lower in the decompensated

group compared to the outpatient PSG AHI (27.6 ±18.4 vs 34.5 ±27.5) though it was the opposite for stable HFrEF (34.5 ±26.7 vs 23 ±21.65). T88 was 76.3 ± 91.8 vs 73.6 ±109.3 min in decompensated patients and 65.9 ± 78.5 vs 59.5 ± 97.5 min in stable patients, with the former group desaturating more. The prevalence of CSA was notably low (6%,11%) with predominance of OSA (68% and 55%), mixed sleep apnea(8% and 11%). Quadruple therapy was prescribed more in the decompensated group, which also had higher 180-day ED and hospital readmissions (21/30 and 26/31) and mortality (12/50 vs 3/27).
Conclusion: The incidence of CSA for HFrEF was significantly lower compared to prior studies in ambulatory settings. This could be due to availability of better therapy. The decompensated group was observed to have worse AHI on PSG than with in-hospital portable sleep study as well as high 180-day ED and hospital re-admission and mortality.

TRENDS AND IMPACT OF OBSTRUCTIVE SLEEP APNEA ON IN-HOSPITAL OUTCOMES IN PATIENTS WITH END-STAGE RENAL DISEASE

Yamna Waseem[1], Vishal Saini[1]
[1] Central Michigan University

Introduction: Obstructive Sleep Apnea (OSA) is a common condition marked by repeated airway obstructions during sleep, leading to arousals, oxygen drops, and hypoxia. Chronic kidney disease (CKD), a leading cause of death, may progress due to overlooked sleep disturbances. OSA affects 50-60% of CKD patients with End-Stage Renal Disease (ESRD), with its prevalence in CKD patients being 10 times higher than the general population. Although studies have explored the CKD-OSA link, no research has focused on how OSA impacts mortality in ESRD patients. This study uses national inpatient data to analyze trends and outcomes of OSA in ESRD patients on dialysis.
Methods: This retrospective study used data from the National Inpatient Sample (NIS) database (2018-2020) to examine ESRD patients on dialysis. The study included adults diagnosed with Stage 5 CKD (ICD-10 codes N18.5xx) or ESRD (N18.6xx), excluding those with active cancer, HIV, or under 18. Patients were grouped based on whether they had obstructive sleep apnea (OSA). Primary outcomes included in-hospital mortality, hospital length of stay, and total charges, while secondary outcomes focused on cardiac arrest and gastrointestinal hemorrhage rates. Demographics, hospital characteristics, and comorbidities (e.g., hypertension, obesity, CAD) were adjusted for in the analysis.
Results: The study identified 3,385,755 hospitalization cases, with 362,855 (10.7%) involving patients with obstructive sleep apnea (OSA). Significant differences were found between the OSA and non-OSA groups in terms of inpatient mortality, sex (female), age, length of stay, race, income, and health insurance. Inpatient mortality was lower in the OSA group (4.0%) compared to the non-OSA group (5.5%). Cardiac arrest occurred less frequently in the OSA group (1.9% vs 2.4%, p< 0.001). OSA patients had a longer median length of stay (5.0 days vs 4.0 days). Total hospital charges were similar between the groups ($52,011 vs $51,542, p=0.2).
Conclusion: Our study in contrast to previous data showed that patients with OSA in ESRD patients on dialysis had improved mortality outcomes compared to those without OSA. However, a limitation in our study was that the presence of CPAP therapy in the OSA group could not be confirmed and the potential mortality benefit of CPAP therapy should be further studied.

A NARRATIVE REVIEW OF THE RELATIONSHIP BETWEEN HEAD AND NECK CANCER AND OBSTRUCTIVE SLEEP APNEA: CLINICAL STUDIES AND STATISTICAL ANALYSIS

Abhay Sharma[1], Trung Le[1], Toan Le[1], Phat Huynh[2]
[1] University of South Florida, [2] North Carolina A&T

Introduction: Obstructive sleep apnea (OSA) is an underestimated and overlooked comorbidity in head and neck cancer (HNC) care. Refining HNC-OSA management requires an improved grasp of the HNC-OSA relationship. Thus, this paper reviews the current course of HNC therapy, causal and associative relationships before and after treatment, and statistical methods quantifying HNC-OSA interactions.
Methods: The preferred reporting items for systematic reviews and meta-analyses (PRISMA) guidelines are tailored to establish a systematic and rigorous narrative review, ensuring transparency and methodological rigor in selecting and analyzing pertinent literature in this study. PubMed, Google Scholar, Web of Science, Microsoft Academic, Semantic, Europe PMC, Scopus, and Crossref databases were used to collect articles related to OSA in patients with HNCs.
Results: The investigation confirms a positive correlation between the apnea-hypopnea index (AHI) and primary tumor size, consistent with prior findings. However, causality between the two disease processes could not be confirmed based on the current level of evidence in the literature.
Conclusion: This paper provides an overview of existing statistical models and offers suggestions for model selection and a framework for designing experiments that delve into research questions surrounding the link between OSA and HNC across various stages of cancer treatment. Despite progress, understanding the HNC-OSA interplay remains incomplete due to limited histological, molecular, and clinical data. Future studies with longitudinal data are crucial for comprehensive insights.

COMPARATIVE ANALYSIS OF OBSTRUCTIVE SLEEP APNEA AND DESATURATION IN COPD AND OBESITY

Alejandra Lastra[1], Omar Lopez[2], Gorav Sharma[2], Nathan Nowalk[2]
[1] University of Chicago, [2] The University of Chicago

Introduction: Patients with both chronic obstructive pulmonary disease (COPD) and obesity are at a higher risk of developing severe sleep-related breathing disorders. This study aims to compare key sleep-related variables and demographics among three groups: patients with COPD, patients with BMI ≥ 40 kg/m2, and patients with both COPD and BMI ≥ 40 kg/m2.
Methods: A retrospective analysis was conducted on sleep study data from three patient groups: (1) patients with COPD, (2) patients with BMI ≥ 40, and (3) patients with both COPD and BMI ≥ 40. Variables analyzed included obstructive apnea-hypopnea index (AHI), oxygen desaturation levels (% time under: T

90, T 80, T 70), Epworth Sleepiness Scale (ESS), and demographics. Statistical comparisons were performed using ANOVA, with p-values considered significant at < 0.05.
Results: A total of 2,876 patients were analyzed, and divided into three groups: COPD (n = 1,020), BMI ≥ 40 (n = 1,278), and COPD+BMI ≥ 40 (n = 578). OAHI (Obstructive Apnea-Hypopnea Index) was highest in the COPD+BMI ≥ 40 group (mean 18.85 ± 18.63, 75% female, n = 578), followed by the BMI ≥ 40 (mean 17.47 ± 19.09, 68% female, n = 1,278), and COPD group (mean 15.61 ± 16.10, 62% female, n = 1,020) (p = 0.001). Desaturation were more severe in the COPD+BMI ≥ 40 group. Oxygenation: T 90, the mean was 101.22 ± 175.76 (75% female, n = 578), significantly higher than both the BMI ≥ 40 (71.24 ± 168.24, 68% female, n = 1,278) and COPD groups (65.70 ± 127.37, 62% female, n = 1,020) (p < 0.001). Desats T 80, with the highest mean in the COPD+BMI ≥ 40 (23.28 ± 80.51), compared to the BMI ≥ 40 (17.14 ± 87.81) and the COPD group (11.40 ± 54.69) (p = 0.02). ESS scores were significantly elevated in the COPD+BMI ≥ 40 group.
Conclusion: Patients with both COPD and obesity exhibit more severe obstructive sleep apnea, greater oxygen desaturation, and increased daytime sleepiness compared to those with either condition alone. Further phenotyping of morbidly obesity patients with COPD is needed.

EXPLORING DRIVERS OF PAP THERAPY ADHERENCE AND OSA SEVERITY: INSIGHTS FROM A SEQUENTIAL ANALYSIS IN NHPI POPULATIONS IN HAWAII

Andrew Mettias[1], Kaela Iwai[2], Krystalyn Edwards-Calma[1], Hannah Miura[1], Anita Cheung[2], Ryan Nakamura[2], D-Dré Wright[2], Meliza Roman[3], Kore Liow[1], Enrique Carrazana[4], Nicholas Anderson[1]

[1] Sleep and Insomnia Center, Hawaii Pacific Neuroscience, [2] University of Hawaii John A Burns School of Medicine, [3] JABSOM Biostatistics Core Facility, University of Hawaii John A Burns School of Medicine, [4] John A. Burns School of Medicine, University of Hawaii

Introduction: Native Hawaiian and Pacific Islander (NHPI) populations are disproportionately affected by more severe obstructive sleep apnea (OSA), often complicated by higher comorbidity rates and limited access to healthcare resources. This study utilized a sequential analysis approach to investigate drivers of OSA severity, demonstrated by initial apnea-hypopnea index (AHI) scores, adherence patterns among Hawaii's White, Asian, and NHPI populations, and a further segmentation into socioeconomic factors.
Methods: A retrospective chart review was performed on 340 patients diagnosed with OSA at Hawaii Pacific Neuroscience, a single-center clinic in Hawaii. Three stages of sequential analysis were performed: BMI vs initial apnea-hypopnea index (AHI) score to assess the relationship between body mass and OSA severity across ethno-racial groups, adherence vs AHI to assess positive airway pressure (PAP) therapy adherence patterns, and a census-derived zipcode-level analysis to assess socioeconomic drivers of adherence. Statistical significance was determined using linear regressions alongside two-tailed Student's t-tests, as well as Mann Whitney U tests (Wilcoxon rank-sum).
Results: The first sequential analysis demonstrated that BMI was a significant driver of initial AHI severity across all ethno-racial groups, with NHPI patients presenting with higher initial AHI scores due to elevated BMI scores. However, the BMI-AHI relationship showed similar slopes across all ethno-racial groups analyzed (p > 0.05). The second sequential analysis revealed higher PAP therapy adherence in NHPI patients with worsening initial AHI severity, a trend more pronounced than in Asian and White counterparts (p < 0.05). The third sequential analysis found limited associations between socioeconomic variables and adherence; notably, the employment rate was negatively correlated with adherence (p = 0.007) in NHPI populations, suggesting external stressors like work schedules may play a potential role.
Conclusion: This study indicates BMI as a significant contributor to initial OSA severity across ethno-racial groups and presents unique adherence patterns exhibited by NHPI populations that may suggest potential sociocultural influences on adherence, warranting further qualitative investigation. These findings highlight the importance of interventions addressing obesity and qualitative studies to further explore unique patient-level drivers of adherence in NHPI populations.

A STUDY ON THE DEVELOPMENT OF LONG-TERM MONITORING DEVICE USING RELIABLE NON-CONTACT SENSORS WITH AI ON SLEEP APNEA

TAE HWAN HAN[1], Kisub Jung[2], Jung-Won Shin[3], Kyu Young Chae[3]

[1] Yongin Severance Hospital, Yonsei University Health System, [2] Vitar Co., [3] CHA Bundang Medical Center, CHA University School of Medicine

Introduction: Obstructive sleep apnea (OSA) is a significant health concern affecting an estimated 936 million individuals globally, with approximately 60% of cases exhibiting moderate to severe symptoms. The condition is typified by recurrent episodes of partial or complete obstruction of the airway during sleep, resulting in intermittent hypoxemia and disrupted sleep patterns. Although polysomnography (PSG) is the gold standard for diagnosing OSA, it is an expensive, intrusive, and often uncomfortable procedure for patients. The objective of this study is to investigate the potential of frequency-modulated continuous wave (FMCW) radar, when used in conjunction with an ensemble artificial intelligence (AI) framework, for the accurate, non-contact detection of OSA events.
Methods: A diagnostic framework was developed which utilises a 60 GHz TI AOP6843 FMCW radar and the Differentiate and Cross Multiply (DACM) algorithm for the extraction of respiratory signals. Our approach integrates an ensemble of machine learning methods, including Convolutional Recurrent Neural Networks (CRNN) for log-spectrogram analysis, Continuous Wavelet Transformation (CWT) for R-R intervals (RRI) and R-R amplitudes (RRA), and random forest analysis for heart rate variability (HRV) metrics. Validation was conducted using overnight recordings from 66 subjects, employing a leave-one-out cross-validation approach.
Results: The ensemble framework exhibited promising performance, achieving an average accuracy of 81.14% and an F1 score of 73.7%. Specifically, the CRNN (spectrogram) achieved an accuracy of 77.48% with an F1 score of 69.67%, the CWT

(RRI/RRA) achieved 76.06% accuracy with an F1 score of 67.13%, and the HRV random forest analysis reached 74.84% accuracy with an F1 score of 65.53%. Moreover, our approach demonstrated a correlation coefficient of 92.4% with the Apnea-Hypopnea Index (AHI), indicating a high degree of clinical relevance.
Conclusion: Our non-contact radar and AI-based ensemble framework represents a viable alternative to traditional PSG for the detection of OSA. This approach offers a cost-effective, non-invasive solution that enhances patient comfort and accessibility to diagnostics. The results indicate the existence of a significant potential for the enhancement of clinical management and early intervention for patients diagnosed with OSA.

PRECISION SLEEP CARE USING LONGITUDINAL SLEEP TESTING

Sahil Chopra[1], Savit Malhotra[1], Robert Thomas[2]
[1] Empower Sleep, [2] Beth Israel Deaconess Medical Center

Introduction: Traditionally, single-night sleep studies have been the primary tools used to understand sleep health and sleep disorders. While these diagnostic devices are valuable tools for obtaining sleep data, they are only a snapshot of overall sleep health. Although not the standard of care, research from multi-night sleep testing has demonstrated the dynamic nature of sleep physiology and sleep pathology. In this presentation we demonstrate the pragmatic use of longitudinal home sleep testing to provide endotype directed personalized sleep care.
Methods: Empower Sleep is a treatment agnostic telemedicine platform/clinic that uses software processing, data aggregation, and longitudinal sleep testing to derive insights for personalized sleep care. We utilize tools such as the SleepImage system, to understand sleep health, diagnose sleep disorders and track progress to sleep optimization. All patients in the program own a Sleep Image ring and use it as a nightly sleep testing device. By applying software processing on data from a clinical history, 10-14 night baseline sleep study and data from health exchanges we are able to understand co-morbidities and sleep biology. Through sleep testing data and objective "responses" to specific modalities we are able to cluster patients into different endotypes. Care plans are depended on the identified disorder, burden of disorder and treatments trialed. During the patient journey, patients meet with their provider via telemedicine. Patients view their processed results in the patient facing app similar to how they view data from other consumer grade devices.
Results: 1. Over the last 2.5 years over 2000 patients have received care and collected over 600,000 hours of longitudinal sleep testing data. 2. We share the observations of wide discrepancies of sleep data (AHI) from PAP downloads and sleep testing data. 3. We share observations of identifying and modifying high loop gain or low arousal thresholds with changes in sleep fragmentation/stable sleep/SQI on PAP or other sleep apnea therapies. 4. As a byproduct of personalized care we have achieved PAP compliance of ~ 80%.
Conclusion: In this presentation the authors share their experience of using longitudinal sleep testing to diagnose, endotype, provide care and measure outcomes.

ASSESSMENT OF DISEASE BURDEN IN PAP-INTOLERANT OSA PATIENTS USING HOME POLYSOMNOGRAPHY: A PILOT STUDY

Heiser Clemens[1], Verena Plankl[1], Marcel Braun[2], Katharina Heiser[1]
[1] ENT Center Mangfall-Inn, Bad Aibling (Germany), [2] University Hospital Essen, West German Lung Center Essen, Essen (Germany)

Introduction: While Positive Airway Pressure (PAP) therapy remains the gold standard for treating Obstructive Sleep Apnea (OSA), 30-50% of patients cannot maintain consistent usage. This pilot study investigated the residual disease burden and sleep impairments in patients who discontinued PAP therapy, utilizing self-applied home polysomnography.
Methods: This exploratory cross-sectional study included 50 adults (61% male, mean age 57.4±9.9 years) with confirmed OSA diagnosis who previously attempted PAP therapy. Polysomnography was performed using a self-applied patch-based system (Onera STS), enabling assessment of sleep staging and respiratory events in the patient's natural sleep environment. Data collection included standardized questionnaires (ESS, FOSQ) and structured medical history. Primary endpoint was the prevalence of residual OSA after PAP termination. Secondary endpoints included objective parameters like Oxygen Desaturation Index and sleep architecture, as well as subjective measures such as daytime functioning.
Results: Polysomnographic findings showed a mean AHI of 22.7±23.5/h, with questionnaire data indicating significant daytime sleepiness (ESS 12.3±4.5). Sleep architecture analysis revealed increased N1 (12.1%), reduced N3 (12.9%) and REM sleep (15.6%), and prolonged REM latency (120.3±87.3 min). Respiratory parameters showed significant nocturnal hypoxemia (ODI 23.5±18.6/h, time < 90% O2 saturation 9.9±16.8% TST, O2 nadir 81.6±6.8%). FOSQ scores (82.4±23.8) indicated marked functional impairment. Despite an average disease duration of 86.9±65.8 months, 75.7% of patients received no alternative therapy after PAP discontinuation.
Conclusion: This pilot study demonstrates substantial residual disease burden in PAP-intolerant OSA patients, characterized by altered sleep architecture, moderate OSA, significant nocturnal hypoxemia, and impaired daytime functioning. The findings suggest an urgent need for structured therapeutic alternatives in PAP-intolerant individuals and validate the feasibility of comprehensive sleep assessment in the home environment.

CO-MORBID INSOMNIA AND SLEEP APNEA INCREASE THE RISK OF UNCONTROLLED HYPERTENSION IN A MIDDLE-AGED POPULATION

Mio Kobayashi Frisk[1], Joel Bergqvist[1], Sven Svedmyr[1], Philippe Diamantis[1], Göran Bergström[1], Ding Zou[1]
[1] University of Gothenburg

Introduction: Co-morbid insomnia and sleep apnea (COMISA) is associated with poorer health outcomes and increased all-cause mortality. We investigated the relationship between COMISA

and uncontrolled hypertension in the population-based Swedish CardioPulmonary BioImage Study (SCAPIS).

Methods: A cross-sectional analysis was conducted on 3832 SCAPIS participants (54.2% females, age 57.5±4.3 years, body mass index 26.6±4.2 kg/m²). Subjects underwent comprehensive assessments, including an overnight home sleep apnea testing. Obstructive sleep apnea (OSA) was defined using a respiratory event index >10 events/hour per European Respiratory Society guidelines, while COMISA was defined as OSA combined with an Insomnia Severity Index score ≥15. Blood pressure (BP) was categorized into three groups: uncontrolled hypertension (office systolic/diastolic BP ≥140/90 mmHg), controlled hypertension (physician-diagnosed hypertension treated with antihypertensive medication and systolic/diastolic BP < 140/90 mmHg), or normotension (systolic/diastolic BP < 140/90 mmHg without antihypertensive treatment).

Results: The prevalence of COMISA was 3.1% in the population and 14.5% among OSA patients. The rate of uncontrolled hypertension was 4.4%, 4.5%, 7.9%, and 10.2% in the non-insomnia/OSA, insomnia-only, OSA-only, and COMISA group, respectively (P< 0.001). A generalized ordinal logistic regression model revealed a significantly increased risk of uncontrolled hypertension in the OSA-only group (odds ratio [OR] [95% CI]: 1.35 [1.06–1.73], P=0.017) and the COMISA group (OR: 1.90 [1.22–2.96], P=0.004), compared to the non-insomnia/OSA group, after adjusting for anthropometric, lifestyle, comorbidities, sleep duration, excessive daytime sleepiness, and 4% oxygen desaturation index. Mediation analysis indicated that the percentage of time spent with SpO_2 ≤90% mediated the relationship between OSA and uncontrolled hypertension.

Conclusion: OSA is associated with an increased risk of uncontrolled hypertension in the general population, with COMISA further elevating the risk. These findings highlight the importance of identifying COMISA patients for tailored treatment approaches.

Support (if any): The main funding body of SCAPIS is the Swedish Heart-Lung Foundation. The study was supported by the Swedish Heart-Lung Foundation (project 20230759) and the Swedish state funds for clinical research (ALFGBG-984575).

MORTALITY ASSOCIATED WITH SLEEP APNEA, INSOMNIA, AND COMISA MAY BE LOWER FOR TREATED RACIAL AND ETHNIC MINORITIZED VETERANS

Douglas Wallace[1], Alexander Sweetman[2], Luis Buenaver[3], Javad Razjouyan[4], Charles Crew[4], Amir Sharafkhaneh[4]

[1] University of Miami, [2] Flinders University, [3] Johns Hopkins University, [4] Baylor College of medicine

Introduction: Few data exist exploring the relationship between treatment of sleep apnea (SA), insomnia, comorbid insomnia and sleep apnea (COMISA) with mortality among racial and ethnic minoritized (REM) US veterans receiving sleep care. We compiled a large Veterans Health Administration (VA) database to compare all-cause mortality among veterans with these sleep disorders by race-ethnicity.

Methods: The study included veterans with confirmed diagnoses and prescribed treatment for insomnia and/or SA, within the VA, from 1999 to 2023. Self-reported race and ethnicity were extracted from the medical record and categorized as Non-Hispanic White (NHW), Non-Hispanic Black (NHB), White Hispanic (WH), Non-Hispanic Asian (NHA), or Indigenous (Native American/Alaskan/Hawaiian/Pacific Islander [NAAHPI]). Insomnia diagnosis required sleep medication prescription or CBT-I while SA diagnosis required PAP prescription. All-cause mortality was extracted from national databases. For each sleep disorder, multivariable logistic regression was used to determine the association between race-ethnicity and all-cause mortality. Models were adjusted for demographics, comorbidities, sleep medications, and time from the initial insomnia or SA diagnosis. NHW served as the reference group for analyses.

Results: This cohort contained 1,544,541 veterans; 70% of the cohort was NHW, 20% NHB, 6.8% WH, 1.8% NAAHPI, and 1.2% NHA. OSA prevalence was highest for NHAs (53.3%) and lowest for NHWs (47.3%). Insomnia prevalence was highest for NHWs (42.1%) and lowest for NHAs (34.8%) while COMISA prevalence was most common among NHBs (13.4%) and least among NHWs (10.7%). In adjusted analyses, compared to NHWs, mortality risk was lower for NAAHPI (HR [95%CI] 0.85 [0.82-0.89]), NHB (0.71 [0.70-0.72]), WH (0.64 [0.62-0.66]), and NHA (0.40 [0.37-0.44]). Similarly, REM veterans with insomnia had lower mortality risk than NHWs (NAAHPI HR 0.91 [0.88-0.95], WH 0.72 [0.70-0.74], NHB 0.69 [0.68-0.70], NHA 0.48 [0.45-0.52]). Furthermore, REM veterans with COMISA also had lower mortality risk than NHWs (NAAHPI HR 0.79 [0.71-0.87], NHB 0.65 [0.62-0.67], HW 0.59 [0.55-0.62], NHA 0.39 [0.32-0.48]).

Conclusion: Overall, racial and ethnic minoritized veterans had lower mortality rates than NHWs. These counterintuitive findings may not be representative of REM veterans with sleep disorders at-large given inherent biases in sleep referrals and acceptance/uptake of therapies. Further clarification of these findings within the VA is needed.

OBSTRUCTIVE SLEEP APNEA COMORBID WITH INSOMNIA WITH OBJECTIVE SHORT SLEEP DURATION PHENOTYPE IS ASSOCIATED WITH INCIDENT HYPERTENSION

Nikolaos Athanasiou[1], Slobodanka Pejovic[1], Alexandros Vgontzas[1], Julio Fernandez-Mendoza[2], Yun Li[3], Kristina Lenker[2], Maria Karataraki[4], Edward Bixler[2]

[1] Sleep Research and Treatment Center, Penn State College of Medicine, [2] Penn State College of Medicine, [3] Shantou University Medical College, [4] University of Crete

Introduction: Co-morbid insomnia and obstructive sleep apnea (COMISA) is associated with higher cardiovascular risks than its individual components. Recent findings in a clinical sample suggest that increased cardiometabolic risks in COMISA appear to be primarily driven by the insomnia short sleep duration (ISSD) but not insomnia with normal sleep duration (INSD) phenotype. The aim of this study is to investigate whether COMISA with ISSD phenotype is associated with an increased risk of incident hypertension in a large random general population sample.

Methods: From the 1741 subjects of the Penn State Adult Cohort, 1395 were followed-up after 7.5 years and 786 (55% women, aged 49.68± 12.98) did not have hypertension at baseline. Hypertension was determined by a self-report of receiving treatment for high blood pressure. Chronic insomnia was defined

as a complaint of insomnia lasting ≥ 1 year or presence of complaint of difficulty falling asleep, staying asleep, nonrestorative sleep, or early morning awakening. All subjects underwent 8-hour polysomnography. Obstructive sleep apnea (OSA) was defined as an obstructive apnea/hypopnea index ≥ 5. Objective short sleep duration was defined as < 6 hours' sleep based on polysomnography. Binary logistic regression was performed while controlling for gender, race, age, BMI, mental health problems, smoking, alcohol consumption, diabetes, sampling weight and follow-up duration.

Results: Compared with normal sleepers with normal sleep duration, the highest risk of incident hypertension was in the COMISA with ISSD phenotype (OR = 4.40, 95% CI = 1.60–12.07, p=0.004), followed by OSA only group, and by ISSD only group (OR= 3.34, 95% CI = 1.87–5.94, p=0.001, OR= 2.23, 95% CI = 1.26–3.94, p=0.005, respectively). The risk of incident hypertension was not significantly increased in normal sleepers with short sleep duration or in those with COMISA INSD phenotype or INSD only group.

Conclusion: These findings suggest that the additive adverse effects of COMISA on hypertension risk are driven primarily by the ISSD phenotype. Furthermore, they underline the need for phenotyping COMISA based on objective sleep duration which differs in terms of pathophysiology, adverse cardiometabolic outcomes and possible differential treatment response.

IMPACT OF BODY MASS INDEX ON THE ASSOCIATION BETWEEN SLEEP-DISORDERED BREATHING AND HYPERTENSION AMONG WOMEN

Hiroo Wada[1], Qinye Zhu[1], Yuito Ueda[1], Takeshi Tanigawa[1]

[1] Department of Public Health, Juntendo University Graduate School of Medicine

Introduction: Sleep-disordered breathing (SDB) is associated with hypertension (HT) by enhancing sympathetic neuronal activity (SNA) among men. Recently, body mass index (BMI) is a mediator of the association between SNA and HT (Chen B, Somers VK, et al. 2021). However, their association in the female population has not been well investigated. The purpose of this study was to examine the impact of BMI on the association between SNA and HT in women.

Methods: A total of 582 women working in nursing homes were included in the study. Demographics and a clinical history of hypertension were examined by questionnaire. Those having the systolic blood pressure ≥150mmHg, diastolic blood pressure >90mmHg or those who were previously diagnosed as HT were determined as those with HT. Sympathetic and parasympathetic activity levels were evaluated using the Orthostatic Master, using Kiritsu Meijin(r), in which the L/H ratio and HF respectively indicates sympathetic and parasympathetic activity. L/H ratios and HF were devided into quartiles. Based on an over-night type III sleep monitoring, respiratory event index (REI) was determined. Logistic regression analysis was used to examine the association between SNA and HT. Covariates included age, body mass index and menopausal condition.

Results: The odds ratio and 95% confidence interval for hypertension were 4.92 (2.08 to 11.65) and 4.75 (2.00 to 11.27) in those with the third and top quartiles of L/H ratio, compared to the bottom, suggesting the significant association between HT and SBD. This association remained statistically significant after adjustment for age or in those whose REI was ≥10/hour. Furthermore, adjusted OR (95%CI) for HT was 0.40 (0.19 to 0.86) in the thrid qurtaile and 0.27 (0.10 to 0.68) in the top qurtaile of HF, respectively, suggesting that para-sympathetic neuronal activation is singnificantly and imbersely associated with HT. This resulted in the dominance in sympathetic neuronal activation related to HT.

Conclusion: There was an association between SNA and HT in women, which was more evident in those with REI ≥10/hour. However, BMI did not seem to be a meditor in this epidemiologic cohort. Furthermore, the reduction in para-sympathetic neuronal activity was associated with HT.

HIGHER INCIDENCE OF CARDIOMETABOLIC COMORBIDITIES IN U.S. VETERANS WITH OBSTRUCTIVE SLEEP APNEA AND WARTIME AIRBORNE HAZARDS EXPOSURE

Eilis Boudreau[1], Connor Smith[1], Omowunmi Osinubi[2], Edward Shadiack[2], Charles Atwood[3], Kathleen Sarmiento[4], Carrie Puckett[5], Silvia Crivelli[6], Drew Levin[7], Patrick Finley[7]

[1] Oregon Health & Science University, [2] VA New Jersey Healthcare System, [3] VA Pittsburgh Health Care System, [4] San Francisco VAMC, [5] VA Portland Health Care System, [6] Lawrence Berkeley National Laboratory, [7] Sandia National Laboratories

Introduction: Forty percent of Veterans express concern about military toxic exposures (TEs) which may include airborne hazards. Veterans with overseas wartime service and TEs show increased rates of cardiometabolic disorders, including heart disease, stroke, and type 2 diabetes mellitus (T2DM). Additionally, 24% of Veterans have been diagnosed with Obstructive Sleep Apnea (OSA), which is epidemiologically linked to cardiometabolic disease. However, the extent to which OSA modifies the risk of developing cardiometabolic comorbidities after military TEs remains unknown

Methods: Using data from the VA Corporate Data Warehouse (CDW), we identified Veterans receiving care in the past five years with a wartime record indicating service overseas in an area where TEs were reported. These Veterans were further stratified based on OSA diagnosis and cardiometabolic comorbidities.

Results: Of the 8.53 million Veterans receiving care within VA between 2019 and 2024 and who had an overseas wartime service record, 1.32 million (16%) had potential TEs. Among these, 452,140 (34%) had a diagnosis of OSA. In the group with both potential TEs plus OSA, 205,646 (45%) had one or more cardiometabolic comorbidities compared to only 210,468 (25%) in those with no OSA.

Conclusion: Veterans with an overseas deployment and potential TEs had higher rates of OSA compared to the general VA population. Furthermore, they were more likely to have at least one or more comorbidities compared to those with an overseas wartime deployment but no OSA. This data suggests that the combination of OSA and military TEs is associated with a higher incidence of cardiometabolic comorbidities, warranting further investigation in this area.

GENDER-SPECIFIC INSIGHTS: ASSOCIATION BETWEEN SLEEP APNEA SEVERITY AND MORTALITY IN FEMALE VETERANS, ACCOUNTING FOR RACE, ETHNICITY, AND AGE

Mehrnaz Azarian[1], Amin Ramezani[1], Arash Maghsoudi[1], Amir Sharafkhaneh[1], Javad Razjouyan[1]

[1] Baylor College of Medicine

Introduction: Our previous study in an overwhelmingly male population demonstrated a U-shaped relationship between sleep apnea (SA) and mortality, with mild to moderate SA associated with the lowest mortality risk. We aim to investigate the association between SA and all-cause mortality in a large cohort of female veterans and its interplay with race/ethnicity, and age.

Methods: Using data from the Veterans Health Administration (1999–2022), a validated natural language processing tool extracted Apnea-Hypopnea Index (AHI) values from electronic medical records. Female veterans were categorized by SA severity: no SA (n-SA, AHI < 5), mild to moderate SA (m-SA, 5 ≤ AHI < 30), and severe SA (s-SA, AHI ≥30). We propensity score matched the patients based on demographics, body mass index (BMI), and 38 factors of Elixhauser comorbidity index. Subgroup analyses included stratification by race/ethnicity (White, Black, and Hispanic) and age (≤40, >40 to < 65, ≥65). Logistic regression models estimated odds ratios (ORs) for mortality using m-SA as the reference.

Results: Among 37,448 female veterans (mean age: 43.0±11.2 years, mean BMI: 30.5±6.0 kg/m², 52.1% White), comorbid conditions were prevalent, with 78% having psychiatric, 34% cardiovascular, 38% metabolic, 28.5% neurologic, and 27.6% pulmonary conditions. Positive airway pressure therapy was prescribed to 43.6% of the m-SA group and 35.7% of the s-SA group. Mortality rates were lowest in the m-SA group, but comparisons between n-SA and s-SA versus m-SA showed no significant differences (n-SA OR: 1.13; 95%CI: 0.98,1.3; s-SA OR: 1.11; 95%CI: 0.96,1.29). Stratification by age did not alter these findings. However, White females with n-SA exhibited significantly higher odds of mortality compared to those with m-SA (OR: 1.32; 95%CI: 1.1,1.58).

Conclusion: A previously observed U-shaped relationship between SA and mortality appears influenced by gender, race/ethnicity, and age. This study identified significantly higher mortality odds for n-SA in White females, while other subgroups showed no significant associations. Further research is needed to explore potential mechanisms, including sex-specific responses to intermittent hypoxia and the effects of PAP therapy in females.

SLEEP APNEA AND RISK OF GESTATIONAL DIABETES AND PREECLAMPSIA: A MENDELIAN RANDOMIZATION STUDY

Pei Chen[1], Yueying Wang[2], Jinjin Yuan[3], Yang Pan[1], Xiao Sun[1], Ghada Abu Irsheed[1], Bingqian Zhu[4], Bilgay Balserak[5]

[1] University of Illinois Chicago, [2] Hong Kong Polytechnic University, [3] Songjiang Hospital Affiliated to School of Medicine, [4] Shanghai Jiao Tong University School of Nursing, [5] University of Illinois at Chicago

Introduction: Sleep apnea has been associated with increased risks of gestational diabetes and preeclampsia. However, it remains unclear whether these associations are causal or influenced by confounding factors. To address this uncertainty, we employed Mendelian Randomization (MR), a robust method for inferring causal relationships using genetic data, to investigate the potential causal effects of sleep apnea on these adverse maternal outcomes.

Methods: We conducted a one-sample MR analysis to evaluate causality between sleep apnea and the risk of three particularly adverse maternal outcomes. Genome-wide association study (GWAS) summary data for sleep apnea were obtained from the FinnGen biobank (16,761 cases and 201,194 controls). We used MR-Egger, weighted median, inverse-variance weighted (IVW), and weighted mode methods, with IVW (multiplicative random effects) as the primary analysis. The Cochran's Q statistic (IVW) and Rucker's Q statistic (MR Egger) were used to detect the heterogeneity of our MR analysis. The horizontal pleiotropy was detected by MR Egger. The sensitivity was investigated by the leave-one-out analysis. To avoid the inflation of false-positive findings, we calculated the false-discovery rate (FDR) corrected p-values for the main analyses. Significance was determined as FDR-corrected p-values< 0.05, whereas p-values < 0.05 that did not meet the FDR-corrected threshold were regarded as suggestive evidence of an association. All cited GWAS, epigenome-wide association studies and summary-level data had been approved by related relevant review boards.

Results: Sleep apnea was associated with an increased risk of gestational diabetes (OR=1.43, 95%CI=1.05-1.95, p=0.024, FDR corrected p-value=0.036) and preeclampsia/eclampsia (OR=1.48, 95%CI=1.08-2.05, p=0.016, FDR corrected p-value=0.036). Sleep apnea did not increase the increased risk of gestational hypertension (OR=1.37, 95%CI=0.991.90, p=0.061, FDR corrected p-value=0.061). No heterogeneity or horizontal pleiotropy was found among the tests. Leave-one-out analysis indicated that the causal estimates of sleep and psychiatric disorders were not driven by any single single-nucleotide polymorphisms (SNPs).

Conclusion: These results provide genetic evidence suggesting a causal relationship between sleep apnea and the increased risk of gestational diabetes and preeclampsia/eclampsia. Addressing sleep apnea before or during pregnancy could be a potential avenue for preventing these adverse maternal outcomes. Further studies are needed to confirm these findings and to explore underlying biological mechanisms.

SLEEP ARCHITECTURE AND OBSTRUCTIVE SLEEP APNEA DIFFERENCES AMONG PACIFIC ISLANDERS: A SINGLE-CENTER STUDY IN SAIPAN

Jasmine May[1], Kavish Khamesra[2], Benjamin Sarta-Moran[3], David Liss[3], Kimberly Hutchison[4]

[1] Oregon Healthy and Science University Hospital, [2] Northeastern University, [3] Pacific Sleep Center, [4] Oregon Health and Science University

Introduction: Saipan, the largest island in the U.S. Commonwealth of the Northern Mariana Islands (NMI) and home to a predominantly native Pacific Islander population, has a high prevalence of obesity and chronic conditions which

increase obstructive sleep apnea (OSA) risk. OSA often goes unrecognized and untreated, especially in minority communities. Additionally, unique craniofacial structures in this population influence the prevalence of OSA and pose challenges for effective management. No prior study has looked at the frequency and characteristics of OSA in this population. We aimed to fill this gap by looking at age, BMI, and sex differences in sleep architecture and OSA frequency.
Methods: Retrospective cross-sectional analysis of polysomnographic data was collected between 2009-2020, in adults aged 18-82, from the only sleep testing center on the island. Variables including sleep architecture, respiratory variables, demographic data, and Epworth Sleepiness Scale scores were assessed. Statistical analyses included descriptive statistics, group comparisons, and logistic regression.
Results: Severity and prevalence of apnea was greater in men than women (94 vs 86%). Obstructive apnea index was 3 times higher in men vs women. Mean oxygen saturation was also lower in men vs women. We also redemonstrated the age impact on OSA severity in women with higher AHIs in older women particularly rising around 50 – 59 years old.
Conclusion: Our findings reveal that males tend to experience more severe forms of OSA compared to females; however, OSA severity in females increases with age, likely due to hormonal fluctuations. This study lays the groundwork for future research to further explore and address OSA in this unique population.

RESPIRATORY EVENT-RELATED HYPOXEMIA, ELECTROENCEPHALOGRAPHIC RESPONSE AND SUBJECTIVE SLEEPINESS IN OSA

Mohammadreza Hajipour[1], Anthony Yeung[2], AJ Hirsch Allen[2], Andrew Beaudin[3], Jill Raneri[3], Rachel Jen[4], Fréderic Series[5], Robert Skomro[6], Rebecca Robillard[7], John Kimoff[8], Patrick Hanly[3], Ali Azarbarzin[9], Najib Ayas[4]

[1] University of British Columbia, [2] The University of British Columbia, [3] University of Calgary, [4] UBC, [5] Laval University, [6] University of Saskatchewan, [7] University of Ottawa, [8] McGill university, [9] Brigham and Women's Hospital and Harvard Medical School

Introduction: Standard metrics of obstructive sleep apnea (OSA) severity, such as apnea-hypopnea index (AHI), do not correlate well with daytime sleepiness. In OSA patients, there is considerable variability in the severity of hypoxemia and the electroencephalographic (EEG) response associated with respiratory events. We hypothesized that nocturnal hypoxemia and EEG responses would be associated with subjective daytime sleepiness in patients with moderate-to-severe OSA.
Methods: We used cross-sectional data from participants enrolled in a Canadian Sleep and Circadian Network's clinical cohort of patients with suspected OSA who had moderate-to-severe OSA (AHI>15/hr). Event-related hypoxemia was quantified as the mean event-related hypoxic burden (HBev): mean area under the oxygen desaturation curve. EEG responses to respiratory events were quantified by calculating the power ratio (log(mean absolute power 6s after / mean absolute power 6s before the event)) across EEG frequency bands; subject-specific responses were defined as the mean EEG response across all events. We calculated an overall Brain Response to Events (BReTE) metric by summing power ratios across all frequency bands. Subjective daytime sleepiness was assessed by the Epworth Sleep Scale (ESS) with an ESS>10 considered indicative of daytime sleepiness). Logistic regression, controlling for age, body mass index, race, sex, AHI and comorbidities was employed to investigate hypothesized associations.
Results: We studied 468 patients (40%female) with a median [IQR] age=56 years [46,63], AHI=43events/hr [23,87], HBev=1.87%min [1.24,2.69]. More severe hypoxemia and a lower EEG response were independently associated with higher odds of daytime sleepiness. One standard deviation (SD) increase in HBev was associated with 41% higher odds of daytime sleepiness (95% CI: 1.14-1.75,p< 0.01), while a one SD increase in BReTE was associated with 27% lower odds of daytime sleepiness (95%CI: 0.58-0.91,p< 0.01). Blunted EEG responses were more prevalent across beta and gamma EEG frequencies. AHI was not associated with daytime sleepiness.
Conclusion: Greater event-related hypoxemia and blunted EEG responses were independently associated with subjective daytime sleepiness in moderate-to-severe OSA, emphasizing the pivotal roles of hypoxemia and EEG in evaluating daytime sleepiness in OSA. EEG findings could be the result of adaptations to chronic OSA exposure, resulting in reduced arousal responses. Future prospective studies should explore these intricate associations further.

THE SHINE SURVEY: UNCOVERING GENDER DIFFERENCES IN PSYCHOSOCIAL BURDEN OF OBSTRUCTIVE SLEEP APNEA

Monica Mallampalli[1], Alissa Mendoza[2], Emma Cooksey[3], John Yee[2], Elizabeth Brouwer[4], Lisa Bloudek[4], Rainie Wu[4], Kristina Yu[2]

[1] Alliance of Sleep Apnea Partners, [2] Apnimed Inc., [3] Project Sleep, [4] Curta Inc.

Introduction: Obstructive sleep apnea (OSA) is a serious, chronic sleep-related breathing disease in which the airway is obstructed during sleep causing disrupted breathing, sleep fragmentation, and reduced oxygenation. OSA may present differently by gender, potentially causing differential underdiagnosis and disease experience. The objective of this study was to assess the psychological and social impact of OSA by gender in U.S. adults with diagnosed OSA.
Methods: The SHINE online patient survey, developed in consultation with patient advocates and OSA experts, was administered to 1,500 OSA patients in the U.S. Results were assessed via generalized linear models with binomial distribution and logit link function, adjusted for age group, BMI category, race, region, income level, comorbidities, and time since diagnosis. Outcomes of interest were whether patients experienced ≥2 negative OSA symptoms in the past 30 days, experienced ≥2 negative feelings with OSA in the past 30 days and agreed (6 or 7 on a 7-point Likert scale) with ≥2 statements of OSA negatively affecting relationships.
Results: Of 1,500 respondents, 755 were men and 745 were women, with mean ages (SD) 50.7 (14.5) and 41.2 (14.4) years, respectively. Of seven listed OSA symptoms (daytime sleepiness, fatigue, irritability, mood changes, loud snoring, morning headaches, inability to concentrate), women were 1.52 times

more likely than men to report ≥2 symptoms in the past 30 days (p=0.04). When asked whether OSA negatively affected relationships (overall impact, impact on care for family/friends, ability to be present, and social engagement), women were 1.42 times more likely than men of agreeing with ≥2 of 5 statements (p=0.01). Of 13 listed negative feelings (hopeless, depressed, frustrated, misunderstood, anxious, irritable, angry, not dependable, isolated, ashamed, embarrassed, scared, and low self-esteem), women were 1.61 times more likely than men to experience ≥2 feelings in the past 30 days (p=0.01).

Conclusion: OSA manifests differently in women compared to men. Our study further supports gender differences in patient reported outcomes, with women experiencing a higher psychosocial burden and more severe lived experiences, even after adjusting for baseline characteristics. These findings underscore the critical need for gender-specific approaches in the screening, diagnosis and treatment of OSA.

IMPACT OF OBSTRUCTIVE SLEEP APNEA ON DAILY LIFE BY DISEASE SEVERITY LEVEL: ANALYSIS FROM THE SHINE SURVEY

Alissa Mendoza[1], Monica Mallampalli[2], Emma Cooksey[3], John Yee[1], Elizabeth Brouwer[4], Lisa Bloudek[4], Rainie Wu[4], Kristina Yu[1]

[1] Apnimed Inc., [2] Alliance of Sleep Apnea Partners, [3] Project Sleep, [4] Curta Inc.

Introduction: Obstructive sleep apnea (OSA) is a serious, chronic, sleep-related breathing disease characterized by intermittent airway blockage during sleep, leading to disrupted breathing, fragmented sleep, and reduced oxygenation. OSA is often underdiagnosed particularly in mild cases, despite its significant negative impact on daily functioning and quality of life. This analysis aimed to evaluate the impact of OSA on daily life of people living with OSA, based on self-reported OSA severity levels.

Methods: The SHINE online patient survey, developed in consultation with patient advocates and OSA experts, was administered to 1,500 OSA patients in the United States. Data were analyzed using generalized linear models with a binomial distribution and logit link function, adjusted for age group, BMI category, race, region, income level, comorbidities, and time since diagnosis. Model outcomes included: (1) whether OSA limited patients' ability to engage in regular, non-work activities (rated 3, 4 or 5 on a 5-point scale), (2) whether OSA affected work productivity (rated 3, 4 or 5 on a 5-point scale), and (3) experienced ≥2 negative OSA symptoms in the past 30 days.

Results: Among respondents, 13% reported mild, 54% moderate, and 30% severe OSA. Results showed that patients at all levels of severity experienced symptoms and negative impact to daily activities and work productivity. The percentage of patients who reported ≥2 symptoms in the past 30 days was 84%, 91% and 86% (p=0.003) among mild, moderate and severe patients, respectively. Mild (48%), moderate (64%) and severe (62%) patients also reported that OSA affected their non-work activities (p< 0.01). Among employed patients, 39%, 51%, and 48% of mild, moderate and severe patients, respectively, reported that OSA negatively impacted work productivity (0=0.002). Comorbidities, including COPD, diabetes, and insomnia, were significantly associated with increased odds of OSA affecting work and non-work activities (p< 0.05).

Conclusion: Patients with OSA across the severity spectrum experienced daily life challenges, with severity generally correlating with greater impact. Surprisingly, even those with mild OSA experienced significant negative impact on their daily work and non-work activities. These findings emphasize the importance of early screening, diagnosis and treatment to delay the progression to severe OSA.

ASSOCIATION BETWEEN REM SLEEP DEPENDENT OSA AND FATIGUE IN POPULATION WITH NORMAL RANGE OF AHI

Kwang Ik Yang[1], Jiwon Lim[2], Seungju Kim[2], Jaeyeong Bae[2], Nam Hun Heo[2]

[1] Sleep Disorders Center, Department of Neurology, Soonchunhyang University Cheonan Hospital, Soonchunhyang University College of Medicine, [2] Soonchunhyang University Cheonan Hospital

Introduction: The population with an overall apnea-hypopnea index (AHI) in the normal range are not diagnosed with obstructive sleep apnea syndrome (OSAS), even if their AHI during REM sleep period is above 5. The clinical significance of REM sleep-dependent OSA (REM-OSA) remains controversial. We investigated the association between REM-OSA and fatigue and factors related to fatigue in population with normal range of AHI.

Methods: 3,061 patients underwent polysomnography (PSG) for suspected OSA. Among them, 480 patients had an overall AHI of less than 5. After excluding patients with total sleep time (TST) less than 120 minutes or the duration of REM sleep less than 30 minutes, 316 patients were retrospectively studied. REM-OSA was defined as a REM-AHI/NREM-AHI of 2 or greater and a REM-AHI of 5 or greater. Demographic data and sleep questionnaires such as Epworth Sleepiness Scale (ESS), Fatigue Severity Scale (FSS), Insomnia Severity Index (ISI), Patient Health Questionnaire (PHQ-9), Pittsburgh Sleep Quality Index (PSQI), and Sleep Apnea scale of the Sleep Disorders Questionnaire (SASDQ) were collected.

Results: 108 patients (34.18%) were classified as REM-OSA and the mean age was 45.69 ± 14.26 (vs. 43.79 ± 15.58), with 67 females (62.04% vs. 57.69%). The BMI was found to be significantly higher in the REM-OSA group (24.89 ± 4.98) (vs. 22.98 ± 3.40) (p=0.001). The SASDQ score was higher in the REM-OSA group (23.27± 6.79 vs. 21.29 ± 7.04) (p=0.017). In univariate regression analysis, REM-OSA was not associated with fatigue (OR, 0.771; 95% CI, 0.481 - 1.236). Age (OR, 0.954; 95% CI, 0.925 - 0.984), ESS (OR, 1.228; 95% CI, 1.105 - 1.364), ISI (OR, 1.081; 95% CI 1.015 - 1.151), PHQ-9 (OR, 4.647; 95% CI, 1.649 - 13.101), and REM-AHI/NREM-AHI (OR, 0.951: 95% CI, 0.906 - 0.999) were statistically significantly associated with fatigue. After adjustment, factors related to fatigue were age (OR, 0.903; 95% CI, 0.823 - 0.991), BMI (OR, 0.812; 95% CI, 0.686-0.962) and EDS (OR, 15.498; 95% CI, 1.673 -143.523).

Conclusion: There was no association between REM OSA and fatigue in the normal range of AHI. Age, BMI, and EDS were related to fatigue in this population.

SHORT-TERM RELIABILITY OF OBSTRUCTIVE SLEEP APNEA SYMPTOM SUBTYPES

Nathan Nesbitt[1], Michael Koenig[2], Brendan Keenan[3], Peter Cistulli[4], Glenn Stewart[4], Nigel McArdle[5], Bhajan Singh[5], Diego Mazzotti[6], Jared Heavens[7], Hao Cheng[8], Fang Han[9], Gonzalo Labarca[10], Thomas Penzel[11], Allan Pack[12], Ulysses Magalang[1]

[1] The Ohio State University, [2] The Ohio State University Wexner Medical Center, [3] University of Pennsylvania, [4] University of Sydney, [5] Sir Charles Gairdner Hospital, [6] University of Kansas Medical Center, [7] The University of Kansas, [8] Miami VA Medical Center, [9] Peking University People's Hospital, [10] School of Medicine Pontificia Universidad Católica de Chile, [11] Charité - Universitätsmedizin Berlin, [12] University of Pennsylvania Perelman School of Medicine

Introduction: Over 10 years ago, a seminal study using cluster analysis in the Icelandic Sleep Apnea Cohort (ISAC) identified subtypes of patients with obstructive sleep apnea (OSA) defined as excessively sleepy (presenting with multiple sleepiness complaints), disturbed sleep (characterized by insomnia-related complains), and minimally symptomatic. These subtypes have since been shown to generalize in clinical and population samples worldwide. An important step towards clinical translation is understanding the short-term (e.g., weeks) reliability of these subtypes. We describe results from an ongoing study to answer this question across sites in the Sleep Apnea Global Interdisciplinary Consortium (SAGIC).

Methods: We used a prospective test-retest study of subjects with newly diagnosed or suspected OSA prior to initiating therapy. Participants completed a questionnaire on OSA symptoms twice (at least two weeks apart). A patient's symptom subtype at each timepoint was determined based on questionnaire responses using a prediction model derived in existing SAGIC patients. To understand short-term reliability of subtypes, we calculated the percent agreement and simple kappa coefficients. Kappa values indicate slight (0.00-0.20), fair (0.21-0.40), moderate (0.41-0.60), substantial (0.61-0.80), and almost perfect (0.81-1.00) reliability.

Results: Our sample included 116 participants from 4 SAGIC sites: Ohio State (n=43), Kansas (n=7), Sydney (n=37) and Perth (n=29). The sample was 50% male, 55.2±13.9 years-old, had a BMI of 31.8±6.8 kg/m2, and an AHI of 22.3±18.5 events/hour. Questionnaires were completed an average (±SD) of 18.8±7.8 days apart. At the first visit, 51 (44.0%) patients had the disturbed sleep subtype, 42 (36.2%) were minimally symptomatic, and 23 (19.8%) were excessively sleepy. At the second visit, 47 (40.5%) had the disturbed sleep subtype, 43 (37.1%) the minimally symptomatic and 26 (22.4%) the excessively sleepy. Overall, 84.5% (95% CI: 77.9%, 91.1%) of patients fell within the same subtype at both timepoints. The Kappa (95% CI) was 0.759 (0.657, 0.853), indicating substantial short-term reliability.

Conclusion: While recruitment is ongoing across all SAGIC sites, this early analysis suggests substantial reliability of symptom subtypes over a short timeframe (without treatment). This further supports the potential clinical utility of the symptom subtype framework in advancing more personalized patient care.

THORACOABDOMINAL ASYNCHRONY IN MILD SLEEP-DISORDERED BREATHING: PEDIATRIC ADENOTONSILLECTOMY FOR SNORING (PATS)

Samer Bou Jawde[1], Raichel Alex[2], Michael Rueschman[3], Youmeng Wang[3], Scott Sands[2], Ali Azarbarzin[2], Susan Redline[4]

[1] Brigham and Women's Hospital, [2] Brigham and Women's Hospital and Harvard Medical School, [3] Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Harvard Medical School, [4] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Mild Sleep-disordered Breathing (mSDB), characterized by habitual snoring, is associated with adverse health outcomes, possibly due to increased inspiratory effort despite few apneas and hypopneas. Thoracoabdominal asynchrony (TAA) has been used to quantify inspiratory effort in children with obstructive sleep apnea, but has not been evaluated in children with mSDB. Hence, in the Pediatric Adenotonsillectomy for Snoring study, we aimed to quantify TAA in children with mSDB and examine its responsiveness to intervention by studying changes after adenotonsillectomy.

Methods: Children with mSDB (snoring, apnea-hypopnea index < 3) and ages 3 to 12 years were studied with polysomnography at baseline and at 12-months after randomization to adenotonsillectomy (AT) or watchful waiting (WW). TAA was calculated from the Fourier transforms of the abdomen and thoracic respiratory inductance plethysmography band signals as the phase angle difference at the dominant frequency. Regions that included noise, movements, respiratory events, and arousals were excluded to obtain periods of quiet sleep. The TAA's effect of adenotonsillectomy was assessed via repeated measures ANCOVA using a linear mixed-effects model, with and without adjustment for race, BMIz, change in BMIz, age, and sex.

Results: 304 participants (n=149 WW; n=155 AT) were analyzed (age: 6.5±2.26 years; BMIz: 0.52±1.25; 48% females; 63% White, 29% Black; AHI 1.29±1.03 events/hour). Median TAA was 29 [IQR: 18,47] degrees at baseline and did not differ between intervention groups but were higher in females (vs. male) and lower with higher BMIz. Children who underwent AT showed TAA reduction during NREM sleep at follow-up (vs. baseline) compared to WW by -6 degrees (95% CI: [-11, -1], p-value=0.016). There was no change in TAA during REM sleep. Adjustment for covariates yielded similar results.

Conclusion: The potential utility of TAA in children with mSDB was supported by demonstrating improved asynchrony following adenotonsillectomy in NREM sleep. Future work will investigate TAA's role as a predictor of behavioral and physiological outcomes in children with mSDB.

ADOLESCENT PATIENTS WITH OSA HAVE GREATER SLEEP DISTURBANCES EVEN AT LOW AHI

John Karstens[1], Soumendro Goswami[1], Hema Murali[1], Sreelatha Naik[1]

[1] Geisinger

Introduction: The AASM Scoring Manual permits the use of adult criteria for diagnosing obstructive sleep apnea in patients 13 and older. There is a lack of consensus regarding the preferred criteria in adolescent patients. WASO (wake after sleep onset, as a marker of sleep disruption) and percentage of TST (total sleep time) with saturations less than 89% (as a marker of degree of hypoxia) can be used as surrogate criteria for severity of sleep apnea in adolescents and may be associated with OSA comorbidities.
Methods: Data was collected from the EMR for the census of pediatric patients using sleep lab records at the Geisinger Wilkes-Barre Sleep Lab between December 2023 and August 2024. Measures collected included gender, age, AHI, WASO, and total sleep time (TST). Average WASO and percentage of TST with saturations less than 89% were calculated for adolescents and younger pediatric patients at AHI of 1-4.9 (identified here as pediatric criteria) and 5.0 and greater (identified here as adult criteria).
Results: Application of the full pediatric criteria led to increased diagnosis of OSA in adolescents, as an AHI of 1-4.9/hr was adequate to lead to a diagnosis of OSA. Average WASO was relatively unchanged for patients younger than 13 regardless of which criteria were utilized with an average WASO of 51.2 minutes by pediatric criteria for mild OSA and 52.6 minutes by the adult criteria. For adolescent patients, WASO increased from 79.5 minutes by pediatric criteria for mild OSA to 88.5 minutes by the adult criteria. The hypoxic burden worsened in both groups as AHI increased. For patients younger than 13, hypoxia was 0.28% of TST by pediatric criteria for mild OSA and 1.66% by the adult criteria. For adolescent patients, the same measure was 0.04% by pediatric criteria for mild OSA and 4.34% by the adult criteria.
Conclusion: Among adolescent patients (13-17), when utilizing the "pediatric criteria" for OSA diagnosis, there was a lower burden of hypoxia, but a greater degree of sleep disturbance as measured by WASO. More studies are needed to demonstrate whether treatment of OSA established by this criteria will help improve WASO and daytime functioning.

VALIDATION OF A NOVEL PATCH-BASED TYPE II POLYSOMNOGRAPHY SYSTEM

H Schneider[1], W Galetke[2], H Woehrle[3], G Nilius[4], C Schobel[5], W Randerath[6], Christian Viniol[7]
[1] ASC, [2] VAMED Klinik, [3] Lungenzentrum, [4] MD, [5] Rurlandklinik, [6] Nlinik Bethanien, [7] Universitätsklinikum Marburg

Introduction: While in-laboratory polysomnography (PSG) remains the benchmark for sleep assessment, it faces challenges of high cost, time requirements, and the limited availability of trained technicians. A novel home-based alternative, the Onera Sleep Test System (STS), offers patch-based monitoring for unattended sleep evaluation.
Methods: A multi-site clinical investigation enrolled 206 participants (66% male) with potential sleep disorders. Each participant underwent simultaneous monitoring with traditional PSG and the patch-based system during one night. Sleep data was evaluated independently by three scorers using AASM guidelines in a blinded manner.
Results: Setup time showed marked differences: 19.5±6.8 minutes for traditional PSG versus 5.8±1.8 minutes for the patch system. Statistical analysis revealed strong correlation between the two methods across key metrics including total sleep time (0.87), NREM sleep (0.80), REM sleep (0.80), AHI with 3% desaturation (0.90), and oxygen desaturation index (0.80). The patch system demonstrated robust diagnostic performance at various AHI thresholds: for AHI≥5, accuracy measures were 0.86 (precision), 0.85 (sensitivity), and 0.75 (specificity). Similar strong performance was observed at higher thresholds. No safety concerns emerged during testing.
Conclusion: The patch-based system offers significantly faster setup while maintaining strong agreement with traditional PSG measurements. Its performance metrics support its potential as a reliable tool for home-based sleep assessment.
Support (if any): Supported by Onera Health.

PATIENT PERCEPTION OF A NOVEL PATCH-BASED TYPE II POLYSOMNOGRAPHY SYSTEM

H Schneider[1], W Galetke[2], H Woehrle[3], G Nilius[4], C Schobel[5], W Randerath[6], Christian Viniol[7]
[1] ASC, [2] VAMED Klinik, [3] Lungenzentrum, [4] MD, [5] Rurlandklinik, [6] Nlinik Bethanien, [7] Universitätsklinikum Marburg

Introduction: The demand for in-laboratory polysomnography (PSG) is expected to outgrow the amount of dedicated beds, PSG equipment and trained personnel over the next 10 years. The Onera Sleep Test System (STS) is a patient applied, patch-based, type II PSG system, which enables PSG studies to be performed unattended at the patient's home. We report patient perception of the patch-based system and confidence in using it to perform an unsupervised home study.
Methods: 356 patients (age: 50.6 ± 12.7, male/female: 66.7%/33.3%, BMI: 30.2 ± 7.9) were recruited for a multicentre trial in Germany validating the Onera STS patch-based PSG system against traditional PSG in the sleep laboratory. 333 patients completed a first impressions questionnaire in full, and 328 completed a user perception questionnaire in full. 204 patients completed the second phase of the study where they used the patch-based system unsupervised at home, from which 172 patients completed the At-Home questionnaire in full. Demographics for each subset of participants were similar to the original cohort.
Results: Upon first impression, 84.1% of patients liked the size of the patch-based PSG system, 93.7% had no concerns about wearing it and 82.6% were confident that they could fit the device at home, unsupervised. Following at-home use, 77.3% reported no difficulties in applying the system, 90.7% were confident that they had placed the sensors correctly and 90.7% were satisfied with the system in general. Comfort with the patch-based system was high with the majority of patients agreeing that the leg (90.1%), flow (90.7%), chest (89.4%) and head sensor (80.1%) were comfortable.
Conclusion: Upon first impression, the majority of patients were not intimidated by the patch-based PSG and were confident that they could fit it unsupervised at home. The level of issues experienced during unsupervised home use was low and most patients were satisfied with their experience. The majority of patients rated the patch-based PSG as comfortable following overnight use.

ENHANCING PREDICTION OF SLEEPINESS, INSOMNIA, AND COGNITIVE IMPAIRMENT USING MACHINE LEARNING ON POLYSOMNOGRAPHY

Archita Srivastava[1], Mohammadreza Hajipour[2], Andrew Beaudin[3], Patrick Hanly[3], Eric Smith[4], Fréderic Series[5], Rebecca Robillard[6], John Kimoff[7], Jill Raneri[3], Ghassan Hamarneh[1], Najib Ayas[8]

[1] Simon Fraser University, [2] University of British Columbia, [3] University of Calgary, [4] University Calgary, [5] Laval University, [6] University of Ottawa, [7] Mcgill university, [8] UBC

Introduction: Obstructive sleep apnea (OSA) is a prevalent disorder affecting approximately a billion people globally. Traditional diagnostic metrics from polysomnography (PSG) such as the apnea hypopnea index (AHI) are limited in predicting OSA-related impacts. This study aims to leverage machine learning (ML) methods to enhance PSG prediction of three outcomes: daytime sleepiness (defined as Epworth Sleepiness Scale >10), insomnia (Insomnia Severity Index >15) and cognitive impairment (Montreal Cognitive Assessment < 25) in patients with moderate to severe OSA.

Methods: This pilot study utilized a subset of Canadian Sleep and Circadian Network participants (patients with suspected OSA recruited from academic sleep centres). Advanced signal processing was used to derive 790 features from PSG European Data Format (edf) files including: respiratory events, heart rate variations, limb movements, and EEG based metrics from leads C3/C4 (e.g., sleep stages, spindle metrics, power frequencies, sleep depth, arousal intensity). 541 participants with moderate to severe OSA (AHI>15/hr) were included. Python 3.11.6 was used for analysis. For each outcome, dimensionality reduction was done using Lasso Regression, Principal Component Analysis (PCA), and Recursive Feature Elimination (RFE). Binary classification models with Logistic Regression (LR), Support Vector Classification (SVC), Random Forest (RF), Multi-Layer Perceptron (MLP), Gaussian Naïve bayes, and XGBoost were then used (18 models tested). Model accuracy was assessed using 5-fold cross validation.

Results: Models that employed RFE for feature selection and LR for classification (based on 50-70 features depending on outcome) yielded the best performance. The average accuracy/F1 values across all target outcomes were 0.71/0.71 for sleepiness, 0.68/0.61 for insomnia, and 0.62/0.62 for cognitive impairment. However, accuracy of all the ML models surpassed the predictive accuracy of AHI alone (accuracy of 0.55, 0.60, 0.53 using logistic regression).

Conclusion: This preliminary study supports the concept of applying advanced signal processing and ML techniques to PSG to help predict OSA-related outcomes. Future research with larger sample sizes, more diverse patients, more refined ML methodologies, and better feature engineering should further improve accuracy of these models.

CLINICAL VALIDATION OF ECG-BASED OBSTRUCTIVE SLEEP APNEA SCREENING USING MACHINE LEARNING

Yoav Nygate[1], Matt Sprague[2], Sam Rusk[1], Chris Fernandez[1], Nathaniel Watson[3]

[1] EnsoData Research, EnsoData, [2] EnsoData, [3] University of Washington

Introduction: Obstructive sleep apnea (OSA) is an underdiagnosed sleep-related breathing disorder. It is strongly associated with cardiovascular disorders, suggesting a moderate-to-high incidence of co-occurrence among cardiovascular diseases and OSA in patients indicated for multi-night cardiac diagnostic testing. This presents an opportunity to screen for sleep disorders during ambulatory cardiology testing, referring flagged patients for further sleep testing, ultimately increasing the diagnosis and treatment throughput of sleep disorders.

Methods: A Machine Learning (ML) system was developed utilizing over 100,000 diagnostic polysomnography (PSG) studies with concurrently recorded electrocardiogram (ECG) signals. The system leveraged multiple deep neural network models to identify respiratory and sleep-stage-specific ECG patterns, forming an automated tool for ECG-based sleep quality assessment and OSA screening. Clinical validation was performed on a dataset of 185 subjects from a prospective clinical study. PSG results were scored by three RPSGTs, with board-certified sleep physicians providing quality assurance. The ML system's performance was evaluated against the gold-standard OSA diagnosis using an AHI threshold of 15 events per hour to identify positive OSA cases. Furthermore, to assess ECG-based sleep staging performance, sleep stages were reduced to Wake, Light Sleep (N1 + N2), Deep Sleep (N3), and REM, and agreement was evaluated utilizing an epoch-by-epoch approach.

Results: The ML system achieved a sensitivity and specificity of 90.1% (81.7%, 96.7%) and 84.9% (78.4%, 90.4%) for OSA screening. Furthermore, the ML system produced a sleep staging epoch-by-epoch agreement with a sensitivity and specificity of 91.3% (91.0%, 91.5%) and 95.5% (95.4%, 95.6%) for Wake, 78.7% (78.4%, 78.9%) and 91.2% (91.0%, 91.4%) for Light Sleep, 83.5% (82.7%, 84.3%) and 93.2% (93.1%, 93.3%) for Deep Sleep, and 89.2% (88.7%, 89.6%) and 97.6% (97.5%, 97.6%) for REM.

Conclusion: The ECG-based ML system demonstrated its potential as a scalable solution for automated OSA screening with high sensitivity and specificity in comparison to the gold-standard. The results highlight the ML system's capability to expand OSA screening, facilitating further diagnosis and treatment of sleep disorders in the broader patient population with cardiovascular disease.

IT'S THE HEART: NOVEL SUBTYPE OF OBSTRUCTIVE SLEEP APNEA SYNDROME USING OXYGEN SATURATION AND HEART RATE

Seung Soo Kim[1], Han Na Jang[1], Woojoong Kim[2], Sung Hwan Byun[3], Hyewon Woo[4], Jin-Hwa Moon[5]

[1] Department of Pediatrics, Soonchunhyang University College of Medicine, [2] Department of Pediatrics, Seoul National University Children's Hospital, [3] Department of Pediatrics, Bundang Jaesaeng Hospital, [4] Department of Pediatrics, Chungbuk National University Hostpital, [5] Department of Pediatrics, Hanyang University College of Medicine

Introduction: Studies predicting survival using the apnea-hypopnea index (AHI) have not produced consistent results in Obstructive sleep apnea syndrome (OSAS) patients. Authors conducted this study to subtype OSAS using heart rate and oxygen saturation, which reflect cardiac health that has a significant impact on survival.

Methods: We conducted the study using the PSG and clinical information of the sleep heart health study dataset (Quan SF, et al., 1997). Only subjects with an AHI ≥ 5/hour on the first PSG were included in the analysis. K-means clustering was performed using the variance of oxygen saturation and heart rate during sleep after the uniform manifold approximation projection (UMAP). We also calculated a brain age index using electroencephalography channel (C3A2) (Sun H, et al., 2019). Cox proportional hazard analysis was performed using the cluster revealed along with the other variables (gender, age, body mass index [BMI], AHI, and brain age index).
Results: 4803 subjects (male 52.3%, 64.2 [standard deviation, SD 11.1] year-old at the first visit) were included in the analysis. We revealed distinctive 2 clusters (average silhouette score = 0.44, Calinski-Harabasz score = 6837.92). Cluster 2 (n=2688, male 56.2%, 64.9 [SD 10.8] year-old) showed lower BMI, AHI, average heart rate, and higher average oxygen saturation compared to cluster 1 (n=2089, male 47.4%, 63.4 [SD 11.3] year-old). In the cox proportional hazard model, each variable showed the following hazard ratio (HR) and 95% confidence interval (95% CI): cluster 2 (0.70 [95% CI 0.62, 0.79]), male gender (1.43 [95% CI 1.27, 1.62]), age (1.13 [95% CI 1.12, 1.13]), BMI (0.99 [95% CI 0.98, 1.00]), AHI (1.00 [95% CI 1.00, 1.01]), brain age index (1.02 [95% CI 1.01, 1.03]).
Conclusion: Authors identified the novel subtype of OSAS using variance of heart rate and oxygen saturation in PSG. And that have a greater impact on survival prognosis than AHI and brain age index reported in previous studies.

RECOGNITION OF HIGH LOOP GAIN RESPIRATION: COMPARISON OF SELF-SIMILARITY ANALYSIS AND CLINICIAN INTERPRETATION

Joseph Russo[1], Sullivan Abigayle[1], Aqsa Anwar[1], Thijs-Enagnon Nassi[2], Eline Oppersma[3], Gonzalo Labarca[4], M. Brandon Westover[5], Robert Thomas[5]

[1] Beth Israel Deaconess Medical Center/ Harvard Medical School, [2] Beth Israel Deaconess Medical Center | Harvard Medical School, [3] University of Twente, [4] School of Medicine Pontificia Universidad Católica de Chile, [5] Beth Israel Deaconess Medical Center

Introduction: High Loop Gain (HLG) respiration noted on diagnostic Polysomnography (PSG) or during positive airway pressure titration is a marker of treatment complexity for Obstructive Sleep Apnea (OSA). Self-Similarity (SS) software analysis of breathing cycles occurring in association with respiratory events has been shown to be an accurate and clinically useful tool to detect HLG; however, little data exist regarding identification by sleep medicine physicians. Our goal was to compare SS scores with clinician interpretation of periodic breathing or central sleep apnea.
Methods: SS analysis was run on a selection of polysomnograms from a data archive with a calculated central Apnea Hypopnea Index (SScAHI) in addition to %SSany index representing self similarity in breathing cycles. Demographic data and basic PSG values including AHI, and oxygenation data were recorded from the archived reports. Clinician interpretations from the archived studies were also examined for identification of key terms including "periodic breathing" and "high loop gain". Chi square analysis was performed to examine the relationship between clinician recognition of HLG and %SSany.
Results: Data from 148 patients (81 female, 67male) (mean ± SD) age 58.2 ± 18.2 years with BMI 29.7 ± 7.4. PSG revealed mean AHI (18.0 ± 15.4), cAHI (2.6 ± 6.0). SS analysis revealed mean %SS 10.9 ± 11.2. When stratified across 3 separate categories of SS 5% (Pearson chi2 = 9.50 Pr = 0.002), 10% (Pearson chi2 = 5.59 Pr = 0.018) and 20% (Pearson chi2 = 16.1509, Pr = 0.000) clinician interpretation lacked mention of HLG. Taking into account cAHI at even the SS 20% category also failed to elicit recognition of high loop gain (Pearson chi2 = 5.07, Pr = 0.024).
Conclusion: High Loop Gain respiration is often overlooked in clinician interpretation of polysomnography, and thus the potential benefit of adjunctive therapies including pharmacotherapy and CO2 modulation which target HLG are being lost. This highlights the benefits of methods such as SS analysis which can be used to detect HLG independent of clinician recognition of breathing cycle patterns.

EVALUATING THE IMPACT OF MULTI-NIGHT HOME SLEEP APNEA TESTING FOR OBSTRUCTIVE SLEEP APNEA DIAGNOSIS

Yoav Nygate[1], Jan Wodnicki[1], Sam Rusk[1], Chris Fernandez[1], Dennis Hwang[2], Nathaniel Watson[3]

[1] EnsoData Research, EnsoData, [2] Kaiser Permanente Southern California, [3] University of Washington

Introduction: Obstructive sleep apnea (OSA) is a prevalent sleep-related breathing disorder. The majority of adults with OSA remain undiagnosed and untreated, highlighting the importance of accurate diagnosis to ensure timely and effective treatment. While single-night polysomnography remains the gold standard for diagnosing OSA, the lack of access coupled with night-to-night variability contributes to underdiagnosis and inconsistent results, compromising diagnostic accuracy and increasing patient management cost.
Methods: A non-randomized all-comers retrospective dataset of 4,527 patients was collected throughout 2024 from clinical home sleep apnea testing using FDA-cleared wearable PPG devices. Each patient had at least three nights of recordings, and only nights with a minimum of four hours of technically adequate PPG signals and at least one hour of sleep were included. The mean number of nights was 3.29 and the maximum number of nights was 16. Furthermore, the dataset had an overall mean AHI of 15 events/hour and a median AHI of 9 events/hour. Night-to-night variability was assessed by determining whether the first night's results would have resulted in misdiagnosis. Additionally, maximum difference in OSA severity (None, Mild, Moderate, Severe) across all nights was evaluated. The overall pooled standard deviation of multi-night AHI was also calculated to provide a comprehensive assessment of variability in OSA severity.
Results: When comparing the first night to subsequent nights, 11.8% of OSA patients would have been missed, and 26.4% of patients experienced an increase in OSA severity by at least one severity category. When assessing overall variability across all nights, 50% of patients showed no change in OSA severity, 46% experienced an increase of one severity category, and 4% showed an increase of two severity categories. Additionally, the dataset revealed a pooled AHI standard deviation of 5.8 events per hour.

Conclusion: Multi-night sleep testing revealed a level of variability that could negatively affect diagnostic accuracy when conducting single-night sleep studies. Multi-night sleep testing can mitigate this issue by aggregating the sleep quality and respiratory disturbance information across multiple nights, providing a more comprehensive assessment of a patient's condition, and reducing the risk of misdiagnosis by ensuring that treatment decisions are based on a fuller understanding of OSA severity.

MODIFIED SCORING CRITERIA TO IMPROVE ACCURACY OF THE HOME SLEEP APNEA TEST

Philip Cushman[1], Matthew Brock[1], Zahari Tchopev[1], Aaron Burch[1], James Kang[1], Amanda Radtke[1], H. Samuel Scheuller[1]
[1] San Antonio Uniformed Services Health Education Consortium

Introduction: The Home Sleep Apnea Test (HSAT) has good diagnostic performance for patients with a high pretest probability of moderate to severe obstructive sleep apnea (OSA). However, the false negative rate has been reported to range from 17% - 46%, and the false positive rate is estimated to be 5-10%. For this reason, the American Academy of Sleep Medicine (AASM) recommends polysomnography (PSG) after nondiagnostic HSAT results (AHI < 5/hr). Our objective in this study is to improve the accuracy of HSATs by using hyperpneas as a surrogate for arousals.
Methods: A retrospective analysis was conducted on 69 patients with non-diagnostic Type 3 HSATs who underwent subsequent PSG. Original HSATs were re-scored using the recommended hypopnea scoring rule as defined by the AASM. For the purposes of this study, a hyperpnea was used as a surrogate for an arousal. A hyperpnea is defined in this study as a breath with ≥ 50% increase in amplitude over baseline breathing. Hypopneas were scored when there was a >30% decrease in flow for at least 10 seconds followed by a hyperpnea without significant oxygen desaturation (< 3%). The AHI from the experimental scoring criteria was compared to the original AHI from HSAT as well as the AHI from the PSG.
Results: Using the modified scoring criteria, the mean difference in AHI between HSAT and PSG was of 3.7/hr. Comparatively, the originally scored HSAT showed a mean difference in AHI of 5.9/hr from the PSG. Additionally, the modified scoring criteria HSAT had a false negative rate of 5% for this population, and had a false positive rate of 17%.
Conclusion: Incorporating a surrogate indicator of a cortical arousal such as a hyperpnea following an obstructive respiratory event can improve the accuracy of the HSAT AHI, decrease the false negative rate, and prevent repeat testing. One limiting factor in this study is that the HSAT and PSG were performed on different nights and in different environments. Further studies using these criteria on the same night as the PSG can validate this as a more accurate method to diagnose OSA using an HSAT.

AI-POWERED BELUN RING FOR STRATIFYING OSA AND COMORBID INSOMNIA SYMPTOMS IN INDIAN MONODISCIPLINARY CLINICS

Manvir Bhatia[1], Chih-Wei Tsai[2], Lydia Leung[2], Cynthia Cheung[2]
[1] Neurology and Sleep Centre, [2] Belun Technology Company Limited, Hong Kong

Introduction: Co-morbid insomnia and obstructive sleep apnea (COMISA) pose significant healthcare challenge due to their combined association with more severe cardiovascular outcomes than either condition alone. In India, diagnosis and treatment are often delayed due to restricted access to multidisciplinary care. The AI-powered Belun Ring (BR), a medical-grade wearable device, has shown promise in addressing this gap by facilitating OSA severity stratification and aiding COMISA management. This study explores the feasibility of using the BR for OSA diagnosis and sleep stage classification to triage patients with insomnia symptoms in resource-constrained monodisciplinary clinical settings.
Methods: A total of 257 participants (median age: 54 years, BMI: 27.9, 40% female) were recruited from a neurology clinic and monitored for 1-3 nights using the BR. Participants were classified into four groups based on BR-derived AHI4% (≥15 events/h) and sleep efficiency (< 80%): Normal (AHI < 15), OSA (AHI ≥15), COMISA (AHI ≥15 & SE< 80%), or Insomnia (SE < 80%). Sleep metrics such as sleep onset latency (SOL), wake after sleep onset (WASO), and heart rate variability (HRV) metrics were compared using the Mann-Whitney test. Co-morbidity frequencies, including diabetes and hypertension, were analysed with the Mantel-Haenszel Chi-Squared test.
Results: Among participants, 49% were Normal, 25% OSA, 10% COMISA, and 16% Insomnia. COMISA and Insomnia groups had significantly higher WASO than the OSA group ($p< 0.001$). The Insomnia group exhibited longer SOL compared to OSA and COMISA ($p< 0.001$, $p< 0.01$), along with the lowest SDNN ($p< 0.01$, $p< 0.05$). Among 155 patients with comorbidity data, COMISA had the highest rates of co-morbidities ($P< 0.001$) among OSA-alone ($p< 0.05$) and Insomnia-alone ($p< 0.05$) (Diabetes: 41%, 21%, 26%; Hypertension: 53%, 42%, 42%; ≥2 comorbidities: 35%, 12%, 26%) compared to normal respectively (Diabetes: 15%; Hypertension: 32%, ≥2 comorbidities: 12%).
Conclusion: The AI-powered BR effectively stratifies high-risk OSA patients with comorbid insomnia symptoms, highlighting their increased comorbidity burden. This scalable and reliable tool provides a novel solution for triaging high-risk patients in monodisciplinary clinical settings with limited access to comprehensive sleep care.

WHO HAS OSA? AN UPDATED DESCRIPTION OF PEOPLE THAT ARE BEING DIAGNOSED

Kate Cole[1], Anita Malik[2], Caleb Woodford[2], Naomi Alpert[2], Will McConnell[2], Kimberly Sterling[2]
[1] ResMed, [2] ResMed Science Center

Introduction: The biggest barrier to adequate treatment for obstructive sleep apnea (OSA) is the underdiagnosis of the condition. It is important to understand the diversity of clinical characteristics of people with OSA, so that clinicians can better screen for OSA and improve the rate of diagnosis. Using real-world data of people diagnosed with OSA who go on to receive positive airway pressure (PAP) treatment, we sought to describe the presentation of OSA at the time of diagnosis.
Methods: This was a retrospective cohort study conducted among people who had a OSA confirmed by a sleep test (index date) between January 2019 and February 2023 and later started on PAP therapy. De-identified insurance claims data were linked

with PAP data and electronic medical records. Characteristics from the year prior to index included demographics, body mass index (BMI), presence of comorbid conditions, and laboratory results. BMI and laboratory results were averaged only amongst those who had a measurement.
Results: The final sample included 211,089 people with newly diagnosed OSA. Of these, 47% were female, 61% were between the ages of 45 and 64, with an average age of 51.5 years. On average, patients had 3.3 other conditions at the time they were diagnosed with OSA and 90% were managing at least one other chronic condition (60% hypertension, 54% hyperlipidemia, 31% anxiety, 31% gastroesophageal reflux disease, 29% depression, and 26% type 2 diabetes). Average blood pressure readings were 131/80 indicative of stage 1 hypertension. Average total cholesterol was in normal range at 184mg/dL, and average A1C was 6.4 indicative of prediabetes. 59% had at least class 1 obesity, and the average BMI was 35.0 kg/m2. Compared to men, women were older, had more conditions, lower blood pressure, and higher cholesterol. The prevalence of women and mean number of conditions increased by age, while BMI and cholesterol decreased by age.
Conclusion: These real-world data show that diagnosis of OSA typically occurs during middle-age for women and men, and commonly presents with mild hypertension or prediabetes. These data should be used to raise awareness of the presentation of OSA to improve the rate of diagnosis.

SEX-BASED DIFFERENCES IN PULSE OXIMETRY FROM THE SNOOZZZE COHORT

Brynn Norby[1], Pamela DeYoung[2], Christopher Schmickl[2], Robert Owens[2], Ali Azarbarzin[3], Jeremy Orr[2]
[1] University of California San Diego, [2] University of California, San Diego, [3] Brigham and Women's Hospital and Harvard Medical School

Introduction: Pulse oximetry has been under scrutiny due to recent findings that SpO2 accuracy is worse in non-white individuals. Dynamic SpO2 changes may be particularly impacted, which may lead to bias in OSA diagnosis and severity determination (e.g. hypoxic burden). OSA may be underdiagnosed in women, but little is known about sex-based differences in pulse oximetry performance during polysomnography.
Methods: We utilized the San Diego Multi-Outcome OSA Endophenotype (SNOOzzzE) Cohort which comprises adults who underwent clinical in-laboratory PSG at UCSD between 2015 and 2022 (IRB #182136). Raw PSG signals were used to determine oximetry-independent Apnea-hypopnea index ("AHIflow"), which was compared with AHI using AASM AHI3A and AHI4 criteria, as well as hypoxic burden. Differences between men and women were compared using multivariable models adjusted for BMI, wake oxygen saturation and percent hypopneas.
Results: 2,583 individuals were included in the analysis (1,145 women, 1,438 men). Female participant median age was 57(IQR 45,66) years, BMI 33(27,41) kg/m2, and AHI3A 20(11,38) events/hr. Male participant median age was 55(42,68) years, BMI of 30(26,35) kg/m2, and AHI3A 29(14,57) events/hr. AHIflow was significantly associated with AHI3A ($p< 0.001$), but there was no significant difference in the relationship between AHIflow and AHI3 between women and men ($p=0.269$). AHIflow was significantly associated with AHI4 ($p< 0.001$), and there was a statistically significant difference between AHIflow and AHI4 between women and men ($p=0.041$) but the absolute difference was very small (i.e., difference between men and women of 0.3 events/hr if AHI was 100 events/hr). AHIflow was significantly associated with hypoxic burden ($p< 0.001$), but there was no significant difference in the relationship between AHIflow and hypoxic burden between women and men ($p=0.878$).
Conclusion: This analysis does not reveal major differences in pulse oximetry performance in the detection of OSA severity between men and women, particularly when adjusting for other factors that might influence propensity for desaturation. Nonetheless, there is potential for unmeasured imbalances that obscure differences in ability to detect a true desaturation. There may be differences in propensity for oxygen desaturation during respiratory events between men and women; Our findings suggest that oximetry should be technically reliable for evaluating these biological differences.

ASSESSING LOW AROUSAL THRESHOLD IN OBSTRUCTIVE SLEEP APNEA: INSIGHTS FROM A GENERAL POPULATION STUDY

Carlos jaime Faria[1], Dalva Poyares[2], Monica Andersen[3], Pedro Genta[2], Sergio Tufik[4]
[1] Universidade Federal de Sao Paulo, [2] Universidade de Sao Paulo, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo, [4] Universidade de Federal de São Paulo

Introduction: Obstructive sleep apnea (OSA) results from a combination of anatomical and non-anatomical endotypes. Among the non-anatomical factors, a low arousal threshold (LAT) can make it challenging for individuals to tolerate and adhere to certain treatments. The aim of this study was to determine the prevalence of the LAT endotype among the participants in the 4th edition of the Sao Paulo Epidemiological Sleep Study (EPISONO), and analyze the sociodemographic characteristics associated with LAT.
Methods: We used the algorithm proposed by Edwards et al. (2014) to identify LAT that is based on polysomnographic (PSG) parameters, namely the apnea-hypopnea index (AHI), peripheral oxygen saturation (SpO_2) and the percentage of hypopneas. Questionnaires on quality of life, fatigue, daytime sleepiness, and insomnia were also applied to assess gender-related differences between male and female non-OSA, LAT and high arousal threshold (HAT) participants.
Results: The groups differed significantly in terms of age and body mass index; however, there were no significant differences between ethnicities and for most of the assessed symptoms. A higher frequency of symptoms was observed in women, especially in those belonging to the LAT (OSA) group compared to men in the same group. Clinically significant insomnia was also more prevalent in females. In respect of the LAT (OSA) participants, no differences were observed between participants with and without clinically significant insomnia in the OSA group.
Conclusion: The characterization of the LAT endotype, and the higher frequency of symptoms in OSA women highlight

the importance of valuing polysomnographic findings and the symptoms reported by women during clinical assessment. LAT showed no relationship with worsening arousability among participants with co-morbid insomnia and sleep apnea (COMISA) compared to those with OSA-only in this study.

EXPLORATORY STUDY OF THE EFFECT OF ALCOHOL ON HOME SLEEP APNEA TESTING UTILIZING PERIPHERAL ARTERIAL TONE

Aaron L Schnell[1], Chad Ruoff[2], Yasemin Tashman[1], Ashley L Garrett[1], Umesh Goswami[1], Kari A. Martin[1], Ann M. Petersen[1], Caitlin C. Haley[1], Kimberly Rogers[1], Matthew J. Lizak[1], Caroline J. Schaal[1], Christopher M. Lamas[1], Claire I. Yee[1], Philip J. Lyng[1], Lois E. Krahn[3]

[1] Mayo Clinic Arizona, [2] Mayo Clinic, [3] Mayo Clinic College of Medicine, Department of Psychiatry and Psychology

Introduction: A previously published case report suggested that alcohol might cause false-negative results in home sleep apnea testing (HSAT) utilizing Peripheral Arterial Tonometry (PAT). Alcohol is consumed by nearly a third of people globally. Based on this, along with rapid growth in PAT HSAT utilization, we aimed to prospectively study the interaction between alcohol consumption and PAT HSAT technology. We hypothesized that alcohol use would significantly attenuate sleep disordered breathing metrics in contrast to existing literature suggesting alcohol may exacerbate sleep apnea.

Methods: We planned to recruit subjects (N=100) from Mayo Clinic Arizona sleep clinic who were being evaluated for sleep-disordered breathing and elected to undergo home sleep apnea testing (WatchPAT ONE). Participants were required to report social alcohol use (no more than 1-3 drinks per day). The first and second home sleep apnea test were conducted on separate nights (night 1: without alcohol; night 2: with alcohol). Patients also completed a questionnaire, detailing their normal alcohol intake as well as intake during the respective sleep tests. Statistical analysis included paired sample t-test as well as a descriptive analysis.

Results: A total of 75 subjects were recruited (mean age [± SD] 56.8 ± 11.9; 90.7% male; mean BMI 29.8 ± 5.8) and 56 patients completed both sleep tests. The mean apnea hypopnea index (AHI) was not statistically different (p=0.784) between night 1 and night 2 (without alcohol: 19.6/hour ± 21.0; with alcohol: 19.3 ± 21.5, respectively). Similarly, no statistically significant difference was found in the AHI during REM and NREM sleep.

Conclusion: Preliminary data does not suggest a statistically significant difference in AHI without or with alcohol. While no significant change in AHI was observed, this study highlights the need for further investigation into the impact alcohol may have on PAT technology. Further analyses and data enrichment are underway.

EXAMINING THE DIAGNOSTIC VALIDITY OF PAT DEVICE AGAINST CONCURRENT NOCTURNAL POLYSOMNOGRAPHY RECORDING IN A COMMUNITY DWELLING COHORT OF OLDER ADULTS

Daphne Valencia[1], Anhiti Dharmapuri[2], Anna Mullins[1], Thomas Tolbert[1], Rachel McCray[2], Julian McBride[2], Anamarie Sogade[2], Elena Valkanova[3], Joshua Gills[2], Omar Burschtin[2], David Rapoport[1], Ricardo Osorio[4], Omonigho Michael Bubu[4], Indu Ayappa[5]

[1] Icahn School of Medicine at Mount Sinai, [2] NYU Grossman School of Medicine, [3] University of South Florida, [4] Department of Psychiatry, New York University Grossman School of Medicine, [5] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: In a cohort of community dwelling participants, we previously showed a modest correlation for Obstructive Sleep Apnea (OSA) severity between WatchPAT™(WP) and polysomnography (PSG) used on separate night recordings. Given the known night-to-night variability in OSA, we reassess the diagnostic validity of simultaneous peripheral arterial tonometry (PAT) and PSG.

Methods: 65 participants recruited from the community without a prior diagnosis of OSA (39 Female, mean Age=67 yrs (range 56-85), 95% black, mean BMI=29.4 (SD=6.56 kg/m2), mean ESS=7 (SD±3.8) underwent 1-night concurrent in-lab PSG and WP (event detection using PAT), with both oximeters on the same hand. AHI4 by PSG=8.2 (SD 12.9 events/h); 60% had AHI4< 5, 26% mild OSA and 14% moderate-severe OSA. Diagnostic accuracy was assessed using 3 definitions for OSA: AHI4 ≥ 5 events/h, AHI4>15, and RDI ≥ 15. AHI4, RDI, total respiratory events, total sleep time (TST), and percentage TST with oxygen saturation< 90% (O2Sat90) were compared between PSG and WP by correlation and bland Altman plots.

Results: WP data was invalid in three participants. The mean TST assessed by WP was 344mins versus 320mins by PSG (mean ΔPSG-WP=-24.1mins, 95%CI -38 to-10, ICC=0.73). The average number of events for AHI4 detected by WP was 96 vs 50 by PSG (mean ΔPSG-WP=-46, 95%CI -60 to -32, ICC=0.8). The mean pAHI4 assessed by WP was 17.9 events/h versus 8.4 by PSG (mean ΔPSG-WP= – 9.5 events/h, 95%CI -12.4 to -6.5, ICC=0.74). The mean pRDI assessed by WP was 33.3 events/hr versus 13.4 by AHI3A (mean ΔPSG-WP= –19.9 events/h, 95%CI -24 to -15.8, ICC=0.57). The mean O2Sat90 by WP was 0.7% versus 1.0% by PSG (mean ΔPSG-WP = -0.3%, 95%CI 0.2 to -0.7, ICC=0.46). Sensitivity, specificity, PPV, and NPV for OSA using AHI4≥5 were 92%, 38%, 50%, 88%; for AHI4≥15 were 100%, 70%, 36%, 100%, and for RDI≥15/hr were 89%, 30%, 34%, 87%.

Conclusion: The PAT OSA severity metrics were consistently higher than PSG due to detection of greater number of respiratory events by WP and cannot be explained by the slightly higher TST detected by WP. These findings call into question the uncritical use of PAT severity in community dwelling cohorts.

RETROSPECTIVE CHART REVIEW ON ACCURACY HOME SLEEP APNEA TESTING AND EFFECTIVENESS OF STOPBANG: A COMPARISON TO POLYSOMNOGRAPHY

Powen Hsueh[1], Talha Memon[2], Lena Nune[3]

[1] Southwest Healthcare Medical Education Consortium/ Temecula Valley Hospital, [2] Sleep Medicine Department, Southwest Healthcare Medical Education Consortium, Temecula Valley Hospital, [3] Sleep Medicine Department, Southwest Healthcare Medical Education Consortium, Temecula Valley Hospital

Introduction: Obstructive sleep apnea (OSA) is a prevalent disorder caused by intermittent collapse of the upper airway, leading to disrupted ventilation while asleep. A type-III home sleep apnea test (HSAT) can be a convenient way to diagnose OSA due to its ability to detect obstructive apneas and hypopneas. The limitation in a pretest probability tool like STOP-BANG results in underdiagnosis of atypical OSA.
Methods: This is a retrospective chart-review study in a single sleep center conducted at Complete Sleep Solution, Temecula, California, from December 2022 to 2023. Patients selected for this review were 18 and older without comorbidities that required in-lab polysomnography (PSG). All patients had an initial HSAT with records of respiratory events index (REI), apnea hypopnea index (AHI), age, gender, and BMI, respiratory disturbance index (RDI), Epworth, hypertension diagnosis (HTN), snoring symptoms, witness apnea, and STOP-BANG score. Included individuals had an initial HSAT REI< 5 and returned for in-lab PSGs for the confirmation study. The HSAT and PSG results were compared to verify the accuracy of the HSAT.
Results: Among the 1815 charts reviewed, 231 showed negative HSAT results with REI< 5. Only 75 out of 231 patients with negative HSAT results returned to the lab for confirmatory testing. Upon follow-up, 71% of these patients had confirmed diagnoses of OSA via AHI or RDI criteria. With correlation analysis, there is essentially no correlation with the STOP-BANG score (average of 4.3 in the false-negative HSAT group and an average of 3.7 among the true-negative HSAT group). There was further break down on the correlation of AHI, RDI, and REI with each component of the STOP-BANG score (age, sex, gender, snoring, witness apnea, Epworth, HTN, and collar size), and none of each component shows any statistical significance within the correlation analysis.
Conclusion: HSAT is a quick, convenient tool for OSA diagnosis, but due to this, it may lead to delayed diagnosis in patients. In this group of patients, STOP-BANG appears to be an inadequate predictor for negative HSAT testing. Further modification to the screening tool can help screen individuals for whom a home test is inappropriate.

VALIDITY OF THE NEW GENERAL PRACTICE SLEEPINESS SCALE "GPSS" WITHIN A LARGE COMMUNITY SAMPLE

Timothy Howarth[1], Subash Heraganahally[2]

[1] Darwin respiratory and sleep health, [2] Department of Respiratory and Sleep Medicine, Royal Darwin Hospital

Introduction: The GPSS is a new tool for screening at risk patients for obstructive sleep apnoea (OSA) at primary healthcare. However, the GPSS was designed and developed amongst a relatively small and young population with a high pre-test probability of OSA. To better define the accuracy and validity of this tool, broader, community sampled populations are needed.
Methods: We utilised first visit data from the Sleep Heart Health Study (SHHS), defining OSA as an AHI≥15. Questions 5-8 of the GPSS (snoring, witnessed apnoeas, sleepiness and presence of hypertension/diabetes/heart disease/depression) were not directly assessed in the SHHS, thus derived from composites. We compared the GPSS against the STOP-Bang (derived in a similar manner to the GPSS) and the Epworth sleepiness scale (ESS).
Results: 3959 (47.6% female median age 63-years, BMI 27.8) participants had data available to be included. 943 (23.8%) recorded OSA. The median GPSS was 8 (IQR 5, 11), STOP-Bang 3 (IQR 2, 4) and ESS 8 (5, 11). The total continuous GPSS score was significantly associated with OSA (OR 1.24 (95% CI 1.21, 1.26)). GPSS moderate (>7) significantly increased odds for OSA compared to mild (≤7) (OR 3.18 (95% CI 2.59, 3.90)), and GPSS severe (>13) did so compared to moderate (OR 2.59 (95% CI 2.16, 3.11)). Sensitivity and specificity of GPSS moderate was 85.8 & 41.9% respectively, correctly classifying 52.3%, and of GPSS severe was 35.1 & 87.7% respectively, correctly classifying 75.2%. Sensitivity and specificity of STOP-Bang ≥3 was 77.8 & 54.8% respectively, correctly classifying 60.3%, and ESS ≥11 was 34.6 & 74.3% respectively, correctly classifying 64.9%. The ROC, AUC for the 3-level GPSS was 0.69 (95% CI 0.67, 0.71). For the 2-level STOP-Bang this was 0.66 (95% CI 0.65, 0.68) and for the 2-level ESS 0.55 (95% CI 0.53, 0.56). Due to the higher age in the SHHS compared to the GPSS development cohort, we tested adding additional scores for age thresholds 60-75 & >75. This slightly improved the 3-level GPSS AUC to 0.70 (9%% CI 0.68, 0.72).
Conclusion: The GPSS is a valid and reliable tool in a community setting and appears to outperform both the STOP-Bang and the ESS.

MODIFIED STOP-BANG QUESTIONNAIRE TO DETECT OBSTRUCTIVE SLEEP APNEA IN INDIVIDUALS WITH BMI OF LESS THAN 35 KG/M2

Napassorn Sinsopa[1], Viriya Tripakornkusol[1], Sittichai Khamsai[1], Kittisak Sawanyawisuth[2]

[1] Khon Kaen University, [2] Khon Kaen University Faculty of Medicine

Introduction: Obstructive sleep apnea (OSA) is a common disease in clinical practice. Due to high prevalence of OSA, a waiting list for polysomnography is long. Using a screening tool to select the high-risk for OSA to be tested for polysomnography is needed. A previous study showed that the STOPBANG questionnaire has a good sensitivity to detect OSA at 83.6%. However, 34 patients out of 177 patients (19.21%) included in the study had body mass index of more than 35 kg/m2. Obese patients grade II, indicated for bariatric surgery, may have different clinical features of OSA. This study aimed to evaluate if the STOPBANG questionnaire needed to be modified in patients with body mass index of less than 35 kg/m2.
Methods: This was a retrospective, analytical study. The inclusion criteria were adult patients who were suspected of OSA and

tested for OSA by polysomnography. Those who were pregnant or met the criteria for bariatric surgery with a body mass index of more than 35 kg/m2 were excluded. Patients were categorized into two groups; OSA and non-OSA group. The STOPBANG factors were calculated to predict presence of OSA by using logistic regression analysis.
Results: There were 188 patients included in the study. Of those, 158 patients (84.04%) were diagnosed as OSA. Among eight factors in the STOPBANG criteria, only age was independently associated with presence of OSA after adjusted by other variables. An adjusted odds ratio for age was 1.04 (95% confidence interval of 1.02, 1.08). The cut-off points of three numerical factors to predict presence of OSA including age, body mass index, and neck circumference were as follows: age of 40 years with sensitivity of 84.18%, body mass index of 23 kg/m2 with sensitivity of 82.91%, and neck circumference of 35 cm with the highest sensitivity of 86.08%.
Conclusion: The STOPBANG questionnaire may need to be modified for individuals with body mass index of less than 35 kg/m2 who were suspected for OSA. Age, neck circumference, and body mass index cutpoints were 40 years, 35 cms, and 23 kg/m2, respectively.

REMOTE PATIENT MONITORING (RPM) OF OBESE OBSTETRIC PATIENTS TO IDENTIFY ONSET OF OSA USING THE REST TRACKER: MONITORING AT RISK POPULATIONS

Jerald Simmons[1], Robert Thomas[2], George Saade[3], Renee Ivins[4], Brian Kirshon[4], Sam Sadeghian[5], Ashley Paige[1], Christopher Mann[5], Karolina Adam[4], Timothy Van Meter[5]
[1] Comprehensive Sleep Medicine Associates, [2] Beth Israel Deaconess Medical Center, [3] Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, [4] Obstetrix Maternal-Fetal Medicine Specialists of Houston / Pediatrix, [5] REST Technologies, Inc.

Introduction: Obstructive-Sleep-Apnea (OSA) can develop during pregnancy and is associated with gestational-diabetes, hypertension, preeclampsia, and eclampsia risk. Continuous evaluation is necessary throughout pregnancy; however, this is not currently a standard practice. The REST-Tracker, a Remote Patient Monitoring platform for OSA management is being assessed for the feasibility to identify the onset of OSA in the obese pregnant population.
Methods: The REST-Tracker utilizes data from a Ring-Oximeter worn nightly, using Cardiopulmonary Coupling (CPC)analysis, an FDA cleared cloud-based computing system called SleepImage™. It provides OSA metrics with two levels of sensitivity (sAHI_3% & sAHI_4%). Inclusion-criteria: BMI >27, entry < 16 weeks gestational-age, (GA) no prior OSA diagnosis. Analysis: paired t-test of average AHI prior to 16 weeks gestation compared to Ave AHI from the last 4 collection points prior to delivery.
Results: 30 subjects screened of which 27 subjects completed the study to delivery, 1 suffered an early termination, 2 excluded for lack of compliance. Statistics from those completing the study: Initial BMI: 36.7 (+/- 5.91), GA on initiation of monitoring 12.39 weeks (+-3.29), GA at Delivery 36.8 (+/- 2..6). The initial sAHI3% sleep was 5.01 (+/-2.79), the final sAHI3% 9.35 (+/-5.74) with a significant increase across pregnancy (p< 0.001). The initial sAHI4% was 2.94 (+/-1.56), the final sAHI4% 5.48 (+/-3.40), with a significant increase across pregnancy (p< 0.001). Initial High Frequency Coupling (Stable-Sleep) Average was 52.04 (+/-17.60) and final was 39.44 (+/-18.18) with a significant decrease in Stable Sleep (< 0.001)
Conclusion: This study demonstrates the REST-Tracker provides OSA monitoring of at-risk maternal patients in a fashion that may provide the ability to help mitigate obstacles in managing OSA during pregnancy. OSA tends to evolve through the course of pregnancy. The REST-Tracker can become a routine method to monitor at-risk maternal patients to identify the onset of OSA, allowing quick interventions to be implemented when necessary, such as CPAP or dental appliances. This approach can also be used to further assess the relationship between OSA adverse gestational outcomes, including hypertension, diabetes and eclampsia. This approach can translate to address other at-risk populations and improve treatment decisions.

UNDERDIAGNOSIS OF OBSTRUCTIVE SLEEP APNEA IN HOSPITALIZED PATIENTS WITH HEART FAILURE DETECTED BY RESPIRATORY POLYGRAPHY AT TERTIARY HOSPITAL IN PERU

Eduardo Bazán[1], Jose Camones[2], Cecilia Raraz[2], Nikole Vasquez[2], Pedro Ayala[2], Carlos Cruzado[3], Luis Novoa[3], Diana Rodriguez[4]
[1] Rest Peru, [2] Universidad Peruana Cayetano Heredia, [3] Hospital Nacional Arzobispo Loayza, [4] Universidad Peruana de Ciencias Aplicadas

Introduction: Obstructive Sleep Apnea (OSA) is often undiagnosed in heart failure (HF) patients. Early identification using affordable sleep studies could improve patient outcomes in resource-limited clinical settings like Peru. Therefore, the main objective of this study was to determine the frequency of OSA in hospitalized HF patients using respiratory polygraphy (RP) (Sleep Study Type III).
Methods: A cross-sectional study was conducted. We included patients >18 years, with exacerbated HF, and STOP-BANG ≥ 3. Enrolled patients underwent overnight RP using ApneaLink Air™. Data collected included clinical parameters, Epworth Sleepiness Scale, and echocardiography results. Statistical analysis was carried out using R Studio.
Results: From 46 enrolled patients, 39 underwent successful RP; 84.61% were diagnosed with OSA. Patients exhibited a mean Apnea-Hypopnea Index (AHI) of 14.41 ± 10.08/h with mild (51.28%), moderate (25.64%), and severe (7.69%) cases. Symptoms associated with OSA included lack of restorative sleep and concentration problems. RP data showed a mean minimum SpO2% of 76.85 ± 9.99% and an Oxygen Desaturation Index (ODI) of 20.01 ± 10.66. Correlation analysis indicated a strong positive correlation association between AHI and ODI (r = 0.73, p < 0.001) and a moderate negative correlation between AHI and LVEF (r=- 0.64, p= 0.056)
Conclusion: This study highlights a high frequency of OSA among HF inpatients in our institution, emphasizing its relationship with symptoms and cardiovascular parameters

RESULTS OF AN INPATIENT SLEEP APNEA SCREENING PILOT WITH STOPBANG IN PATIENTS ADMITTED TO A CARDIOLOGY WARD

Varun Badami[1], Anna Ransom[2], Maria Moning[2], Andrea Munoz Erazo[2], Shanshan Huang[2], Grace Pien[3], Luu Pham[1]

[1] Division of Pulmonary and Critical Care, Johns Hopkins University School of Medicine, [2] Johns Hopkins University, [3] Division of Sleep Medicine, Department of Medicine, University of Pennsylvania

Introduction: Obstructive sleep apnea (OSA) is a widely prevalent but underrecognized condition that shares many risk factors with major cardiac disease. OSA is an independent risk factor for cardiac readmissions with an effect size exceeding that of other known predictors in heart failure readmissions. The STOP-BANG questionnaire represents an easy and cost-effective screening tool for OSA, but the feasibility and utility of implementing this screening in hospitalized cardiac patients at scale is unknown. We hypothesized that STOP-BANG can be successfully administered by nursing staff and higher STOP-BANG is associated with hospital readmission in patients admitted to a cardiac specialty ward.

Methods: We conducted a prospective quality improvement project in patients admitted to the Johns Hopkins Hospital Progressive Cardiac Care Unit (PCCU) from May 2022 through May 2024. Patients underwent screening with STOP-BANG upon admission intake by nursing-administered questionnaire. We analyzed proportion of patients screened and readmission rates from internal and external health record databases. Patients with known sleep disordered breathing adherent to positive airway pressure therapy were excluded from analysis.

Results: We screened a total of 1981 patients admitted between May 2022 and May 2024, of whom 36.7% were extended surgical recovery, 53.6% were inpatient and 9.7% were observation status. Initial screening rate was 92%; however this gradually declined through the study. 13.7%, 37.1% and 49.2% of respondents were classified by risk of OSA as high (STOP-BANG scores 5-8), intermediate (3-4), and low (≤2), respectively. The net 30 day readmission rate was 8.7%. Elevated STOP-BANG score was not associated with higher 30 day, 90 day or 1 year readmissions, or total days of hospitalization. Analysis by admission class, presence of comorbid conditions and severity of illness did not identify subgroups in whom STOP-BANG predicted elevated re-admission risk.

Conclusion: Among patients admitted to a cardiac ward, systematic OSA screening by nursing was feasible but OSA risk assessed by STOP-BANG did not predict hospital readmission or cumulative hospitalization days. Since cardiac patients are at risk for central sleep apnea, current screening tools may misclassify these patients. Alternative scalable methods are necessary to discern the impact of untreated sleep apnea on readmission risk in this population.

EVALUATING THE LONGITUDINAL UTILITY OF THE BERLIN QUESTIONNAIRE FOR OBSTRUCTIVE SLEEP APNEA RISK: A SEQUENCE ANALYSIS APPROACH

David Appel[1], Alexandra Mueller[2], David Goldfarb[2], Rachel Zeig-Owens[2], David Prezant[2]

[1] Montefiore Medical Center, [2] Fire Department of the City of New York

Introduction: The Berlin Questionnaire (BQ), validated cross-sectionally and widely used, identifies Obstructive Sleep Apnea (OSA) risk. Its longitudinal performance remains unexamined. We used Sequence Analysis to evaluate temporal trajectories of BQ-identified-OSA risk, distinguish clusters with similar trajectories, and characterize cluster differences.

Methods: Retrospectively, we studied Fire Department of the City of New York World Trade Center Program participants who completed BQ across multiple time points from 2009-2024. At each exam, participants scored into one of four categories based on their number of positive BQ domains – snoring, fatigue, blood pressure/body mass index: no-risk (0/3), low-risk (1/3), high-risk (2/3), extreme-risk (3/3). We applied Sequence Analysis to identify longitudinal sequences of BQ risk classifications, clustering participants with similar risk trajectories. We calculated relative risk (RR) using log-binomial regression and computed p-for-trend for all outcomes. Models adjusted for age at first BQ, race, sex, and smoking status.

Results: From 13,038 participants with 3 or more BQ exams (Mean=11), we identified 6 distinct sequence clusters: mostly no-risk (20.4%), mostly low-risk (29%), mostly high-risk (14.7%), mostly extreme-risk (8.1%), intermittent survey gaps (16.7%), and truncated follow-up (11.1%). 80% of participants consistently scored into their cluster's corresponding BQ-risk category >50% of surveys, with the mostly extreme-risk cluster showing similar results, doing so 80% of the time. Increasing risk severity cluster is associated with having a polysomnogram (PSG), PSG-diagnosed OSA, and self-reported use of positive airway pressure (PAP) (p-for-trends< 0.0001, separate model per outcome). Respectively, those in mostly high-risk and mostly extreme-risk clusters had 6.38 (RR=6.38; 95%CI=5.56-7.32) and 9.10 (RR=9.10; 95%Cl=7.95-10.42) times greater likelihood to have PSG-AHI>15 events/hour compared with the mostly no-risk cluster. Those in the mostly extreme-risk cluster had 43% greater likelihood of PSG-diagnosed OSA compared with the mostly high-risk cluster (RR=1.43; 95%Cl=1.35-1.51).

Conclusion: Generally, most participants remained consistent in BQ-OSA-risk category over 15 years of study. Increasing risk severity cluster is associated with PSG-diagnosed OSA outcomes. Extreme- and high-risk clusters differed significantly, providing rationale for the use of three BQ risk categories in research settings. These findings suggest potential use of BQ risk as an OSA proxy in longitudinal studies.

PREDICTION OF OBSTRUCTIVE SLEEP APNEA BASED ON HEAD AND NECK MORPHOLOGY

Seo-Young Lee[1], Hye-Jin Moon[2], Jisoo Kim[1], Woo Hyun Lee[1], PilHoon Jang[3]

[1] Kangwon National University, [2] Soonchunhyang University, [3] Kakao Mobility Corp.

Introduction: Craniofacial morphology is a significant predisposing factor in the pathogenesis of obstructive sleep apnea (OSA). A screening tool for OSA that can be used by individuals or primary care physicians before overnight sleep studies would be beneficial. This study aimed to develop an artificial

intelligence (AI)-based OSA prediction tool using head and neck photographs and clinical information.
Methods: We analyzed a retrospective cohort of 2,538 subjects from the sleep clinic of Kangwon National University Hospital in Korea. The center routinely collected frontal and lateral face and neck photographs, age, sex, body mass index (BMI), and Epworth Sleepiness Scale (ESS) scores before polysomnography. Of these, 855 subjects with photographs of suitable quality were included in the study. To predict OSA status, we employed logistic regression and machine learning techniques, including random forests (RF), gradient boosting (XGBoost and LightGBM) and neural networks.
Results: The study included 616 men and 239 women, with a mean age of 50.2 years (standard deviation: 17). The distribution of apnea-hypopnea index (AHI) categories was as follows: AHI < 5 (n=246), 5–15 (n=204), 15–30 (n=202), and >30 (n=297). When classifying into AHI < 15 versus ≥15 groups, models incorporating age, sex, and BMI achieved the following accuracies: 0.72 (RF), 0.68 (XGBoost), 0.72 (LightGBM), and 0.70 (logistic regression). Adding the ESS reduced accuracy across all methods. For models that included head and neck photographs, accuracy remained at 0.72 without ESS but improved to 0.79 when ESS was added using a neural network model. When differentiating between AHI < 5 and AHI >30), the accuracy further increased to 0.79 without ESS and 0.88 with ESS.
Conclusion: Head and neck photographs enhance the accuracy of AI-based models for predicting OSA. ESS improved performance when photographs were included in the model. AI-driven prediction tools show potential as screening methods for differentiating between normal and severe OSA.

EXPLORING KNOWLEDGE ABOUT OBSTRUCTIVE SLEEP APNEA (OSA) AMONG HEALTHCARE PROVIDERS: A NARRATIVE REVIEW OF RESEARCH USING THE OSAKA QUESTIONNAIRE

Rebecca Robbins[1], Aleah St. Martin[2], Rashon Lane[3], Sophia Schneider[4], Brett Avery[5], Chidera Ejikeme[6]
[1] Harvard Medical School, [2] University of Massachusetts Dartmouth, [3] Sutter Health, [4] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [5] Sutter Health, Center for Health Systems Research, [6] Brigham and Woman's Hospital, Harvard Medical School

Introduction: Obstructive Sleep Apnea (OSA) is a concerning sleep disorder, yet awareness about OSA remains low among many healthcare clinicians. A global study of medical schools revealed that the average medical student receives only 2 hours of sleep education during their medical education. Given this training gap, we conducted a systematic review of published research assessing OSA knowledge and attitudes among primary care clinicians using the Obstructive Sleep Apnea Knowledge and Attitudes (OSAKA) questionnaire.
Methods: We conducted a review of the published literature to identify studies that administered the OSAKA questionnaire to samples of primary care clinicians and/or resident physicians. The population was not restricted to U.S providers and included providers in rural communities. The search strategy included ("OSAKA," apnea, and "primary care"). The search was implemented in PubMed on August 16, 2024. Studies conducted in English were eligible, excluding 10 papers written in Spanish. Studies that met inclusion criteria underwent rigorous qualitative data extraction. Data extracted included details about the participants, sample size, country of origin, and summary statistics for OSAKA questionnaire responses. Low and high mean responses are reported. All but 2 studies provided mean values for OSA knowledge and attitude responses. We provide an overall mean for OSA knowledge and attitude sub scales, calculated as the aggregate mean of studies reporting these statistics.
Results: The search resulted in 10 articles that included data collected in cross-sectional studies of 2,623 providers. Among the studies included in this review, 60% recruited primary care clinicians, 20% recruited physician residents, 10% recruited cardiologists, and 10% recruited general practitioners. Provider OSA knowledge, according to the OSAKA ranged from 54% to 77% with an average knowledge score of 66.6%. OSA attitudes ranged from 46% to 75% with an average OSA attitude score of 60.1%.
Conclusion: The results of this review reveal significant gaps in OSA knowledge and attitudes among primary care clinicians. Primary care clinicians can serve as an integral role in identification and screening of OSA in the general population. These findings suggest an urgent need for expanded medical education that can bolster OSA knowledge and attitudes among providers.

MEASURING SLEEP BETWEEN SEX: ACCURACY, SENSITIVITY, AND SPECIFICITY OF WRIST ACTIGRAPHY COMPARED TO POLYSOMNOGRAPHY

Anhiti Dharmapuri[1], Joshua Gills[1], Shriya Mareedu[2], Myra Dhingra[2], Mark Bernard[1], Shrestha Shah[3], Anthony Briggs[1], Luisa F. Figueredo[2], Julian McBride[1], Elena Valkanova[4], Arlener D. Turner[5], Andrew Varga[6], Girardin Jean-Louis[7], Ricardo Osorio[8], Omonigho Michael Bubu[8]
[1] NYU Grossman School of Medicine, [2] NYU Langone Health, [3] Georgia Institute of Technology, [4] University of South Florida, [5] Miami Dade College, [6] Icahn School of Medicine at Mount Sinai, [7] University of Miami Miller School of Medicine, [8] Department of Psychiatry, New York University Grossman School of Medicine

Introduction: Sleep patterns differ between sex, so it is imperative that sleep metrics used are consistent across sex. We investigated the accuracy, sensitivity, and specificity of actigraphy-measured sleep vs. PSG in older males and females.
Methods: PSG for each participant was recorded overnight at bedside. During a separate period of seven consecutive nights, actigraphy was collected for each participant at home using wrist-worn actigraphs on the non-dominant hand. Sleep time was validated with participant-provided sleep logs. Statistical analyses, including t-tests, chi-square tests, and sensitivity-specificity assessments, were performed. Lin's concordance correlation coefficient (CCC) and reduced major axis regression (RMAR) were utilized as measures of agreement and proportional bias, respectively
Results: The study included 151 community-dwelling older adults (ages 47-84) evaluated at the NYU Alzheimer's Disease Research Center and enrolled in studies investigating sleep health and aging. Of the 151 participants, 108 (71.5%) were white, 97

(64.2%) were females, and 71 (47.0%) had OSA (defined as apnea hypopnea index [AHI] > 5%). Among mean PSG-measured sleep parameters, Sleep Efficiency was 81.2% (SD 11.81%), Total Sleep Time (TST) 373.4 (76.06) minutes, Sleep Latency 12.4 (22.34) minutes, and Wake Time 72.6 (45.4) minutes. Among male participants, sensitivity was moderate (0.637), and specificity was low (0.238). Among female participants, sensitivity was moderate (0.642), and specificity was low (0.206). The largest difference among measures was in TST in both males and females: actigraphy overestimated TST by 23.06 (85.92) minutes in males, and 27.99 (107.61) minutes in females. Lin's CCC was low (< 0.9) for all actigraphy-measured parameters compared to PSG, regardless of sex. In addition, RMAR slopes (≠ 1) suggest proportional bias across all measures, while RMAR intercepts (≠ 0) for all measures show fixed bias, regardless of participant's sex.
Conclusion: In this study population, there was low accuracy and concordance of actigraphy measured sleep parameters compared to PSG, with both proportional and fixed bias across measures, regardless of sex. Additional research with a larger sample size is needed to ensure PSG/Actigraphy concordance across sex.

PERFORMANCE OF SLEEP APNEA QUESTIONNAIRES AMONG DIFFERENT SKIN TONES USING SANSA DEVICE

William Merwin[1], Amit Saha[1], Kristin Sheehan[1], Stephanie Cedeno[1], Abigail Koch[1], Priya Das[2], Kang Rui Xiang[3], Andrew Namen[1]

[1] Wake Forest School of Medicine, [2] Ohio State University, [3] Wake Forest University School of Medicine

Introduction: Obstructive sleep apnea (OSA) is a common condition associated with multiple co-morbidities, however, diagnostic challenges limit its recognition. Sleep screening has improved our recognition, and Home Sleep Apnea Testing (HSAT) has improved access to testing for OSA. The SANSA© device is an FDA cleared novel HSAT patch device that records 8 essential physiologic parameters (pulse oximetry, actigraphy, ECG-based heart rate and rhythm, respiratory effort, chest movement, snoring, and body position) to diagnosis OSA. We aimed to evaluate the performance of validated sleep apnea screeners, STOP-Bang (SB) and DOISNORE50 (DIS), in predicting OSA using the SANSA device and in-lab polysomnogram (PSG) comparing the results with lighter and darker skin tones.
Methods: In this multi-centered prospective trial, patients referred for PSG underwent simultaneous SANSA testing and completed the SB and DIS questionnaires. An AHI of > 5 was diagnostic of OSA, and skin tones were graded on the Fitzpatrick scale. SB and DOISNORE50 thresholds of disease (> 3 and > 4, respectively) were used to identify a patient at risk of OSA.
Results: Analysis included 154 patients who completed sleep screening questionnaires of whom 141 (91.6%) of patients tested positive for OSA. Receiver operating characteristic (ROC) curve analysis demonstrated that both SB and DIS questionnaires performed similarly in identifying patients who tested positive for OSA by SANSA, with area under ROC (AUROC) values of 0.711 and 0.677 among lighter skin tones (Fitzpatrick < 3), and AUROC values of 0.520 and 0.515 among darker skin tones (Fitzpatrick ≥ 3), respectively. Further, AUROC for each questionnaire improved by increasing the questionnaire positivity threshold by one (SB > 4, DIS > 5) in patients with darker skin tones for SB (0.520 to 0.716, $p < 0.001$) and DIS (0.515 to 0.714, $p < 0.001$) respectively.
Conclusion: These data demonstrated similar performance of the STOP-BANG and DOISNORE50 to predict OSA across skin tone with both Sansa and in lab polysomnogram. Additionally, adjusting the previously validated thresholds of SB and DIS for patients with darker skin tones improved test performance for OSA. Further study is needed.

SINGLE-NIGHT SLEEP STUDIES SHOW REDUCED SENSITIVITY IN CLASSIFYING MILD OSA IN WOMEN COMPARED TO MEN

Jonna Morris[1], Paul scott[2], Faith Luyster[3], Garrett Funck[2], Meghan Fissore[2], Weiwen Wang[2], Sara Klein[2], Lynn Baniak[4], YUE DONG[2], Diego Mazzotti[5]

[1] University of Pittsburgh, [2] University of Pittsburgh, [3] University of Pittsburgh School of Nursing, [4] VA Pittsburgh Healthcare System, [5] University of Kansas Medical Center

Introduction: Studies assessing obstructive sleep apnea (OSA) across multiple nights indicate that single-night studies may misclassify up to 50% of diagnoses. This discrepancy may result from sex-based differences in classification using diagnostic devices (i.e. home sleep studies, wearables). This study aimed to 1) evaluate how night-to-night variability in OSA severity affects diagnostic classification using cardiopulmonary coupling derived metrics, and 2) assess the impact of sex differences on classification accuracy over multiple nights.
Methods: In this prospective study of 44 adults (20 men, 24 women) mean age 53.5±18.6 years; range 22–78) with untreated OSA, participants wore a sleep tracker (SleepImage®) at home for 15 nights ≥2 hours per night. The apnea-hypopnea index(-sAHI) was measured using cardiopulmonary coupling derived metrics (mean sAHI3%= 20.6, SD=14.3; sAHI4% = 14.0, SD=11.9). In participants with at least 13 nights, the 1st, 3rd,7th, & 12th night averages for sAHI3% and sAHI4% were classified as no OSA (AHI ≤ 5), mild (5< AHI< 15), moderate (15≤ AHI< 30), & severe (AHI≥ 30) with a confusion matrix used to evaluate classification accuracy as compared to the average metrics across all nights.
Results: In the total sample, sAHI3% and sAHI4% overall sensitivity respectively was 75% and 71% for 1 night, 84% and 71% for 3 nights, 96% and 89% for 7 nights, and both were 96% for 12 nights. Sensitivity of women classified as mild OSA (sAHI3%) over one night was 57%, compared to 80% for men. Sensitivity of mild OSA in women (sAHI4%) over one night was 64%, compared to 86% for men. When averaging 7 nights, the sensitivity of mild OSA was 100% for both men and women at sAHI3% and 100% in women and 91% in men at sAHI4%.
Conclusion: Sleep apnea classification is more accurate in men than in women with mild OSA when measured ≤7 nights. Greater variability in women's sAHI may reduce the accuracy of standard OSA severity classification for both sexes.

CONCORDANCE OF PSG AND ACTIGRAPHIC MEASUREMENT OF SLEEP AND WAKE IN A PRELIMINARY SAMPLE OF COGNITIVE NORMAL BLACK/AFRICAN AMERICAN OLDER ADULTS

Shrestha Shah[1], Joshua Gills[2], Anthony Briggs[2], Mark Bernard[2], Joanna Dominguez[2], Laurel Browne[2], Elena Valkanova[3], Korey Kam[4], Anna Mullins[5], Ankit Parekh[4], Girardin Jean-Louis[6], Arlener D. Turner[7], Andrew Varga[4], Ricardo Osorio[8], Omonigho Michael Bubu[8]

[1] Georgia Institute of Technology, [2] NYU Grossman School of Medicine, [3] University of South Florida, [4] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [5] Icahn School of Medicine at Mount Sinai, [6] University of Miami Miller School of Medicine, [7] Miami Dade College, [8] Department of Psychiatry, New York University Grossman School of Medicine

Introduction: This study evaluated the concordance between polysomnography (PSG) and actigraphy in assessing sleep and wake patterns among cognitively normal Black/African-American older adults. Specifically, the study sought to evaluate the precision of actigraphy as a screening tool compared to PSG and determine whether actigraphy yields comparable accuracy to PSG across different racial groups.
Methods: The study analyzed data from 43 Black/African Americans aged 60 years or older, all participants in NYU Langone studies on sleep and aging. Each participant wore an actigraph for seven days and underwent one or two nights of PSG in a supervised laboratory setting. Key variables assessed included sleep efficiency (proportion of time spent asleep relative to time in bed), total sleep time (duration from sleep onset to awakening), sleep latency (time taken to fall asleep after lights-off), and wake-up time (time of awakening from sleep).
Results: For Black/African American participants, the actigraph showed mixed agreement with PSG across sleep variables. Overall, sensitivity (0.641) was moderate, whereas specificity (0.220) was low; similarly, for blacks the sensitivity (0.624) was moderate, and specificity (0.254) was low. The mean difference (±SD) for total sleep time was 4.21 (11.98), with a 95% CI of -213 to 222. Sleep efficiency demonstrated a mean difference of -3.05 (14.15), with a 95% CI of -30.7 to 24.6. Wake time had a mean difference of 2.53 (57.92), with a 95% CI of -111 to 116. Sleep onset latency exhibited a mean difference of 8.32 (21.06), with a 95% CI of -33 to 49.6. The actigraph showed limited agreement with PSG across sleep variables in both racial groups, with lower concordance observed for Non-Hispanic White participants compared to Black/African American participants.
Conclusion: Actigraphy demonstrated limited agreement with the gold-standard PSG in both Black/African American and non-Hispanic White participants. Among Black participants, the actigraph overestimated total sleep time, highlighting a discrepancy in accuracy. These findings suggest further research to concurrently evaluate actigraphy and PSG in diverse populations to improve actigraphy's reliability as a sleep assessment tool.

DEVELOPMENT OF SLEEP APNEA SCREENING TOOL USING ECG AND OXIMETRY FROM POLYSOMNOGRAPHY: APPLICATION IN STROKE UNIT

Do-Hyung Kim[1], So Young Lee[1], Byeong Gu Jeon[1], Kiyong Kim[2], Nak Gyeong Ko[3], Seung Hwan Kim[4], Tae-Won Yang[5], Young-Soo Kim[6], Oh-Young Kwon[6], Suji Yoo[7]

[1] Department of Neurology, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, [2] Research and Development Department, Codevision Inc., [3] Department of Biostatistics, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, [4] Department of Neurosurgery, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, [5] Department of Neurology, Gyeongsang National University Changwon Hospital, Gyeongsang National University College of Medicine, [6] Department of Neurology and Institute of Health Science, Gyeongsang National University Hospital, Gyeongsang National University College of Medicine, [7] Department of Internal Medicine, Changwon Hanmaeum Hospital

Introduction: We previously conducted a retrospective analysis of polysomnography (PSG) electrocarttiography (ECG) data to classify obstructive sleep apnea (OSA) using deep learning analysis (DLA). The study achieved a ROC AUC score of 0.7077 and an F1 score of 0.67, demonstrating its potential as a screening tool for OSA. In this study, we further analyzed oximetry data extracted from PSG and explored the integration of ECG- and oximetry-based screening tools into vital sign monitoring devices within the stroke intensive care unit (SU) to evaluate their clinical utility in real-world settings.
Methods: We retrospectively analyzed PSG data collected between 2015 and 2023. OSA was classified into two categories: normal/mild and moderate/severe, based on the apnea-hypopnea index (AHI). For DLA, oximetry data were converted into Mel-spectrograms and analyzed using a Convolutional Neural Network, generating a confusion matrix. Additionally, we assessed the utility of the screening tool in patients admitted to the SU between January and October 2024. PSG was conducted for patients meeting the following criteria: STOP-BANG score ≥3, witnessed snoring or apnea, and a Modified Mallampati Score ≥3.
Results: Out of 1,806 PSG records, 252 cases with arrhythmias were excluded, leaving 1,554 records for analysis. OSA was classified as normal/mild in 616 cases and moderate/severe in 938 cases. The DLA results for oximetry yielded a ROC AUC score of 0.7814 and an F1 score of 0.79. In the SU cohort, 211 patients were evaluated. After excluding 34 cases with arrhythmias and 67 instances of data loss, 110 patients remained. Among these, 49.5% had a STOP-BANG score ≥3, 40.4% were suspected of having OSA based on oximetry data, and 60.6% based on ECG data. Among the five patients who underwent final PSG testing, oximetry demonstrated an accuracy of 80%, while ECG achieved 100%.
Conclusion: Our findings suggest that DLA using oximetry showed higher accuracy in retrospective PSG data compared to ECG. However, in the SU setting, oximetry faced challenges due to variations in sampling rates across devices. In contrast, ECG data demonstrated more consistent sampling rates, providing a clinical advantage. Further studies are warranted to validate and optimize both approaches for widespread application.

SAMPLING OF ARTERIAL BLOOD GAS ANALYSIS BEFORE PSG FOR EVALUATION FOR HYPOVENTILATION: WHEN IS THE BEST TIME?

Bimaje Akpa[1], Wajahat Khalil[1], Conrad Iber[1], Snigdha Pusalavidyasagar[2]

[1] University of Minnesota, [2] University of Minnesota Medical School

Introduction: Carbon dioxide (CO2) levels change during sleep in patients with obesity hypoventilation syndrome (OHS), obstructive sleep apnea with coexistent OHS, and respiratory failure. Transcutaneous carbon dioxide monitoring (TCM) during polysomnography (PSG) provides both continuous and non-invasive estimation of the CO2. TCM can be helpful in early recognition of hypoventilation. Untreated hypoventilation is associated with high morbidity and mortality. Recognizing hypoventilation and initiating appropriate treatment interventions can help lower this burden of morbidity and mortality. Despite TCM's potential benefits, it's not always included during PSG and not used at all sleep centers. Arterial blood gas (ABG) sampling before PSG can be helpful in determining the accuracy of the CO2 measurement using TCM at sleep onset during PSG. There is no current consensus on when ABG sampling should be performed before PSG. We are obtaining ABG sampling within 48 hours before the PSG at our center and will evaluate the accuracy of pTCO2 measurement with PaCO2 from ABG with the timing of the ABG sampling.
Methods: Starting in early March 2024, as a quality improvement effort, we added ABG sampling within 48 hours and included TCM during the PSG for patients who presented at an community-based academic sleep center for clinical evaluation for hypoventilation. We are collecting demographic variables including age, gender, body mass index range and cardiovascular and pulmonary comorbidities. We plan to evaluate the association between 1) the PaCO2 and 2) bicarbonate from the ABG with the 3) sleep onset and peak TCO2.
Results: To date, 30 patients seeking clinical evaluation for hypoventilation who completed ABG sampling within 48 hours before PSG and TCM during the PSG. 67% of the patients are female. Mean age of 51 ± 15.4 years and a BMI of 40.79 ± 10.73kg/m2. We will plan to continue this quality improvement effort until March 2025. Results to be shared.
Conclusion: ABG sampling within 48 hours before PSG and TCM during the PSG is feasible and might help with early recognition of hypoventilation.

TESTOSTERONE THERAPY AND THE RISK OF OBSTRUCTIVE AND CENTRAL SLEEP APNEA IN TRANSMASCULINE PATIENTS: A POPULATION-BASED COHORT STUDY

Anastasia Christ[1], Matthew Loria[1], Tomasz Tabernacki[1], Ambrose Chiang[1]

[1] Case Western Reserve University School of Medicine, University Hospitals Cleveland

Introduction: Testosterone can impact factors such as neck circumference, fat distribution, and airway characteristics, potentially elevating the risk of obstructive sleep apnea (OSA). It may also affect respiratory control, raising the apneic threshold and contributing to central sleep apnea (CSA). While studies in cisgender men have produced inconclusive findings regarding the relationship between testosterone and sleep apnea (SA), research in premenopausal women with hyperandrogenic conditions indicates a higher SA prevalence. This study aims to investigate the association between testosterone therapy and the diagnosis of OSA and CSA in transmasculine individuals.
Methods: Data were sourced from TriNetX, a database with de-identified health records of over 120 million U.S. patients across 84 healthcare organizations. Transmasculine individuals were identified using ICD-10 codes for gender identity disorders and testosterone therapy, excluding those with a prior SA diagnosis. The index date was defined as three months post-testosterone initiation to account for physiological changes. Cisgender male and female cohorts were matched using propensity scores for BMI, smoking, and other SA risk factors. The primary outcome was SA incidence, identified through ICD-10 G47.3x codes. Kaplan–Meier analysis was used to estimate the probabilities of SA, with log-rank test group comparisons. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated using the Cox proportional hazards model, with significance set at $p < 0.05$.
Results: Among 22,745 transmasculine patients, the SA risk was significantly higher compared to matched cohorts of cisgender women (HR: 3.01, CI: 2.70–3.36, $p < 0.0001$) and men (HR: 1.64, CI: 1.49–1.81, $p < 0.0001$). The risk of OSA was elevated, with HRs of 3.25 (CI: 2.88–3.67, $p < 0.0001$) and 1.74 (CI: 1.57–1.95, $p < 0.0001$) compared to cisgender women and men, respectively. Moreover, there was an 18-fold increased risk of CSA compared to cisgender women (HR: 18.44, CI: 4.24–80.12, $p < 0.0001$).
Conclusion: Transmasculine individuals receiving testosterone therapy are at significantly higher risk of developing both OSA and CSA compared to cisgender individuals. These findings underscore the need for heightened clinical vigilance for SA in this population. Future studies should explore the underlying mechanisms and assess the impact of testosterone dose, duration, and patient-specific factors on SA risk.

BRIDGING SPECIALTIES: AN INTEGRATED SLEEP MEDICINE-CARDIOLOGY REFERRAL PROGRAM FOR SLEEP APNEA

Stanley Abraham[1], Anna Chang[1], Harly Greenberg[1], Stella Hahn[1], Ronald Wharton[1], Luis Quintero[1], Sean Duenas[1], Ivleen Singh[1], Annamaria Iakovou[1]

[1] Northwell Health

Introduction: OSA is associated with cardiovascular disease and contributes to morbidity and mortality. Much of the population with cardiovascular disease who are at risk for OSA remains undiagnosed. To increase the identification of patients with OSA in this population, we implemented OSA screening and HST testing in cardiology practices. We describe the results of a cooperative effort between seven Cardiology practices and Sleep Medicine within the Northwell Health system.
Methods: We conducted a retrospective analysis of 446 cardiology practice patients deemed to be at risk for OSA by screening questionnaire or clinical assessment who underwent WatchPAT

HST between 1/1/23 to 12/31/23. Patients were referred for sleep medicine consultation if HST showed AHI ≥5/hr.
Results: Of the patients with valid HST data (n=432), 8% had heart failure, 79% of which were found to have OSA (41% AHI≥15). 5.3% had a history of MI, 70% of which had OSA (53% AHI≥15). 26% had atrial fibrillation, 71% of which had OSA (36% AHI≥15). 4% had a history of CVA, 65% of which had OSA (41% AHI≥15). 71% of patients (n=432) had AHI≥5/hr (n=306). Of those with AHI≥5/hr, 47% had mild (n=145), 29% moderate (n=89), and 24% severe OSA (n=72). 74% of patients with AHI≥5/hr (n=226) initiated care with sleep medicine physicians. 41% of patients chose CPAP for initial treatment (n=124), 23% were mild (n=29), 33% were moderate (n=41), and 44% were severe OSA patients (n=54). 70% of patients who chose CPAP initiated CPAP (n=87), 24% were mild (n=21), 28% were moderate (n=24), and 48% were severe OSA patients (n=42). Of the patients who initiated CPAP, 45% (n=39) were adherent to therapy (usage ≥4hr/night for 70% of nights) during the initial 90-day compliance period, 26% were mild (n=10), 26% were moderate (n=10), and 49% were severe OSA patients (n=19).
Conclusion: In this retrospective study, a notably high proportion (71%) of screened Cardiology patients were diagnosed with OSA via HST. 53% of those diagnosed had moderate to severe OSA. CPAP adherence rates among patients referred to sleep medicine were suboptimal. Further intervention is needed to improve adherence to therapy in this at-risk population.

PHYSICAL ACTIVITY, DIETARY QUALITY, AND WEIGHT MANAGEMENT BEHAVIORS IN PATIENTS WITH UNTREATED OBSTRUCTIVE SLEEP APNEA

Rachel Kutler[1], Marie-Pierre St-Onge[1], Yi Cai[1]
[1] Columbia University Irving Medical Center

Introduction: Obstructive sleep apnea (OSA) increases the risk of cardiovascular (CV) disease. However, many patients remain untreated due to intolerance of OSA therapies. A healthy lifestyle is foundational to CV health and may mitigate CV risk in these patients. Herein, we examine physical activity, dietary quality (DQ), and weight management behaviors in patients with untreated OSA.
Methods: Patients with untreated OSA (n=28) were recruited from an academic sleep surgery clinic. Healthy Eating Index scores (HEIs) were obtained via Mini-EAT questionnaires (unhealthy DQ = score < 61; intermediate = score 61-69; healthy = score >69). Physical activity level was determined via Nordic Physical Activity Questionnaire-short survey (suboptimal = < 150 minutes/week based on the U.S. Department of Health and Human Services' Physical Activity Guidelines). Patients were also surveyed about weight management behaviors. OSA treatment history and apnea-hypopnea index (AHI) were determined from chart review. Welch's t-tests and chi-square tests were applied in analyses.
Results: On average, participants were middle-aged (52.6 ± 12.7 years), had overweight (BMI, 27.2 ± 4.8 kg/m2), moderate-severe OSA (AHI, 24.0 ± 21.8), and unhealthy DQ (HEI 60.3 ± 6.6). Sixteen participants had previously tried and/or were intolerant of continuous positive airway pressure (CPAP, n=10), oral appliance therapy (OAT, n=2), or both (n=4). Physical activity level in the overall cohort was low, with 18 participants (64.3%) engaging in < 150 minutes of weekly exercise, including 7 reporting < 30 minutes of weekly exercise. Of 18 patients with a BMI ≥ 25 kg/m2, 10 (55.6%) were attempting to lose weight, of whom 5 had attempted dietary modifications.
Conclusion: The majority of patients with untreated OSA presenting to sleep surgery clinic had not tolerated or had been inadequately treated with medical OSA therapy. Despite the association between untreated OSA and elevated CV risk, these patients demonstrated suboptimal physical activity levels and DQ. Targeted support for lifestyle interventions to improve physical activity and DQ may be warranted in this clinical population to curb CV risk.

COMPARISON OF TRACKING OSA FROM PAP MACHINE DATA VS CARDIOPULMONARY COUPLING BASED ASSESSMENT OBTAINED FROM NIGHTLY RING MONITORING

Jerald Simmons[1], Sam Sadeghian[2], Maggie Lavender[1], Olivia Hua[1], Jordan Manganello[1], Catherine Mira[1], Stormy Lopez[1]
[1] Comprehensive Sleep Medicine Associates, [2] REST Technologies, Inc.

Introduction: Management of OSA by Remote-Patient-Monitoring (RPM) methods has been gaining momentum, mainly utilizing the data obtained from PAP devices providing a metric represent an Apnea-Hypopnea-Index (pAHI). The REST-Tracker, a ring-based RPM platform, provides FDA-cleared methodology by SleepImage rendering AHI metrics ('ahi_3%' and 'ahi_4%') vai cardiopulmonary-coupling analysis. This study evaluates the REST Tracker AHI metrics to the ResMed PAP pAHI metric from patients utilizing both systems.
Methods: Data from 70 patients on PAP with at least 30 nights of simultaneous data from both REST-Tracker and PAP device. Nights with < 20% difference in usage time between devices were included, resulting in 7,835 nights of data for statistical analysis. Metrics included 'ahi_3%' and 'ahi_4%' (REST Tracker / SleepImage) and 'pap_ahi' (ResMed-AirView). Statistical analyses, including T-test and Bland-Altman plots, were used to assess agreement between the methods.
Results: The average AHI values and standard deviations were as follows: 'ahi_3%' had a mean of 10.67 (±8.45), 'ahi_4%' had a mean of 5.38 (±5.69), and 'pap_ahi' had a mean of 4.21 (±6.73). Average usage times were 7.26 (±1.43) hours for the REST Tracker and 7.60 (±1.40) hours for the PAP device, demonstrating similar nightly usage. T-tests revealed significant differences between the REST Tracker metrics and PAP AHI values, with t-statistics of 52.99 ($p < 0.001$) for 'ahi_3%' vs 'pap_ahi' and 11.72 ($p < 0.001$) for 'ahi_4%' vs 'pap_ahi'. Bland-Altman analysis showed mean differences of 6.47 and 1.17 for 'ahi_3%' and 'ahi_4%' vs 'pap_ahi', respectively, with wide 95% limits of agreement, indicating variability and non-equivalence.
Conclusion: Our findings demonstrate that PAP AHI measurements are not equivalent to REST Tracker / SleepImage metrics, as demonstrated by Bland-Altman analysis and significant t-test results. The ResMed AHI was less sensitive than the REST Tracker's ring-based (SleepImage) platform. Additional limitations of PAP-based RPM approaches include no data when the PAP device is not in use, further limiting the value of this approach. As an alternative to the current trend of utilizing PAP-based metrics for RPM, implementing FDA-cleared

wearables with better sensitivity of OSA characterization should be embraced as these approaches will raise the standard of care.

THE DIFFERENTIAL IMPACT OF RESPIRATORY EVENT SCORING RULES ON HEALTHCARE DISPARITIES IN SLEEP MEDICINE

Sandya Subramanian[1], Annalise Miner[1], Andrew Spector[2], Sanford Auerbach[1]

[1] Boston University Chobanian & Avedisian School of Medicine, [2] Duke University School of Medicine

Introduction: The relationship between sleep regularity and health outcomes in obstructive sleep apnea (OSA) is gaining recognition; however, its connection to continuous positive airway pressure (CPAP) treatment remains underexplored. This study hypothesized that CPAP treatment enhances sleep regularity, which may subsequently improve cognitive function and reduce 24-hour ambulatory blood pressure (BP) variability.
Methods: Patients with moderate-to-severe OSA from two centers were randomized (1:1) to 12 weeks of CPAP or inactive control. The primary endpoint was 7-day sleep onset, offset, and midsleep time measured by actiwatch. Secondary endpoints included mean reaction time from the Psychomotor Vigilance Task (PVT), correct trials from the Digit Symbol Substitution Test (DSST), and 24-hour BP. Variability in outcomes was assessed using standard deviation. CPAP effects were analyzed by intention-to-treat and per-protocol methods, including participants who adhered to the protocol.
Results: Of 67 participants, 52 were randomized to CPAP (n=26) or control (n=26). In the CPAP group, 75.2% averaged ≥4 hours of nightly use. CPAP did not significantly affect sleep onset (median=00:06), offset (median=-00:17), midsleep time (median=-00:16), PVT mean reaction time (median=5 msec), or DSST correct trials (median=0) (all P>0.05). However, CPAP reduced variability in awake systolic (median=-1 mmHg) and mean BP (median=-1 mmHg), as well as asleep diastolic (median=-2.6 mmHg) and mean BP (median=-2.5 mmHg) (all P< 0.05).
Conclusion: Short-term CPAP treatment did not improve sleep regularity but significantly reduced 24-hour ambulatory blood pressure variability, with no notable effects on cognitive function.

AUSTRALIA'S SLEEP REVOLUTION: TECHNOLOGY-ENABLED, PHYSIOLOGY-INFORMED, PERSONALIZED CARE FOR OSA, INSOMNIA & COMISA

Danny Eckert[1], Claire Dunbar[2], Jack Manners[2], Peter Catcheside[2], Charmaine O'Reilly[2], Bastien Lechat[2], Leon Lack[1], Nicole Lovato[2], Ching Li Chai-Coetzer[2], Robert Adams[2], Geoffrey Pitcher[2], Andrew Vakulin[2], Carolin Tran[2], Alison Leviton[2], Sutapa Mukherjee[2]

[1] Flinders University, [2] Adelaide Institute for Sleep Health, Flinders University

Introduction: The causes of common sleep disorders including obstructive sleep apnea (OSA), insomnia and their combination (COMISA) vary between patients. Yet, conventional diagnostic and treatment approaches do not fully capture or account for disease heterogeneity. Instead, treatment typically follows a one-size-fits-all, trial-and-error approach, often with suboptimal outcomes. This study aimed to use novel technology and methods to

better define underlying individual pathophysiology of common sleep disorders and use this information to tailor therapy with existing and emerging treatments.
Methods: 32 people with chronic sleep disorders enrolled in an 8-week intensive treatment program that was filmed for a television series titled "Australia's Sleep Revolution with Dr Michael Mosley". Participants completed polysomnography before and after treatment, plus multiple questionnaires including the Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS) and Flinders Fatigue Scale (FFS). A range of monitoring technology was also used such as an under-mattress sensor and oximetry to track nightly sleep parameters including apnea/hypopnea index (AHI), core body temperature capsules to estimate daily circadian timing and actigraphy. OSA endotypes were estimated to guide therapy in people with OSA. Data were reviewed bi-weekly during multi-disciplinary team meetings with scientists and clinicians to identify the optimal individualized treatment approach and modify as required. Options for insomnia and circadian misalignment included cognitive behavioural therapy (CBTi), melatonin, and light therapy. Treatments for OSA included oral appliances, supine avoidance therapy, emerging pharmacotherapy and continuous positive airway pressure (CPAP) as a last resort. Primary outcomes were ISI for insomnia/COMISA and AHI for OSA/COMISA.
Results: 28 participants (50% female) aged 51 [35, 60] years (median [IQR]) completed the trial (n=10 OSA, n=9 insomnia, n=9 COMISA). OSA endotype-informed targeted therapy reduced AHI from 28 [15,57] to 13 [10,23] events/h, p=0.01 in people with OSA/COMISA, most without CPAP. ISI reduced from 20 [19,23] to 9 [4,13], p< 0.01 in people with insomnia/COMISA. Participants also felt better post-treatment (e.g., ESS reduced by >30% and FFS by >70% in people with OSA and insomnia, respectively).
Conclusion: These findings highlight the potential to transform sleep disorders care to improve outcomes for patients using a novel multi-disciplinary, technology-enabled, physiology-informed, individualized approach.

CHALLENGING THE 90-DAY CPAP ADHERENCE STANDARD: INSIGHTS INTO DISPARITIES AND HEALTHCARE INEQUITIES

Dennis Hwang[1], Indu Ayappa[2], Martha Billings[3], Amy Sawyer[4], Rui Yan[5], Jiaxiao Shi[5], Matthew Klimper[5], Jessica Jara[5], Nathanael Hwang[5], Kendra Becker[5], Joseph Kim[5], Anupamjeet Sekhon[5], Rosa Woodrum[5], Sanjay Patel[6]
[1] Kaiser Permanente Southern California, [2] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, [3] University of Washington, [4] University of Pennsylvania School of Nursing, [5] Kaiser Permanente, [6] University of Pittsburgh

Introduction: The continuous positive airway pressure (CPAP) policy of Centers for Medicare & Medicaid Services (CMS) requires adherence over 90-days for continued coverage. This may result in premature treatment discontinuation, potentially exacerbating disparities and introducing healthcare inequities. We evaluated one-year CPAP adherence within an integrated healthcare system without rigid adherence criteria to assess longer-term adherence potential of initially non-adherent patients.
Methods: We evaluated all adult patients with OSA newly prescribed CPAP between 2020 and 2023 within Kaiser Permanente Southern California. We classified patients into Early Adherent (meeting CMS criteria within 90 days), Late Adherent (not meeting CMS criteria until between days 91-360) and Never Adherent (never meeting CMS criteria up to day 360) and compared demographic and sleep characteristics between groups.
Results: Out of a total of 132,492 patients, 49.0% were Early Adherent, 8.3% were Late Adherent, and 42.7% were Never Adherent. Compared to Early adherent, Late and Never Adherent, patients were progressively more likely to be female (31.5% vs 34.7% vs 37.9%; p< 0.0001), non-white (8.1% vs 9.2% vs 11.8% Black, 31.0 vs 33.3% vs 38.8% Hispanic, 8.7% vs 9.9% vs 9.3% Asian p< 0.0001), reside in lower income neighborhoods (4.2% vs 4.8% vs 5.9% living in <$45,000 income neighborhoods; p=0.0002), and have less severe OSA (AHI 35.4±25.0 vs 33.9±25.6 vs 29.4±24.0; p< 0.0001). Among the Late Adherents, the most common month to reach CMS adherence criteria was in month 4 (44% of all Late Adherent patients). When analyses were restricted to patients ≥ 65 years of age, results were similar. Mean time to achieve adherence was day 165.8±69.1 and was longer for Hispanics, Blacks, and other race/ethnicities versus White (171.6±71.7, 173.6±72.2, 166.6±67.9 vs 159.3±66.2; p< 0.0001).
Conclusion: Extending payer adherence interval to at least 120 days (4 months) may improve CPAP treatment access, reducing inequities and disparities in OSA treatment.

FULLY TELEHEALTH VS. FULLY FACE-TO-FACE MANAGEMENT OF OBSTRUCTIVE SLEEP APNEA: A COMPARATIVE STUDY OF CPAP COMPLIANCE

Zeynep Seckin[1], Timothy Morgenthaler[2]
[1] Mayo Clinic, [2] Mayo Clinic, Rochester, Minnesota

Introduction: Obstructive sleep apnea (OSA) is effectively treated with continuous positive airway pressure (CPAP), but access remains a challenge. The COVID-19 pandemic accelerated telehealth, offering a convenient alternative to in-person visits for OSA evaluation and treatment initiation. This study compares patients managed entirely via video telehealth to those managed entirely in person. We hypothesize that virtual are as effective as in-person evaluations in managing most OSA patients.
Methods: The study is approved by the Mayo Clinic IRB. We retrospectively studied adult patients diagnosed with OSA requiring CPAP initiation between June 2020–2023. Data collected included baseline demographics, home sleep apnea testing (HSAT) results, polysomnography (PSG) results, Epworth Sleepiness Scale (ESS) scores, OSA severity, compliance results, other relevant comorbidities (i.e. cardiovascular diseases). Visit type categorized as "in-person" for patients who had both initial and follow-up appointments in-person, while "telehealth" group included patients who had both appointments virtually.
Results: Of 59 patients, 33 had telehealth (56%). The groups had similar medians in age (66 vs 62), sex (73% vs 67% male), and BMI (30 vs 32). There was no significant difference in median ESS scores (8 vs 7, p=0.7). However, the severity of OSA (moderate to severe) was higher in the in-person group (73% vs 45%, p=0.03). When baseline sleep study data was investigated, there

were no differences in AHI and average SpO2 values measured by HSAT or PSG between the two groups (p>0.05 for all). CPAP compliance was significantly higher in the telehealth group compared to in-person (78% vs 40%, OR: 5.5, 95% CI: 1.7-17.1, p=0.003). Virtual visit type was the only independent predictor of compliance (p=0.006), after adjusting for age, BMI, comorbidities and OSA severity in multivariate analysis. However, there was no difference in average daily CPAP usage (6:39 vs 7:18, p=0.5) and percentage of days with usage >4 hours (91% vs 95, p=0.5). Median AHI after treatment improved in both groups, with no significant difference between groups (1.7 vs 2.4, p=0.8).
Conclusion: Telehealth offers a successful alternative to in-person visits for OSA evaluation, with similar outcomes and significantly better compliance, enhancing OSA management.

A PROSPECTIVE, MULTICENTER, REAL-WORLD STUDY ON THE LONG-TERM EFFECTIVENESS OF A CAD/CAM 3D-PRINTED ORAL APPLIANCE TO TREAT OSA: AN UPDATE

Robyn Woidtke[1], Frederic Gagnadoux[2], Didier Recart[3], Jérôme Forcioli[4], Mirentchu Toubal-Biret[5], Claude Ferret[6], Robert Clavel[7], Jean-Arthur Micoulaud-Franchi[8], Martine Fortin[9], Isabelle Dupuy-Bonafé[10], Vincent Trevillot[11], Benoît Griffet[12], Jean-Daniel Kün-Darbois[2], Morgan Le Balc'h[13]
[1] RVW Clinical Consulting, [2] CHU ANGERS, [3] Les Praticiens du Souffle - Centre du sommeil, [4] Centre médical de la Route Blanche - Gardanne, [5] Le Cabinet Mirentchu Toubal, [6] CABINET DU DR FERRET, [7] Clinique Clémentville, [8] CHU Bordeaux, [9] Panthera Dental Inc., [10] CHU MONTPELLIER, [11] Beau Soleil, [12] Clinic Benoît Griffet, [13] Clinic Morgan Le Balc'h

Introduction: Oral appliance therapy (OAT) for treating obstructive sleep apnea (OSA) is one of the cornerstones of OSA management and requires multidisciplinary care management. When complete, the study will provide data on the use of the Panthera D-SAD, a CAD/CAM, 3D printed biocompatible nylon oral appliance. The primary endpoint of at least a ≥50% reduction in baseline apnea-hypopnea index (AHI) will be evaluated at five years, with interim sleep data at 3-6 months. The study fulfills French reimbursement requirements.
Methods: OAT naïve individuals with an AHI of 15-30 or those with severe OSA (AHI > 30) who decline CPAP and meet all other criteria will be included. Sites will follow the standard of care in France. Fifteen centers will enroll 217 participants via consecutive sampling. Participants will be medically and dentally evaluated. Evaluation time points are three to six months (sleep testing/medical), annual check-in, and five years (both). Secondary endpoints include side effects, oxygenation metrics, quality of life, self-reported adherence, and subjective symptoms. Ethics approval obtained.
Results: Enrollment is complete (N=257). Baseline demographics n=239 (mean/SD): Age 50.7 (12.8), BMI 26.6 (4.7), M 51%, AHI 22.7 (9.0), ODI 17.0 (11.4), lowest SpO2 84.6% (6.8), ESS >10, 42.4% (n=198). Change from baseline sleep respiratory variables at 3-6 Mos (n=179): a mean decrease in AHI of 10.5 (8.1) and an AHI reduction ≥ 50% in 60.3%. Additionally, 87.8% of moderate and 83.4% of severe transitioned to a lower AHI classification. ODI decreased to 9.7 (8.4). Subjective usage was sustained >4 hrs./night at six months in 94.8% of participants and 91.9% at one year (n=76), averaging 6.4 nights per week, demonstrating sustained adherence. Treatment satisfaction was 85.8% at three months. The mean ESS decreased from 9.1 (5.3) to 7.4 (4.8). The ≥50% AHI reduction was not influenced by BMI categories or gender, (p= 0.813 and 0.694, respectively).
Conclusion: These data demonstrate a reduction in total mean AHI with a substantial transition migration to a less severe AHI category. High OAT acceptance and adherence were found. In this sample, the percentage of patients whose AHI decreased by at least 50% does not differ between the subgroups.

Introduction: Obstructive sleep apnea (OSA) is a well-established risk factor for cardiovascular disease. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have demonstrated promising potential in reducing cardiovascular risk and alleviating the severity of OSA. However, a significant knowledge gap remains regarding the impact of GLP-1RAs on cardiovascular events in OSA patients. This study utilizes large-scale global electronic healthcare record data to evaluate the associations of GLP-1RAs with improved cardiovascular outcomes.
Methods: We conducted a propensity score-matched retrospective cohort study using aggregate data from the TriNetX Global Network, which includes over 160 million patients from more than 120 healthcare organizations worldwide. The study population comprised patients with a BMI over 30 who were diagnosed with OSA between January 2010 and November 2021. Patients with a diagnosis of heart failure, pulmonary hypertension, or myocardial infarction were excluded. Two cohorts were created: one consisting of patients prescribed GLP-1RAs (semaglutide, liraglutide, or dulaglutide) within one year before their OSA diagnosis, and the other comprising OSA patients who were never prescribed any GLP-1RAs. Propensity score matching was performed using TriNetX software, which relies on the greedy nearest neighbor methodology. Cox proportional hazards analyses were conducted over a three-year follow-up period. The primary outcome was heart failure. Secondary outcomes included pulmonary hypertension and acute myocardial infarction (AMI).
Results: We included 16,992 patients in the GLP-1RA cohort and 727,130 patients in the non-GLP-1RA cohort. Propensity score matching resulted in 16,881 patients remaining in each cohort, which were well-matched in demographics (age 54.8 vs. 55.7, White: 62.3% vs. 61.9%, Female: 51.3% vs. 53.1%), comorbidities, medications, BMI (40.7 vs. 40.8), and HbA1c (7.6 vs. 7.5). In the GLP-1RA cohort, most patients received liraglutide

(50.2%), followed by dulaglutide (36.1%), and semaglutide (20.1%). After 3 years of follow-up, the GLP-1RA cohort had a significantly lower risk of newly developed heart failure (1,206 vs. 1,579 cases; HR: 0.73, 95% CI: 0.67-0.78), pulmonary hypertension (329 vs. 499 cases; HR: 0.63, 95% CI: 0.55-0.73), and AMI (324 vs. 482 cases; HR: 0.65, 95% CI: 0.56-0.74).
Conclusion: GLP-1RA use was associated with reduced risks of heart failure, pulmonary hypertension, and AMI in obese OSA patients. Prospective studies are needed for validation.

Introduction: The Dual-sided hypoglossal neRvE stimulAtion for the treatMent of obstructive sleep apnea (DREAM) trial is a prospective, multicenter study evaluating safety and efficacy of bilateral hypoglossal nerve stimulation (HNSBL) in obstructive sleep apnea (OSA) patients with moderate and severe OSA.
Methods: A prospective non-randomized study of moderate-to-severe OSA (AHI4% 15.1-64.9 hr), body mass index ≤32 kg/m2, and lack of complete concentric palatal collapse during drug-induced sleep endoscopy who failed or refused positive airway pressure therapy evaluated two co-primary efficacy endpoints at at 12 months: proportion of patients with AHI4 (4% SaO2 drop for hypopnea) reduction of > 50% and < 20 hr and proportion of patients achieving a ≥25% reduction in 4% oxygen desaturation index (ODI4). Secondary study endpoints included changes in polysomnographic and subjective quality-of-life metrics.
Results: A total of 115 patients were included in the analysis. Majority of the patients were middle-aged (56.8±7.3 years) men(70.4%). Eighty-eight patients completed a 12-month polysomnography study at fixed HNS settings per protocol. 63.5% (73/115) and 71.3% (82/115) of patients met the AHI4 (p=0.002) and ODI4 endpoints (p< 0.001), respectively. In the per protocol set mean AHI4 was reduced from 28±11.5 to 9.5±9.4 events/h (p< 0.001), and supine AHI4 was reduced from 48.9±19.6 to 22.7±19.9 events/h (p< 0.001). All secondary endpoints changed significantly (p< 0.001). There were eight (7.0%) device/procedure-related serious adverse events.
Conclusion: Bilateral HNS yielded statistically significant changes in quality-of-life variables and OSA disease severity with significant improvement in supine AHI.
