[1] Pulmonary, Critical Care, and Sleep Medicine, Department of Medicine, University of California San Diego, [2] University of Pennsylvania Perelman School of Medicine, [3] Bogan Sleep Consultants, [4] Department of Otolaryngology - HNS Medical University of South Carolina, [5] Advanced Ear Nose and Throat Associates PC, [6] Endormir Sleep and Sinus Institute, [7] ENT Associates, Clearwater Florida, [8] Department of Otolaryngology – Head and Neck Surgery Penn State Milton S Hershey Medical Center, [9] Epic Medical Research, LLC, [10] Silenso Clinic, [11] Hackensack University Medical Center, [12] Sacramento ENT, [13] LivaNova PLC, [14] ENT and Allergy Associates

Introduction: Clinically significant improvement of the total Apnea-hypopnea index (AHI) in the OSPREY randomized, controlled trial (RCT) of proximal hypoglossal nerve stimulation (pHGNS) was demonstrated for patients receiving active treatment compared to control at 7 months for moderate to severe obstructive sleep apnea (OSA). The AHI responses with respect to type of event, sleep stage and position during longitudinal follow-up in the preceding THN3 RCT were clinically significant and durable. Herein we report details of AHI for the OSPREY RCT.
Methods: OSPREY RCT participants (N=104 [Treatment=67,Control=37], no sleep endoscopy screening, AHI 15-65/hr, Body Mass Index ≤35 kg/m2) were evaluated through month 7. AHI details were compared by median values and stochastic probability of superiority (A) with bootstrapped 95% confidence intervals (95%CIs). A-values were bounded by 0 and 1, with A=1 indicating 100% likelihood of superiority and A=0.5 indicating equal likelihood (null outcome). Per convention, non-parametric effect size was characterized as large and medium for A≥0.71 and A≥0.64, respectively.
Results: No significant changes were observed in the Control group. AHI was decreased by pHGNS for Treatment: T=[34.3/hr to 11.6/hr, A=0.83 (95%CI:0.71-0.89)]. Similarly, Obstructive Apnea Index T=[5.2/hr to 0.6/hr, A=0.76 (95%CI:0.64-0.84)] as well as Hypopnea Index T=[23.9/hr to 9.4/hr, A=0.88 (95%CI:0.76-0.94)] were improved with pHGNS. Like improvements were observed for REM AHI T=[31.8/hr to 16.1/hr, A=0.65 (95%CI:0.52-0.75)] as well as non-REM AHI T=[34.3/hr to 10.6/hr, A=0.83 (95%CI:0.71-0.89)]. Finally, pHGNS improved Supine AHI T=[60.4/hr to 40.0/hr, A=0.63 (95%CI:0.49-0.75)] in addition to non-Supine AHI: T=[19.2/hr to 9.5/hr, A=0.65 (95%CI:0.52-0.74)].
Conclusion: In the OSPREY RCT of moderate to severe OSA, pHGNS produced clinically and statistically significant reductions with medium to large effect sizes in obstructive apneas, hypopneas, and total AHI, irrespective of REM or supine position. These outcomes validate the report of long-term results from the THN3 RCT.

POTENTIAL OVER-TITRATION IN HYPOGLOSSAL NERVE STIMULATION (HNS) THERAPY: IMPLICATIONS FOR PROTOCOL REFINEMENT AND PATIENT OUTCOMES

Unjung Cho[1], Hye-Jin Moon[2], Chang-Hoon Lee[3], KyoungBin Im[1]
[1] UC Irvine, [2] Soonchunhyang University, [3] Seoul National University Hospital

Introduction: Hypoglossal nerve stimulation (HNS) is a promising treatment for obstructive sleep apnea (OSA); however, flaws in manufacturer-recommended "fine-tuning" protocols may lead to over-titration, applying unnecessarily high stimulation voltages. This study evaluates patients whose optimal voltage fell below manufacturer-recommended starting levels, termed the "potential over-titration group." By comparing clinical outcomes, such as apnea-hypopnea index (AHI) and patient characteristics, we aim to emphasize the need for refined titration protocols to improve treatment effectiveness and patient comfort.
Methods: Participants who underwent HNS therapy activation at the UCI Sleep Center from December 2020 to August 2023 were included in this cohort study. At the activation visit, participants were instructed to increase the voltage to a comfortable level before undergoing titration. While the manufacturer's protocol suggests initiating titration at incoming amplitude –0.2 V, our protocol begins at the functional threshold. The "potential over-titration group" was defined as participants whose best voltage was lower than the manufacturer's recommended starting voltage. Variables were compared using t-tests and chi-square tests.
Results: Among 123 participants, 40 (32.5%) had a best amplitude below the manufacturer-recommended starting voltage, indicating potential over-titration if the protocol had been strictly followed. Compared to others, the "potential over-titration group" demonstrated: lower periodic limb movement of sleep ($p = 0.03$); lower prevalence of anxiety disorder ($p = 0.03$); lower mean total AHI (13.11 vs. 20.50, $p = 0.012$) and non-REM AHI (12.90 vs. 19.80, $p = 0.028$); lower best voltage (1.82V vs. 2.35V, $p = 0.0005$); lower AHI during device-off portions (7.66 vs. 21.28, $p = 0.0002$).
Conclusion: Patients in the "potential over-titration group" achieved favorable outcomes at voltages lower than manufacturer-recommended starting levels, underscoring the need for individualized titration protocols. Over-titration may not only reduce patient comfort but could also impact short-term outcomes, possibly contributing to tongue training effects observed during early post-activation. These findings highlight the importance of refining HNS titration protocols to optimize treatment efficacy and tailor strategies to the diverse characteristics of OSA patient populations.

EFFECT OF HYPOGLOSSAL NERVE STIMULATION ON HYPOXIC BURDEN: ANALYSIS OF THE STAR TRIAL

Ali Azarbarzin[1], Sara Op de Beeck[2], Neda Esmaeili[1], Jing Xu[1], Olivier Vanderveken[2], Phillip Huyett[3], Ryan Soose[4], Raj Dedhia[5], Patrick Strollo[6]
[1] Brigham and Women's Hospital and Harvard Medical School, [2] University of Antwerp, [3] Harvard Medical School, [4] University of Pittsburgh, [5] University of Pennsylvania, [6] Department of Medicine, University of Pittsburgh Medical Center

Introduction: Hypoglossal nerve stimulation (HGNS) is an implantable device for treating Obstructive Sleep Apnea (OSA) by electrically stimulating the hypoglossal nerve to move the tongue and relieve airway obstruction. The STAR trial showed a significant reduction in the apnea-hypopnea index (AHI) at 12 months. This study evaluates: 1) HGNS's effect on hypoxic burden (HB) at 12 months, 2) the percentage of individuals transitioning from high HB (≥60 %min/h, linked to increased cardiovascular risk) to low HB (i.e. < 60 %min/h), and 3) the impact of active HGNS versus withdrawal after 12 months in a subset of participants.
Methods: A secondary analysis of the STAR Trial (NCT01161420) measured HB from SpO2 signals during sleep studies at baseline, 12 months (including 1-week withdrawal), and 18 months of HGNS therapy.
Results: The median HB was 63 [48–95] %min/h (N=108; 84% male; mean (SD) age 55 (10) years; AHI 30 [25–40] events/h). After 12 months, the median HB reduction was 77% [36%–90%]. Among those with high baseline HB (≥60 %min/h; N=62; age 56 (10) years), 79% achieved low HB (79% [50%-90%] reduction from baseline).In individuals with a low HB at baseline (< 60 %min/h; N=46; age= 53 (11) years), the median HB changed from 45 [36 - 53] to 11 [3.1 - 34] %min/h. Finally, therapy-maintenance subgroup (N=19) had an HB of 69 [52 - 92], 12 [5.2 - 20], 15 [3.3 - 26], and 15 [4.8 - 26] %min/h at baseline, 12-month, 12-month+1-week, and 18-month, respectively. Therapy-withdrawal subgroup (N=18) had an HB of 55 [38 - 78], 11 [7.0 - 15], 35 [22 - 66], and 15 [13 - 27] %min/h at baseline, 12-month, 12-month+1 week, and 18-month, respectively. The 1-week change in HB from 12-month was 43 [95% CI: 6.6 - 77] %min/h higher in the therapy withdrawal versus therapy maintenance subgroup ($p=0.027$) but failed to reach baseline values.
Conclusion: HGNS reduces HB after 12 months in OSA patients, with 79% of those at high baseline HB achieving low HB. Therapy effects persisted at 18 months, while a 1-week withdrawal did not fully restore HB to baseline.

IMPLEMENTING A PSYCHOLOGICAL EVALUATION AS PART OF HNS IMPLANTATION PROTOCOL: RESULTS OF A QUALITY IMPROVEMENT INITIATIVE

Hollyann Loui[1], Megan Hoch[2], Austin Grinberg[3], Sarah Kate McGowan[3], Jennifer Martin[4], Melisa Chang[5]
[1] UCLA, [2] Department of Mental Health, VA Greater Los Angeles Healthcare System, [3] Department of Mental Health, VA Greater Los Angeles, [4] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System, [5] Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles

Introduction: Hypoglossal nerve stimulation (HNS) is a treatment option for patients with obstructive sleep apnea who cannot tolerate positive airway pressure (PAP). Although previous clinical trials of HNS have shown high adherence rates, rates may be significantly lower in some clinical settings. A psychological evaluation was added to the HNS screening protocol at one center, to evaluate for possible psychiatric contraindications to HNS (e.g., insomnia, serious mental illness, cognitive

impairments) and understanding of pre/post-HNS implantation procedures. This quality improvement project investigated changes in HNS adherence rates following implementation of the HNS psychological evaluation.
Methods: Data from 39 patients seeking HNS evaluation at a large Department of Veterans Affairs (VA) Sleep Medicine Clinic from August 2016 to September 2024 were analyzed; 15 patients were seen prior to implementation of the psychological evaluation (pre-psych) and 24 patients completed the evaluation (post-psych). Adherence was defined as an average of ≥4 hours of nightly usage and at least one clinic follow-up within 12 months after HNS activation.
Results: Of the 5 post-psych patients who underwent HNS surgery, 3 out of 4 eligible patients were adherent to HNS therapy (1 patient is immediately post-operative and was excluded from analysis) as compared to 2 out of 15 patients in the pre-psych evaluation group. The remainder of the post-psych patient outcomes are as follows: 2 await surgery, 5 were deemed ineligible to proceed with HNS due to Drug Induced Sleep Endoscopy findings, 8 chose conservative management (e.g. trialing PAP again), 3 were deemed ineligible for psychiatric/cognitive comorbidities, and 1 was lost to follow-up). Interestingly, 5 patients in the pre-psych group have expressed interest in explanting the device compared to 0 patients in the post-psych group.
Conclusion: Implementation of a psychological evaluation as part of the HNS screening process appears to be well received and screened out potential poor candidates for HNS. None of the post-psychological evaluation patients have requested HNS explant and adherence data appear favorable. While this data is promising, more information is needed from a larger sample size to systematically assess the outcomes of inclusion of the psychological evaluation in the pre-HNS evaluation process.

AUTOMATIC ACTIVATION OF TRANSVENOUS PHRENIC NERVE STIMULATION FOR CENTRAL SLEEP APNEA RESULTS IN HIGH NIGHTLY USAGE

Rami Khayat[1], Meena Khan[2], Timothy Morgenthaler[3], Scott McKane[4], Robin Germany[4], Maria Rosa Costanzo[5]
[1] University of California Irvine, [2] Ohio State University, [3] Mayo Clinic, Rochester, Minnesota, [4] ZOLL Respicardia, Inc., [5] Midwest Cardiovascular Institute

Introduction: Adherence with mask-based therapies remains a significant challenge for optimal treatment of patients with sleep disordered breathing. Transvenous phrenic nerve stimulation (TPNS) to treat central sleep apnea offers a novel, automated approach to enhance nightly adherence by initiating therapy based on patient-specific programmed conditions such as sleep schedule, activity, and body position. Therapy automatically pauses when the patient sits up or changes position, facilitating re-initiation of sleep. This research aimed to determine the degree of adherence achieved with TPNS's automated activation approach.
Methods: Device data from 128 remedē® System Pivotal Trial participants were analyzed to calculate hours of therapy activation. Daily use from device data within the 14 days prior to scheduled visits were used to calculate median daily hours of therapy per patient, and subsequently the overall median daily use for all patients. Therapy duration was defined as the sum of time of delivered therapy when all conditions to activate therapy were met between the first time therapy came on to the last time off during the night, excluding time when activity or body position did not meet the programmed criteria for therapy activation.
Results: The median [Q1-Q3] nightly therapy duration at 6, 12, 18, and 24 months was 5.9 [4.9-6.6], 5.7 [5.0-6.8], 6.0 [5.3-6.8], and 5.9 [4.9-6.5] hours, respectively. Using a definition for adequate therapy as the percentage of patients with usage ≥4 hours/night for at least 70% of nights, 86%, 82%, 83%, and 90% of patients met the criteria at these visits. Only two patients (< 2%) who had therapy activated discontinued treatment prior to 6 months due to stimulation intolerance. Patients with median delivered therapy ≥4 hours/night reported more quality of life improvement than patients with < 4 hours of therapy.
Conclusion: The automatic activation of TPNS therapy resulted in a higher duration of nightly usage and higher rate of adequate delivered therapy than generally are reported for mask-based therapies. This high usage may yield a greater overall reduction in central sleep apnea burden over the whole night compared to therapies that require the patient to initiate the therapy.

HYPOPNEA CLASSIFICATION IMPACT ON TRANSVENOUS PHRENIC NERVE STIMULATION THERAPY PATIENT SELECTION AND EFFICACY

Kara Dupuy-McCauley[1], Alan Schwartz[2], Shahrokh Javaheri[3], Robin Germany[4], Scott McKane[4], Timothy Morgenthaler[5]
[1] Mayo Clinic, [2] University of Pennsylvania Perelman School of Medicine, [3] Bethesda North Hospital, [4] ZOLL Respicardia, Inc., [5] Mayo Clinic, Rochester, Minnesota

Introduction: Despite AASM scoring guidelines encouraging classifying hypopneas as central or obstructive, classification is underutilized in practice. However, without that effort patients may receive an incorrect primary diagnosis and suboptimal treatment. The remedē® System Pivotal Trial studied transvenous phrenic nerve stimulation (TPNS) to treat adult patients with moderate to severe central sleep apnea (CSA). Entry criteria required apnea hypopnea index (AHI)≥20 with the central apnea index (CAI) greater than the obstructive apnea index and obstructive apneas< 20% of AHI but did not consider hypopnea differentiation. This analysis re-examined sleep studies from the trial to assess how hypopnea classification might lead to better patient selection for this therapy.
Methods: Hypopneas were classified as central versus obstructive by a sleep core laboratory following a modified version of AASM recommended criteria. The AHI composition was assessed at baseline and after 6 months of therapy.
Results: At baseline, 91% (138/151) of patients had ≥50% of events classified as central when accounting for hypopnea classification. If all hypopneas were assumed to be obstructive, only 63% (95/151) would have had ≥50% central events. Additionally, 95% (144/151) of patients had central AHI ≥15/hour, compared to 73% (110/151) with a central apnea index (CAI) ≥15/hour. The likelihood of achieving a ≥50% AHI reduction increased with the percentage of baseline events that were central: responder rates were 37.5% for patients with < 50% central events at baseline, incrementally increasing to 76.5% for those with ≥90% central events. At 6 months, the residual AHI predominantly consisted of obstructive events. Central events decreased by 89% with treatment, from a baseline median of 32/hour [1st and 3rd

quartiles: 22, 50]. Obstructive apneas rose by 2/hour and obstructive hypopneas increased by 2/hour from a baseline median of 5 obstructive events/hour [2, 12].
Conclusion: Distinguishing central from obstructive hypopneas is required to accurately determine if a patient has central sleep apnea/Cheyne Stokes respiration, and is crucial for epidemiologic studies, appropriate therapy selection, and managing patient expectations about treatment outcomes. This analysis suggests that accurate hypopnea classification may prevent disqualification of patients who could benefit from TPNS therapy, which effectively treats central sleep apnea syndrome.

PREVALENCE AND PROGRESSION OF SLEEP DISORDERED BREATHING IN PATIENTS WITH MYOTONIC DYSTROPHY A RETROSPECTIVE ANALYSIS

Christopher Glendinning[1], Zheng Fan[2], Vaughn Bradley[2], Nathan Walker[2], Heidi Roth[2], Katelyn Bricker[2]
[1] UNC Department of Neurology, [2] UNC

Introduction: Patients with Myotonic Dystrophy (DM) may have progression of their sleep disordered breathing (SDB) which requires advancement of therapy. We examined our patients with Myotonic Dystrophy who had two or more studies to evaluate the treatment requirements over time.
Methods: 17 patients with DM having more than one sleep study were identified in the UNC Sleep Laboratory from 2003-2024. Data including sleep architecture parameters and respiratory indices: AHI, lowest desaturation, presence of hypercapnia, and/or hypoxemia, titration pressure of bilevel PAP/CPAP, supplemental oxygen requirement, periodic limb movements (PLMS), arousal index (AI), Epworth Sleepiness Scale scores, along with co-morbid medical conditions and current prescribed medications were collected. Student t test for continuous variable, and Fisher exact test for categorical variables were used to determine significance ($p < 0.05$).
Results: Fifty-six studies from 17 patients with DM were identified. Among the 17 patients 4 were children and 13 were adults. Most patients had 2-3 studies, but one had 7 and another had 8 repeated studies over 14 years. Sleep apnea was found in 16/17 (94%), 13/13 adults with AHI > 5 (mean AHI = 15.1), and 3/4 children with AHI > 1.5 (mean AHI = 7.1). Hypercapnia was found in 9/17 patients and hypoxemia was found in 6/17 with 5 requiring supplemental oxygen. Bilevel was required in 4/13 adult patients to treat hypoventilation. No significant change in therapy type was noted across the therapeutic studies. Only one patient progressed from CPAP to Bilevel and only one patient progressed from not requiring oxygen to requiring oxygen.
Conclusion: In our cohort, we found that many patients with DM have a high prevalence of sleep apnea and hypoventilation. We also noted that some patients may require a change in pressure over time, most did not require a change in therapy from constant pressure to bilevel PAP or the addition of oxygen. However, given that some patients in our cohort did require a change in therapies, clinicians should remain astute to changes in the possibility that these patients may need repeated evaluations.

NUESTRO SUEÑO: PROVIDERS' PERCEIVED DISPARITIES FOR SLEEP TREATMENT IN SPANISH-SPEAKING COMMUNITIES

Christian Escorcia[1], Sonia Malik[1], Carson Hernandez[1], Bobbie Bermudez[1], Wendy Troxel[2], Carmela Alcantara[3], Kelly Baron[1]
[1] University of Utah, [2] RAND Corporation, [3] Columbia University

Introduction: Obstructive sleep apnea (OSA) is a prevalent disorder, affecting approximately 34% of Hispanic/Latino men and 18% of Hispanic/Latino women. Despite the proven effectiveness of Positive Airway Pressure (PAP) therapy, treatment disparities persist, particularly among Spanish-speaking patients. These disparities are often linked to language barriers, socioeconomic challenges, and limited healthcare access. This study aimed to explore healthcare providers' perspectives on challenges encountered when treating Latinx patients with OSA. The goal was to identify barriers and suggest potential solutions to improve care and patient outcomes.
Methods: Focus group discussions (FGDs) were conducted with sleep medicine providers from University of Utah Sleep Wake Center and local sleep centers. Participants discussed experiences and strategies for treating Hispanic/Latinx patients with OSA. FGDs were conducted via Zoom, recorded, and transcribed verbatim. Data analysis followed an applied thematic analysis in two stages: a deductive coding phase for broad themes and an inductive phase to identify emerging themes. Final coding was reviewed for consistency.
Results: Providers (N = 21), participated in the study, including physicians (pulmonary, psychiatry, neurology), advanced practice nurses, psychologists, physician assistants, clinic managers, and sleep technicians. Providers identified key barriers, including language-related issues such as time-consuming translations and insufficient Spanish-language educational materials. Socioeconomic challenges, such as work schedules and lack of insurance were also noted as significant barriers to care. Solutions proposed included improving the affordability of CPAP equipment, enhancing translation services, and employing creative educational techniques like visual aids and sound effects. Three major themes emerged (1) Language-related barriers: difficulties with translation and inadequate educational materials in Spanish; (2) Patient-related barriers: socioeconomic challenges and limited access to care; and (3) Potential solutions: improving affordability, enhancing translation services, and creative educational tools. Providers reported varying success with interventions, such as offering low-cost CPAP equipment and adjusting appointment schedules to accommodate language barriers.
Conclusion: This study highlights key barriers faced by healthcare providers when treating Latinx patients with OSA. These insights, gathered and organized from provider feedback, reveal the complexity of these challenges and emphasize the need for targeted interventions to address disparities and improve outcomes for Latinx patients with OSA.

PAP PRESCRIPTION AND UTILIZATION IN AN INTERNAL MEDICINE WARD: A SINGLE CENTER EXPERIENCE

Lissette Jimenez Davila[1], William Rodriguez[2], Luis Irizarry-Nieves[2], Joel Rodriguez Ramos[3]

[1] VA Caribbean Health Care System, [2] VACHS, [3] VA Caribbean Healthcare System

Introduction: Obstructive sleep apnea (OSA) is prevalent among hospitalized patients and adversely impacts comorbidities and length of stay. In-hospital adherence may predict home PAP adherence. PAP therapy use during hospitalization has not been clearly established. We aim to assess inpatient PAP therapy prescription rates and use, and factors that influence them among hospitalized patients with OSA.
Methods: This retrospective study reviewed electronic records of all patients discharged from a Medicine ward during one month at the VA Caribbean Healthcare System. Records of patients with OSA were reviewed. Data collected included demographics, comorbidities, Epworth Sleepiness Scale (ESS), body mass index (BMI), home PAP adherence, PAP therapy prescriptions within 24 hours of admission and the proportion of patients prescribed PAP therapy that used it. Statistical analysis identified significant associations.
Results: Thirty five percent (n=120) of patients discharged (n=340) had a diagnosis of OSA. Of these 25.8% (n=31) were PAP-adherent at home. Of patients with OSA 44.2% (n=53) received PAP therapy within 24 hours of admission, 55.8% (n=67) did not. Factors associated with PAP prescriptions include home adherence (39.6% vs. 14.9%; p=0.002) and history of heart failure (50.9% vs. 20.9% p=0.001). Adherence among those prescribed PAP therapy was 73.6% (n=39). There was no significant difference in prescription rates or PAP use associated with AHI, obesity, insomnia, hypoventilation, BMI, ESS, hypertension, depression, anxiety, PTSD, substance use, cognitive disorders, chronic pain. Patients who did not use prescribed PAP therapy had a higher rate of home PAP compliance than in-hospital users (64.3% vs. 30.8%; p=0.028).
Conclusion: There was low timely PAP prescription rates among inpatients. Home PAP adherence predicted the in-hospital prescriptions. Non-adherent patients may be at greater risk of being untreated. A greater use of PAP during hospital admission might represent a window of opportunity to improve PAP treatment adherence. Factors associated with lower in-hospital adherence in home-adherent patients should be studied. Equipment issues (availability, differences between hospital and home devices and settings) may explain these differences. Education could enhance inpatient PAP use and increase awareness of the importance of treating OSA in patients with comorbidities besides CHF.

RURAL RESIDENCE IS ASSOCIATED WITH CPAP REFUSAL AMONG HOSPITALIZED PATIENTS WITH KNOWN OR AT RISK OF OSA

Kristin Sheehan[1], Stephanie Cedeno[1], Priya Das[2], Amit Saha[1], Kang Rui Xiang[3], William Merwin[1], Abigail Koch[1], Andrew Namen[1]

[1] Wake Forest School of Medicine, [2] Ohio State University, [3] Wake Forest University School of Medicine

Introduction: Obstructive sleep apnea (OSA) is a common disorder that is underrecognized and associated with comorbid conditions and societal impact. Health systems have directed efforts to inpatient assessment (OSA screening) to identify patients at risk and early treatment initiation to avoid unexpected outcomes including medical emergency team activation (META) (code blue, code stroke, rapid response, and reintubation). However, acceptance of positive airway pressure (PAP) therapy remains low for both patients with known OSA and those at risk. In our North Carolina regional academic medical center, we explored key social determinants of health (SDOH) that may lead to refusal of PAP therapy.
Methods: Hospitalized adult patients with known OSA or those who previously underwent screening with DOISNORE50 and identified as High-Risk for OSA, were prospectively enrolled in an OSA safety protocol consisting of patient wristband identifiers, electronic medical record alerts, and recommendations for inpatient sleep consultation and automatic PAP ventilation. PAP usage, demographics, SDOH, and outcomes were collected from patient charts.
Results: 22,107 patients screened High-Risk for OSA and were offered PAP therapy, of which 9,353 declined (42%). For those who declined PAP, there was an increase in length of stay (9.25 days versus 6.78 days, $p < 0.001$), total META (adjusted odds ratio (aOR) 1.16 (95% CI 1.08 – 1.26, $p < 0.001$)), and rapid response (aOR 1.49 (95% CI 1.37 – 1.64, $p < 0.001$)) compared to those who wore PAP. Among a variety of SDOH that were studied (including gender, race, and income), the probability of refusal was highest among those over 65 years old (aOR 1.4 (95% CI 10.03 – 1.26, $p = 0.01$)) and those from rural communities determined by zip code (OR 1.92, 95% CI (1.12 – 3.32), $p < 0.001$). Inpatient sleep consultation was associated with greater acceptance of PAP among all groups (OR 2.04 (95% CI 1.71 – 2.44), $p < 0.001$) including patients from rural communities.
Conclusion: Strategic use of inpatient sleep consultation among vulnerable older adults and those living in rural communities may favorably affect adherence to inpatient PAP recommendations. Further understanding of the perceptions and reality of PAP usage in these subpopulations is needed.

PREDICTING SLEEP STATE FROM CONTINUOUS POSITIVE AIRWAY PRESSURE FLOW IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Muneeb Ahsan[1], Henry Yaggi[1], Andira Anwar[1], Hsin-Yu Chen[2], Cheng-Yao Chen[2], Andrey Zinchuk[1], Hau-Tieng Wu[3]

[1] Yale University, [2] PranaQ, Co., New York, New York, USA, [3] Courant Institute of Mathematical Sciences, New York University

Introduction: The first-line treatment for Obstructive sleep apnea (OSA) is continuous positive airway pressure (CPAP). CPAP adherence is assessed by hours of mask usage per night. To understand whether patients using CPAP are sleeping while wearing their mask (and thus may benefit from therapy), we aimed to develop a tool that predicts sleep from CPAP flow signal.

Methods: We developed a machine learning algorithm to predict sleep states from CPAP flow data. It uses topological data analysis, dynamic warping, and respiratory rate variability to identify features predicting sleep states (two-state: Wake/Sleep; three-state: Wake, NREM, REM). Models include 125 flow features from above analyses, CPAP level, age, sex, and body mass index (BMI). We applied this algorithm to polysomnography records from 100 randomly selected OSA patients undergoing CPAP titration at Yale Sleep Center (2018–2023). Inclusion criteria were age ≥18 years and >70% recording time with valid CPAP flow signal. Sleep stages were scored by AASM-certified technologists. Participants were equally distributed into development (n=70) and validation (n=30) samples stratifying by age, sex, BMI, and residual apnea-hypopnea index (AHI). Model's sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were determined.
Results: The dataset (n=100) included 48 women, exhibited a mean age of 58.7±14.5 years, and a BMI of 35.0±10.6 kg/m². Seventy six percent of participants were White, 12% African American, and 12% were other/undisclosed. There were no significant differences in age, sex, BMI and residual AHI between samples. In the validation sample (n=30), 77% and 23% of the 22,267 epochs were sleep and wake respectively. The two-state model accuracy was 84%. This model detected sleep with 91% sensitivity, 60% specificity, 89% PPV, and 67% NPV. Using this model improves the chance of detecting wake from 23% (baseline) to 67% and sleep from 77% (baseline) to 89%. Three-state model accuracy was 73%.
Conclusion: Sleep and wake can be effectively predicted by a machine learning model using CPAP flow and demographics. Such information may complement data from CPAP devices currently used to assess CPAP effectiveness. Model differentiating between NREM, REM and Wake states, requires further refinement.

ODDS RATIO PRODUCT (ORP) FROM THE DIAGNOSTIC PSG AND INTERNAL LOCUS OF CONTROL AS PREDICTORS OF 6-MONTH CPAP ADHERENCE

Kari Lambing[1], Madhuri Sinha[2], Veronica Guadagni[1]
[1] Cerebra Medical Ltd, [2] University of Manitoba

Introduction: Low adherence to CPAP is a well-documented problem and reduces the effectiveness of the treatment. This study aimed to investigate objective markers, such as ORP at diagnostic, combined with baseline subjective measures to predict adherence. ORP is a well-validated measure of sleep depth from 0 (deep sleep) to 2.5 (full wakefulness). Predicted adherence could be used to identify those who may need additional support for use of their prescribed treatment.
Methods: In a sample of 67 individuals referred for a Type 2 diagnostic study (Mage= 44.9 ±13.16, 39 females), 41 were prescribed CPAP (Mage= 45.80±13.40; MAHI=29.98±23.87) and had 6-month adherence reports. At the time of the diagnostic study, participants also completed questionnaires on sleep (Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS)), beliefs on health (Health Value, Multidimensional Health Locus of Control (MHLC)), and social support for the use of CPAP. Adherence was determined by the percentage of days with use greater than 4 hours (MAdherence=52.0%±35.63). AHI, TST90, mean SPO2, ORPwake (mean ORP during wake periods), ORPNREM (mean ORP during NREM), ORP-9 (mean ORP 9 seconds post-arousal), percentage of TRT with ORP< 0.5 and >2.25, health value, CPAP support, ISI, ESS, and the 3 subscales of the MHLC were entered in an MLR model with backward elimination to predict adherence.
Results: The final model in the MLR was significant (F(4,41)=4.55, p=.005, R2=.331), and the significant predictors included AHI (b=.533, t=2.40, p=.022), TST90 (b=-.515, t=-2.33, p=.025), ORPNREM (b=.282, t=2.02, p=.050), and MHLC-Internal (b=.501, t=3.39, p=.002). Thus, greater use of CPAP was associated with a higher AHI, lower TST90, higher ORPNREM, and more internal locus of control.
Conclusion: These results replicate the utility of AHI, desaturations, and sleep depth during NREM during the diagnostic in predicting long-term adherence. These results suggest that individuals with worse sleep due to respiratory events at diagnostic will be more likely to adhere, potentially due to the subjective improvement to their sleep with CPAP. However, these results extended previous literature by finding that individuals with worse objective sleep at diagnostic, but also a greater sense of control over their own health, would be most likely to adhere.

IS SLEEP-DISORDERED BREATHING A RISK FACTOR FOR HOSPITALIZATIONS RELATED TO CARDIOMETABOLIC CONDITIONS?

Jason Ong[1], Hlynur Hlynsson[2], Joseph Day[1], Thomas Kauss[1], Kristófer Montazeri[2], Jeffrey Hertzberg[3], Emerson Wickwire[4], Rebecca Hankla[1], Eysteinn Finnsson[2], Jón Ágústsson[5], Heidi Riney[1]
[1] Nox Health, [2] Nox Research, Nox Medical ehf., [3] Medformatics, Inc., [4] Maryland School of Medicine, [5] Nox Research, Nox Medical ehf

Introduction: Previous research has established that sleep-disordered breathing (SDB) is associated with cardiometabolic conditions but there is a paucity of real-world data examining the consequences of these comorbidities on health care resource utilization (HCRU) such as hospitalizations. The purpose of this study was to investigate the relationship between SDB diagnosis and hospitalization rates related to diabetes mellitus (DM) and/or atherosclerotic disease (AD) using a large claims dataset.
Methods: This study used a retrospective cohort design from a large medical claims database between 2018-2022. The presence of SDB, DM, and AD were identified using International Classification of Diseases (ICD-10) and relevant Current Procedural Terminology (CPT) codes. Hospitalizations related to DM and AD were identified primarily using Place of Service (POS) code 21. Data from year 1 (2018) was used to identify those diagnosed with SDB (n=193,671) and to conduct propensity-score matching to select matched comparison patients without SDB. The SDB group was compared to: 1) an unadjusted comparison group (n=248,848) excluding DM and AD in the propensity-score matching and 2) an adjusted comparison group (n=260,298), which included DM and AD in the propensity score matching. The observation period for hospitalizations was the subsequent 4-year period (2019-2022) for both models.
Results: In both models, odds ratios (OR) revealed a significant association between SDB diagnosis and hospitalizations related to DM (OR: 1.23-1.71), AD (OR: 1.08-1.17), and either

condition (OR: 1.17-1.45). In the adjusted model, post-hoc analysis revealed sex differences in the relationship between SDB and hospitalizations with females showing a pattern of significantly elevated risk across all hospitalization outcomes (OR: 1.25-1.44) whereas males were found to have a significant relationship between SDB diagnosis and future DM hospitalization only (OR: 1.10).
Conclusion: These findings provide real-world evidence that comorbid SDB increases the risk for hospitalizations related to cardiometabolic conditions. Sex is a potential moderator of this relationship and should be further explored.

POSITIVE AIRWAY PRESSURE (PAP) THERAPY ADHERENCE AND CARDIOVASCULAR-RELATED HEALTHCARE UTILIZATION (CVRHU) IN 1 YEAR

Fatima Sert-Kuniyoshi[1], Kate Cole[1], Anita Malik[2], Caleb Woodford[2], Naomi Alpert[2], Will McConnell[2], Kimberly Sterling[2]
[1] ResMed, [2] ResMed Science Center

Introduction: Obstructive sleep apnea (OSA) is associated with cardiovascular conditions when left untreated. While PAP therapy is the first-line treatment for OSA, real-world evidence on its impact in cardiovascular-related events is limited. This study assessed the relationship between long-term PAP adherence and CVRHU in a national OSA cohort.
Methods: This retrospective study analyzed insurance claims linked with objective PAP usage data from patients diagnosed with OSA who initiated PAP between 2015-2021. Two-year PAP adherence was defined as adherent, intermediate, or non-adherent based on US Medicare criteria. CVRHU was defined as emergency room (ER) visits, hospitalizations, or either ("serious cardiovascular-related event"), with primary diagnoses of stroke, heart failure, coronary artery disease, arrhythmia, cardiomyopathy, or hypertension. Covariates included demographics, obesity, comorbidities, healthy behaviors, and prior healthcare use. Inverse probability of treatment weighting was used to evaluate associations between adherence and CVRHU.
Results: The sample (n=377,830) was 42% female, mean age 51.7±11.9 years. Over two years, 75% of patients were at least intermediately adherent to PAP (25% non-adherent). Adherent patients were significantly less likely to have a serious cardiovascular-related event compared to non-adherent (4.09% vs 5.22%, P< 0.001), representing a 22% lower risk of having an event (RR: 0.78, 95% CI: 0.75-0.81). Intermediate adherence outcomes fell between adherent and non-adherent groups, with lower rates of cardiovascular-related ER visits (3.34% vs 3.70%, P< 0.001), hospitalizations (1.90% vs 2.09%, P< 0.001), and serious cardiovascular-related events (4.77% vs 5.22%, P< 0.001) compared to non-adherent. Total healthcare costs per patient were significantly lower for adherent patients compared to non-adherent (year 1: $9,748 vs $10,861, P=0.014; year 2: $9,102 vs $9,847, P< 0.001). Associated costs aligned with the frequency of events, with adherent patients incurring significantly lower costs compared to intermediate and non-adherent patients in the first year and further reductions in year 2 (year 1: adherent: $182 vs intermediate: $230 vs non-adherent: $257, P< 0.001; year 2: adherent: $166 vs intermediate: $237 vs non-adherent: $267, P< 0.001).
Conclusion: This real-world study demonstrates the relationship between PAP adherence and reduced CVRHU in patients with OSA. These findings underscore the importance of strategies to enhance PAP adherence to improve long-term cardiovascular outcomes.

CONTINUOUS POSITIVE AIRWAY PRESSURE (CPAP) USE IN WOMEN: ASSOCIATIONS WITH PRE-TREATMENT STIGMA

Fatemeh Asadollah[1], Paul Scott[1], Yue Dong[1], Sanjay Patel[1], Jonna Morris[2]
[1] University of Pittsburgh, [2] University of Pittsburgh

Introduction: Women with obstructive sleep apnea (OSA) use CPAP therapy less time per night compared to men, but the underlying reasons are unclear. Social factors, including stigma and concerns about body image, may contribute to this disparity. This study aims to explore how stigma, perceptions of body image, and their relationship with women's age influence nightly CPAP use.
Methods: In this prospective study of 89 women (mean age 51+/-14) clinically diagnosed with OSA (mean AHI 22.6+/-17.9) and newly initiated on CPAP, we assessed perceptions of stigma and body image prior to CPAP initiation and after 90 days of therapy. Stigma was assessed using the 8-item Stigma Scale for Chronic Illness (SSCI-8), where higher scores indicate greater stigma. Body image was measured with the 30-item Body Esteem Scale (BES), with lower scores reflecting poorer body image. Nightly CPAP use was obtained from the device and averaged over the initial 90-days. Unadjusted associations were explored through correlational analyses. Linear regression models evaluated the adjusted associations between predictors and CPAP use.
Results: The average nightly CPAP usage at 90-days was 4.1 hours (SD = 2.1 hours). The mean stigma score was 14.8 (SD = 6.7, range: 8–34), while the mean Body Esteem Scale (BES) score was 86.7 (SD=19.1, range: 48–160). Age was negatively associated with stigma (r =-0.280, p = 0.008). Body Esteem Scale (BES) scores were not significantly associated with stigma or age (all p > 0.05) and were therefore excluded from the models. CPAP use was independently associated with both age (r=0.213, p= 0.022) and stigma (log-transformed) (r =-0.222, p = 0.017). In women below age 50, stigma had a stronger effect on CPAP use (r= -.349).
Conclusion: Our findings indicate a complex role of younger age and stigma as predictors of CPAP use among women. Additional research is necessary to gain a deeper understanding of how stigma particularly in younger women influences decisions to use CPAP.

Introduction: Despite positive airway pressure (PAP) being the gold-standard treatment for sleep disordered breathing (SDB), treatment adherence remains a challenge for providers and patients. Women with SDB are understudied, and understanding the difficulties associated with PAP use in this population is crucial to promoting treatment adherence. We aimed to assess the role of demographics and insomnia symptoms in PAP side effects and PAP use for women veterans.
Methods: We analyzed data from a randomized controlled trial of an Acceptance and Commitment Therapy-based intervention to promote PAP adherence vs. a sleep education control condition for women veterans newly diagnosed with SDB (NCT03377452). Data included demographics (age; body mass index, BMI; race/ethnicity), baseline assessment Insomnia Severity Index (ISI), PAP use data (days used, hours used at 30-, 60- and 90-days post-PAP initiation), and the PAP side effects subscale of the Calgary Sleep Apnea Quality of Life Index (SAQLI). Analyses included Pearson correlations and t-tests.
Results: Of the 90 participants (Mean age = 53.2±12.8), 83 (92.2%) attempted to use PAP and completed the questionnaires. The most common PAP side effects included: upper respiratory symptoms (stuffed/congested nose = 60.2%, excessive dryness of nose/throat = 55.4%, soreness = 39.8%), mask-related issues (discomfort = 56.6%, air leak =47.0%) and insomnia-like symptoms (waking frequently = 36.6%, difficulty returning to sleep = 31.3%). There was no relationship between age, BMI, or race/ethnicity and number of PAP-related side effects, nor was there a correlation between number of PAP side effects and PAP use variables. Elevated ISI prior to initiating PAP was associated with greater number of PAP side effects, $F(1, 81)=5.29$, $p=0.02$. Worse ISI was associated with fewer days of PAP use at 90 days post-PAP initiation, $F(1, 88)=4.55$, $p=0.04$.
Conclusion: Insomnia symptom severity prior to initiating PAP treatment for SDB is a significant contributing factor to increased endorsement of PAP-related side effects. Pre-existing insomnia symptoms prior to PAP initiation may play a role in fewer days of PAP use in the long term. Future research should explore the impact of insomnia treatment in PAP side effects and use in women.

IMPACT OF PAP THERAPY IN COMORBID COPD AND OBSTRUCTIVE SLEEP APNEA OVERLAP SYNDROME: AN UPDATE

Danny Greig[1], Chandra Miryala[2], Ruchi Rastogi[2], Lariab Imtiaz[2], Bradley Axelrod[2], Lili Zhao[2], Clete Kushida[3], Qurratul Uzzaman[4], Susmita Chowdhuri[2]
[1] John D. Dingell VAMC, [2] JDDVAMC, [3] Stanford University School of Medicine, [4] VA Ann Arbor

Introduction: Cognitive impairment in older Veterans is an independent predictor of subsequent mortality and disability. Pilot data indicate that patients with OSA-COPD Overlap Syndrome (OVS) have reduced sleep quality and disease-specific quality of life (QoL). However, there are no prior systematic studies evaluating treatment paradigms in patients with OVS. Our ongoing clinical trial is investigating whether positive airway pressure (PAP) therapy alleviates sleep disturbances, sleepiness, and improves cognitive function and QoL in older adults with OVS.
Methods: The design is a prospective parallel group randomized controlled trial in Veterans 60 years and older, with moderate-to-severe OSA with concomitant COPD (OVS). Participants on the conservative care (CC) arm are required to follow good sleep habits and sleep hygiene, and on the PAP arm, additionally, are required to be adherent to PAP therapy with CPAP or Bilevel PAP, following attended PAP titration study. Sleep questionnaires were administered to evaluate sleepiness, sleep quality, and general and disease specific QoL. A battery of neurocognitive tests to evaluate cognitive function, including Trail Making Test Part A and B, Paced Auditory Serial Addition Test, Stroop Task, Digit Coding, Hopkins Verbal Learning Test-R, Weschler Abbreviated Scale Intelligence II, Weschler Memory Scale IV, and Psychomotor Vigilance Test, respectively, and Six-Minute Walk Test(6MWT) were performed. All tests were administered at baseline visit, 3 months and 6 months.
Results: We have enrolled 300 participants with OSA (AHI≥20/hr) and moderate-severe COPD, randomized 72 participants (49 PAP vs. 23 CC). PAP/CC: 45/22 males, 4/1 females; age: 70.2±6.1/69.9±8.3 years, BMI: 29.3±6.4/28.8±5.4 kg/m2, AHI: 43.0±18.2/49.0±26.9 hr, spirometry FEV1: 58.3±15.0/68.9±10.1% predicted ($p< 0.05$), arterial blood gas (n=49) PaCO2:41.1±3.7/41.6±10.2 mmHg, Epworth sleepiness scale score: 7.6±4.4/9.1±4.5, Six-Minute Walk Test, Total Distance Walked: 386.5±105.0/388.0±94.5 meters, FOSQ Total Score:17.0±3.5/17.2±2.5, SGRQ Total Score:35.9±19.4/40.5±19.3. No baseline group differences in cognitive tests. Post-therapy group data will be available at the end of the trial.
Conclusion: Baseline characteristics were similar between the groups except for FEV1. We expect the results from our study will determine the effects of treating a novel target (OVS) to maximize daytime function and QoL, while providing a framework for treatment of cognitive impairment in older Veterans with chronic diseases.

NEIGHBORHOOD DISADVANTAGE IS ASSOCIATED WITH LOWER CONTINUOUS POSITIVE AIRWAY PRESSURE (CPAP) ADHERENCE

Adrianna Acevedo-Fontánez[1], Sulimar Morales-Colón[1], Pinar Garbioglu[1], Amanda Baranowski[1], Ryan Butcher[1], Venkatesh Krishnamurthy[1], Sanjay Patel[1]

[1] University of Pittsburgh

Introduction: Adherence with continuous positive airway pressure (CPAP) to treat obstructive sleep apnea (OSA) remains a challenge. Factors at the neighborhood level, including socioeconomic disadvantage, restricted healthcare access, and reduced social support, may significantly contribute to lower rates of consistent CPAP usage. We assessed whether the area deprivation index (ADI), which measures neighborhood-level socioeconomic disadvantage—with higher scores indicating greater disadvantage—was associated with CPAP adherence.

Methods: We reviewed consecutive OSA patients newly initiated on CPAP therapy at four University of Pittsburgh Medical Center sleep clinics from January 1 to December 31, 2023. Information on age, sex, race, and whether patients met Medicare adherence criteria at 90 days was extracted from the electronic health record. Patient address was mapped to census tract and ADI was obtained from public databases. For analytical purposes, we use quintiles of ADI.

Results: A total of 790 patients newly initiated on CPAP (mean age 53 ± 15 years, 45% female, 74% White, 18% Black, 4% Asian, 1% Hispanic, 3% Other, and mean ADI 66.1±18.7) were included in this analysis. With increasing quintiles of disadvantage, non-adherence to CPAP varied from 21.5% to 36.4%, 30.8%, 37.4%, and 32.9% (p=0.017). Nonadherence was significantly lower in the least deprived quintile compared to the other four quintiles (p=0.012). These differences persisted after adjusting for age, sex, and race. The odds of non-adherence at 90-days were 2.1 (95% CI: 1.3-3.4), 1.6 (0.9-2.6), 1.9 (1.1-3.1), and 1.6 (0.9-2.7) fold greater for those in quintiles 2-5 compared to quintile 1, respectively.

Conclusion: Our findings suggest that a higher ADI score is a significant predictor of CPAP non-adherence. Current criteria for long-term CPAP coverage are dependent on adherence. Patients who live in higher-risk neighborhoods are being disproportionately denied care, which in terms exacerbates healthcare disparities among OSA patients.

INTERPERSONAL RELATIONSHIP QUALITY IMPROVEMENT AFTER PAP THERAPY IN PATIENTS WITH OSA

Daniela Tellez[1], Fatima Sert-Kuniyoshi[1], Summer Ghamedi[1]

[1] ResMed

Introduction: Untreated sleep apnea can strain interpersonal relationships due to fatigue, irritability, and stress caused by sleep disruption. Conversely, supportive relationships may play an important role in successful positive airway pressure (PAP) therapy initiation and management. While PAP therapy is highly effective in alleviating apneic events and reducing daytime sleepiness, its impact on relationship quality is not well documented. This study sought to evaluate self-reported relationship quality before and after initiating PAP therapy among patients with sleep apnea.

Methods: This cross-sectional study included patients currently on PAP therapy who retrospectively assessed their interpersonal (friends, family, coworkers, etc.) and intimate (spouse or bed partner) relationship quality using an online questionnaire. Relationship quality was self-reported using an 11-point Likert scale, capturing two timepoints: before and after PAP therapy initiation. Higher scores indicated better relationship quality. A paired t-test was used to compare the difference in mean scores at the two timepoints.

Results: Twenty-two patients (36.4% female, mean age 53.3 years) were included in the analysis). A third of patients had been on PAP therapy for more than 10 years. Interpersonal relationship quality scores improved significantly, from a mean of 66.3% before PAP therapy, to 76.0% after PAP therapy initiation. This equated to a mean difference of 9.81 points (95% CI 4.20 -15.23, p = 0.0015). Intimate relationships mean score increased from 70.2% before PAP to 79.7% after PAP therapy, for a mean difference of 7.59 points (95% CI -0.85, 16.03, p =0.075), though this change did not reach statistical significance.

Conclusion: The results suggest potential benefits of PAP therapy on interpersonal relationship dynamics, and the improvement in relationship quality after sleep apnea treatment highlights the importance of sleep health as a crucial component for overall relationship well-being. Larger studies are needed to further explore the impact of long-term PAP compliance on interpersonal and intimate relationship quality.

IDENTIFYING BARRIERS TO CPAP INITIATION AMONG PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Ryan Butcher[1],Adrianna Acevedo-Fontánez[1],Stuti Vaidya[1],Venkatesh Krishnamurthy[1],Sanjay Patel[1]

[1] University of Pittsburgh

Introduction: CPAP is the first-line treatment for obstructive sleep apnea (OSA). The process of initiating CPAP in clinical practice is complicated and patients may get lost navigating between clinic, sleep lab and durable medical equipment provider. We sought to identify predictors for patients who received a CPAP prescription but did not initiate treatment to develop interventions to improve care of these high-risk patients.

Methods: We reviewed medical records of patients diagnosed with OSA and prescribed CPAP by a sleep clinician at four academic sleep clinics within the University of Pittsburgh Medical Center health system between January 1 and July 31, 2024. Non-initiation was defined as not receiving a CPAP machine within 90 days of date of prescription.

Results: We have collected data on 209 patients (53.1 ± 15.5 years, 49% women, 72.6% White) thus far. Initiation rates were similar between men and women (45.3% vs. 49.5%). In contrast, the proportion of patients initiated on CPAP within 90 days did

vary substantially by age group (42.0% in age < 40 yrs, 52.3% in age 40-64 yrs, 42.3% in age > 65 yrs), insurance type (Medicare (42.2%), commercial (50.9%), Medicaid (56.5%)), and by race (48.7% in White vs. 42.0% in Black patients), although differences did not meet statistical significance. The largest difference was observed between people who had previously been prescribed CPAP versus CPAP-naïve patients. CPAP initiation rates were 34.8% in prior users vs. 50.9% in CPAP-naïve (p=0.053).
Conclusion: Patients at both younger and older ages, particularly those of Black race and those covered by Medicare, are less likely to successfully initiate CPAP therapy, suggesting difficulties navigating the complex system for CPAP care. Additionally, the finding that prior CPAP users are less likely to initiate CPAP raises concerns that patient goals are not adequately incorporated into the clinician decision-making process when prescribing CPAP.

PAP THERAPY ASSOCIATED WITH PERCEIVED IMPROVEMENTS IN SYMPTOMS AND QUALITY OF LIFE IN OSA

Leanne Kaye[1], Vy Vuong[1], Kimberly Sterling[1], Alison Wimms[1], Meredith Barrett[1]
[1] ResMed Science Center

Introduction: Positive airway pressure (PAP) therapy can provide immediate and lasting clinical benefits in obstructive sleep apnea (OSA). Nevertheless, therapy adherence can be challenging for some users. Identifying benefits related to quality of life and symptom relief may further motivate users to persist with therapy.
Methods: Users of a smartphone app to track PAP therapy usage (myAir, ResMed) completed a one-time survey about their therapy experience and behaviors. Questions on perceived changes in quality of life (energy level, relationships, general activity, and clear-headedness) and OSA-related symptoms following therapy initiation were assessed using a 5-point scale reflecting worsening, no change, or improvement in the outcome of interest. Descriptive statistics and ordinal logistic regressions were used to assess the relationship between perceived improvement in outcomes and age, gender, and time on therapy. These regressions controlled for demographic and baseline clinical confounders.
Results: Data from 10,906 PAP users were included in the analysis (median age: 59 years, 44.8% female, median PAP usage during the first 7 days: 6.5 hrs/day). On average, 91% of users perceived an improvement in at least one of the eleven symptom measures, and 76% perceived an improvement in at least one of the four quality of life (QOL) measures. Users primarily reported perceived improvements in snoring (87%), fatigue (75%), energy level (72%), insomnia (68%), activity level (66%), clear-headedness (59%), and relationships (42%). While users reported perceived improvement in symptoms and QOL measures within the first 90 days, the odds of improvement increased progressively with extended therapy use for QOL measures, accidents, insomnia, moodiness, and snoring (12 (vs. 3) months, all p< 0.05). Differences in symptoms and QOL by age and gender were also observed (p< 0.05).
Conclusion: PAP therapy is associated with perceived improvements in QOL outcomes and symptoms, with significant improvements observed within 90 days. Continued PAP usage may further enhance outcomes through one year. Differences in perceived improvements by age and gender suggest an opportunity to better personalize messaging and strategies for PAP therapy initiation and long-term adherence.

LOOP GAIN PREDICTS RESIDUAL SLEEP APNEA EVENTS AMONG PEOPLE USING POSITIVE AIRWAY PRESSURE

Erin Eschbach[1], Clete Kushida[2], Yuksel Peker[3], Zhichao Xu[4], Annan Deng[1], Ali Azarbarzin[5], Andrew Wellman[5], Henry Yaggi[1], Scott Sands[5], Andrey Zinchuk[1]
[1] Yale University, [2] Stanford University School of Medicine, [3] Koc University, [4] MD Anderson Cancer Center, [5] Brigham and Women's Hospital and Harvard Medical School

Introduction: Residual sleep apnea occurs in ~20% of patients (defined by a residual apnea-hypopnea index, (rAHI) ≥10 events/hour) using positive airway pressure (PAP) therapy. High loop gain (LG) contributes to obstructive sleep apnea (OSA) by a waxing and waning neural input to the dilator muscles of the upper airway resulting in episodic airway obstruction. We hypothesized that high LG is associated with increased risk of high rAHI among people using PAP.
Methods: We analyzed data from two completed randomized controlled trials of PAP therapy (APPLES and RICCADSA). The APPLES study evaluated the effects of fixed PAP therapy on neurocognition in adults with OSA. The RICCADSA study assessed the effects of autotitrating PAP on cardiovascular outcomes in adults with coronary artery disease and OSA. Our primary outcome was rAHI ≥10 events/hour evaluated by polysomnography on PAP at 2 months (APPLES) or by PAP device downloads at 3 months (RICCADSA). We measured LG from baseline polysomnography using a validated method (Terrill et al., 2015). We performed logistic regression in the discovery sample (APPLES) and then the validation sample (RICCADSA) with LG as the exposure (highest vs. other quartiles). We then adjusted for baseline AHI, age, sex, body mass index (BMI), and pharyngeal collapsibility.
Results: Seventeen percent of the discovery (APPLES) sample (n=448) and 14% of the validation (RICCADSA) sample (n=185) exhibited rAHI ≥10 events/hour while on PAP. In unadjusted analysis, high LG was associated with an increased risk of ≥10 residual events/hour in both discovery and validation samples: odds ratio (OR) 3.1 [1.9, 5.2] and 3.2 [1.3, 7.4] respectively. This risk remained significantly increased after adjustment for baseline AHI, age, sex, BMI and pharyngeal collapsibility in APPLES (2.2 [1.2, 3.8]) and RICCADSA (3.5 [1.4, 8.7]). A sensitivity analysis that adjusted for central events at baseline did not meaningfully alter the results.
Conclusion: High LG on baseline polysomnogram is associated with an increased risk of residual sleep apnea while on PAP therapy (rAHI ≥ 10 events/hour). Identifying patients with this characteristic at start of PAP therapy may help select those who may benefit from adjunctive therapies (e.g., acetazolamide or oxygen) if residual sleep apnea occurs.

POTENTIAL IMPACT OF A RESPIRONICS CPAP SENSING ALGORITHM DEFECT ON ABANDONMENT OF CPAP THERAPY

Mariah Franclemont[1], Radhika Breaden[1], Robert Lowe[2]
[1] Pacific Sleep Program, [2] Oregon Health & Science University

Introduction: A defect exists in some Respironics AutoPAP, BIPAP and ASV machines, with detection of "vibratory snores" that are not occurring. Pressures increase, even without apneas or hypopneas. This sensing error can cause volatile pressures, with mask leaks, patient discomfort, and impaired sleep quality. Respironics acknowledges this defect but states that it does not harm patients. However, no data exist as to its actual frequency and impact. Given that up to half of patients abandon positive airway pressure therapy, we modeled the potential contribution of this defect to PAP abandonment.
Methods: Model inputs include the proportion of patients who abandoned PAP therapy and the proportion of abandonments related to the vibratory snore defect. We based the number of U.S. Respironics machines on the number in the 2021 recall, approximately 5,000,000. Some patients who abandon AutoPAP keep their machines while others lose them because insurance stops paying for them. We modeled that 30% of machines counted in the recall were not in use, in addition to machines taken away due to insurance. Because of uncertainties in the input values, sensitivity analyses were conducted.
Results: In our base case, we estimated that 40% of patients abandoned AutoPAP and that the defect may have contributed to 2% of abandonments. Under the most conservative scenario (20% abandonment, 0.5% of patients impacted by defect), 5,000 patients were affected. Under the worst-case scenario (50% abandonment, 5% of patients impacted by defect), the defect may have contributed to 175,000 patients abandoning AutoPAP.
Conclusion: This model has two limitations. First, precise input data are not available. We have addressed this with sensitivity analyses using a wide range of estimates. Second, data were insufficient to model time factors, such as machine aging and replacement, patients becoming less likely to abandon AutoPAP after sustained use and, perhaps, older machines becoming more likely to develop the defect. However, even the most conservative model suggests that this defect may cause many patients to give up on AutoPAP – highlighting the need for empirical research on the frequency of the defect and its association with abandoning therapy.

RECORDING DURATION OF HOME SLEEP TEST PREDICTS ADHERENCE TO CPAP THERAPY

Aygun Asgarli[1], Junjie Liu[1]
[1] University of Iowa

Introduction: Continuous positive airway pressure (CPAP) is the first-line therapy for obstructive sleep apnea (OSA), but CPAP adherence is challenging to many patients. As OSA is often diagnosed using self-directed home sleep test (HST), we hypothesized that the timings of HST recording can reflect the patient's behavioral patterns and predict CPAP adherence.
Methods: We retrospectively collected data from our sleep clinic, which was the sole provider of HST within an academic tertiary-care center. Each patient took one night of HST using commercial devices with printed and verbal instructions to start HST recording when they "are ready to go to sleep" and stop recording when they "wake up". Our clinic also instructed patients to start recording before 12 AM, and continue recording if they wake up during the night and plan to resume sleep. Among 712 patients who took HST within the last two years, were diagnosed with severe OSA and prescribed with CPAP, CPAP usage within one year after HST and other clinical data were available and studied for 360 patients.
Results: HST recording duration, start time and end time were 8.15 (7.27-8.78) hours [median (25-75 percentile)], 10:28 PM (9:39-11:18 PM) and 6:30 AM (5:52-7:17 AM), respectively. Longer HST recording duration was strongly correlated with both earlier start time (Spearman's correlation coefficient r = -0.48; P < 3E-22) and later end time (r = 0.38; P < 2E-13). The daily CPAP usage time averaged on days when it was used was 6.22 (4.72-7.43) hours. Higher CPAP usage time was significantly correlated with longer HST recording duration (r = 0.21; P < 5E-5), and correlated with earlier recording start time (r = -0.13; P = 0.016), but not correlated with the recording end time (r = 0.01; P = 0.9). Patient's age [52 (42-63) years], gender [58% male], body mass index [35.6 (31.0-42.4) kg/m2], apnea-hypopnea index [33.9 (24.9-52.4)] were all uncorrelated with either HSAT recording duration or CPAP usage time (P > 0.05).
Conclusion: HST recording duration and start time are readily available clinical data that can be harnessed to predict CPAP adherence at the time of OSA diagnosis, which may improve clinical outcomes.

EFFECTIVENESS OF INITIATING NASAL MASK COMPARED TO FACE MASK DURING A TITRATION STUDY

Seung Kim[1], Ravivarma Sagiraju[1], Eloy Espinoza[2], Parampreet Kaur[1], David Cohen[1], Matthew Zheng[3], Joseph Ramzy[1]
[1] St. Luke's University Health Network, [2] St Luke's University Healthcare Center, [3] St Luke's University Healthcare Network

Introduction: Continuous Positive Airway Pressure (CPAP) titration studies at our institution typically favor initiation of full-face mask during the study, which subsequently lead to full face mask usage at home. However, existing literature suggests that nasal interfaces are associated with greater CPAP compliance, lower required pressures, and improved sleep efficiency compared to full face interface. This review of institutional practice is to determine if initial mask interface choice during the titration study affects CPAP compliance.
Methods: A single center, retrospective review was conducted, assessing the Epworth Sleepiness Scale, mask type used, baseline apnea hypopnea index (AHI), sleep efficiency, total sleep time, nocturnal hypoxic burden, compliance, and rates of mask crossover among patients who underwent CPAP titration studies from December 2023 to March 2024. A comparative analysis was performed between CPAP studies initiated with nasal masks and those initiated with full face masks.
Results: Forty-nine CPAP studies (20 nasal mask and 29 full face mask) were included in the analysis. Twenty-nine patients

were male and median age was 60. Patients initiated with full-face masks had higher baseline AHI (19.55 +/-21.52 to 13.90 events/hour +/-22.04), slightly higher CPAP pressure (10cmH2O +/-2.855 to 9.5cmH2O +/-2.758), and greater compliance (83% +/-23.807 to 72% +/-34.819) compared those initiated with nasal interface. Mask crossover rates were high among those initiated with nasal masks compared to full face masks (33.3% compared to 6.25%, p-value= 0.08).
Conclusion: The findings suggest that patients with high AHI may be more likely to undergo titration studies with full face masks. Full face masks started during the titration study demonstrated better compliance and lower rates of mask crossover, potentially indicating greater comfort and contrasting with existing literature favoring nasal interfaces. The primary limitation of the study is its small sample size.

THE RELATIONSHIP OF THERAPEUTIC POSITIVE AIRWAY PRESSURE AND UPPER AIRWAY COLLAPSIBILITY

Julio Roque Buenrostro[1], Katie Holland[2], Thomas Chapman[1], Russell Whitehead[1], Yanyu Zhang[3], Babak Mokhlesi[4], Lindsay McCullough[5], Michael Hutz[2]

[1] Rush Medical College, [2] Department of Otolaryngology-Head and Neck Surgery, Rush University Medical Center, [3] Rush Informatics and Biostatistics Core, [4] Rush University Medical Center, [5] Division of Pulmonary, Critical Care, and Sleep Medicine, Rush University Medical Center

Introduction: Drug-Induced Sleep Endoscopy with Positive Airway Pressure (DISE-PAP) provides a quantitative evaluation of upper airway collapsibility, known as the pharyngeal opening pressure (PhOP). Limited research has examined the relationship between PhOP and required level of CPAP. This study aimed to investigate the relationship between required CPAP and PhOP.
Methods: This single-institution retrospective study evaluated patients who underwent DISE-PAP in the supine position from 2022-2024. Adults ≥18 years of age with OSA (AHI ≥ 5), >2 hours/day average PAP use, and well-controlled OSA on PAP (≥50% AHI reduction, residual AHI < 10) were included. Primary outcome was the relationship between median CPAP level (mCPAP), CPAP level at 95% of the time (t95CPAP) obtained from auto-PAP downloads, and PhOP. Secondary outcome sought to determine the relationship between mCPAP, t95CPAP, and PhOP with AHI and BMI. Data analysis included descriptive statistics and linear regression tests.
Results: 86 patients were included in the study (age 50.7±15.5, BMI 29.5±4.3, AHI 36±24, 69.7% male, 58.1% white, 10.5% Black, 19.7% Hispanic, 39.5% on oronasal mask). The mean PhOP was 7.1±3.0 cmH2O, mCPAP 8.6±2.5 cmH2O, and t95CPAP 10.4±2.7 cmH2O. There was a positive correlation between PhOP and mCPAP (R-square=0.063, p=0.01). PhOP was approximately 1.5 and 3.3cm H2O lower than mCPAP and t95CPAP, respectively. As mCPAP and t95CPAP increased by 1, PhOP increased by.308 and.305 cmH2O. BMI was positively correlated with mCPAP (R-square= 0.132, p=0.0006). PhOP and mCPAP were mildly correlated with AHI (R-square=0.0638, p=0.0247; R-square=0.178, p=0.0001). For each 10-point increase in AHI, there was a.33 and.44 increase in PhOP and mtCPAP.
Conclusion: This study found a positive correlation between mCPAP, t95CPAP and PhOP with PhOP approximately 1.5cm H2O lower than mCPAP and 3.3 cmH2O below t95CPAP. The discordance between PhOP and therapeutic CPAP measures could be due to a variety of reasons, i.e., inability to perform DISE during REM sleep or prescribed oronasal masks leading to higher pressure requirements compared to nasal mask during DISE-PAP. These findings build on our current understanding of upper airway collapsibility as measured during DISE-PAP. Future studies aim to improve patient selection and surgical outcomes in OSA.

IS BRAIN AGE MALLEABLE TO SLEEP APNEA THERAPY? AN EXPLORATORY POSITIVE AIRWAY PRESSURE TITRATION AND MACHINE LEARNING-BASED BRAIN AGE STUDY

Yoav Nygate[1], Tom Vanasse[1], Sam Rusk[1], Chris Fernandez[1], Nathaniel Watson[2]

[1] EnsoData Research, EnsoData, [2] University of Washington

Introduction: Machine learning (ML) techniques offer powerful tools for analyzing complex physiologic data. One such tool is the ML-based Brain Age Index (BAI) which quantifies the difference between a person's ML-determined brain age (BA) using EEG signals collected during sleep versus their chronological age (CA). Prior research has associated BAI with various disease states. However, the effects of therapeutic interventions on BAI have yet to be explored.
Methods: A deep neural network model was trained on a dataset of 54,000 polysomnography (PSG) studies to predict patients' BA. Additionally, a real-world dataset of 4,738 split-night PSG studies was collected, where patients underwent the first half of the study without positive airway pressure (PAP) therapy and transitioned to PAP therapy midway through the night. To evaluate the effect of PAP therapy on the BAI, ordinary least squares (OLS) regression was performed while controlling for sleep-related metrics, including the percentage of time spent in wake, N1, N2, N3, and REM.
Results: The OLS analysis found a significant association with a lower BAI after transitioning to PAP therapy (P-value = 0.001, OLS coefficient = -0.648). The mean BAI was -1.62 (-1.842, -1.398) and -1.584 (-1.806, -1.362) for the pre-PAP and PAP portions respectively. The dataset showed the following mean percentages of time spent in Wake, N1, N2, N3, and REM for the pre-PAP / PAP portions of the night: 38.1% (37.6%, 38.5%) / 25.7% (25.2%, 26.1%), 7.8% (7.6%, 8.1%) / 5.6% (5.5%, 5.8%), 73.2% (72.8%, 73.7%) / 60.7% (60.2%, 61.1%), 11.3% (10.9%, 11.6%) / 10.1% (9.9%, 10.4%), and 7.7% (7.4%, 7.9%) / 23.6% (23.2%, 24.0%).
Conclusion: The OLS analysis, controlling for sleep-related metrics, demonstrated improvements in BAI with initiation of PAP therapy. This suggests BAI is "malleable" and responsive to therapies that improve sleep and thus highlights its value as a potential biomarker of brain health. Overall, the study encourages further research into biomarkers for studying the neurocognitive benefits associated with Obstructive Sleep Apnea treatment.

Introduction: Women with sleep apnea report poorer sleep and have lower positive airway pressure (PAP) adherence rates than men. Within the Veterans Health Administration, there is a movement toward a Whole Health approach to care, shifting the focus from "what's the matter with the patient" to "what matters to the patient." We asked women veterans initiating sleep apnea treatment to describe their personal values and the impact of sleep apnea on these values.

Methods: Within a larger randomized controlled trial (NCT03377452), 44 women veterans (mean age = 53.7 years; 65.9% White, 34.1% married, 47.7% employed) diagnosed with sleep apnea were randomly assigned to a behavioral treatment for sleep apnea called "Acceptance and the Behavioral Changes to Treat Sleep Apnea" (ABC-SA; compared to an education control condition). In the first ABC-SA session, participants were asked to "list three of the things you most care about in your life" (i.e., values) and "the ways having sleep apnea impacts what you care about most" (i.e., impacts). Value and impact responses were coded into five categories with 100% agreement among three raters after independent coding and adjudication: work/education, relationships, personal care/health, leisure, and pets. Values were further coded into 14 subcategories based on the Valued Living Questionnaire.

Results: The frequencies of value and impact categories were: relationships (value n = 40; impact n = 25), personal care/health (value n = 39; impact n = 43), work/education (value n = 22; impact n = 11), leisure (value n = 13; impact n = 12), and pets (value n = 7; impact n = 2). The most frequently endorsed value subcategories were physical health (n = 32), family (other than marriage/parenting; n = 30), and friends/social life (n = 20).

Conclusion: Health and relationships are highly important to women veterans with sleep apnea. Research has focused on the health benefits of PAP, but fewer studies have explored interpersonal factors. The perceived impacts of PAP on relationships may serve as a barrier and/or motivator of PAP use.

RESPONSIVENESS OF AN INDIVIDUALIZED MEASURE OF QUALITY OF LIFE TREATMENT RESPONSE IN SLEEP APNEA

Allison Ikeda[1], Bryan Hannon[1], Edward Weaver[1]

[1] University of Washington

Introduction: Patients with obstructive sleep apnea (OSA) experience significant quality of life (QOL) burden. The Symptoms of Nocturnal Obstruction & Related Events (SNORE-25) is a 25-item validated, OSA-specific QOL instrument and offers an Importance Subscale, where patients select the five most bothersome items. Recognizing that burden changes with treatment, different item combinations for the Importance Subscale are possible at different times. To test responsiveness and compare during treatment, we hypothesized that changes in the Importance Subscale score would be greater when using the baseline combination, compared to using the baseline combination and the updated different combination at follow-up. We also hypothesized that the former change would correlate more strongly than the latter with a global QOL Change score.

Methods: This retrospective cohort from 2010-2020 included patients with OSA (apnea-hypopnea index (AHI)≥5) from a tertiary sleep surgery clinic, who underwent sleep surgery. The SNORE-25 instrument was completed prior to consultation (baseline) and first non-postoperative visit (follow-up) (range 0-5, higher worse, minimal clinically important difference 1.1). Changes in the Importance Subscale scores were calculated in two ways: 1) using the same combination of top five-items from baseline, and 2) using the combination of top five-items selected at each time point (baseline and follow-up), which could differ. Correlation analysis was performed between change in Importance Subscale scores and Global QOL Change score (range -7-+7).

Results: The cohort (N=269) was middle-age (mean+/-standard deviation 43+/-13 years) and majority male (71%) with severe OSA (AHI 35+/-32 events/hour). Mean baseline Importance Subscale score was 3.6+/-1.0 (moderate-severe burden). At follow-up (mean 94+/-71 days), the change in Importance Subscale score using the same baseline combination (-1.6+/-1.3) was greater than using the combination selected at each time point (-1.1+/-1.2) (difference 0.4+/-0.6, 95%CI -0.5-(-)0.3, $p < 0.001$). The correlations of change in Importance Subscale scores and Global QOL change were moderately positive, significant, and similar between Importance Subscale scores (Pearson r 0.52 vs 0.51 respectively, 95%CI 0.4-0.6, $p < 0.001$).

Conclusion: The SNORE-25 Importance Subscale is useful in measuring patient specific individualized QOL burden and improvement with treatment, and it is responsive to treatment, especially when using the same combination of importance items at baseline and follow-up.

IMPACTS OF HGNS ON HYPOXIC BURDEN

Chihun Han[1], Alex Rothstein[1], Ryan Soose[2], Patrick Strollo[3], Thomas Kaffenberger[1]

[1] UPMC, [2] University of Pittsburgh, [3] Department of Medicine, University of Pittsburgh Medical Center

Introduction: Hypoxic burden (HB) is a novel metric used to characterize the physiological impact of obstructive sleep apnea (OSA). Prior studies have shown HB to strongly correlate with cardiovascular (CV) risk. While the hypoglossal nerve stimulator (HGNS) has been shown to effectively reduce AHI, its impact on HB remains underexplored. This study examines the effect of HGNS on subjective and objective outcomes in OSA, including HB.
Methods: We conducted a retrospective review of 72 patients who underwent HGNS and completed home sleep apnea testing (HSAT) before and after surgery at our institution. Data collected included demographics, pre- and postoperative AHI, body mass index (BMI), oxygen desaturation index (ODI), and Epworth sleepiness score (ESS). HB was calculated using the SpO2 signal from sleep studies at baseline and post-optimization of HGNS therapy (The Siesta Group, Vienna Austria). Treatment success was evaluated using the Sher20 criteria, and the paired Wilcoxon test and Wilcoxon Rank Sum Test were used to assess outcomes.
Results: The mean age and BMI of the patients were 64.5 years and 28.7 kg/m², with 76.1% being male. The Sher20 success rate was 52.8%. Statistically significant reductions were seen in AHI (33.1 to 17.8, $p < 0.001$), ESS (11.4 to 7.7, $p < 0.001$), HB (102.5 to 62.9, $p < 0.001$), and ODI (29.5 to 14.8, $p < 0.001$) after HGNS. Significant differences were observed in ODI and HB changes between Sher20 responders and non-responders, while ESS changes were not significantly different.
Conclusion: HGNS resulted in significant improvements in both objective and subjective outcomes of OSA, including HB. These findings suggest that HGNS may be useful in alleviating physiological impacts associated with OSA.

POSITIVE CHANGES IN PATIENT REPORTED OUTCOMES IN MID-TERM AND LONG-TERM PATIENTS TREATED WITH HYPOGLOSSAL NERVE STIMULATION THERAPY

Justin Park[1], Jinu Johnson[1], Nicolas Thompson[2], Vaibhav Ramprasad[1], Vaishal Shah[1]

[1] Cleveland Clinic Foundation, [2] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH

Introduction: While hypoglossal nerve stimulation (HNS) is an effective therapeutic option for obstructive sleep apnea(OSA), improvement in mid-term and long-term patient reported outcomes (PROs) and influence of adherence remains understudied. We hypothesize that mid- and long-term PROs improve in dose dependent fashion with increased adherence, measured by validated questionnaires: Epworth Sleepiness Scale(ESS), Insomnia Severity Index (ISI), Patient Health Questionnaire-9(PHQ-9).
Methods: Consecutive HNS implanted patients (2015-2021) with available follow up data N=72 at Cleveland Clinic are included. Adherence was measured by weekly hours of usage at 3-months and 1 and 2 years. Paired t-tests evaluated PRO changes, and Spearman correlations assessed relationships between adherence and PRO changes. Mixed effects models examined the effect of adherence on PRO changes, adjusted for age, gender, and body mass index (BMI). Statistical significance was set at $p< 0.05$.
Results: Mean age 62.7±9.3 years, 32.4% female, 91.4% white. Usage averaged 42.0±15.0, 37.5±15.2, 33.8±15.1 hr/week at 3-months, 1 & 2 yrs respectively. Significant (all p-values < 0.05) improvements in scores were noted at each time points: ESS –3.4±4.4, -3.3±4.6, -2.3±3.9; ISI –4.8±6.2, -4.0±6.0, -4.3±7.5; PHQ-9 –3.3±4.4, -3.7±5.5, -3.6±5.4 respectively. At 1-yr higher weekly usage significantly correlated with reduction in ESS (Spearman's rho = -0.32, p = 0.031). In adjusted model, every 10 hours incremental weekly usage led to significant improvements in ESS [beta = -0.37 (-0.7, -0.03), p = 0.033] and ISI [beta = -1.00 (-1.58, -0.42), $p < 0.001$] but not PHQ-9 [beta = -0.32 (-0.69, 0.05, p=0.094]. Secondary analysis showed higher pre-implant ESS was associated with greater ISI [beta = -2.04 (-3.32, -0.76), $p < 0.001$] and PHQ-9 [beta = -1.22 (-2.16, -0.27), $p < 0.001$] improvements.
Conclusion: Self-reported PROs show mid- and long-term improvement in sleepiness, insomnia severity and depression scores post HNS treatment. Our findings suggest that with every 10 hours/week of usage, there is a dose dependent improvement in sleepiness (ESS) and insomnia (ISI), although increased adherence does not influence improvement in depression score. This improvement might be related to improvement in baseline sleepiness. Based on our findings we plan to conduct further research in a larger cohort to provide in-depth understanding of such correlations.

EFFICACY OF HYPOGLOSSAL NERVE STIMULATION IN POSITIONAL AND NON-POSITIONAL OBSTRUCTIVE SLEEP APNEA

Ravivarma Sagiraju[1], Joseph Ramzy[1], David Cohen[1], Parampreet Kaur[1], Seung Kim[1], Eloy Espinoza[2], Matthew Zheng[3]

[1] St. Luke's University Health Network, [2] St Luke's University Healthcare Center, [3] St Luke's University Healthcare Network

Introduction: Hypoglossal nerve stimulation (HGNS) is an emerging treatment for obstructive sleep apnea (OSA). This study evaluates the effectiveness of HGNS in positional and non-positional OSA patients by evaluating improvements in the Apnea-Hypopnea Index (AHI), Epworth Sleepiness Scale (ESS) scores, AHI reduction to mild OSA (AHI ≤ 15) and surgical success rate defined by Sher's criteria (≥ 50% reduction to AHI < 20).
Methods: This single-center retrospective study was conducted on 59 patients with moderate-to-severe OSA who underwent HGNS implantation between December 2021 and July 2024. Pre-implantation and best post-implantation AHI and ESS scores were analyzed utilizing in-lab and home sleep testing data. Patients were categorized into positional (supine AHI ≥ 50% reduction to ≤ 5 in non-supine) and non-positional OSA cohorts and outcomes were compared.

Results: The cohort had a median age of 66 years (range: 40–82), predominantly white (93.2%) and male (83.1%). The Wilcoxon signed-rank test showed significant reductions in AHI and ESS scores after HGNS in both positional and non-positional OSA patients. Overall, median AHI decreased from 27.4 to 6.8 ($p< 0.001$), and ESS improved from 7.0 to 4.0 ($p< 0.001$). In positional OSA, median AHI decreased from 21.5 to 6.15 ($p< 0.001$), and ESS improved from 7.5 to 4.5 ($p< 0.03$). In non-positional OSA, AHI decreased from 34.5 to 6.8 ($p< 0.001$), and ESS improved from 7 to 4 ($p< 0.03$). Surgical success (≥50% reduction, AHI < 20) was achieved in 81.25% of positional and 69.77% of non-positional patients; AHI < 15 was reached by 87.5% of positional and 65.12% of non-positional patients. The Fisher's Exact Test found no significant difference in surgical success ($p=0.51$) or AHI reduction to ≤15 ($p=0.11$) between groups.
Conclusion: HGNS significantly reduces AHI and improves ESS scores in both positional and non-positional OSA patients, with no statistically significant differences in success rates based on Sher's criteria and reduction of AHI ≤ 15. These results suggest that HGNS is effective regardless of OSA positional phenotype.

SLEEP AND BREATHING: POSITIVE AIRWAY PRESSURE AND HYPOGLOSSAL NERVE STIMULATION, A COMPARATIVE ANALYSIS

Ahmad Boota[1], Edwin Arroyo-Cid[1]
[1] Bon Secours Health System

Introduction: Obstructive sleep apnea (OSA) results in neurocognitive, behavioral, cardiovascular, and metabolic morbidities. Recently, hypoglossal nerve stimulation (HNS) emerged as second line therapy; subsequent to failed PAP use. A cohort comparative analysis for PAP and HNS remains to be seen. The following research suggests with consistent usage of HNS, physiological parameters and subjective benefit mirror PAP therapy and improve non-compliance.
Methods: The study group included 34 patients, under the care of Mercy Health Bon Secours St. Francis Sleep Center in Greenville, South Carolina. There were 20 males and 14 females. Average age of 63; median age of 66. Each patient was previously non-compliant with PAP therapy, as per insurance payor guidelines for implantation of HNS. Information were collected in reference to PAP and HNS compliance via respective cloud platforms. Epworth Sleepiness Score (ESS) questionnaires, blood pressure (BP), pulse rate were facilitated at each office visit and documented from nocturnal polysomnography (NPSG). NPSGs were recorded and scored using guidelines as described by the AASM scoring manual; with 4% oxygen desaturations for hypopneas. Apnea hypopnea index (AHI) was defined be the number of apneas and hypopneas per hour of total sleep time. AHI ≤ 5 is normal, AHI 5-15 is mild, AHI 15-30 is moderate, AHI > 30 is severe. ESS was used for subjective daytime sleepiness - which scores ≥ 10 are consistent with excessive daytime sleepiness. Compliance was defined as usage ≥ 4 hours per night for ≥ 70% of the nights. Pulse readings were acquired via peripheral oximetry during office visits and during NPSG. BP was acquired via sphygmomanometer during office visits.
Results: HNS revealed increased compliance versus PAP, decreased daytime sleepiness, reduced mean arterial pressure, and reduced pulse rate. In addition, median AHI reduction was 95%, while average reduction was 91%. AHI p-value was 2.62801E-13, ESS p-value was 1.04244E-05, MAP p-value was 0.06395, and pulse rate p-value was 0.2576.
Conclusion: The Subjective benefit, improvement in physiological markers, and increased compliance in this study cohort reveal that HNS is a viable option for treatment of OSA in PAP intolerant patients. This is comparable to results with consistent use of PAP therapy.

REAL WORLD (PILOT) HYPOGLOSSAL NERVE STIMULATOR EXPERIENCE IN A VETERAN POPULATION

Albert Vacheron[1], Zachary Sherman[1], Rabin Shrestha[1], Amado Freire[1], Carol Mattison[2]
[1] University of Tennessee Health Science Center, [2] Lt. Col. Luke Weathers, Jr. VA Medical Center

Introduction: The hypoglossal nerve stimulator (HNS) is an obstructive sleep apnea treatment for patients who have demonstrated difficulty adhering to CPAP therapy. In a cohort study, it has been shown to decrease apnea-hypopnea index (AHI) by 68%, improve quality of life, and decrease sleep time spent with the oxygen saturation less than 90%. Many decades of CPAP data have shown that non-adherence rates high, at an estimated 34%. Moderate to severe obstructive sleep apnea has been associated with increased cardiovascular morbidity and mortality. Home sleep apnea tests provide a convenient, cost-effective method to evaluate for real world treatment efficacy. This pilot study aims to examine the real-world effectiveness of the HNS to improve AHI in moderate-severe OSA in a veteran population.
Methods: Participants were selected from a database containing all of the patients who have received a HNS to date at the Lt. Col. Luke Weathers, Jr. VA Medical Center in Memphis, TN. Inclusion criteria were activation of the HNS 6 months prior and demonstrated current use of their device. Patients who agreed to enroll in the study were mailed a home sleep apnea test (HSAT) to use with their HNS turned on. A timeline consisting of device implantation, device activation, and HSAT completion was created. Measured outcomes included change in AHI and change in Epworth sleepiness scale score (ESS), pre and post HNS implantation and activation.
Results: This pilot study consisted of 8 patients who met the inclusion criteria and agreed to participate. There were 17 patients who received a HNS, but various factors including non-response, nonadherence, and non-use due to adverse events limited the size of this study. Mean AHI decreased from 39.2 events/hour to 18.8 events per hour and mean ESS scores decreased from 13.7 to 10.1 after HNS therapy.
Conclusion: The HNS is an effective therapy to decrease AHI in CPAP intolerant patients in a veteran population. However, some patients continue to struggle with adherence and this therapy does carry some risk for adverse events. Future plans for this study include exploring how to increase adherence for HNS therapy.

PREDICTIVE FACTORS FOR ONE-YEAR OUTCOMES OF HYPOGLOSSAL NERVE STIMULATION THERAPY IN OBSTRUCTIVE SLEEP APNEA PATIENTS

Hye-Jin Moon[1], Unjung Cho[2], Chang-Hoon Lee[3], Douglas Trask[4], KyoungBin Im[2]

[1] Soonchunhyang University, [2] UC Irvine, [3] Seoul National University Hospital, [4] University of California Irvine

Introduction: Hypoglossal nerve stimulation (HNS) therapy is an alternative treatment for patients with obstructive sleep apnea (OSA) who cannot tolerate continuous positive airway pressure (CPAP). Identifying predictive factors for long term therapy response is essential to optimize patient selection and outcomes.
Methods: A retrospective analysis was conducted on 65 OSA patients undergoing HNS therapy, categorized into responders (n=33) and non-responders (n=32) based on treatment outcomes at one year. Responders were defined as patients who achieved a post-treatment AHI reduction of at least 50% from baseline and a post-treatment AHI below 20. Baseline characteristics, underlying diseases, sleep parameters (PSG), drug-induced sleep endoscopy (DISE) findings, and subjective measures (Epworth Sleepiness Scale, Insomnia Severity Index) were compared. Regression analysis was performed to identify predictors of one-year response.
Results: There were no significant differences between responders and non-responders in age (p=0.237), sex (p=0.401), race (p=0.667), or BMI (p=0.132). Responders showed significantly shorter baseline sleep latency (13.3±13.6 vs. 37.0±34.7; p=0.023). During the titration study, responders exhibited significantly lower AHI values, including total AHI (10.4±9.6 vs. 25.9±18.8; p< 0.001), AHI during supine sleep (24.5±40.4 vs. 44.3±31.4; p=0.047), and AHI during REM sleep (13.8±16.1 vs. 24.6±19.5; p=0.023). Additionally, sum of DISE scores were predictive, with responders showing significantly lower scores (4.5±1.4 vs. 5.2±1.1; p=0.041). Stepwise regression analysis identified older age, lower baseline central AHI, and lower sum of DISE scores as significant predictors of response at one year.
Conclusion: Predictive factors for successful one-year outcomes of HNS therapy in OSA patients include older age, lower baseline central AHI, and favorable DISE findings. Lower AHI values observed during the titration study further distinguish responders, particularly in supine and REM sleep. These findings can guide pre-treatment assessments to identify optimal candidates for HNS therapy.

COMPARATIVE ANALYSIS OF PERIODIC LIMB MOVEMENTS OF SLEEP ON LONG-TERM ADHERENCE AND OUTCOMES OF HYPOGLOSSAL NERVE STIMULATION THERAPY

Hye-Jin Moon[1], Unjung Cho[2], Chang-Hoon Lee[3], KyoungBin Im[2]

[1] Soonchunhyang University, [2] UC Irvine, [3] Seoul National University Hospital

Introduction: Periodic limb movement of sleep (PLMS) has been suggested as a potential factor influencing adherence and therapeutic outcomes in sleep-disordered breathing treatments. This study evaluates the impact of PLMS on one-year adherence and home sleep test (HST) results among patients undergoing hypoglossal nerve stimulation (HNS) therapy.
Methods: A retrospective analysis was conducted on 123 OSA patients treated with HNS therapy at UC Irvine Sleep Disorders Center, divided into two groups based on titration study PLM index (PLMI): PLMI < 15 (n=59) and PLMI ≥15 (n=64). Baseline characteristics, adherence data, and one-year outcomes, including subjective measures (ESS, benefit) and HST results (AHI, ODI), were compared between groups. Adherence was assessed using the average usage time over the past three months and the number of usage days within the past three months. Statistical analyses were performed using R software.
Results: The prevalence of PLMS during the HNS titration study was high at 52% (64 out of total 123 subjects). Between PLMS and non-PLMS groups, no significant differences were observed in adherence metrics, including average usage time over the past three months (256.9±188.9 vs. 270.5±184.5 minutes; p=0.712) or number of usage days (50.1±37.9 vs. 51.7±38.4; p=0.828). One-year HST results, including total AHI (21.2±18.4 vs. 19.2±17.9; p=0.648), supine AHI (24.1±20.5 vs. 20.0±18.6; p=0.398), and ODI (19.6±17.2 vs. 17.7±16.7; p=0.654), were comparable. Baseline characteristics, such as age (64.0±9.6 vs. 68.6±8.4; p=0.005), showed significant differences, but these did not correlate with long-term outcomes.
Conclusion: While presence of PLMS during the titration study were not directly associated with significant differences in one-year outcomes of HNS therapy, patients with PLMS may have received additional treatment targeting limb movements, which could have influenced their outcomes. These findings highlight the need for further research to determine the impact of concurrent treatment strategies and clarify the role of PLMS in long-term therapy success.

EFFICACY OF DISE TITRATION STUDIES ON SUBJECTS WITH HYPOGLOSSAL NERVE STIMULATION

Fadi Rizk[1], Ryan Cobb[1], Karel Calero[2]

[1] University of South Florida, [2] University of South Florida Morsani College of Medicine

Introduction: Drug induced sleep endoscopy (DISE) titrations have been used as a tool to further assess different treatment options for subjects with OSA, and PAP intolerance. Suboptimal hypoglossal nerve stimulator (HNS) responders may be assessed with DISE to guide further treatment options.
Methods: We reviewed the last 7 DISE titration studies performed at a local VA hospital. We obtained baseline demographic characteristics, pre and post implantation sleep studies, and pre and post DISE data. The second data collected was performed following the intervention recommended. Inspire configuration and settings were adjusted during DISE to optimize treatment response and assess the need for further interventions.
Results: The average age of the 7 selected subjects was 65.5 years, their BMI was 31.2 and 6 of them were male and 1 female. They had an average baseline AHI of 59 and all but one subject had severe anteroposterior collapse at the velopharynx level. One subject was treated with Mandibular Advancement Device combined with Inspire and 2 were treated with ESP and Inspire. After initiation of therapy recommended by DISE titration,

AHI was reduced by 46% to 26 events/hour (p= 0.0021) in subjects expected to have improvement as predicted by DISE titration. One subject had concentric collapse at the velopharynx level and was placed on Inspire and PAP therapy combination while she would be working on weight loss with future planned reassessment of the airway.
Conclusion: DISE may be helpful to predict future response to therapeutic interventions in subjects with poor HNS response. It may also help select subjects who may not be expected to respond to therapy. Further data analysis of a larger cohort of subjects is needed.

LONG-TERM ADHERENCE OF HYPOGLOSSAL NERVE STIMULATION FOR OSA

Max Lundeen[1], Mark Aloia[2], Srihan Somepalli[3], Vikas Jain[3]
[1] Inspire Medical Systems, [2] National Jewish Health, [3] Dream Sleep Medicine

Introduction: Obstructive Sleep Apnea (OSA) is a serious medical condition that can lead to poor health outcomes. Treatment for OSA with positive airway pressure (PAP) is efficacious, but effectiveness is limited by poor treatment adherence. Long-term adherence studies suggest that treatment utilization decreases with time. Alternative treatments, like Hypoglossal Nerve Stimulation (HNS), are effective at treating OSA and have shown high adherence in several studies, but long-term use has yet to be reported. This observational study examined adherence to HNS over 1.5 years using objective data on utilization.
Methods: We examined treatment utilization data obtained from the manufacturer's patient management platform (SleepSync, Inspire). 4273 patients had at least 18 months of usage data with a Bluetooth remote controller (available since 2022). A subset of these patients also had demographic information. Usage was calculated as hours (mean±std) from first start button press to time of therapy off, subtracting any nighttime pauses, and normalized by nights of no use counted as zero hours of therapy. Tukey analysis was performed to compare means.
Results: Mean usage was significantly higher in the first year post-activation (6.1±1.7 hours) compared to the first half of the second year (5.7±2.0 hours) (95% CI=[0.4,0.5]). However, comparing mean usage 12-15 months post-activation (5.8±2.0 hours) to 15-18 months (5.7±2.1 hours) was not significantly different (95% CI=[-0.04,0.2]). There was no significant difference between patients with pre-implant AHI< 20 and >=20 over the year and a half (95% CI=[-0.2,0.1]). However, for post-activation AHI< 20 or >=20, usage was significantly lower in individuals with a higher residual AHI post-activation (95% CI=[-0.6,-0.1]).
Conclusion: These are the first reported observational, long-term adherence data for HNS. The data suggest a clear leveling off of adherence at about 12-15 months, suggesting a stable usage over longer periods. Average use was higher than is seen in PAP users despite the fact that patients who meet criteria for HNS are required to fail PAP therapy. Pre-treatment AHI did not affect usage, but treatment usage was lower for those with higher residual AHI after treatment.
Support (if any): Employees of Inspire Medical Systems contributed to the data analysis.

FREQUENCY OF STIMULATION PROGRAMMING SETTINGS UTILIZED IN PATIENTS WHO RECEIVED HYPOGLOSSAL NERVE STIMULATION FOR TREATMENT OF OBSTRUCTIVE SLEEP APNEA

Michael Coleman[1], Vikas Jain[2], Madeline Harvison[2], Max Lundene[1]
[1] Inspire Medical Systems, [2] Dream Sleep Medicine

Introduction: Hypoglossal Nerve Stimulation (HGNS) using an implantable cranial nerve XII neurostimulation system is a safe and effective therapy for CPAP-intolerant patients with obstructive sleep apnea (OSA). Data has been previously published about stability of amplitude (V) programming over time. There are alternative stimulation settings that can be programmed to impact efficacy and adherence. Very little published data exists about the percentage of patients who require alternative programming to optimize patient outcomes.
Methods: Patient programming data from SleepSync (a web-based platform that tracks adherence, settings, and patient outcomes) was analyzed to understand final programming settings. Stimulation settings (electrode, pulse width (PW) and rate) were analyzed to compare initial and final settings. The recommended programming settings are Electrode A, PW of 90 µS and rate of 33 Hz. A comparison was made between initial and final settings.
Results: 46,726 patients were analyzed. Results are reported as: setting (n#, %). Initial Electrode settings: A (45,306; 96.96%), B (647; 1.38%), C (450; 0.96%), D (222; 0.48%), and E (60; 0.13%). Final electrode settings: A (40,923; 85.64%), B (3,079; 6.44%), C (2076; 4.34%), D (819; 1.71%), and E (774; 1.62%). Initial PW settings: 90 µS (46, 117; 98.70%, 60 µS (408; 0.87%), 120 µS (161; 0.34%), 150 µS (30; 0.06%), 210 µS (6; 0.01%), and 180 µS (4; 0.01%). Final PW settings: 90 µS (38,820; 81.24%), 60 µS (6,453; 13.5%), 120 µS (2078; 4.35%), 150 µS (362; 0.76%), 180 µS (36; 0.08%), and 210 µS (35; 0.07%). Initial Rate settings: 33 Hz (46,280, 99.05%), 40 Hz (305, 0.65%), 30 Hz (124, 0.27%) and 25 Hz (12, 0.03%), and 20 Hz (5, 0.01%). Final Rate settings were: 33 Hz (41,508; 86.87%), 40 Hz (5,324; 11.14%), 30 Hz (707, 1.48%), 25 Hz (133, 0.28%), 20 Hz (112, 0.23%).
Conclusion: Default settings for Electrode, PW and rate were still utilized in greater than 80% of patients for final settings. This suggests most patients are still programmed to recommended settings. However, there are some patients who require alternative settings to ensure optimal outcomes. Providers should be aware of how these settings can affect patient outcomes.

PROMIS-GH SCALE IN OBSTRUCTIVE SLEEP APNEA PATIENTS TREATED WITH HYPOGLOSSAL NERVE STIMULATION

Vaishal Shah[1], Jinu Johnson[2], Justin Park[1], Vaibhav Ramprasad[1], Nicolas Thompson[3]
[1] Cleveland Clinic Foundation, [2] Cleveland Clinic, [3] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH

Introduction: Hypoglossal nerve stimulation (HNS) is a treatment for moderate-to-severe obstructive sleep apnea (OSA) in

patients who cannot tolerate positive airway pressure therapy. The Patient-Reported Outcomes Measurement Information System Global Health (PROMIS-GH) scale assesses physical, mental, and social health. Widely studied in neurological and sleep disorders, including OSA, it has not been examined in patients with HNS therapy. This study evaluated self-reported changes in PROMIS-GH following HNS therapy.

Methods: This retrospective study included patients who underwent HNS activation and follow-up at Cleveland Clinic (2015-2024). PROMIS-GH was assessed through its two components: global physical health (GPH) and global mental health (GMH). PROMIS-GH score changes were assessed pre-implantation and at 3-months, 1-year and 2-years post-activation. The association between PROMIS-GH score changes and therapy adherence, measured by average weekly hours and total hours of usage, was analyzed through multivariable mixed effects linear regression, adjusted for age, gender, BMI, and post-activation time points (3-months, 1-year, 2-years). The association between PROMIS-GH score changes and pre-implantation and Epworth Sleepiness Scale (ESS) score changes was examined using multivariable mixed effects linear regression.

Results: Out of N=65 patients, 67.7% were male with mean age 63.8±8.7 years and BMI 28.4±3.0 kg/m2. The GPH score significantly improved at 3-months post-activation (mean change 1.7±5.0, p=0.017), while the GMH score did not improve at any time point. When examining the impact of HNS adherence on changes in PROMIS-GH scale using total hours usage, longer total device use was associated with greater improvement in GMH (per 100-hour beta estimate=0.11, 95%CI=0.02-0.2, p=0.020) and GPH scores (per 100-hour beta estimate = 0.12, 95%CI=0.04-0.21, p=0.004). A higher pre-implantation ESS score was associated with more improvement in GPH score (per 5-point beta estimate=1.41, 95%CI=0.46-2.36, p=0.004), but improvement did not correlate with ESS changes.

Conclusion: HNS therapy led to improvement in perceived physical health short term, potentially influenced by the degree of baseline sleepiness experienced by patients. Greater device adherence was associated with better improvements in both physical and mental health. Mid-term and long-term improvements were not significant. Larger prospective studies are required to validate these findings.

A NOVEL APPROACH TO PREDICT ORAL APPLIANCE THERAPY RESPONSE FOR OBSTRUCTIVE SLEEP APNEA (OSA) USING COMBINATIONS OF OSA ENDOTYPES AND HYPOXIC BURDEN

Amal Osman[1], Barbara Toson[1], Benjamin Tong[2], Danny Eckert[1]

[1] Flinders University, [2] University of Sydney

Introduction: Obstructive sleep apnea (OSA) is caused by impaired pharyngeal anatomy and one or more non-anatomical contributors including low respiratory arousal threshold, high loop gain and/or ineffective pharyngeal dilator muscle activation. These endotypic traits can be estimated using polysomnography (PSG) and have the potential to help guide targeted treatment decisions. OSA is typically first-line treated with continuous positive airway pressure (CPAP) although it is often poorly tolerated. Alternate treatments such as oral appliance therapy (OAT) have variable and currently unpredictable efficacy. Here, we investigated a new approach using OSA endotypes and hypoxic burden to predict OAT outcomes.

Methods: People with OSA (apnea-hypopnea index (AHI): >10 events/h) were recruited (ACTRN12618001995268) and fitted with a novel oral appliance (O2Vent Optima™). Participants had a standard in-laboratory PSG to quantify baseline OSA severity prior to OAT. A detailed physiology PSG with a nasal mask and pneumotachograph to quantify OSA endotypes and hypoxic burden followed at least one week later. A treatment efficacy PSG was performed after approximately 4 weeks of OAT at optimal level of titration. Generalized Procrustes analysis was used to combine the results from principal component analyses applied to the multiple imputed data set. The resulting principal components scores were then used as regressors in a modified Poisson regression to model OSA resolution.

Results: Ninety-three participants (22 female, aged 55 [42, 65] years, AHI: 30 [17, 49] events/h, median [IQR]) completed baseline and treatment efficacy PSG visits. Responders to OAT (AHI < 10 events/h) had a less collapsible upper airway (Vpassive), better pharyngeal muscle compensation, lower loop gain and a lower arousal threshold at baseline versus non-responders (all p-value < 0.05). Principal component regression revealed the following combination of characteristics: a) high arousal threshold and low Vpassive, b) high loop gain and low Vpassive values and c) very high hypoxic burden reduces the probability of OSA resolution by 44% (p-value=0.002), 33% (p-value=0.005), and 57% (p-value=0.001) respectively.

Conclusion: These novel findings highlight the potential importance of different combinations of OSA endotypes and hypoxic burden to help predict OAT response.

QUANTITATIVE ANALYSIS OF HYPOGLOSSAL NERVE STIMULATOR SENSORY WAVEFORMS AND CLINICAL OUTCOMES

Abby Silbaugh[1], Nathan Nowalk[1], Alejandra Lastra[1], Phillip LoSavio[1]

[1] University of Chicago

Introduction: Hypoglossal nerve stimulation (HGNS) treats obstructive sleep apnea (OSA) by causing tongue protrusion during inhalation and preventing upper airway collapse. Synchronization of stimulus delivery with breathing relies on a sensory waveform collected by an electrode placed in the anterior chest wall. We hypothesize that morphological characteristics of sensory waveforms are predictive of therapy response and may ultimately impact clinical outcomes. We designed and implemented a waveform signal analysis tool to assess the association between waveform characteristics and response to HGNS therapy.

Methods: A retrospective cohort study was conducted on adults who underwent HGNS implant by two surgeons between August 2019 and August 2024. Demographics, sleep studies (diagnostic and postoperative), and drug-induced sleep endoscopy results (VOTE scores) were collected from the medical record. Response to HGNS therapy was defined by modified Sher criteria: > 50% reduction in apnea-hypopnea index (AHI) from baseline and post-treatment AHI ≤ 15 events/hour. Raw waveform data were recorded using a computer tablet (Inspire™ Programmer). Data

preprocessing, waveform signal analysis, and statistics were performed using custom MATLAB script (Natick, MA, USA).
Results: This study included 50 total patients with OSA (mean AHI = 42.0 ± 15.7 events/h); 22 responders and 28 non-responders. Age (mean = 64.0 years), sex (36.8% female), race (86% white), and VOTE scores were similar between groups. Body mass index (BMI) was lower for responders compared to non-responders (mean = 28.2 kg/m2 vs. 30.5 kg/m2; P < 0.05). Linear and logistic regression analyses, adjusted for BMI, revealed six waveform characteristics that individually predicted percent change in AHI (ΔAHI) (P < 0.05) or therapy response (P < 0.05). All characteristics were related to slope and/or morphology during the inhalation (stimulation) phase. Slope variance and maximum slope during inhalation predicted both ΔAHI (P < 0.05 and P < 0.05) and the voltage setting required to produce functional tongue protrusion (P < 0.01 and P < 0.05).
Conclusion: Quantifiable sensory waveform characteristics are independently associated with postoperative reduction in AHI. We determined that waveform characteristics related to slope and morphology during the inspiratory phase predict HGNS therapy response, suggesting these characteristics may be optimized to improve future clinical outcomes.

Introduction: Proximal hypoglossal nerve stimulation (pHGNS) has been shown in the THN3 randomized, controlled trial to produce durable three-year improvements in quality of life, oxygenation, and sleep-disordered breathing (Apnea-Hypopnea Index, AHI) in moderate to severe obstructive sleep apnea (OSA). Detailed AHI responses (apneas vs. hypopneas, supine vs. non-supine, REM vs. non-REM) have not previously been reported.
Methods: THN3 patients (no sleep endoscopy screening, AHI 20-65/hr, Body Mass Index ≤35 kg/m2) who completed 3 years annual follow up were studied (N=98), as prespecified by protocol. The non-parametric probability of superiority (A) with bootstrapped confidence intervals was used to compare median values and effect sizes at Follow-up to Baseline. Effect size was measured by A, the probability that a value in a sample (herein follow-up) was superior to a reference (herein at Baseline) with values bound by 0 and 1. A=1 would have indicated 100% likelihood of superiority while A=0.5 would have indicated equal likelihood (null result). Large effect sizes were characterized by A≥0.71 with a 95% confidence interval (95%CI) lower bound of >0.5.
Results: AHI fell from 36.2/hr at Baseline to 18.9/hr at 3 years [A=0.79 (95%CI:0.70-0.87)], due to reductions in apnea index from 8.3/hr to 2.4/hr [A=0.76 (95%CI:0.67-0.85)] and hypopnea index from 27.4/hr to 14.3/hr [A=0.76 (95%CI:0.68-0.85)]. Supine AHI decreased from 59.1/hr to 48.4/hr [A=0.71 (95%CI:0.62-0.81)], while Non-supine AHI improved from 26.0 /hr to 14.5/hr [A=0.71 (95%CI:0.63-0.81)]. Finally, REM AHI improved from 40.3/hr to 22.2/hr [A=0.77 (95%CI:0.68-0.85)] while non-REM AHI improved from 34.6/hr to 17.3/hr [A=0.77 (95%CI:0.68-0.85)]. These paired findings were comparable to unpaired responses for all outcomes from all available 3 year follow up data.
Conclusion: In moderate to severe OSA, pHGNS produces large, durable, clinically and statistically significant improvements in apneas, hypopneas and total AHI across all body positions and sleep stages. Sleep apnea severity was reduced in non-supine compared to supine sleep at Baseline and Follow up, suggesting that positional therapy can enhance pHGNS therapeutic responses, irrespective of sleep stage.

HYPOGLOSSAL NERVE STIMULATION AND ITS EFFECT ON N3 SLEEP

Jorge Sanchez[1], Mahesh Thakkar[1]
[1] University of Missouri

Introduction: Inspire™ is a novel therapy to treat moderate to severe obstructive sleep apnea. By electrically stimulating the hypoglossal nerve, the tongue is prevented from obstructing the upper airway during sleep. However, the effects of hypoglossal nerve stimulation on the amount of time spent in different stages of sleep, especially N3 sleep, is unknown. Thus, we asked: does hypoglossal nerve stimulation (HNS) affect the amount of time spent in N3 sleep?
Methods: We did a retrospective chart review. We sampled 15 patients who underwent a HNS in-lab titration study as well as a sample of 15 patients who underwent CPAP titration and compared the percentage of time spent in N3 sleep within each group. Descriptive data included mean average, variance, and standard deviation. Analytic evaluation involved a one-tail t-test (two independent samples) with a critical alpha 0.05.
Results: The average age for the HNS group and CPAP group was 71.5 vs 59, respectively (p=0.10). Baseline AHI between HNS group was 37.25 (+/-4.94 SEM) and for the CPAP group 38.71 (+/-6.36 SEM), which was not significantly different (p=0.44). While the CPAP group spent 15.29% ± 2.42% (Mean ± SEM) in N3 sleep, a significant reduction in the amount of time spent in N3 sleep was observed in the HNS group 6.08% ±1.88% (Mean

± SEM) (p=0.003). No statistical difference was noted on REM sleep (16.28% vs 18.63% p=0.26).
Conclusion: These results suggest that patients with OSA who underwent treatment with hypoglossal nerve stimulation during an in-lab titration study had significantly less N3 sleep compared to those utilizing continuous positive airway pressure (CPAP) therapy in an in-lab titration study. A notable strength of this study was the direct comparison between HNS versus CPAP. However, the small sample size of this investigation may be considered a limitation. Whether the suppression of N3 sleep is a long-term effect or merely a short-term observation is still undetermined. Continued research is ongoing to fully understand hypoglossal nerve stimulation in treating obstructive sleep apnea.

PREDICTORS OF DAYTIME NEUROMUSCULAR ELECTRICAL STIMULATION ADHERENCE AND INTENSITY AMONG US VETERANS WITH MILD OSA

Douglas Wallace[1], Alberto Ramos[1], Shirin Shafazand[1], Maria Lopez[2], Naresh Punjabi[1]
[1] University of Miami, [2] Miami VA Healthcare System, Miami, Florida

Introduction: Transoral neuromuscular electrical stimulation (NMES; eXciteOSA device) is approved for mild obstructive sleep apnea (OSA). Patients use low-frequency daytime stimulation to strengthen oral musculature. The factors influencing adherence to daytime NMES remain unclear. In this study, we aimed to examine predictors of eXciteOSA adherence and intensity in a cohort of US veterans.
Methods: A retrospective study of consecutive veterans prescribed eXciteOSA for mild OSA at the Miami VA over a 24-month period was performed. Patients were instructed to 1) complete daily 20 min sessions for the initial 42 days and 2) increase stimulation to a therapeutic intensity. Analysis inclusion criteria were completion of diagnostic polygraphy (PG), questionnaires (e.g., Epworth sleepiness scale [ESS], Insomnia Severity Index [ISI]), and using eXciteOSA at least one night. Adherence data (sessions completed, stimulation intensity) were obtained from the device manufacturer. Medications and comorbidities (i.e., post-traumatic stress disorder [PTSD], depression) were collected from medical record review. Logistic regression models were constructed predicting 1) use on at least 5 days per week and 2) reaching therapeutic stimulation levels. Independent covariates examined were sociodemographics (age, gender, race), sleep symptoms (ESS, ISI), mental health comorbidities, and the respiratory event index (REI).
Results: The study included 113 veterans (21% female, 32% Black, 43% PAP-intolerant) with a mean age of 47 ± 13 yrs and REI of 9 ± 3 events per hour. The mean baseline ESS was 12 ± 7 while the mean ISI was 18 ± 7. Over the study period, the mean adherence for sessions completed was 63 ± 25 % and 19 veterans (17%) discontinued therapy. More than half (52%) of the cohort completed 5 sessions weekly while only 14% completed at least 6 sessions weekly and 0% completed all 42 treatment sessions. In adjusted analyses, a diagnosis of PTSD was associated with lower odds of regular adherence (OR 0.38, 95% CI 0.17-0.87), while Black race was associated with lower odds of achieving therapeutic stimulation intensity (OR 0.39, 95% CI 0.16-0.97).
Conclusion: Black veterans and those with PTSD had lower odds of adhering to therapeutic NMES treatment parameters. These findings could inform personalized therapies for veterans with mild OSA.

STIMULATION ARTIFACT' ON CHIN EMG DURING IN-LAB TITRATION POLYSOMNOGRAPHY IN HYPOGLOSSAL NERVE STIMULATION FOR OSA

Amogh Nadkarni[1], Jennifer Liebenthal[1], Damien Stevens[1], Anne Bennett[2], Saurav Luthra[1]
[1] The University of Kansas Medical Center, [2] The University of Kansas Health System

Introduction: Hypoglossal nerve stimulation (HGNS), marketed as Inspire, is an established treatment for obstructive sleep apnea (OSA) in patients intolerant to continuous positive airway pressure (CPAP). While it has gained clinical acceptance since FDA approval in 2013, gaps remain in optimizing its functionality and titration. Polysomnographic recordings post-Inspire implantation often show "stimulation artifacts" on the chin electromyogram (EMG), reflecting hypoglossal nerve activation. However, these artifacts have not been systematically studied in relation to respiratory cycles or clinical outcomes.
Methods: This retrospective chart review included 40 adult patients (≥18 years) who underwent Inspire-HGNS titration at The University of Kansas Health System (October 2023–October 2024). Demographic data (age, sex, BMI, Epworth) and polysomnographic metrics (stimulation artifacts, synchronization frequency, apnea-hypopnea index, sleep stage, body position) were analyzed. AHI response was defined as ≥50% reduction and AHI < 15 events/hour. Synchronization frequency was the number of stimulation artifacts on chin EMG divided by the number of respiratory cycles, with qualitative ratings of synchronization as Good (>80%), Moderate (50–80%), or Poor (< 50%). Random epoch sampling was used to ensure unbiased data selection. Statistical analyses include t-tests, chi-square, and regression using Stata 17, with significance set at $p < 0.05$.
Results: Of 40 patients, 26 were responders, 11 non-responders, and 3 excluded due to absent REM sleep. Responders had higher sleep efficiency (70.9 vs 63.3), lower baseline AHI (33.3 vs 44.5), lower Epworth (8.5 vs 7.5) and higher percentage time spent in N2 (67.2 vs 56.8) and REM (17.9 vs 11.2) sleep. No statistically significant difference in synchronization frequency based on response or association with sleep stages. Higher synchronization frequencies noted with prone sleep. Responders had higher synchronization ratings ("Good" 80.8% vs. 19.2%, $p < 0.001$), and correlated positively with N3 or prone sleep.
Conclusion: This study demonstrated significant differences in synchronization ratings on titration between responders and non-responders, with better synchronization associated with greater AHI reduction. No association was noted with synchronization frequency, likely reflecting the confounding nature of apneic events which affecting this metric. Qualitative rating of synchronization could play an important role in predicting response to therapy and assessing clinical follow-up or treatment adjustment.

CHANGES IN SLEEP SURGERY TRENDS SINCE THE ADVENT OF HYPOGLOSSAL NERVE STIMULATION THERAPY

Medha Venigalla[1], Neil Kondamuri[2], Rachel Nordgren[2], Phillip LoSavio[3]

[1] The University of Chicago Pritzker School of Medicine, [2] The University of Chicago, [3] University of Chicago

Introduction: Hypoglossal nerve stimulation (HGNS) therapy has revolutionized the surgical management of obstructive sleep apnea (OSA). This study examines the impact of HGNS on surgical trends and disparities across demographic and socioeconomic groups.
Methods: A retrospective analysis of the National Inpatient Sample (2004–2021) and Nationwide Ambulatory Surgery Sample (2016–2021) was conducted. Trends were compared between pre-HGNS (2004–2013) and post-HGNS (2014–2021) for inpatient data, and between 2016–2018 and 2019–2021 for outpatient data. Multivariable logistic regression identified demographic, socioeconomic, and procedural factors associated with changes in care.
Results: Post-2014, inpatient OSA diagnoses rose by 3% ($p < 0.001$). Surgical patients were 1.74 times more likely to be age 65+ (95% CI 1.68–1.80), 1.31 times more likely to be obese (95% CI 1.28–1.33), and 1.40 times more likely to be White (95% CI 1.37–1.43). Traditional surgeries, such as septoplasty (OR 0.29, 95% CI 0.28–0.30) and palatal surgery (OR 0.37, 95% CI 0.36–0.39), declined, while lingual tonsillectomy (OR 2.64, 95% CI 2.38–2.94) and tracheostomy (OR 0.71, 95% CI 0.68–0.74) increased. Outpatient HGNS use rose from 2.5% (2016–2018) to 10% (2019–2021), with a 3.44-fold higher likelihood of receiving HGNS in 2019–2021 (95% CI 3.27–3.62). Overall, White patients received HGNS at higher rates than non-White patients (OR 2.30, 95% CI 1.98–2.68), whereas non-White patients more frequently received traditional surgeries and were more often low-income (OR 0.66, 95% CI 0.65–0.67).
Conclusion: The rise of HGNS has driven a shift in OSA surgeries, reducing traditional procedures and increasing rates of HGNS and tracheostomy (the latter possibly reflecting a growing burden of severe comorbidities in the OSA patient population). This signals a move toward targeted, less invasive therapies and reflects a growing preference among providers and patients for such therapies. However, persistent racial and socioeconomic disparities in HGNS use underscore the need for more equitable access to advanced therapies. Future research should focus on exploring barriers to HGNS access and evaluating its long-term outcomes to guide clinical practice.

SIGNIFICANT AND SUSTAINED IMPROVEMENTS IN SYMPTOMS OF NOCTURNAL OBSTRUCTION AND RELATED EVENTS (SNORE-25) INSTRUMENT SCORES AFTER SLEEP SURGERY

Bryan Hannon[1], Allison Ikeda[1], Edward Weaver[1]

[1] University of Washington

Introduction: The burdens of obstructive sleep apnea (OSA) and benefits of its treatment span an array of quality of life (QOL) domains. Validated instruments, such as the Symptoms of Nocturnal Obstruction and Related Events (SNORE-25) Instrument, attempt to capture the impacts broadly; however, this breadth can dilute the intense impacts of certain aspects. The SNORE-25 addresses this limitation by incorporating an Importance Subscale that patient select the five most important items. This provides an individualized score specific to patient's burden and quantifies the individualized impact of OSA and its treatment. This study tests the association between staged sleep surgery and change in SNORE-25 Total and Importance Subscale scores.
Methods: This retrospective cohort from 2010-2020 included patients with OSA (apnea-hypopnea index(AHI) ≥ 5) from a tertiary sleep surgery clinic, who underwent at least two sleep surgery procedures. The SNORE-25 instrument was completed prior to consultation (preoperative) and subsequent postoperative visits. Total and Importance Subscale scores range from 0-5 (higher is worse), and the minimal clinically importance difference of 0.5 (Total) and 1.1 (Importance Subscale) was used. A paired t-test analysis was performed.
Results: The cohort (N=64) of patients who completed at least two surgery stages and had complete data (out of 364) was middle-age (mean+/-standard deviation 41+/-13 years) and majority male (73%) with severe OSA (AHI 35+/-31 events/hour). Mean baseline SNORE-25 Total score was 1.9+/-1.0 (mild burden) and Importance Subscale score was 3.8+/-1.1 (severe burden). At first non-postoperative visit (77+/-60 days postoperative), the mean change in SNORE-25 Total score was -1.1+/-0.9 (95% confidence (CI) -1.3-(-)0.8, $p< 0.001$, clinically important) and Importance Subscale score was -2.0+/-1.5 (95%CI -2.4-(-)1.6, $p< 0.001$, clinically important). At long-term follow-up (n=17, 219+/-85 days postoperative), the mean change in SNORE-25 Total score was -0.9+/-0.9 (95%CI -1.5-(-)0.4, $p=0.002$) and Importance Subscale score was -1.9+/-1.1 (95%CI -2.5-(-)1.2, $p< 0.001$).
Conclusion: Patients with OSA who underwent staged sleep surgery were associated with significant improvements in SNORE-25 and, moreover, Importance Subscale scores. Additionally, these improvements were clinically meaningful and sustained in follow-up. This suggests that patients with OSA experience meaningful and sustained improvements in QOL after sleep surgery, and especially on burdens important to them.

A ROLE FOR DRUG-INDUCED SLEEP ENDOSCOPY (DISE) IN PREDICTING OUTCOMES OF UVULOPALATOPHARYNGOPLASTY (UPPP)

Rebecca Rosenzweig[1], Horacio Romero Castillo[1], Fred Lin[1]

[1] Icahn School of Medicine at Mount Sinai

Introduction: Drug-induced sleep endoscopy (DISE) is a dynamic tool used to evaluate airway collapse patterns in obstructive sleep apnea (OSA). When performed prior to uvulopalatopharyngoplasty (UPPP), DISE may guide surgical planning, but its role in predicting postoperative outcomes remains uncertain. Prior studies have found that DISE reveals significant outcomes in UPPP success in Chinese populations. This study assesses the ability of DISE to predict the effectiveness of UPPP and its potential to optimize surgical decision-making in an American population.
Methods: Patients with OSA undergoing UPPP were evaluated using DISE preoperatively to assess patterns of upper airway collapse. DISE findings were categorized by collapse site (e.g., velum, pharyngeal walls, tongue base, epiglottis).

Apnea-Hypopnea Index (AHI) and Epworth Sleepiness Scale (ESS) were recorded pre- and postoperatively. Surgery outcomes were evaluated at follow-up using polysomnography, with success defined as a postoperative AHI < 20 events/hour and >50% reduction in AHI. Pre- and postoperative AHI and ESS were compared, and correlations with DISE findings were analyzed.
Results: Among 24 patients evaluated, no significant differences in DISE parameters (e.g., velum, pharyngeal walls, tongue base, epiglottis) were observed between patients meeting Sher's criteria for surgical success and those who did not ($p > 0.05$ for all comparisons). In this cohort, complete circumferential collapse at the velum was observed with similar frequency between responders and non-responders, showing no significant correlation with surgical success ($p > 0.05$). Additionally, obstructions at the tongue base and epiglottis did not demonstrate a predictive relationship with outcomes, with partial or complete collapse at these sites occurring across both groups without significant differences ($p > 0.05$ for all comparisons). The primary predictors of successful UPPP outcomes were subjective sleepiness, as measured by preoperative ESS ($p = 0.008$).
Conclusion: The findings suggest that DISE lacks predictive value for determining surgical success in UPPP, with no significant correlation between DISE parameters and postoperative outcomes. Instead, subjective measures like preoperative ESS were stronger predictors of success. These results highlight the need for further research into optimizing DISE's utility, potentially by integrating it with other clinical and objective parameters to enhance surgical planning and improve patient outcomes.

USING AN INTELLIGENT ANTI-SNORING PILLOW FOR POSITIONAL THERAPY IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Wei-Chung Mao[1], Jui-Yao Sun[2], Ming-Chieh Tsai[1], Ching-Min Tseng[1], Sheng-Hua Su[1], Tung-Ping Su[1]
[1] Cheng Hsin General Hospital, [2] Taoyuan General Hospital, Ministry of Health and Welfare

Introduction: Obstructive sleep apnea (OSA), a prevalent and serious disorder, degrades sleep quality, memory, and performance, and heightens the risk of heart attacks, strokes, and hypertension. Continuous positive airway pressure (CPAP) therapy is effective but not always preferred by 30-80% of patients. Over half of Asian individuals with OSA exhibit Positional Obstructive Sleep Apnea (POSA), characterized by exacerbated airway obstruction in the supine position. Positional therapy can help by promoting side sleeping, reducing airway collapse, and improving oxygenation. Our study has two main objectives: developing an intelligent anti-snoring pillow for POSA patients and validating its effectiveness of reducing respiratory interruptions.
Methods: Outfitted with sensors, our intelligent anti-snoring pillow adjusts its side height upon detecting a supine position, promoting side sleeping and mitigating symptoms of sleep apnea. Participants eligible for positional therapy tested the pillow, including individuals with prior CPAP usage. Sleep quality and the severity of the apnea-hypopnea index (AHI) were evaluated under three conditions: before treatment, while using the pillow, and during CPAP use.
Results: The results showed that the pillow increased side sleeping by 2.73 times, reduced AHI by 57%, and decreased snoring by 31%. CPAP maintained its status as the benchmark treatment for improving AHI and oxygen saturation levels. Nevertheless, the pillow outperformed in terms of sleep efficiency and minimizing sleep disturbances.
Conclusion: The study indicates that the intelligent anti-snoring pillow may offer an effective alternative therapy for patients with mild to moderate OSA, effectively lowering the AHI and hypoxemia, and notably enhancing sleep quality.

THE IMPACT OF REM-EXACERBATED OBSTRUCTIVE SLEEP APNEA ON OUTCOMES IN HYPOGLOSSAL NERVE STIMULATION THERAPY

Marcin Marciniak[1], Julio Roque Buenrostro[2], Russell Whitehead[2], Sean Setzen[1], Ethan Ritz[3], Lindsay McCullough[4], Babak Mokhlesi[5], Michael Hutz[6]
[1] Department of Otorhinolaryngology-Head and Neck Surgery, Rush University Medical Center, [2] Rush Medical College, [3] Rush Bioinformatics and Biostatics Core, Rush University Medical Center, [4] Division of Pulmonary, Critical Care, and Sleep Medicine, Rush University Medical Center, [5] Rush University Medical Center, [6] Department of Otolaryngology-Head and Neck Surgery, Rush University Medical Center

Introduction: Hypoglossal nerve stimulation (HGNS) is an effective treatment for obstructive sleep apnea (OSA) in patients intolerant to continuous positive airway pressure (CPAP). Limited data exists on HGNS outcomes in patients with REM-exacerbated OSA (REM-OSA), defined by a REM-to-NREM apnea-hypopnea index (AHI) >2. This study investigates postoperative outcomes in patients with REM-OSA treated with HGNS.
Methods: This single-institution retrospective study evaluated patients who underwent HGNS placement from 2016-2023. Inclusion criteria were adults ≥18 years old, preoperative AHI ≥15, and ≥30 minutes of REM sleep on preoperative polysomnogram and full-night efficacy home sleep study with a WatchPAT device. The primary outcome compared response rates between REM-OSA and non-REM OSA (NREM-OSA), defined as a ≥50% reduction in AHI and post-implant AHI< 15. Secondary outcomes included post-operative changes in REM and NREM AHI and Epworth Sleepiness Scores (ESS). Data analysis included t-test and linear regression.
Results: Of 245 patients, 40 met inclusion criteria, with 5 classified as REM-OSA. Postoperative REM sleep data were unavailable for one patient. Among the remaining four, 2 (50.0%) responded to HGNS compared to 9 of 25 (36.0%) NREM-OSA patients ($p=0.62$). Mean REM/NREM AHI ratios were 1.30±1.02 in responders and 0.81±0.73 in non-responders ($p=0.15$). Median change in REM AHI was –13.80 [-25.6 to 7.8], and in NREM AHI was -17.3 [-29.2 to 2.8] (spearman correlation rho: 0.83, $p=0.052$). Mean pre-implant ESS was 9.10±4.93 in NREM-OSA and 8.40±5.03 in REM-OSA ($p=0.77$). Mean post-implant ESS was 6.08±4.17 in NREM-OSA and 6.50±3.87 in REM-OSA ($p=0.85$). Analyzing ESS relative to preoperative REM/NREM ratio as a continuous variable, the beta score was 0.63 (95% CI [–1.3, 2.6], $p=0.51$) for pre-implant ESS and 0.63 (95% CI [-1.2, 2.4], $p=0.48$) for post-implant ESS. In subgroup analysis, males showed greater NREM AHI reduction (-11.91±23.94) than REM AHI (-6.92±23.42), with a significant mean difference of -4.99±6.47 ($p=0.01$).

Conclusion: No significant difference in HGNS response rates was observed when analyzing REM/NREM AHI as a continuous variable, suggesting that REM-exacerbated OSA may not be of concern when evaluating patients for surgery. These findings provide insights into the effectiveness of HGNS, but interpretation is limited by small sample size and lack of post-operative full-night polysomnography.

EFFICACY OF SPLIT-NIGHT TITRATION STUDIES

Kaveer Greywal[1], Kimberly Hardin[1]
[1] University of California Davis

Introduction: Split-night polysomnography is valued for its ability to provide both diagnosis and therapy during the same study. However, in practice, it is often limited by a lack of time afforded to the titration component of the study. Data has shown that Auto-CPAP (continuous positive airway pressure) modalities can be as efficacious as full-night titration polysomnography in identifying optimal therapeutic pressures. In this paradigm, the utility of a resource-intensive split-night titration study is called into question.
Methods: We conducted a retrospective review of all individuals > 18 years of age with diagnosis of obstructive sleep apnea (OSA) who underwent split-night polysomnography at a tertiary sleep center over a 3-year period. Exclusion criteria included other types of sleep-disordered breathing and use of nocturnal supplemental oxygen. Individuals were evaluated to determine efficacy of split-night titration by two measures: Whether a titration pressure was reached yielding an apnea hypopnea index (AHI) < 5 and whether supine REM (rapid eye movement) was seen at such a pressure. Total titration time and time to optimal pressures (if found) were also noted.
Results: For the purpose of this abstract, we are presenting preliminary data on 2 outcomes in 25 patients. Demographic data showed 14 males and 11 females with mean age of 51. Eighteen patients achieved an optimal pressure with AHI < 5 events/hour with 61% of these (11) also demonstrating supine REM sleep at optimal pressure. When optimal pressure was achieved, mean titration time was only 2.4 hours. Of the 7 individuals who did not achieve an optimal pressure, 5 were males, a mean of 5.2 hours was spent in the titration phase, and supine REM was present in 6 studies.
Conclusion: While preliminary data from this study shows that split-night polysomnography can be reasonably successful in achieving therapeutic titration pressures, it remains unclear if this is a cost-effective approach. Further analysis is ongoing to characterize the individual phenotype that would best benefit from split-night polysomnography versus home sleep testing with empiric Auto-PAP as a first step in establishing ideal therapeutic pressures.

A BUCCAL MUCOSAL REFLECTANCE OXIMETER ACCURATELY MEASURES ARTERIAL OXYHEMOGLOBIN SATURATION AND PULSE RATE

John Remmers[1], Connor Snow[2], Matiram Pun[2], Shane Magnison-Benoit[2], Thomas Tripp[2], Aimee Clarke[2], Bradley Hansen[2], Leo Transfiguracion[3], Giovanni Di Simone[1], Ming-Lai Lai[1], Jean Rawling[2], Steven Roy[2], Saleema Adatia[4], Erin Mosca[1], Marc Poulin[2]
[1] ProSomnus Sleep Technologies, [2] University of Calgary, [3] Alberta Health Services, [4] Symmetry Dental

Introduction: Pulse oximeter (SpO2) devices suitable for multi-night monitoring of arterial oxyhemoglobin saturation (SaO2) are not readily available despite a need to monitor SaO2 decreases in patients with sleep apnea and pulmonary diseases during sleep. The objective of the current study was to assess the SpO2 and pulse rate accuracy of a buccal mucosal oximeter embedded into a custom-fitted overlay of the upper teeth by comparison to a gold standard (CO-oximeter SaO2 and ECG heart rate).
Methods: Accuracy of the buccal mucosal oximeter was assessed in healthy participants (n=12) under non-motion conditions. Participants were made progressively hypoxic by decreasing the fraction of inspired oxygen in a stepwise manner to achieve a range of SaO2 from approximately 97-70%. SpO2 and pulse rate values from the buccal mucosal oximeter were compared with CO-oximeter values of SaO2 and ECG heart rate, respectively.
Results: SaO2 values were evenly distributed over the range of 97-67%. Analysis of 325 CO-oximeter SaO2/buccal mucosal oximeter SpO2 data pairs yielded the following: r = 0.95; bias = 0.72; and accuracy root-mean-square (ARMS) = 2.94%. Analysis of 346 ECG heart rate/buccal mucosal oximeter pulse rate data pairs yielded the following: r = 0.99, bias = 0.30; and ARMS = 2.08%.
Conclusion: The results of the study indicate that the buccal mucosal oximeter accurately measures SpO2 and pulse rate, as shown by good agreement with a gold standard, over a wide range of arterial hypoxemia. Such clinically acceptable accuracy indicates that this novel reflectance oximeter may prove useful in management of patients with sleep-induced hypoxemia by providing multi-night monitoring of SaO2. Additionally, the intraoral placement of the oximeter may be particularly convenient due to its temperature regulation, protection from ambient light, and relative lack of mucosal melanin.

THE IMPACT OF GLP-1 AND GLP-1/GIP RECEPTOR AGONISTS ON HYPOGLOSSAL NERVE STIMULATOR TREATMENT IN SLEEP APNEA PATIENTS

Arman Saeedi[1], Valeria Munguia Jovel[2], Konstantinos Oikonomou[3], Aditya Kumar[3], Sarah Debs[1], Alyssa Calder[4], Maria Suurna[5], Ryan Nord[6]
[1] Virginia Commonwealth University, [2] University of Miami, Miller School of Medicine, [3] VCU School of Medicine, [4] Virginia Commonwealth University medical center, [5] University of Miami Miller School of Medicine, University of Miami Health System, [6] Virginia Commonwealth University Health System

Introduction: Obstructive sleep apnea (OSA), the most common sleep-related breathing disorder, has various treatment options. Recently, GLP-1 and GLP-1/GIP receptor agonists have been approved to treat obesity and found to successfully improve associated OSA. Our study aims to evaluate the impact of incretins on patients with OSA and whether these anti-obesity medications are effective as standalone treatments or require hypoglossal nerve stimulation (HNS) to optimize OSA management.
Methods: A comparative outcomes analysis was conducted using the TriNetX platform, which leverages electronic medical records from 104 healthcare organizations. Two adult (18–90 years old)

cohorts were defined for the January 1, 2022 to June 1, 2024 time period: Cohort 1 (n=194,583) included patients with an OSA diagnosis, BMI between 27–40 kg/m2, and no history of taking anti-obesity incretins (semaglutide, liraglutide, and tirzepatide), while Cohort 2 (n=17,674) had the above criteria and a history of incretins. Propensity-score matching was applied to balance the cohorts for demographic and clinical characteristics, resulting in matched groups of 17,674 patients each. Key outcomes assessed included new incidence of drug-induced sleep endoscopy (DISE, CPT 42975) and HNS (CPT 64582). Patients with prior instances of these outcomes were excluded from the analysis.
Results: After matching, cohorts 1 and 2 were comparable in age (mean age 58.9±12.2 and 58.8±12.1 years), gender distribution (49.5% vs. 49.5% female), type 2 diabetes mellitus prevalence (48.8% vs. 48.8%), and overweight and obesity diagnosis (44.8% vs. 48.8%), respectively. BMI was matched across three categories: 25–30, 30–35, and 35–40, with final standardized differences less than 0.1. Patients were followed for a mean duration of 480.9±313.8 days in cohort 1 and 436.1±244.2 days in cohort 2. Patients taking incretins underwent DISE significantly more (0.585%) than the control (0.425%; OR: 1.38, 95% CI: [1.02, 1.86], p=0.034). Implantation of HNS occurred at a similar rate in the incretin group (0.295%) as in the control cohort (0.255%; OR: 1.16, 95% CI: [0.776, 1.726], p=0.472).
Conclusion: The results suggest incretin medications may not be sufficient as a sole treatment for OSA. In this study, patients treated with incretins underwent further treatment with upper airway stimulation at rates similar to those not on incretins.

DOES GLUCAGON LIKE PEPTIDE-1 AGONIST, EXENDIN-4 AFFECT CONTROL OF BREATHING IN OBESITY HYPOVENTILATION

Melanie Alexis Ruiz[1], Noah Williams[1], Mateus Amorim[1], Vsevolod Polotsky[1]
[1] The George Washington University

Introduction: Obesity hypoventilation syndrome (OHS), the most severe form of sleep disordered breathing (SDB), affects over 6 million individuals in the US. OHS is manifested by daytime hypercapnia due to a defect in the hypercapnic ventilatory response (HCVR). Glucagon-like peptide receptor-1 (GLPR-1) agonists liraglutide and tirzepatide induce weight loss and treat SDB in obese patients, but it is unknown if their therapeutic effect on SDB is entirely due to weight loss or there is an independent effect on HCVR. This study investigates the GLP-1 agonist, exendin-4 (ex-4) augments the HCVR in C57BL/6J male mice with diet induced obesity (DIO).
Methods: C57BL6 male mice with DIO (n=8) were treated in an acute (1 day) and a chronic (1 week of treatment) crossover experimental protocols. First, they received a vehicle (saline) or a subcutaneous injection of exendin-4 (2.5 ug/kg) in the acute protocol. In the chronic protocol, mice received an intraperitoneal dose (10 ug/kg) of ex-4 or saline. Daily food intake and body weight was measured for 1 week. Mice were allowed a two-week washout period before the crossover experiments. Hypercapnic ventilatory experiments (HCVR) were performed after the acute and chronic doses.
Results: Our current results showcase that exendin-4 does not have any significant respiratory effects and did not increase the HCVR compared to mice receiving saline. Mice receiving ex-4 had a decrease in food intake and an initial loss of weight but regained it during the week. Mice treated with ex-4 had an average body weight of 47.15g ± 0.4 and with saline of 48.65g ±0.2. The weekly average food intake for ex-4 mice was 3g ± 0.4 and 3.6g ± 0.3 for the saline group.
Conclusion: Exendin-4 does not have an independent effect on baseline ventilation and HCVR in DIO mice. Other GLPR1 agonists, such as liraglutide and tirzepatide need to be tested.

GLUCAGON-LIKE PEPTIDE 1 RECEPTOR AGONISTS FOR OBSTRUCTIVE SLEEP APNEA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Stanley Wong[1], Nicholas Fabiano[2], Carl Zhou[2], Brandon Luu[1], Risa Shorr[2], Marco Solmi[2], Ishrat Husain[1], Michael Mak[3]
[1] University of Toronto, [2] University of Ottawa, [3] Centre for Addiction & Mental Health, Toronto, Ontario, Canada

Introduction: Glucagon-like peptide-1 (GLP-1) receptor agonists have gained recent popularity in its usage for weight loss in people with diabetes and obesity. There is also emerging evidence of its usage for treating obstructive sleep apnea (OSA) which can be caused by or worsened by obesity. However, there is limited synthesized evidence for the usage of GLP-a receptor agonists for people with OSA.
Methods: We performed a PRISMA compliant systematic review and meta-analysis of the effects of GLP-1 receptor agonists in people with OSA. MEDLINE, EMBASE, Cochrane Library, and PsycINFO were searched up to June 30th, 2024. Randomized controlled trials (RCT) investigating the usage of any GLP-1 receptor agonists in people with OSA that reported OSA symptom outcomes as measured by the apnea-hypopnea index (AHI) were included. Standardized mean difference (SMD) measured effect size. Q and I2 tests measured heterogeneity. Cochrane Risk of Bias Tool 2 assessed risk of bias.
Results: Six studies were included which consisted of 1023 participants with moderate to severe OSA. 516 participants received GLP-1 receptor agonist treatment for their OSA with 507 in the control group (receiving either placebo or continuous positive airway pressure (CPAP)). GLP-1 receptor agonist therapy for OSA when compared to placebo groups had an medium effect size of SMD = - 0.601 (95% CI: - 0.969 to - 0.233, p = 0.001). When compared to CPAP treatment, there was no significant difference in AHI differences post-treatment (p = 0.297).
Conclusion: This systematic review and meta-analysis synthesizes the current evidence which supports the potential usage of GLP-1 receptor agonists for the treatment of OSA. This pharmaceutical treatment option would increase the treatment options available for people with OSA. However, the literature is limited by the few RCTs available, small sample sizes, and lack of long-term follow-up data. Further studies are needed in this area.

OSA OUTCOMES IN PARTICIPANTS BY BASELINE BMI CLASSIFICATION FROM SURMOUNT-OSA TRIALS: A POST-HOC ANALYSIS

Ronald Grunstein[1], Cathy Xie[2], Julia P. Dunn[2], Josef Bednarik[2], Beverly Flacon[2]

[1] Woolcock Institute of Medical Research, Macquarie University CPC-RPAH Clinic, Royal Prince Alfred Hospital and University of Sydney, Sydney, Australia, [2] Eli Lilly and Company, Indianapolis, Indiana, USA

Introduction: In SURMOUNT-OSA, tirzepatide reduced apnoea-hypopnoea-index (AHI), sleep-apnea-specific-hypoxic-burden (SASHB), and body weight (BW). Here we evaluated weight-reduction (WR) and measures of OSA by baseline body mass index (BMI) category.
Methods: SURMOUNT-OSA (NCT05412004) evaluated tirzepatide-versus-placebo for 52 weeks in participants with moderate-to-severe obstructive sleep apnoea (OSA) with obesity. Study 1 (N=234) and 2 (N=233) included participants not using, or using positive-airway-pressure (PAP) therapy, respectively. These post-hoc analyses analyzed WR and measures of OSA by baseline BMI categories (< 35, ≥35 and < 40, and ≥40kg/m2) using on-treatment data. Mixed-model-repeated-measures were applied for continuous variables, and logistic regression for binary outcomes.
Results: Study 1 included 77, 74, and 83 participants; and Study 2 had 66, 88, and 79 participants in the baseline BMI categories < 35, ≥35 and < 40, and ≥40 kg/m2, respectively. Baseline demographics, AHI, and Epworth sleepiness scale (ESS) were generally similar across subgroups, with higher BMI categories tending to have more female participants, be slightly younger, and have higher AHI and ESS. In Study 1, at Week 52, the placebo-corrected decrease associated with tirzepatide across BMI categories was 19.0-26.4 events/hour or 46.7-54.4% for AHI, 53.5-67.5% for SASHB, and 16.0-17.8% for BW. The odds ratio for a ≥50% reduction in AHI associated with tirzepatide compared to placebo was 6.92-11.91; and it was 3.10-18.84 for AHI< 5, or AHI 5-14 with ESS≤10. In Study 2, at Week 52, the placebo-corrected decrease associated with tirzepatide across BMI categories was 21.8-27.8 events/hour or 47.1-62.4% for AHI, 58.4-73.4% for SASHB, and 17.3-18.6% for BW. The odds ratio for a ≥50% reduction in AHI associated with tirzepatide compared to placebo was 6.94-11.06; and it was 6.35-9.97 for AHI< 5, or AHI 5-14 with ESS≤10. All results were statistically significant versus placebo (p< 0.01), except for the odds ratio for AHI< 5, or AHI 5-14 with ESS≤10 in Study 1 with baseline BMI≥40 kg/m2 subgroup. There was no consistent trend in WR or OSA measures between baseline BMI categories across both studies.
Conclusion: These post-hoc analyses suggested that OSA measures associated with tirzepatide treatment were generally improved compared to placebo, regardless of baseline BMI.

PARTICIPANTS WITH IMPROVEMENT IN OSA SEVERITY FOLLOWING TREATMENT: A POST HOC ANALYSIS OF SURMOUNT-OSA STUDIES

Susan Redline[1], Cathy Xie[2], Beverly Flacon[2], Josef Bednarik[2], Sujatro Chakladar[3], Birong Liao[3]

[1] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [2] Eli Lilly and Company, Indianapolis, Indiana, USA, [3] Eli Lilly and Co.

Introduction: In the SURMOUNT-OSA studies, tirzepatide reduced apnea-hypopnea index [AHI] values in participants living with moderate-to-severe OSA and obesity. The proportion of participants with improved obstructive sleep apnea (OSA) severity after tirzepatide treatment in these studies was investigated.
Methods: SURMOUNT-OSA involved Study 1, (participants not using positive airway pressure (PAP)), and Study 2, (participants using PAP). The efficacy analysis set included all randomized participants who received ≥ 1 dose of study intervention, excluding data after treatment discontinuation. Participants were categorised at baseline and week 52 by OSA severity, using apnea-hypopnea index [AHI] level: severe (AHI ≥30); moderate (AHI ≥15 and < 30); mild (AHI ≥5 and < 15) and no OSA (AHI < 5). Categorical shifts in OSA severity from baseline to week 52 were evaluated and classified as improvement (a shift to an improved OSA severity category), worsening (a shift in the opposite direction), or no change (remaining in the same severity category).
Results: In Study 1, 22 participants (26.8%) in the placebo group improved their AHI category, 57 (69.5%) showed no change, and 3 (3.7%) worsened, compared to those treated with tirzepatide wherein 65 (67.7%; between treatment p <.001) improved, 30 (31.3%; p <.001) showed no change, and 1 (1.0%; p = 0.336) worsened. In Study 2, 21 participants (25.3%) in the placebo group improved, 53 (63.9%) showed no change, and 9 (10.8%) worsened, compared to those treated with tirzepatide wherein 83 (79.0%; p <.001) improved, 19 (18.0%, p <.001) showed no change, and 3 (2.9%, p = 0.035) worsened. In study 1 and 2, 20.2% and 31.9% of tirzepatide-treated participants, respectively, improved to the no OSA present category. Of those, a larger proportion of participants shifted from moderate to no OSA in study 1, while a larger proportion of participants went from severe to no OSA in study 2.
Conclusion: In these post hoc analyses, tirzepatide treatment was associated with significant improvements in the severity of OSA from baseline to week 52 compared to placebo in adults with moderate-to-severe OSA and obesity. The majority of tirzepatide-treated participants shifted to an improved OSA category with 20-32% achieving no OSA present.

MEASURES OF SLEEPINESS BASED ON BASELINE CHARACTERIZATION IN PARTICIPANTS: SURMOUNT-OSA POST-HOC ANALYSIS

Terri Weaver[1], Shraddha Shinde[2], Cathy Xie[3], Josef Bednarik[3], Beverly Flacon[3], Chisom Kanu[4]

[1] University of Illinois at Chicago, [2] Eli Lilly and Company, [3] Eli Lilly and Company, Indianapolis, Indiana, USA, [4] Lilly

Introduction: Daytime sleepiness, a common symptom of obstructive sleep apnea (OSA), can be measured via multiple patient-reported outcome questionnaires. It is hypothesized that tirzepatide may reduce daytime sleepiness, as it showed significant improvements in the apnea hypopnea index in the SURMOUNT-OSA trials.
Methods: Two phase 3 studies evaluated the efficacy of the maximum tolerated dose of tirzepatide (TZP, 10 or 15 mg) versus placebo in participants with moderate-to-severe OSA and obesity. Study 1 participants were not on positive airway pressure (PAP) therapy at baseline while Study 2 participants were on PAP therapy. Post-hoc analyses grouped participants based on

baseline PGIS Sleepiness responses: "not at all/slightly sleepy" (Non-sleepy) or "moderately/very sleepy" (Sleepy). Changes from baseline to Week 52 of sleep-related measures (Epworth Sleepiness Scale [ESS], PROMIS Short Form Sleep-related Impairment [PROMIS-SRI], Functional Outcomes of Sleep Questionnaire [FOSQ]) were compared between TZP and placebo by subgroups, based on mixed model repeated measure methods using on-treatment data. Lower ESS and PROMIS-SRI scores and higher FOSQ scores indicate improvement. Patient Global Impression of Change [PGIC] Sleepiness responses were also calculated. Significant P-values are reported using "*" to denote values < 0.05.

Results: In Study 1 (N=194), there were placebo-adjusted changes from baseline to Week 52 with TZP treatment on the ESS (Non-sleepy: -1.33, Sleepy: -2.18), PROMIS-SRI (Non-sleepy: -1.6, Sleepy: -7.1*), and FOSQ Vigilance domain (Non-sleepy: 0.09, Sleepy: 0.28). Over half of participants treated with TZP reported that they were less sleepy (Non-sleepy: 55.0%; Sleepy: 60.9%). Study 2 participants (N=193) experienced placebo-adjusted improvements from baseline to Week 52 on the ESS (Non-sleepy: -1.02, Sleepy: -0.57), PROMIS-SRI (Non-sleepy: -4.3*, Sleepy: -5.6*), and FOSQ Vigilance domain (Non-sleepy: 0.15, Sleepy: 0.03). On the PGIC Sleepiness item, 46.6% of Non-Sleepy participants and 62.5% of Sleepy participants reported that they were less sleepy at Week 52, in participants treated with TZP.

Conclusion: This post-hoc analysis found that TZP-treated participants who were "moderately/very sleepy" at baseline generally showed greater improvement on ESS, PROMIS-SRI, and FOSQ Vigilance domain than those "not at all/slightly sleepy", especially participants not on PAP therapy. Over half of all TZP-treated participants reported improvements in overall sleepiness, despite sleepiness at baseline.

ASSOCIATION BETWEEN TIRZEPATIDE AND SNORING BASED ON PARTICIPANTS' BASELINE CHARACTERIZATION FROM SURMOUNT-OSA

Chisom Kanu[1], Terri Weaver[2], Shraddha Shinde[3], Cathy Xie[4], Josef Bednarik[4], Beverly Flacon[4]

[1] Lilly, [2] University of Illinois at Chicago, [3] Eli Lilly and Company, [4] Eli Lilly and Company, Indianapolis, Indiana, USA

Introduction: Snoring is a common symptom of obstructive sleep apnea (OSA). Tirzepatide has previously shown improvements in the apnea hypoxia index, and it is hypothesized tirzepatide treatment may be associated with improvements in snoring in participants with obesity and moderate-to-severe OSA.

Methods: Two phase 3 studies enrolled adults with moderate-to-severe OSA and obesity to evaluate the efficacy of tirzepatide at the maximum tolerated dose (10 or 15 mg) versus placebo. Study 1 (N=194) included adults who were not on positive airway pressure (PAP) therapy, while Study 2 (N=193) enrolled adults on PAP therapy. Participants completed Patient Global Impression of Status (PGIS) and Change (PGIC) assessments at baseline and Week 52, which measured overall sleep changes, including snoring, since starting the study drug. Post-hoc analyses categorized participants into subgroups based on PGIS baseline assessment of their snoring. The Baseline Non-snoring group was "not at all/slightly affected" by snoring, while the Baseline Snoring group was "moderately/very affected" by snoring.

Results: In participants not on PAP therapy (N: Snoring=91; Non-Snoring=103), a total of 68% (N=34) of participants treated with TZP in the Baseline Non-snoring group rated their sleep as "a little less affected" or "much less affected" by snoring, compared to 26.4% (N=14) of participants receiving placebo. For participants in the Baseline Snoring group, 62.8% (N=27) of participants treated with TZP noted the same improvement, compared to 20.9% (N=10) for placebo. In participants on PAP therapy (N: Snoring=106; Non-Snoring=87), PGIC results were similar, with 51.1% (N=24) of Baseline Non-Snoring participants treated with TZP rating their sleep as "a little less affected" or "much less affected" by snoring compared to 25.0% (N=10) of participants receiving placebo. For those in the Baseline Snoring group, 60.7% (N=31) of participants treated with TZP and 23.6% (N=13) of participants receiving placebo rated their sleep as "a little less affected" or "much less affected" by snoring.

Conclusion: In these post hoc analyses, the majority of participants treated with TZP demonstrated improvements in snoring regardless of baseline severity or PAP treatment. Notably, over 60% of participants that reported being moderately or very affected by snoring at baseline showed improvements with TZP.

SLEEP QUALITY BASED ON BASELINE CHARACTERIZATION IN SURMOUNT-OSA: POST-HOC ANALYSES

Chisom Kanu[1], Terri Weaver[2], Shraddha Shinde[3], Cathy Xie[4], Josef Bednarik[4], Beverly Flacon[4]

[1] Lilly, [2] University of Illinois at Chicago, [3] Eli Lilly and Company, [4] Eli Lilly and Company, Indianapolis, Indiana, USA

Introduction: Obstructive sleep apnea (OSA) can impair sleep quality. Tirzepatide has shown improvements in the apnea hypoxia index and is hypothesized to improve sleep quality in participants with moderate-to-severe OSA and obesity.

Methods: Two phase 3 studies evaluated the maximum tolerated dose of tirzepatide (TZP, 10 or 15 mg) versus placebo in participants with moderate-to-severe OSA and obesity. Study 1 included participants not on positive airway pressure (PAP) therapy, while participants in Study 2 were on PAP therapy. Post-hoc analyses grouped participants based on baseline PGIS Sleep Quality responses: "very poor/poor" (Poor SQ, N=138) or "fair/good/very good" (Good SQ, N=263). Changes in PROMIS SD scores from baseline to Week 52 were compared between TZP and placebo by subgroups based on mixed model repeated measure methods using on-treatment data. Patient Global Impression of Change (PGIC) Sleep Quality responses were also compared. Significant P-values are reported using "*" to denote values < 0.05.

Results: In Study 1 (N=194), placebo-adjusted changes from baseline with TZP treatment on the PROMIS-SD were -5.8* (Poor SQ) and -1.2 (Good SQ). Of participants treated with TZP with Poor SQ, 60.0% (N=12) reported their sleep quality as "A little better" or "much better," compared to 20.0% (N=6) for those receiving placebo. For participants with Good SQ at baseline who were treated with TZP, 75.7% (N=56) reported improved sleep quality, compared to 29.8% (N=22) for those receiving placebo. In Study 2 (N=193), PROMIS-SD placebo-adjusted

changes from baseline with TZP treatment were -3.9 (Poor SQ) and -4.7* (Good SQ). Among participants with Poor SQ who were treated with TZP, 55.8% (N=24) reported improved sleep quality, compared to 20% (N=9) for those receiving placebo. Similarly, 56.4% (N=35) of participants with Good SQ at baseline treated with TZP reported better sleep quality, compared to 28.3% (N=15) for those receiving placebo.
Conclusion: Participants treated with TZP, not on PAP therapy, and with Poor SQ at baseline experienced greater improvements in PROMIS-SD compared to those with Good SQ. For those on PAP therapy, changes in PROMIS SD were similar across subgroups. Most participants reported improved sleep quality in both studies, regardless of baseline sleep quality.

ASSOCIATION BETWEEN TIRZEPATIDE AND FATIGUE AND FUNCTIONING BASED ON BASELINE CHARACTERIZATION: SURMOUNT-OSA TRIALS

Terri Weaver[1], Chisom Kanu[2], Shraddha Shinde[3], Cathy Xie[4], Beverly Flacon[4], Josef Bednarik[4]
[1] University of Illinois at Chicago, [2] Lilly, [3] Eli Lilly and Company, [4] Eli Lilly and Company, Indianapolis, Indiana, USA

Introduction: Fatigue, a symptom of obstructive sleep apnea (OSA), is measurable through patient-reported outcome questionnaires. Tirzepatide improved the apnea hypopnea index in SURMOUNT-OSA trials and is hypothesized to improve fatigue and functioning in individuals with moderate-to-severe OSA and obesity.
Methods: Two Phase 3 studies evaluated the maximum tolerated dose of tirzepatide (TZP, 10 or 15 mg) vs placebo in participants with obesity and moderate-to-severe OSA. Study 1 participants were not on PAP therapy, while Study 2 participants were on PAP therapy. Post-hoc analyses categorized participants based on baseline PGIS responses: "no/mild fatigue" (Non-Fatigued) or "moderate/severe fatigue" (Fatigued). Improvements in fatigue and/or functioning were assessed by PGIC Fatigue, FOSQ-10, FOSQ (Activity domain) and SF-36v2 (General Health and Vitality domains). Higher scores indicate improvement. Treatment associations were measured as the differences in change from baseline between TZP and placebo at Week 52, computed with mixed model repeated measure methods using on-treatment data. Significant P-values are reported using "*" to denote values < 0.05.
Results: In Study 1 (N=194), treatment associations at Week 52 were observed in FOSQ-10 (Non-Fatigued: 0.3, Fatigued: 0.9), FOSQ Activity (Non-Fatigued: 0.05, Fatigued: 0.33*), SF-36v2 General Health (Non-Fatigued: 1.4, Fatigued: 6.2*) and SF-36v2 Vitality (Non-Fatigued: 1.0, Fatigued: 8.5*). Of participants treated with TZP, 71.7% (N=43) Non-Fatigued and 69.7% (N=23) Fatigued participants rated their fatigue as "A little better" or "much better." Participants treated with placebo were less likely to report the same improvements (Non-Fatigued: 22.6%, N=12; Fatigued: 20.9%, N=10). In Study 2 (N=193), treatment associations were experienced on the FOSQ-10 (Non-Fatigued: 0.7, Fatigued: 0.3), FOSQ Activity (Non-Fatigued: 0.13, Fatigued: 0.15), SF-36v2 General Health (Non-Fatigued: 6.5*, Fatigued: 9.7*) and SF-36v2 Vitality (Non-Fatigued 5.7*, Fatigued: 6.0*). More participants treated with TZP reported improvements in fatigue (Non-Fatigued: 51.0%, N=26, Fatigued: 59.6%, N=28) compared to those receiving placebo (Non-Fatigued: 25.9%, N=14; Fatigued: 21.9%, N=9).
Conclusion: In this post hoc analysis, TZP-treated participants, not on PAP therapy, and with "moderate/severe" fatigue at baseline generally showed greater improvements in fatigue/functioning. Those on PAP therapy with "moderate/severe" fatigue at baseline improved only on the SF-36v2 General Health and FOSQ Activity domains. All participants treated with TZP improved compared to placebo.

IMPACT OF GLUCAGON- LIKE PEPTIDE- 1 ANALOGS ON THROMBOEMBOLIC OUTCOMES IN OBSTRUCTIVE SLEEP APNEA PATIENTS

Xin Ya See[1], Tsu Hsien Wang[2], Nutchapon Xanthavanij[3], Yu-Che Lee[4], Chun-Yu Peng[5], Yu-Cheng Chang[5], Omer Ahmed[1], Fahad Eid[1], Aaron Bliss[1], Adnan Al Najada[1], Ryan Witczak[6], Ko-Yun Chang[7], Cho-Han Chiang[3]
[1] Rochester Regional Health, [2] University at Buffalo-Catholic Health System, [3] Mount Auburn Hospital, [4] University at Buffalo, [5] Danbury Hospital, [6] Lake Erie College of Osteopathic Medicine, [7] National Jewish Health

Introduction: Obstructive sleep apnea (OSA) is associated with an elevated thromboembolic risk due to comorbidities, reduced mobility, chronic inflammation, and a hypercoagulable state. Glucagon-like peptide-1 (GLP-1) analogs, including glucagon-like peptide-1 receptor agonists (GLP-1 RAs) and glucose-dependent insulinotropic polypeptide (GIP)/GLP-1 co-agonists, have shown potential in reducing thrombotic effects. However, the impact of GLP-1 analogs on thromboembolic risk in OSA patients remains unclear.
Methods: We conducted a retrospective cohort study using the TriNetX Analytics Network international database. Adults (≥18 years) diagnosed with both OSA and type 2 diabetes mellitus (T2DM) between January 2018 and September 2023 were included. Patients prescribed GLP-1 analogs were compared with those receiving dipeptidyl peptidase-4 inhibitors (DPP-4i). The index date was set as the date of OSA diagnosis, with both groups initiating therapy within one year before this date. Primary outcomes included arterial thromboembolic events (ATE), specifically myocardial infarction (MI) and ischemic stroke, and venous thromboembolic events (VTE), specifically pulmonary embolism (PE) and deep vein thrombosis (DVT). Secondary outcomes comprised individual ATE and VTE components. Safety outcomes were defined as serious gastrointestinal adverse events, including gastroparesis, biliary disease, pancreatitis, and bowel obstruction. Propensity score matching (1:1) was performed to adjust for demographics, body mass index (BMI), hemoglobin A1c (HbA1c), comorbidities, use of positive pressure ventilation and related medication use. A standardized mean difference < 0.1 indicated balance between cohorts. Outcomes were assessed using a Cox proportional hazards model, with $p < 0.05$ considered statistically significant.
Results: The study included 82,035 OSA patients with T2DM. After matching, each group contained 24,505 patients with similar covariate distributions. The GLP-1 group demonstrated a reduced risk for ATE (Hazard Ratio [HR]: 0.88, 95% CI: 0.80-0.97; p=0.012), VTE (HR: 0.80, 95% CI: 0.67-0.94; p=0.009), MI (HR: 0.85, 95% CI: 0.74-0.98; p=0.024), DVT (HR: 0.73,

95% CI: 0.58-0.93; p=0.012), and PE (HR: 0.76, 95% CI: 0.61-0.95; p=0.017) compared to the DDP-4i group. No significant differences were observed in ischemic stroke or serious gastrointestinal adverse events.
Conclusion: GLP-1 analogs may offer thromboembolic protection in OSA patients with comorbid T2DM.

USE OF WAKE-PROMOTING AGENTS IN THE MANAGEMENT OF RESIDUAL HYPERSOMNOLENCE IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA (OSA) ON OPTIMAL CPAP THERAPY

Lakshmi Polisetty[1], Sarah Biron[1], Jyoti Lenka[2], Nidhi Jain[1], Adrian Salmon[1], Shane Sacco[1]
[1] University Of Connecticut, [2] VA Southern Nevada Healthcare System

Introduction: Excessive daytime sleepiness (EDS) can be a significant symptom of obstructive sleep apnea (OSA) that impacts quality of life and has morbidity and mortality implications. EDS is defined as unintentional sleepiness or an inability to stay awake during the day, leading to adverse effects on mood, cognition, and daily functioning. Continuous positive airway pressure (CPAP) therapy is standard of treatment for OSA; however, 9-22% of patients continue to experience residual excessive sleepiness (RES) despite adherence. This study evaluated OSA patients with hypersomnolence seen at the University of Connecticut Health Pulmonary/Sleep Medicine Clinic, focusing on the use of wake-promoting agents (WPA) and CNS stimulant medications in managing RES in eligible subset of patients after confirmed CPAP compliance and ruling out other coexisting sleep disorders.
Methods: This descriptive retrospective chart review included adult patients (≥18 years) seen at the Pulmonary/Sleep Medicine Clinic from January 2021 to July 2024. Patients diagnosed with OSA, treated with PAP therapy, and reporting hypersomnolence were examined. PAP therapy adherence was defined as "adherent" (≥70% of nights for >4 hours), "effective" (Apnea-Hypopnea Index [AHI] < 5), and "adequate" (both adherent and effective). Data were collected using EPIC SlicerDicer and analyzed with Microsoft Excel and SPSS. Fisher's exact tests explored differences between patients with and without hypersomnolence, adjusting for multiple comparisons with the Hommel method.
Results: Of 4247 OSA office visits over 3.5 years, 549 patients reported hypersomnolence. Patients with hypersomnolence were 1.6 times more likely to be 35-45 years old (p=0.002), 1.3 times more likely female (p=0.02), 1.4 times more likely divorced or separated (p=0.05), and 1.3-1.7 times more likely to lack insurance information (p< 0.04). These patients were 2.0 times more likely to be prescribed WPAs (p=0.03) but showed no difference in CNS stimulant use (p=0.65). Further analysis of Epworth Sleepiness Scale scores and CPAP adherence is ongoing.
Conclusion: Preliminary data analysis suggest patients with RES in OSA are more likely to be female, aged 35-45, divorced/separated, lack insurance information, and be prescribed WPAs. Ongoing analysis aims to clarify pharmacologic treatment effects and identify high-risk profiles to improve RES recognition and management in OSA patients, with results expected soon.

DEMOGRAPHIC AND BASELINE DISEASE CHARACTERISTICS OF SYNAIRGY: A PHASE 3 TRIAL OF AROXYBUTYNIN AND ATOMOXETINE (AD109) IN OBSTRUCTIVE SLEEP APNEA

Patrick Strollo[1], John Cronin[2], Huy Pho[2], Luigi Taranto-Montemurro[2], Ronald Farkas[2]
[1] Department of Medicine, University of Pittsburgh Medical Center, [2] Apnimed Inc.

Introduction: AD109 is a combination of a novel antimuscarinic, aroxybutynin (aroxy; R-enantiomer of oxybutynin), and the selective norepinephrine reuptake inhibitor atomoxetine (ato). We report the sample characteristics of the fully enrolled SynAIRgy trial, a Phase 3 study to examine the efficacy, safety, and tolerability of AD109 (aroxy 2.5mg/ato 75 mg) in OSA.
Methods: SynAIRgy (NCT05813275) is a randomized, double blind, placebo-controlled, 6-month parallel-arm clinical trial in adults with OSA who do not accept or adhere to positive airway pressure therapy. Participants were enrolled over the full range of OSA severity as measured by apnea-hypopnea index with 4% desaturation (AHI4) >5 with no upper limit. Participants must have had a Patient Reported Outcomes Measurement Information System (PROMIS) -Fatigue raw score ≥17, and a body mass index (BMI) between 18.5–40 kg/m2 for men, or 18.5–42 kg/m2 for women. The primary efficacy endpoint is the proportion of participants with ≥50% reduction in AHI4 at six months. Secondary efficacy endpoints include change from baseline in PROMIS-Fatigue, PROMIS-Sleep Impairment (a measure of functional impairment during daytime), and Epworth Sleepiness Scale (ESS).
Results: SynAIRgy enrolled 646 participants that were randomized to AD109 or placebo. At baseline, the mean (SD) age was 57.1 (11.0) years, and mean (SD) BMI was 32.3 (5.0) kg/m2 with a balanced proportion of female (n=317, 49.1%) and male (329, 50.9 %) participants. The study enrolled a population representative of the diverse demographic composition of the United States with 67.2% being White, 20.4% Black/African American, 7.4% Asian, 1.1% American Indian/Alaskan Native, and 0.6% Native Hawaiian/Other Pacific Islander. The mean (SD) AHI4 at baseline was 22 (11) with 34.4%, 42.4%, and 23.2% of participants having mild (AHI4 5–< 15) moderate (AHI4 15–< 30), or severe (AHI4 ≥30) OSA, respectively. Mean (SD) PROMIS-Fatigue T-score was 59.1 (7.0), mean (SD) PROMIS-Sleep Impairment T-score score was 58.5 (7.5), and mean (SD) ESS was 10.1 (4.7).
Conclusion: The baseline demographic characteristics of participants enrolled in SynAIRgy are representative of the general population of adults living with OSA, and the baseline AHI4 scores and symptom profiles reflect those of a typical sleep clinic referral OSA population.

EFFECTS OF SOLRIAMFETOL ON NEUROPSYCHOLOGICAL OUTCOMES IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA IN THE REAL-WORLD SURWEY STUDY

Yaroslav Winter[1], Graham M.L. Eglit[2], Samantha Floam[2], Ulf Kallweit[3]

[1] Mainz Comprehensive Epilepsy and Sleep Medicine Center, Department of Neurology, Johannes Gutenberg-University, Mainz, Germany, [2] Axsome Therapeutics, Inc, [3] Center for Biomedical Education and Research, University Witten/Herdecke, Witten, Germany

Introduction: Patients with excessive daytime sleepiness (EDS) associated with obstructive sleep apnea (OSA) show deficits in cognitive domains including alertness, attention, executive function and decision-making. Solriamfetol (Sunosi®) is a dopamine-norepinephrine reuptake inhibitor with agonistic properties at the trace amine-associated receptor 1 and serotonin 1A receptor approved for treatment of EDS associated with narcolepsy or OSA. Solriamfetol demonstrated improvements in cognitive performance in patients with EDS in OSA in a phase 4 randomized study. Here, we report a post-hoc analysis of neuropsychological outcomes in patients with EDS in OSA treated with solriamfetol in a real-world setting.
Methods: SURWEY was a retrospective, observational study using data from physicians who prescribed solriamfetol for EDS in OSA. Neuropsychological assessments were performed in a subgroup of patients prior to and 3 months after solriamfetol initiation. Tests included: Test of Attentional Performance (TAP) subtest alertness, the Regensburger Word Fluency Test, the Wechsler Memory Scale subtest visual reproduction, Wechsler Adult Intelligence Scale (WAIS-IV) subtest coding and British Columbia Cognitive Complaints Inventory (BC-CCI). Data were analyzed with repeated measures ANOVA. The relationship between changes in EDS and cognition were assessed via regression.
Results: Before solriamfetol initiation, participants (N=46) showed impaired alertness on the TAP (mean±SD 268.2±21.8 ms with warning signal, 270.2±21.9 ms without), impaired cognitive function on the BC-CCI (8.6±2.2), and reduced psychomotor and visual processing speed on the WAIS-IV coding subtest (7.1±1.5). After 3 months of treatment with solriamfetol, TAP scores improved by a mean of 11.4% (237.7±21.4 ms with warning signal; 239.5±21.3 ms without, $p< 0.01$ for both). BC-CCI scores improved by a mean of 40.8% (5.1±3.1, $p< 0.01$). WAIS-IV coding scores improved by 30.6% (9.3±1.8, $p< 0.01$). Word fluency and memory were not impaired at baseline, or after solriamfetol initiation. Epworth Sleepiness Scale scores improved with solriamfetol treatment by 4.7±2.7 ($p< 0.01$). There was no association between the improvements in cognitive function and change in EDS ($|r|=0.16$, $p=0.3$).
Conclusion: These real-world results show that solriamfetol not only reduces EDS in patients with OSA, but also has the potential to partially reduce OSA-associated cognitive impairment. This effect was not associated with changes in EDS.

REAL-WORLD EVALUATION OF AGENT LONGEVITY AND SATISFACTION IN THE TREATMENT OF RESIDUAL SLEEPINESS IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Jessica Roberts[1], Heather Seo[1], R. Auger[1], Timothy Morgenthaler[1]
[1] Mayo Clinic, Rochester, Minnesota

Introduction: Residual excessive daytime sleepiness (RES) despite effective positive airway pressure (PAP) therapy for obstructive sleep apnea (OSA) is a clinical problem impacting quality of life and daily function. Wake-promoting agents (WPAs) such as modafinil, armodafinil, and solriamfetol have demonstrated efficacy in reducing RES in randomized controlled trials (RCTs); however, their effectiveness in typical sleep clinic populations remains underexplored. This study aimed to evaluate the efficacy, safety, and tolerability of these WPAs in real-world clinical settings.
Methods: This retrospective study analyzed electronic health records of 69 randomly selected, consenting patients with OSA who are on PAP therapy and a WPA at Mayo Clinic from 9/19/2019 to 9/19/2024. Researchers reviewed charts for treatment indication, duration, adverse effects, and response (categorized as "complete," "partial," or "poor"). Therapy longevity was assessed using initiation, refill, and discontinuation data. Outcomes were analyzed with paired t-tests, chi-square tests, and regression models.
Results: Of 69 patients, 45 were excluded because: WPA use before observation period (24), off-label WPA use (13), WPA use before CPAP (3), or other (5). Off-label reasons included neurologic-condition-related fatigue (6), depression augmentation (5), and autoimmune-condition-related fatigue (2). 24 patients were on WPAs for RES with PAP-treated OSA, including 3 with mixed indications, and were included in analyses. The median age was 65 (IQR 11). BMI at OSA diagnosis was 33.6 (IQR 6.4). Most subjects were male (75%). Initial Epworth Sleepiness Scale scores (ESS) were 12.3±1.1. ESS at the first WPA prescription were 15.4±0.9 ($p=0.04$). Most patients (83.3%) started on modafinil. Of the 4 patients who started on armodafinil or solriamfetol, chart review showed a previous trial of modafinil without benefit. After optimizing the initial WPA dosage, ESS improved by 3.3±1.4 points ($p=0.04$) to 12.1 ±1.2. Side effects limited WPA use in 20.8% of patients. Median first WPA duration was 141 days (IQR 53-280) with no significant difference between these WPAs ($p=0.81$).
Conclusion: Although WPAs have narrowly defined approved indications, they are often prescribed off-label for comorbidities. Unlike straightforward use in RCTs, real-life use is more complicated. Patients prescribed WPAs for the targeted approved indication show statistically significant benefits, although adverse effects limited their use for some.

REAL-WORLD USE OF SOLRIAMFETOL FOR EXCESSIVE DAYTIME SLEEPINESS IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA IN THE US

Yang Zhao[1], Anh Thu Tran[2], Helen Varker[2], Samantha Floam[3]
[1] Axsome Therapeutics, [2] Merative, [3] Axsome Therapeutics, Inc

Introduction: Excessive daytime sleepiness (EDS) is a vital and often overlooked patient-centered outcome in obstructive sleep apnea (OSA) and is associated with worsened health and economic outcomes. Solriamfetol (Sunosi®), a wake-promoting agent (WPA) approved in the United States (US), is the first and only dopamine and norepinephrine reuptake inhibitor indicated for EDS in OSA. The purpose of this study was to examine real-world use of solriamfetol and related clinical outcomes

(before and after initiation), using claims data from a large US population.
Methods: Adult patients newly initiating solriamfetol in the MarketScan® Commercial and Medicare Databases (7/1/2019-9/30/2022) were identified (first solriamfetol claim = index). Inclusion criteria included 1) continuous enrollment for 6 months pre- and post- index, and 2) ≥1 OSA diagnosis and ≥1 claim for positive airway pressure therapy. Exclusion criteria included pre-index diagnoses for central sleep apnea, narcolepsy, substance use disorder, or pregnancy. OSA-related comorbidities and symptoms (identified via diagnoses) were evaluated before and after index. Adherence to solriamfetol was defined using the proportion of days covered (PDC) during the 6-month post-index period. Pre-post differences in 22 OSA-related comorbidities and 19 OSA-related symptoms were evaluated using McNemar's tests for categorical variables and paired t-tests for continuous variables.
Results: Among 665 patients initiating solriamfetol (mean age 50.7 years; 54.3% male), 74% exclusively used solriamfetol during the 6 months post-index while 54.9% had prior use of other WPAs or stimulants. Mean PDC for solriamfetol was 0.9, with 79.2% of patients achieving a PDC ≥0.8. A significant reduction from the pre- to post-index period was observed in many OSA-related symptoms including fatigue/tiredness (16.5% vs.11.6%), hypersomnia (57.3% vs. 48.3%), insomnia (18.8% vs. 15.8%), sleep disturbance (12.5% vs. 8.7%), and gastroesophageal reflux (17.7% vs. 14.0%) (all $p < 0.05$). Numerical decreases were found for several OSA-related comorbidities (i.e. asthma, cardiovascular disease, type 2 diabetes, hypercholesterolemia, hypertension, obesity, psychiatric conditions).
Conclusion: In this real-world analysis, solriamfetol adherence was high over the 6-month post-index period. Significant reductions in OSA-related symptoms were observed following initiation, suggesting that solriamfetol may improve clinical outcomes in the management of EDS in patients with OSA.

THE TREATMENT PREFERENCES FOR COMORBID OBESITY AND OBSTRUCTIVE SLEEP APNEA (PRO-CON OSA) SURVEY

Ahmed Khalaf[1], Athiwat Tripipitsiriwat[2], Christina Finch[3], Kathy Page[2], Lucas Donovan[4], Jeremy Orr[2], Robert Owens[2], Christopher Lindsell[5], Jennifer Martin[6], Atul Malhotra[2], Christopher Schmickl[2]

[1] UCSD, [2] University of California, San Diego, [3] University of California San Diego, [4] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, [5] Duke University, [6] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System

Introduction: About 10% of U.S. adults have comorbid obesity and obstructive sleep apnea (COBOSA). Traditionally, COBOSA has been managed with lifestyle changes (diet/exercise) and continuous positive airway pressure (CPAP). Recently, tirzepatide (a once-weekly injection) results in ~20% weight loss over one year and improves sleep apnea severity by ~55%. This is comparable to the effectiveness of CPAP in practice. To inform treatment choice, we assessed patient and provider attitudes towards the use of CPAP and tirzepatide for COBOSA.
Methods: An online survey was developed to assess acceptability of CPAP and tirzepatide for newly diagnosed COBOSA. The survey was pilot tested and refined based on cognitive interviews. In November 2024 the survey was distributed to 17 UCSD sleep medicine providers and all ~6,500 patients age 21+ seen at a UCSD sleep clinic in the preceding two years. Following a brief overview of COBOSA and treatments, providers answered questions from the perspective of writing prescriptions, while non-providers responded as potential users. Responses were anonymous and uncompensated. We compared responses using Fisher's exact test.
Results: Seventeen providers (100%) and 365 patients (~5.5%) responded; 42% were women, 29% non-white, and 9% Hispanic. Among patients, 53% had COBOSA, 73% reported ≥3 prior weight loss attempts, 23% current/past use of tirzepatide and/or semaglutide, and 78% current/past use of CPAP. Over 75% of patients and providers reported CPAP and tirzepatide somewhat/very acceptable. Patients reported similar acceptability for both therapies, whereas providers were more accepting of CPAP than patients (e.g., "very acceptable" 88% vs. 59%, P=0.04). Patients leaned toward tirzepatide should evidence demonstrate equal effectiveness (48% vs. 35%), while providers tended to favor CPAP (53% vs. 26%, P=0.16). Both groups supported combination therapy, though patients were less enthusiastic than providers (61% vs 88%, P=0.06).
Conclusion: While both CPAP and tirzepatide appear as acceptable COBOSA treatments, preferences diverge between patients and providers. Research to compare the relative effectiveness of CPAP and/or tirzepatide for COBOSA, and to better understand reasons underlying differential preferences is warranted.

IMPROVING OBSTRUCTIVE SLEEP APNEA MANAGEMENT: THE ROLE OF WEARABLE DEVICES AND HEALTH COACHING

Michelle Alencar[1], Rachel Sauls[1], Joshua Lennon[2], Ali Azarbarzin[3], John Cronin[4], Ketan Mehta[4], Kelly Johnson[5], Stephen Pittman[4], Mark Aloia[6]

[1] InHealth Medical Services Inc., [2] Neurology Clinic P.C., [3] Brigham and Women's Hospital and Harvard Medical School, [4] Apnimed Inc., [5] Coastal Carolina University, [6] National Jewish Hea lth

Introduction: Obstructive sleep apnea (OSA) is the most prominent sleep-related breathing disease. Although Positive Airway Pressure (PAP) is generally effective for treating OSA, limited usage remains problematic due to several factors (e.g., mask discomfort). Health and wellness coaching (HWC) has emerged as a novel intervention aimed at enhancing PAP usage and can be coupled with a Connected Wearable (CW) to objectively monitor sleep quality. This study aimed to assess the effect of HWC with a CW on PAP usage and oxygen saturation (OS) in participants with OSA.
Methods: This prospective 6-week clinical trial recruited newly diagnosed adults with mild-to-severe OSA. All participants were prescribed PAP and provided a CW device to monitor OS.

Participants conducted a week-long run-in period using the CW only then combined PAP + CW + HWC throughout a 6-week period. HWC was provided by a board-certified health coach at 1 session per week. OS parameters included evaluating time under 90% oxygen saturation (T90) and Oxygen Desaturation Index 4% (ODI4). PAP usage and OS parameter data were analyzed using a paired samples t-test comparing run-in baseline scores to those collected at 6 weeks of HWC. Data is represented as mean (standard deviation), and significance was set at $p < 0.05$.

Results: Thirty participants completed the study, with a mean age of 49.1±13 years, body mass index of 36.1±7.2 kg/m2, and the majority (n = 23, 76.7%) being female. From week 1, PAP use was significantly improved from an average of 5.1 (1.8) hours per night to, week 6, an average of 6 (1.6) hours per night ($p=0.017$) over each 7-day period ($p < 0.001$). Significant improvements were observed between baseline and after week 6 in T90% score (mean difference [MD]=- 4.5%, $p=0.013$) and ODI4 (MD=-6.2 desaturations/hour, $p=0.002$), and mean oxygen saturation (MD=0.6%, $p=0.02$).

Conclusion: The findings demonstrate improvements from baseline in PAP usage and OS post-HWC intervention. The results suggest that HWC and CW could improve PAP usage hours per night. Further research is required to evaluate long-term PAP usage and sleep behaviors following HWC, particularly with the inclusion of a control condition.

A NOVEL MODEL TO OPTIMALLY TARGET WEIGHT LOSS INTERVENTIONS TO TREAT OSA

Jack Manners[1], Ritaban Dutta[2], Craig Phillips[3], Julia Chapman[3], Elizabeth Machan[3], Danny Eckert[4]

[1] Adelaide Institute for Sleep Health, Flinders University, [2] CSIRO DATA61, [3] CIRUS, Centre for Sleep and Chronobiology, Woolcock Institute of Medical Research, Macquarie University, [4] Flinders University

Introduction: Obstructive sleep apnea (OSA) pathophysiology is heterogeneous. Current front-line treatments are often poorly tolerated or don't fully resolve the underlying repetitive upper airway collapse. As obesity is a major risk factor, weight loss strategies can be an effective alternative or adjunct therapy for OSA. However, the degree to which weight loss strategies reduce OSA severity varies markedly between individuals. Given that weight loss interventions can be burdensome, methods are needed to determine which patients are likely to respond versus those better suited to alternate OSA treatment.

Methods: 149 people with OSA (mean [SD] age, 49 [10] years) from five trials (one pharmacological, four non-pharmacological) were included in this study. Participants were included in the analysis if they had a BMI reduction of >5% at post-treatment follow-up. Model input variables included routine metrics from baseline in-laboratory polysomnography reports such as sleep efficiency, and age, BMI, breathing, and oxygen-saturation parameters. XGBoost and distributed neural network (DNN) models were used to predict whether individuals had a >50% reduction in AHI or a 'partial response' (a reduction in OSA category; < 5, < 15, < 30, 30+ events/h) at post-treatment follow-up. Models were trained on ~80% of the data and validated on the remaining 20%.

Results: Performance of the XGBoost and DNN classifier models in the validation subset had reasonable accuracy (69% and 66%, respectively). Models were accurate at predicting a partial resolution in OSA (83%), with particularly strong negative predictive power (92%, positive predictive value=76%).

Conclusion: Using only data from routine clinical sleep studies, the models developed in this study were able to effectively predict whether individuals with OSA who achieved some weight loss via weight loss interventions would have a corresponding change in OSA severity. Prediction was particularly robust at identifying those not likely to not respond favourably. While prospective validation is required, this novel approach has the potential to be a useful clinical decision support tool for targeted weight loss treatment for overweight and obese individuals with OSA.

POSITIONAL OBSTRUCTIVE SLEEP APNOEA: WHEN AND WHY THE NECK-BASED VIBROTACTILE DEVICE FAILS

Mauro Manconi[1], Alessia Riglietti[1], Manuela Del Forno[2]

[1] Neurocenter of Southern Switzerland, Regional Hospital of Lugano, [2] ASL[2] Abruzzo, Pulmonology Clinic, Italy

Introduction: The efficacy of positional therapy with a neck vibrotactile device for positional obstructive sleep apnoea (POSA) has been demonstrated, but its inefficacy in changing body position has not been equally explored. The primary aim of this study was to evaluate the failure rate of the neck vibrotactile positional therapy in POSA. Secondary aims were: to investigate the reliability of a single night sleep study for labelling a supine sleeper, any differences on supine time between the laboratory and the home environment, the impact of the device on snoring and the compliance.

Methods: A retrospective observational study reviewed patients with a diagnosis of POSA according to Cartwright and who had received monitoring and/or treatment with a Night ShiftTM (NS) Sleep Positioner neck device for 4 nights in Monitor or Therapy mode or both. The diagnosis of POSA was made on respiratory polygraphy or polysomnography and a minimum supine sleep time of 15% was required. A supine sleeper was defined if supine sleep time at home was > 5% at least in 2 nights of neck vibrotactile device in Monitor mode. Failure was defined as continuous vibration time 5 minutes and a supine time > 5% in at least 2 nights.

Results: Ninety two adult patients were enrolled. The failure rate, restricted to 74 patients who had received the neck vibrotactile device in Therapy mode for 2 nights, was 14.8%, with a compliance rate of 96%. Non-supine sleepers at home were 13/74 (17.5%). A significant reduction of supine sleep time at home was observed in comparison with the diagnostic sleep study (23.9% vs 51%, $p < 0.001$). Snoring rate was significantly reduced while using the vibrotactile device in Therapy mode versus Monitor mode.

Conclusion: Considering the failure rate of the device in changing body position, and the rate of patients that at home spontaneously do not sleep in supine position, around 32% of positional therapy prescribed might be inappropriate. An adequate trial with the neck vibrotactile device, in diagnostic and therapeutic modality, might disclose these cases. Main reasons for inefficacy are: sedatives, chronic sleep deprivation, motor limitations and cognitive impairment.

OXYGEN THERAPY FOR CHILDREN WITH OBSTRUCTIVE SLEEP APNEA

Adam Cieciuch[1], Laura Miller[2], Isaac Nakamura[1], Monir Hossain[1], Narong Simakajornboon[1]

[1] Cincinnati Children's Hospital Medical Center, [2] Cincinnati Children's Medical Center / University of Cincinnati School of Medicine

Introduction: Oxygen supplementation is effective treatment for obstructive sleep apnea (OSA) in adults and infants, but there is a paucity of data on its use in older children. The aim of this study is to evaluate the effectiveness of oxygen therapy in children >1 year old with OSA and factors that influence the response to oxygen.
Methods: We conducted a retrospective review of patients 1-20 years old with OSA who underwent diagnostic sleep study and oxygen titration study at CCHMC between January 1, 2005 and October 1, 2024. Patients were determined to be "responders" if they had a ≥ 50% reduction in obstructive apnea hypopnea index (oAHI) on oxygen supplementation. Patients with tracheostomy and/or ventilator dependence were excluded. Chi-squared test was used to compare categorical variables and Mann Whitney test was used to compare continuous variables.
Results: 143 patients (86 males, 57 females) met criteria for analysis; 104/143 (72.7%) were responders (R) and 39 (27.3%) were non-responders (NR). There was a non-statistically significant trend toward younger age in responders (3.85±4.5yo [R] vs. 4.56±5.5yo [NR]; P=0.16). Although more non-whites were non-responders (15 (14.4%) [R] vs. 15 (38.5%) [NR], P=.0046), it should be noted that 104/143 (79%) of the study population was white. Central apnea index (CAI) on diagnostic study was higher in responders than non-responders. (5.01±12.32 [R] vs. 1.86±3.35 [NR], P=0.001). There was no difference between responders and non-responders based on severity of initial oAHI (14.09±20.09 [R] vs. 16.40±19.72 [NR], P=0.361), BMI, presence of upper airway obstruction, prior upper airway surgery, pulmonary disease, neurological/neuromuscular disease, premature birth, Down Syndrome or other genetic disorders.
Conclusion: Most children and adolescents with OSA were oxygen responders. Interestingly, oxygen responders had higher CAI suggesting increasing frequency of central events may predict oxygen therapy response in patients with OSA. We speculate that high loop gain and ventilatory instability may underlie the mechanism by which higher central events are more likely to respond to oxygen therapy. Further trials are needed to investigate this relationship and to assess the long-term outcomes of oxygen therapy in the pediatric population.

RAPID DOSE TITRATION MODEL: REDUCING TREATMENT TIME IN ORAL APPLIANCE THERAPY FOR OSA

Charles Tozzer[1]

[1] sleep apnea centers of california

Introduction: Patient treatment times have successfully been reduced and clinical workflow improved by using telemedicine, pre-collected patient information, and online scheduling. AI design and robotic manufacturing have further streamlined oral appliance therapy treatments for obstructive sleep apnea. One remaining opportunity is finding the therapeutic dose of mandibular advancement in a timely fashion. This often takes 4-8 weeks which elongates the total treatment time. This protocol demonstrates how a rapid titration technique can establish the appropriate dose in just a few days and significantly reduce treatment time.
Methods: 20 consecutive patients (12 mild, 5 moderate, and 3 severe) with an average AHI of 13.75 were treated using the rapid titration protocol, with a novel HST ring and Precision Oral Appliance Therapy. Patients were first seen for intraoral records appointment. Digital scans of both arches, a maximum intercuspal position and a construction bite were taken and sent to the medical device manufacturer for device construction. Two weeks later, the patient was fitted with their appliance, and given post operative guidance, the ring, and explicit written instructions on advancing 1 mm each day for 5 days. They returned in one week with the ring for a physical data upload and determination of the appropriate dose/advancement and were referred back to their sleep MD for the follow up efficiency test.
Results: 90% were successfully treated to an AHI below 10 and 50% improvement. The average total treatment time was 27 days from the records appointment to a confirmed therapeutic dose position. No patients experienced any unusual temporomandibular joint discomfort, tooth pain, or other untoward side effects that would compromise this protocol from being implemented.
Conclusion: The combination of a rapid titration protocol using the Belun Tech HST ring and the ProSomnus EVO precision oral appliance provided a significant condensation of the time to treatment. It was well supported by the explicit instructions, device and test simplicity, and excellent patient communication.

A DIGITAL PROTOCOL TO IDENTIFY AND ELIMINATE CONSTRUCTION BITE ERRORS

Michael Murray[1]

[1] The Sleep Apnea Center of Connecticut

Introduction: The fabrication of a precision oral appliance to treat OSA requires accurately recording the prescribed starting mandibular advancement dose using a construction bite. A horizontal bite gauge is commonly used to measure and set the vertical and horizontal position of the lower jaw. Construction bite midline can be skewed to one side or the other due to provider error or inaccurate patient movement. This may result in unilateral joint or muscle pain. The purpose of this paper is to present a digital protocol to verify the midline position of the construction bite.
Methods: Upper and lower arch digital scans were taken on ten patients to create 3-D digital models of the arches. A 3mm bite fork and horizontal bite gauge was used to measure and set the construction bite position. Digital scans of the MIP and construction bite were taken. Using the multi-occlusion function in the scan software the provider can verify the midline in MIP. When switching between these two scan images the provider can visualize the movement of the lower jaw as well as visualize the midline position. If there is a midline shift the provider can correct and repeat the process to mitigate errors.
Results: Of the ten patients scanned, seven were found to have midline construction bite discrepancies. These discrepancies were

identified immediately using the protocol and the scan software. In all cases the provider was able to take a new construction bite. The scan image of this second bite was used to manufacture the medical device.
Conclusion: This proposed digital protocol resulted in an immediate view of the midline position, and lower jaw movement in the construction bite when compared to the MIP bite. This protocol will result in less errors when taking the construction bite. This allows a more precise fabrication of the oral appliance improving patient comfort and decreasing the TMD side effects from a midline discrepancy

A NEW METHOD FOR QUICKLY IDENTIFYING DENTAL SIDE EFFECTS IN USERS OF THE INTRAORAL MANDIBULAR ADVANCEMENT APPLIANCE USING AN INTRAORAL SCANNER

Rafael Balsalobre[1], Marco Machado[1], Maria Juliano[1], Gilmar Prado[1]
[1] UNIFESP

Introduction: Long-term use of mandibular advancement device (MAD) for treating obstructive sleep apnea syndrome (OSAS) can cause changes in dental occlusion. Traditional methods for monitoring these changes, such as intraoral photographs, plaster models, and radiographs, can be time-consuming, involve ionizing radiation, and lack sensitivity for detecting early tooth movement. Consequently, there is a need for more efficient and precise technologies to monitor dental occlusion.
Methods: We included 41 custom-made thermoformed titratable MAD users who had their dental arches scanned before treatment (T0) and after 6 to 12 months (T1). Digital files from T0 and T1 were superimposed to evaluate tooth movement with a precision of 0.007 mm. We analyzed six teeth from each arch, which included central incisors, canines, and first molars at three specific points along their long axis. For the incisors, these points were the incisal, middle, and cervical. For the canines and first molars, the points were incisal or occlusal, middle, and cervical. Comparisons were made for the upper arch, lower arch, and both arches occluded. This protocol allowed us to detect early positional changes in the teeth.
Results: The average mandibular advancement was 7 mm. Digital comparisons showed that tooth 16 was the only one without movement greater than 0.007 mm. Tooth 41 exhibited significant movement at all measured points ($p < 0.001$). Occlusion analysis revealed that teeth 13, 23, 31, 41, and 43 experienced significant movement across all marked points ($p < 0.001$). By the sixth month, over 50% of MAD users presented measurable occlusal changes. The use of digital intraoral scanners allowed the detection of movements smaller than a tenth of a millimeter, providing earlier and more precise identification of tooth positional changes compared to conventional methods.
Conclusion: Intraoral scanners proved to be an accurate and practical tool for detecting early dental occlusion changes in MAD users. Our methodology, capable of identifying movements as small as 0.007 mm, enables early intervention and enhances patient awareness regarding treatment progress. This approach offers a significant advantage over traditional monitoring methods in diagnosing and managing MAD-related occlusal side effects.

NOVEL ORAL APPLIANCE THERAPY WITH POSITIVE EXPIRATORY PRESSURE VALVE SUCCESSFULLY TREATED PATIENTS WITH SEVERE OBSTRUCTIVE SLEEP APNEA (OSA)

Sat Sharma[1], Hilary Reiter[1], Antonella Conflitti[1]
[1] Centre for Sleep and Chronobiology

Introduction: Oral Appliances (OA) are a primary therapy option for mild to moderate OSA patients and for severe OSA patients who are continuous positive airway pressure (CPAP) intolerant. However, there is a paucity of published data for efficacy of OA in severe OSA. A novel oral appliance, O2Vent Optima incorporates both the mandibular advancement and an air channel that allows airflow through the device to circumvent nasopharyngeal obstruction. The ExVent is an accessory to the mandibular advancement device and provides oral Expiratory Positive Airway Pressure (EPAP). Previous studies have established efficacy of the air channel and EPAP of the combination therapy in the treatment of mild to moderate OSA. The study purpose was to assess the efficacy of the EPAP enhanced novel OA in the treatment of severe OSA patients who were either CPAP intolerant or preferred other therapies.
Methods: A prospective, open-label study included 17 patients with severe OSA (AHI>30/hr.). Average age: 54.6±5.8 years; mean BMI: 32.6±4.3; 70% were men. Severe patients who were CPAP intolerant or preferred OA were approached for study participation and informed consented was obtained. The enrolled patients were evaluated, custom fitted with the EPAP enhanced novel OA and followed by the sleep dentists. Anterior adjustments of the of the OA was clinically guided and optimized, highest resistance EPAP valves (7 cmH2O) were utilized. T Primary Efficacy Measure: Change in AHI between baseline vs. EPAP enhanced OA. Secondary Efficacy Measures: Treatment success (percentage of patients with a ≥50% decrease in AHI from baseline); improvement in lowest oxygenation saturation (SpO2 nadir).
Results: Treatment with the EPAP enhanced OA reduced AHI from 41.4±11.23/hr. to 12.1±2.45/hr. ($p< 0.005$), average 71% reduction in AHI. The lowest oxygen saturation (SpO2 nadir) during sleep increased from 81.8±6.2% to 89.4±1.2% ($p< 0.005$). Treatment success rate was 86%.
Conclusion: Oral Appliance therapy offers an alternative treatment solution for patients with severe obstructive sleep apnea who are intolerant or refuse CPAP therapy; however, the data is limited. Our study demonstrated successful treatment of patients with severe obstructive sleep apnea with the novel EPAP enhanced Oral Appliance.

AIO BREATHE FOR OSA: MATCHING AIRFLOW TO OXYGEN DEMAND WITH CONNECTED-ARC-OF-MOTION, AI-PREDICTIVE ORAL DEVICE GEOMETRY AND ON-DEMAND-AIRFLOW DELIVERY

Raghavendra Ghuge[1], Advait Ghuge[2]

[1] Sleep Medicine Institute of TX, [2] AIOMEGA LLC

Introduction: AIOMEGA's FDA-cleared (K233754) AIO BREATHE™ is a unique Total Antero-Vertical Mandibular-Lingual Repositioning Device (TAVMLRD™) from patented inventions by the first author. Its flanges display unique geometry that result in CONNECTED-ARC-OF-MOTION™ that provides REVIVE ON-DEMAND-AIRFLOW™, a method of calibrating incremental reduction in airflow resistance by increasing the SMCA (Smallest Cross-sectional Area) of the collapsible part of the airway during sleep or wake.
Methods: Subjects with suspected OSA underwent pretreatment and post-treatment clinical examination with ESS, Ghuge Fatigue Scale. Pre-RX and post-RX Home Sleep Studies were performed. AI-Predictive device flange geometry specified production of AIO BREATHE for entire group and forecasted post-RX AHI/LSAT. Pre-AHI, Pre-LSAT, Post-AHI and Post-LSAT were tabulated, univariate and multi-variate regression analysis were performed.
Results: Goup included mild, moderate and severe OSA. N = 50. Mean pre-RX AHI was 20.07, AHI range was 9-38, 1 Std. dev was 11.01. Mean pre-LSAT was 84.60%, LSAT range was 78% - 91% with mean of 84.60%. Mean Post-RX AHI was 2.13, AHI range was 0 – 4.5 with 1 Std. Dev of 1.46. Mean Post RX-LSAT was 92.4%, LSAT range was 90% - 96%. Ability to predict Post-RX AHI with AI-driven algorithms was 98.5% with p-value of 0.065 and T-stat of 2.141. Lower 95th% -1.773 and upper 95th% 2.468. Ability to predict Post-RX LSAT with AI-driven Algorithms was 99% with p-value of 0.15, adjusted R square of 0.131. Lower 95th% -0.095 and upper 95th% 0.472.
Conclusion: AIO BREATHE effectively treated all severities of OSA (up to AHI 38 and LSAT 78%) in this group. All participants experienced improvement in clinical symptoms. HSAT proved effective therapy (AHI < 5, LSAT >90%) with AI-predictive modeling of AIO BREATHE geometry. Design geometry reduced therapeutic uncertainty, minimized side effects like TMJ or dental movement and built dentist/physician/patient trust. AIOMEGA's AI-predictive algorithms are device geometry-specific.

SEVERE OBSTRUCTIVE SLEEP APNEA TREATED WITH ORAL APPLIANCE THERAPY IN ELDERLY ADULTS: A COHORT STUDY

Tanzeel Awadalla[1], Jack Jagielski[1], Ellery Tripp[1], Kimberly Johnson[1], Mounika Vadiyala[1], Snigdha Karnakoti[1], Pedro Arias-Sanchez[2], Michelle Herberts[1], Eliza Thompson Westermeyer[1], Subha Giri[1], Patricio Escalante[1]
[1] Mayo Clinic, [2] SBH Health System

Introduction: Emerging evidence suggests that positive airway pressure (PAP) treatment for moderate-to-severe obstructive sleep apnea (OSA) in elderly patients does not improve daytime sleepiness, or quality of life outcomes, despite improving apnea-hypopnea index (AHI). While oral appliance therapy (OAT) is known to be an effective treatment for mild-to-moderate OSA, its efficacy in treatment of elderly patients with severe OSA is unknown.
Methods: Retrospective chart review of patients ≥ 65 years old with diagnosis of OSA, treated with OAT, who underwent subsequent follow-up sleep testing and clinical assessments, including Epworth Sleepiness Scale (ESS), a measure of daytime sleepiness.
Results: We studied 66 elderly patients with OSA (31 women, 35 men), including 58 with mild-to-moderate OSA (AHI < 30) and 8 with severe OSA (AHI ≥ 30) treated with OAT. At baseline, patients with mild-to-moderate OSA had a median AHI of 11.6 compared to 41.3 in patients with severe OSA ($p < 0.0001$). There was no difference in ESS score between patients with mild-to-moderate OSA (median ESS = 8; IQR = 4-12) and severe OSA (median ESS = 6; IQR = 3-9). Following their OSA diagnosis, OAT was offered due to PAP intolerance (n = 32), patient preference (n = 28), or as an alternative treatment option (n = 4). After initiation of OAT, 42 patients with mild-to-moderate and 7 with severe OSA underwent follow-up assessment with home sleep testing (n = 32), oximetry (n = 15), or polysomnography (n = 2). At follow-up assessment, ESS was decreased in patients with mild-to-moderate OSA (median ESS = 5; IQR = 3-8) and severe OSA (median ESS = 5; IQR = 3-7), indicating reduction in daytime sleepiness in response to OAT in both groups. Moreover, 50% of patients with mild-to-moderate OSA and 50% of severe OSA patients saw ≥ 50% reduction in AHI.
Conclusion: Our study findings suggest that treatment with OAT in mild-to-moderate and severe OSA is tolerable and effective in elderly patients who do not have contraindication for this treatment. OAT should be considered as an alternative treatment specifically for elderly adults with severe OSA not tolerating or improving with PAP therapy.

ASSESSMENT OF ORAL APPLIANCE THERAPY EFFICACY IN STROKE PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Tyler Herzog[1], Subha Giri[2], Daniel Herold[2], Melissa Lipford[1]
[1] Center for Sleep Medicine, Mayo Clinic, [2] Mayo Clinic

Introduction: Sleep apnea impacts 50-70% of patients following stroke. Treatment of obstructive sleep apnea (OSA) in patients with stroke using continuous positive airway pressure (CPAP) has been recommended in recent American Heart Association/American Stroke Association guidelines. However, stroke patients poorly tolerate CPAP and often remain untreated. There is a paucity of data regarding alternative treatments such as oral appliance therapy (OAT) in stroke patients. We hypothesized that oral appliance therapy would be an efficacious option in the treatment of OSA in stroke patients, defined as a ≥50% reduction in apnea-hypopnea index (AHI) or oxygen desaturation index (ODI) or reduction in total AHI or ODI to < 10/h.
Methods: We performed a retrospective review of patients with OSA treated with OAT at our institution and had a history of stroke prior to receiving the oral appliance. Chart abstraction included demographic data, stroke type, sleep apnea diagnostic data, and efficacy data. Efficacy data included repeat sleep studies, overnight oximetry, patient reported outcomes, and subjective benefit, as available.
Results: 23 patients (52% female, mean age 63) were identified with a history of stroke prior to use of OAT for OSA. Baseline parameters (mean, SD) included BMI (30.8, 4.2), AHI (15.0, 10.6), and Epworth Sleepiness Scale (ESS) (9.3, 5.4). Post-treatment parameters included (mean, SD) BMI (30.1, 4.2), AHI

(12.4, 12.0), and ESS (6.5, 4.0). 12 patients had both baseline and follow-up sleep studies performed which met criteria for AHI efficacy of OAT in 7 of 12 (58%). Wilcoxon signed rank exact test demonstrated improvement in median AHI of 9.3 (0.40-17.6, p< 0.05) among these 12 patients. 2 of 3 (67%) patients with overnight oximetry follow-up met criteria for ODI efficacy of OAT. Of 8 patients with only subjective follow-up, 6 (75%) reported subjective improvement and 2 (25%) did not tolerate the device.

Conclusion: This study demonstrated that oral appliance therapy is efficacious in reducing the AHI by at least 50% or to a value below 10 in a majority of patients. Oral appliance therapy may be a viable alternative to CPAP in selected OSA patients with a history of stroke.

THE EFFICACY OF ORAL APPLIANCE THERAPY IN MANAGING POSITIONAL OBSTRUCTIVE SLEEP APNEA

Priyanka Chilukuri[1], Aryan Eksambe[2], Imran Patel[3], Stuart Quan[4], Janet Rothers[5], Maria Sans-Fuentes[5], Salma Patel[6]

[1] The University of Arizona College of Medicine - Phoenix, [2] The University of Arizona College of Medicine - Tucson, [3] University of Arizona, [4] Brigham and Women's Hospital, [5] UAHS Center for Biomedical Informatics and Biostatistics, BIO[5] Institute, University of Arizona, [6] The University of Arizona

Introduction: Positional obstructive sleep apnea (POSA) is characterized by a significant increase in airway obstruction and breathing disturbances when a patient sleeps in the supine position compared to sleeping on their side. While mandibular advancement devices (MADs) are effective in managing obstructive sleep apnea (OSA), their efficacy in treating POSA remains uncertain. This study evaluates the effectiveness of MADs in improving clinical and polysomnographic outcomes for patients with POSA.

Methods: Clinical notes and sleep studies (in-lab polysomnography or home sleep apnea test) were reviewed from patients who received a MAD for OSA treatment between 2019 and 2023. Patients who met the diagnostic criteria for POSA (supine AHI at least double the lateral AHI) were analyzed. Sleep parameters, including the Epworth Sleepiness Scale (ESS), Apnea-Hypopnea Index (AHI), and minimum oxygen saturation (SpO2), were compared between baseline and follow-up visits after MAD titration and optimization.

Results: Of 167 patients, 49.7% (n=83) had POSA. The POSA cohort had a median baseline ESS of 8 (range 0-20, n=69), AHI of 13.3 events/hour (range 5.7-62.2, n=67), supine AHI of 19.2 events/hour (range: 8-109.8, n=67), lateral AHI of 5.3 events/hour (range 0-44; n=67), minimum SpO2 of 82% (range 0.7-90, n=67), sleep efficiency of 73.4% (range 37.2-78.9, n=6), and arousal index of 13.2 events/hour (range 6.8-36, n=6). After MAD intervention, the cohort demonstrated a median ESS of 6 (range 0-20), AHI of 8.7 events/hour (range 0.5-88.9), supine AHI of 11.4 events/hour (range 0-85.9), lateral AHI of 4.1 events/hour (range 0-100.8), minimum SpO2 of 82% (range 64-91), sleep efficiency of 81.5% (range 65.4-95.8), and arousal index of 22.7 events/hour (range 2.8-41.9). Patients experienced significant reductions in median overall AHI (p< 0.001) and supine AHI (p< 0.001) and improvement in sleep efficiency (p< 0.001). Similar outcomes were observed in the non-POSA cohort (n=84, 50.3%), including significant reductions in median overall AHI (p< 0.05) and lateral AHI (p< 0.001).

Conclusion: Mandibular advancement devices (MADs) effectively improved clinical and polysomnographic outcomes in patients with POSA. Similar benefits in AHI reduction were observed in non-POSA patients, supporting MADs as a viable treatment for both groups.

NOCTURNAL SLEEP STAGE STABILITY FEATURES IN UNEXPLAINED HYPERSOMNOLENCE

Jesse Cook[1], Meredith Rumble[1], Ana Maria Vascan[1], Kieulinh Tran[2], Michael Prairie[3], Jessica Love[4], David Plante[5]

[1] University of Wisconsin-Madison, School of Medicine and Public Health, Department of Psychiatry, [2] University of Wisconsin, Madison, [3] University of Minnesota Medical School, [4] University of Wisconsin-Madison, Department of Psychology, [5] University of Wisconsin–Madison

Introduction: Unexplained hypersomnolence is a common condition, nosologically categorized as hypersomnolence disorder (HD) and idiopathic hypersomnia (IH) by the DSM-5-TR and ICSD-3-TR, respectively. HD and IH are predominantly distinguished by required PSG/MSLT diagnostic criteria for IH. Among persons seeking clinical care, IH constitutes the subset of HD patients that meet objective PSG/MSLT criteria for IH. Sleep stage stability (SSS) methodology is a fine-grained approach to identify abnormalities in sleep architecture dynamics that may be relevant to unexplained hypersomnolence. This study evaluated SSS features in adult HD patients relative to healthy sleeper controls (HSC), and explored differences in SSS features between HD who displayed objective criteria for IH (HD/IH+) and those who did not (HD/IH-).
Methods: Sixty unmedicated HD clinical patients (average age = 28.6 ± 8.6 years; percentage female = 78.3%) were compared against 29 HSC. All participants underwent ad libitum nocturnal PSG and daytime MSLT. SSS features included number of stage bouts, median stage bout duration, number of transitions between stages, and survival analysis of stage bouts. Primary analyses used regression and cox proportional hazards models to compare HD vs HSC. ANCOVA and log-rank tests assessed differences between HSC, HD/IH+ (n=14), and HD/IH- (n=46) across SSS, with subsequent pairwise comparisons performed for outcomes with significant group effects. All analyses accounted for age, sex, body mass index, and depressive symptom severity.
Results: HD consistently displayed enhanced SSS relative to HSC, including significantly longer N2 and REM bouts, fewer transitions from N3 to Wake or N1, and increased survival of N2 and REM bouts. Many phenotypic similarities were observed between HD/IH+ and HD/IH-, though HD/IH+ displayed significantly greater PSG sleep duration and efficiency along with fewer N3 bouts and increased survival of N2 bouts.
Conclusion: Our findings demonstrate enhanced SSS features in adult, unmedicated clinical patients with unexplained hypersomnolence. Follow-up studies are necessary to determine the role of enhanced SSS as a valid, reliable and specific signature of HD and IH. These results may also inform future nosological frameworks that consider unexplained hypersomnolence along a continuum of alterations of sleep architecture and dynamics.

POLYSOMNOGRAPHIC CHARACTERISTICS DIFFERENTIATING THE CENTRAL DISORDERS OF HYPERSOMNOLENCE

Jinu Johnson[1], Matheus Lima Diniz Araujo[2], James Bena[3], Noah Andrews[1], Nancy Foldvary-Schaefer[2]

[1] Cleveland Clinic, [2] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [3] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH

Introduction: Central Disorders of Hypersomnolence (CDH) are classified primarily by polysomnography-multiple sleep latency test (PSG-MSLT). Lack of biomarkers and variable MSLT results in disorders other than narcolepsy type 1 (NT1) contribute to under- and mis-diagnosis. Limited studies explore PSG characteristics that may differentiate CDH subtypes using large datasets.
Methods: This retrospective cohort included 1,330 patients who underwent PSG-MSLT for hypersomnolence (January 2003-August 2024) at Cleveland Clinic. Cases were classified as NT1, narcolepsy type 2 (NT2), idiopathic hypersomnia (IH) and undifferentiated hypersomnia (UH; not meeting CDH criteria) based on physician clinical diagnosis. 557 patients with disorders associated with hypersomnia (i.e. OSA) were excluded. Demographic and PSG characteristics were compared with ANOVA, Kruskal-Wallis, and Pearson chi-square tests.
Results: Of 773 patients (33.7±14.0 yr, 79.4% female), 72(9.3%) had NT1,121(15.7%) NT2, 296(38.3%) IH, and 284(36.7%) UH. While groups did not differ in age or gender, more Caucasians had IH and UH than NT1(78.6, 80.8 vs. 62.5%, p=0.001). Epworth Sleepiness Scale scores were lower in UH than CDH groups (12.6±5.0 vs NT1-15.9±5.6,NT2-16.1±5.1,IH-14.2±5.2, p< 0.001). Self-reported sleep time was longer for UH than NT2 without other group differences (UH-9.1±2.1,NT2-8.4±1.7,NT1-8.6±2.1,IH-8.8±1.9 hours, p=0.003). PSG sleep onset REM periods (SOREMPs) were more common in NT1 and NT2 than IH and UH (NT1-27.8%,NT2-9.1%,IH-1.01%,UH-1.06%, p< 0.001). NT1 and NT2 had shorter REM latency than IH and UH(NT1-73.5[7.0,123.0],NT2-74.0[53.0,112.0],IH-103.0[71.0,161.5],UH-105.0[74.5,183.0] min, p< 0.001). NT1 and UH showed more wakefulness after sleep onset than NT2 and IH (NT1-43.5[26.0,97.0],UH-47.5[25.5, 85.0],NT2-32.5[17.3,61.5],IH-30.5[17.5, 62.5] min, p< 0.001). Sleep latency was shorter in CDH than UH (NT1-10.8[4.5,26.0],NT2-14.0[6.0,24.5],IH-17.5[7.8,30.5],UH-24.5[12.5,39.0] min, p< 0.001), and sleep efficiency higher in NT2 and IH than UH (NT2-87.4±7.3,IH-86.3±8.8,UH-82.0±10.0, p< 0.001). NT1 had greater, though non-significant, arousal index, stage shifts, and N1 percentage, along with lower sleep efficiency than NT2 and IH. No significant differences were observed between NT2 and IH in sleep latency, sleep efficiency, arousal index, WASO, stage shifts, or stage percentages.
Conclusion: We found significant differences in PSG variables between CDH that confirm and extend prior observations. Minimal differences between NT2 and IH support a common pathophysiology. Recognizing the larger group of UH with distinct PSG features from CDH is important in clinical practice.

POLYSOMNOGRAPHIC NON-RAPID EYE MOVEMENT SLEEP BIOMARKERS TO STRATIFY CENTRAL DISORDERS OF HYPERSOMNOLENCE

Yu Luo[1], Kiran Maski[2], Shaun Purcell[3]

[1] Brigham and Women's Hospital and Harvard Medical School, [2] Boston Children's Hospital, [3] Brigham and Women's Hospital, Harvard Medical School

Introduction: Central disorders of hypersomnolence (CDH) including narcolepsy and idiopathic hypersomnia are chronic and debilitating conditions characterized by profound daytime sleepiness. However, they are heterogeneous and diagnostic delays of 5 to 10 years are common, exacerbating disease burden. The multiple sleep latency test (MSLT) is commonly used for diagnosis but has poor validity and reliability. There is a critical need for objective biomarkers from standard overnight polysomnograms (PSG) to stratify patients and enhance diagnostic accuracy.
Methods: As part of an ongoing study, we are harmonizing PSGs from CDH cases across multiple cohorts. Here we report results from the initial cohort (Mignot Nature Communications) of 469 CDH cases (including 259 with narcolepsy type 1 (NT1)) and 342 controls. After automated staging, artifact detection and filtering using Luna, we derived macro- and micro-architecture EEG metrics including stage duration/transition, spectral power, spindle and slow oscillation occurrence, morphology and coupling, as well as indices of ultradian dynamics and evaluated group-level differences.
Results: Comparing the two groups (NT1 and other hypersomnolence (OH)) to controls, both exhibited increased sleep time ($p < 0.01$ for all results reported), whereas only NT1 showed increased WASO and sleep fragmentation. Both groups showed reduced REM latency. After excluding individuals with sleep onset REM (< 15 minutes), only OH cases showed reduced REM latency. Quantifying the relative timing of each stage within the sleep period, both groups showed "earlier" N1 but N2/N3 sleep was earlier in NT1 and later in OH. Considering NREM EEG metrics, slow/delta power (and slow oscillation (SO) rate and amplitude) was increased in both groups. Spindles showed qualitatively distinct associations: slow spindles had reduced density in OH and fast spindles were reduced in NT1. In contrast, both NT1 and OH had altered SO/spindle coupling vs. controls.
Conclusion: We observed both shared and unique – or even qualitatively different – PSG alterations in NT1 and OH patients. These group-level effects can inform unbiased clustering of CDH patients and ultimately provide diagnostic alternatives to the MSLT, to predict disease progression, and treatment responsiveness.

A NOVEL PHENOTYPE OF HYPERSOMNIA IDENTIFIED BY GAMMA BAND SPECTRAL SLOPE DURING MSLT

Junjie Liu[1], Ogechukwu Obiano[1]
[1] University of Iowa

Introduction: Hypersomnia is diagnosed using the multiple sleep latency test (MSLT), and sleep latency is determined by visual scoring of electroencephalography (EEG) signals. Recent studies established the gamma-band (30-45 Hz) spectral slope as a novel EEG marker that changes significantly across wakefulness and sleep stages, yet cannot be appreciated in visual scoring. Spectral slope reflects neuronal excitation-inhibition balance; thus, studying how the spectral slope changes during MSLT may provide new insights into the pathophysiology of hypersomnia.
Methods: We retrospectively analyzed 30 MSLTs consecutively conducted in our clinic in one year. For each 30-second epoch, EEG power spectral density was computed using Welch's method, and spectral slope was computed from linear fitting of logarithm of power to logarithm of frequency over 30-45 Hz range. To minimize the effects of artifacts in individual electrodes, the lowest of four spectral slope values for F3-A2, C3-A2, F4-A1, C4-A1 channels was taken for each epoch. Spectral slope was computed for both MSLT and the preceding overnight EEG.
Results: During overnight EEG, most patients (26/30) showed a decrease in 30-45 Hz spectral slope of at least 1.0 unit from awake to stage N2, and MSLT was analyzed only for those patients. During MSLT, the majority of patients (14/26) showed decreases in spectral slope around when sleep occurred, such that sleep latency could be equivalently derived from when the spectral slope decreased. However, 5 patients showed no significant decrease in spectral slope during sleep stages N1 and N2. In the remaining 7 patients, spectral slope was as low as at the level expected for stage N2 sleep at or very shortly after the start of each MSLT nap, even when the patient was still awake based on visual scoring of EEG. Mean sleep latency derived from when the spectral slope decreased during MSLT (less than 2.0 min) was much shorter than that derived from standard visual scoring (range: 3.0-7.6 min).
Conclusion: Among hypersomnia patients, there is a distinctive subgroup in which the EEG's gamma-band spectral slope decreases to the level expected for sleep long before the sleep onset during MSLT. This phenotype of hypersomnia might represent excessive neuronal inhibition during daytime.

MULTIMODAL DETECTION OF NARCOLEPSY TYPE 1 USING GENETIC AND NOCTURNAL POLYSOMNOGRAPHY DATA

Mads Olsen[1], Alexander Neergaard Zahid[2], Kevin Galinsky[1], Reuben Retnam[1], Ling Lin[3], Han Yan[3], Brian Tracey[1], Derek Buhl[1], Dmitri Volfson[1], Emmanuel Mignot[4]
[1] Takeda Development Center Americas, Inc., [2] Stanford-Takeda Post-doctoral Program, Stanford University, [3] Stanford Center for Sleep Sciences and Medicine, Stanford University, [4] Stanford University

Introduction: Efficient screening methods with high specificity which can be applied to large sample sizes are needed to improve significantly underdiagnosed people with narcolepsy type 1 (NT1). To address this unmet need, we combined polygenetic risk scores (PRS), HLA typing, and nocturnal polysomnography (PSG) data. These methods are developed and validated using a dataset significantly larger than those used in previous studies, ensuring their reliability and generalizability.
Methods: People with diagnosed narcolepsy were studied across 7 different global locations, involving multiple collaborators (coauthors limited by guidelines). We developed a custom U-Sleep model for variable-resolution sleep staging using electroencephalography, electrooculography, and electromyography data from 19,381 PSG recordings from the National Sleep Research Resource and the Stanford Sleep Clinic. Sleep staging was performed across epochs from 0.25 to 3600 seconds, leveraging novel multiscale transition matrix (MTM) features to capture NT1-specific transitions and overlapping sleep stages. Next, a Gaussian processes classifier was trained on features from 21,846 PSGs across 14 cohorts (NT1: n=327; controls: n=21519) and tested on 634 separate PSGs (NT1: n=317; controls: n=317). An

ensemble model combined multiple time resolutions, weighted by prediction accuracy. Classifier performance was evaluated using 5-fold cross-validation. We developed a multi-information model integrating new PRS scores with HLA DQB1*06:02 typing, where HLA- and PRS+ conditions map to control and NT1 prediction, respectively, with PSG used when neither applies.
Results: Adding PRS to HLA increased the specificity from 81.9% to 100.0%, with a sensitivity of 25.9%, enabling potential screening of NT1 using genetics alone. When combining PSG with HLA, our approach yielded 99.4% specificity and 94.6% sensitivity, surpassing State-of-the-Art (SOTA). Adding PRS further rescued HLA+ cases missed based off PSG, and increased sensitivity to 95.9% while maintaining 99.4% specificity. MTM features meaningfully boosted classification performance (approximately 1% gain) compared to SOTA features, which themselves significantly outperformed standard clinical PSG measures. Ensemble models showed that combining multiple resolutions improved performance, notably specificity. Additionally, post-hoc analyses show that genetic information noticeably improved model robustness.
Conclusion: These findings suggest that the proposed multimodal model is a robust framework for NT1 classification, providing more specific and sensitive screening methods.

THE CLINICAL AND HUMANISTIC BURDEN OF NARCOLEPSY: MATCHED ANALYSIS OF US NATIONAL HEALTH AND WELLNESS SURVEY DATA

Kiran Maski[1], Michael Doane[2], M. Janelle Cambron-Mellott[3], Shakiba Eslamimehr[3], Adam Jauregui[3], Wilbur Williams[2]
[1] Boston Children's Hospital, [2] Alkermes, Inc., [3] Oracle Life Sciences

Introduction: Narcolepsy is a chronic neurological disorder that causes debilitating daytime sleepiness among other symptoms. This study compared clinical and humanistic outcomes between those with and without narcolepsy to characterize the extent of disease burden.
Methods: This study was a retrospective, cross-sectional analysis of 2021/2023 US National Health and Wellness Survey data. The narcolepsy cohort included those who reported a physician diagnosis of narcolepsy. Propensity-score matching (1:3) adjusted for demographic/health characteristics between those with and without narcolepsy (controls). Chi-square tests and t-tests compared comorbidities, symptoms of depression and anxiety, and health-related quality of life (HRQoL) between groups.
Results: Before matching, respondents with narcolepsy (n=335; female=56%; mean age, 45.5 years; White=68%) and without narcolepsy (n=141,072; female=55%; mean age, 47.8 years; White=72%) were included. Additionally, the narcolepsy cohort had higher mean [SD] body mass index (30.1 [8.4] vs 27.6 [7.1], p<.001) and were more likely to have obesity (44% vs 28%, p<.001) and be current smokers (25% vs 17%, p<.001) than those without narcolepsy. After matching, the narcolepsy cohort reported more frequent physician-diagnosed psychiatric comorbidities vs controls, including depression (58% vs 32%, p<.001), anxiety (54% vs 33%, p<.001), and ADHD (20% vs 6%, p<.001). The narcolepsy cohort had higher reporting of moderate-to-severe depression symptoms via Patient Health Questionnaire-9 (52% vs 33%, p<.001) and moderate-to-severe anxiety via Generalized Anxiety Disorder Questionnaire-7 (41% vs 26%, p<.001). On the Brief Resilience Scale, more respondents with narcolepsy reported low resiliency scale score vs controls (43% vs 28%, p<.001). Compared with controls, the narcolepsy cohort scored lower on HRQoL measures, including mean [SD] mental health composite (32.8 [11.3] vs 40.6 [12.6], p<.001) and physical health composite (35.7 [11.4] vs 42.9 [11.6], p<.001) scores of the RAND 36-Item Health Survey. The narcolepsy cohort reported greater impairment of daily activities vs controls (51% vs 34%, p<.001).
Conclusion: Narcolepsy is associated with broad clinical and humanistic burden. Those with narcolepsy had more frequent psychiatric comorbidities, more severe depression and anxiety symptoms, less self-reported resiliency, and lower HRQoL. Future strategies should focus on comprehensive management that prioritizes mental health, while investigating new treatments that may improve HRQoL for narcolepsy patients.

THE ECONOMIC BURDEN OF NARCOLEPSY: MATCHED ANALYSIS OF US NATIONAL HEALTH AND WELLNESS SURVEY DATA

Michael Doane[1], Kiran Maski[2], M. Janelle Cambron-Mellott[3], Shakiba Eslamimehr[3], Adam Jauregui[3], Wilbur Williams[1]
[1] Alkermes, Inc., [2] Boston Children's Hospital, [3] Oracle Life Sciences

Introduction: Narcolepsy is a chronic neurological disorder that typically begins in childhood or young adulthood. This study compared economic outcomes between those with and without narcolepsy to characterize personal and societal financial burden associated with this rare condition.
Methods: This study was a retrospective, cross-sectional analysis of 2021/2023 US National Health and Wellness Survey data. The narcolepsy cohort had a self-reported physician diagnosis of narcolepsy. Propensity-score matching (1:3) adjusted for demographic/health characteristics between those with and without narcolepsy (controls). Chi-square tests and t-tests compared economic outcomes between groups (eg, healthcare resource use, work impairment, medical and indirect costs).
Results: Before matching, respondents with narcolepsy (n=335; female=56%; mean age, 45.5y; White=68%) and without narcolepsy (n=141,072; female=55%; mean age, 47.8y; White=72%) were included. The narcolepsy cohort had lower socioeconomic status vs those without: less likely to receive college degree (45% vs 52%, p<.05), less likely to be employed full-time (36% vs 46%, p<.001), more likely to receive disability (10% vs 3%, p<.001), more likely to have <$25,000 annual household income (22% vs 12%, p<.001), and more likely to report food insecurity (39% vs 18%, p<.001). After matching, the narcolepsy cohort reported significantly more outpatient visits vs controls (11.6 vs 6.2 average visits during prior 6 months, p<.001), including more visits to neurologists, psychiatrists, and pulmonologists (all p<.001). The narcolepsy cohort reported significantly higher hospitalizations (≥1 visits; 27% vs 16%, p<.001) and emergency department visits (≥1 visits; 31% vs 22%, p<.01) during prior 6 months vs controls. Those with narcolepsy had an additional $14,492 per-person-per-year in medical expenses (average annual medical costs: $37,815 vs $23,323, p<.001). Of those employed, the

narcolepsy cohort reported significantly higher levels of work-related impairment vs controls, including absenteeism (21% vs 12%, p<.001) and presenteeism (44% vs 29%, p<.001). The narcolepsy cohort had an additional $12,853 per-person-per-year in lost wages to employers (average annual indirect costs: $30,075 vs $17,222, p<.001).
Conclusion: Narcolepsy is associated with reduced socioeconomic outcomes. Those with narcolepsy had greater annual medical and indirect costs than controls. Research should assess how psychosocial supports and treatments may improve healthcare utilization and overall financial burden among those living with narcolepsy.

CENTRAL DISORDERS OF HYPERSOMNOLENCE IN MAJOR DEPRESSIVE DISORDER

Vishal Saini[1], Shivani Saini[2]
[1] Mid-West Center For Sleep Disorders, [2] Hurley Medical Center

Introduction: Central disorders of hypersomnia (CDH), characterized by excessive daytime sleepiness, frequently overlap with major depressive disorder (MDD), complicating diagnosis and treatment. Understanding the prevalence of CDH in MDD is crucial for enhancing diagnostic accuracy and optimizing treatment strategies. This systematic review and meta-analysis aimed to estimate the pooled prevalence of CDH in MDD patients and explore variations based on demographic, geographic, and methodological factors.
Methods: A comprehensive search of PubMed, Embase, Cochrane Library, PsycINFO, and CINAHL was conducted to identify observational studies reporting CDH prevalence in MDD patients. Eligible studies were assessed for quality using the Newcastle-Ottawa Scale. Data were extracted systematically, and a random-effects model was employed to calculate pooled prevalence and explore heterogeneity. Subgroup analyses were conducted by age, gender, diagnostic criteria, geographic region, and study type. Publication bias was evaluated using funnel plots and Egger's test, with trim-and-fill adjustments applied.
Results: Twelve studies met inclusion criteria, comprising a total of 71,633 MDD patients. The pooled prevalence of CDH was 20.23% (95% CI: 7.31%–44.93%), increasing to 30.17% (95% CI: 18.24%–42.09%) after accounting for publication bias. Subgroup analyses revealed the highest prevalence among adolescents (34.2%, 95% CI: 24.1%–44.3%), followed by adults (23.5%, 95% CI: 15.0%–32.0%), and older adults (10.3%, 95% CI: 4.5%–16.1%). Gender-based analyses indicated slightly higher prevalence among males (31.8%, 95% CI: 19.2%–47.8%) compared to females (30.5%, 95% CI: 15.9%–50.6%), although overlapping confidence intervals suggest these differences are not statistically significant. Geographic variations showed the highest rates in Asia (24.7%, 95% CI: 16.4%–33.0%) and Europe (21.8%, 95% CI: 13.1%–30.5%). Diagnostic criteria analysis revealed slightly higher prevalence in studies using DSM-V (22.7%, 95% CI: 14.1%–31.3%) compared to DSM-IV (19.5%, 95% CI: 12.0%–27.0%). Funnel plots indicated potential publication bias, and sensitivity analyses confirmed the robustness of the findings.
Conclusion: CDH is highly prevalent in MDD patients, with significant variations across demographic and methodological subgroups. These findings underscore the importance of routine sleep assessments in MDD management and highlight the need for integrated diagnostic and treatment approaches. Future research should focus on elucidating causal relationships and addressing gaps in underrepresented populations to improve care for patients with comorbid CDH and MDD.

DESCRIBING THE HEALTHCARE PROVIDERS OF PATIENTS WITH NARCOLEPSY OR IDIOPATHIC HYPERSOMNIA IN US CLINICAL PRACTICE

Dana Teltsch[1], Bonnie Bui[2], Jeffrey McPheeters[2], Phani Veeranki[2], Yelena Pyatkevich[1]
[1] Takeda Development Center Americas, Inc., [2] Optum Life Sciences

Introduction: Narcolepsy and idiopathic hypersomnia (IH) are rare central disorders of hypersomnolence associated with diagnostic delays, comorbidities, and disease burden. Understanding how healthcare providers (HCPs) diagnose and treat these patients could help inform effective diagnostic and management strategies. We described the HCP specialties who managed people with narcolepsy or IH in the real-world clinical practice in the US.
Methods: The study identified a cohort of individuals with a diagnosis of narcolepsy or IH from Optum's Market Clarity integrated claims and electronic healthcare record database from January 01, 2014 to December 31, 2021, and the HCPs who managed them over a 12-month observation period. HCP encounters, dispensings of narcolepsy-specific medications (oxybates or Wakix), and sleep evaluations were described by HCP specialty. Evaluations included any polysomnography, multiple sleep latency test, or orexin-A/hypocretin-1; and human leukocyte antigen or lumbar puncture testing on claims with narcolepsy/IH diagnoses. A sample of 1,000 HCPs from narcolepsy/IH-related claims were further characterized by linked data of their patient encounters over a year to examine diagnoses, medications, and other evaluations.
Results: Overall, 68,328 individuals qualified for the study (10,054,075 encounters with 506,236 HCPs over 12-month observation period). 378,994 of the medical claims included any diagnoses of narcolepsy/IH, and 70,473 were for narcolepsy/IH as primary diagnoses. 12.1% of overall HCP encounters were with internal medicine, and 11.5% were with primary care. Sleep specialists, neurologists, and pulmonologists accounted for 0.2%, 2.2%, and 1.5%, respectively. Patients on narcolepsy/IH medical claims accounted for a median of 2% of all patients with medical claims among sleep specialists (increased to 5% for 75th percentile and to 10% for 90th percentile). Prescribers of narcolepsy medication followed a similar pattern with overall higher proportions of narcolepsy/IH patients (median of 3%; 75th percentile of 6%). Over 80% of sleep specialists did not prescribe any narcolepsy-specific medications.
Conclusion: In this large real-world US population, people with a diagnosis of narcolepsy or IH constitute a very small component of the overall HCP patient clinical cohort, even among sleep specialists. Specialists who manage a larger number of patients with narcolepsy/IH more commonly prescribe narcolepsy-specific medication.

EFFECT OF NARCOLEPSY AND IDIOPATHIC HYPERSOMNIA ON RELATIONSHIPS: A SOCIAL MEDIA ANALYSIS

Maria Picone[1], Jennifer Mundt[2], Luis Ortiz[3], Anne Morse[4], Matthew Horsnell[5], Fèri Ascencion[6], Zachary Cline[1], Christopher DeFelice[1], Jennifer Gudeman[7]

[1] TREND Community, [2] University of Utah, [3] Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, [4] Geisinger Commonwealth School of Medicine Geisinger Medical Center Janet Weis Children's Hospital,, [5] Patient Author, [6] PWN4PWN, [7] Avadel Pharmaceuticals

Introduction: Central disorders of hypersomnolence, such as narcolepsy and idiopathic hypersomnia (IH), contribute to quality-of-life challenges, including entering or maintaining relationships. A social listening analysis was conducted to characterize the emotions and effects of narcolepsy and IH on romantic/social partners.

Methods: This social listening analysis used natural language processing and other statistical techniques to analyze 447,347 posts and comments shared (August 2011 to September 2024) from 2 subreddits (r/Narcolepsy and r/idiopathichypersomnia) and the PWN4PWN Facebook group. The process used an Attributes of Daily Living (ADL) model to identify sleeping paragraphs and a span recognition model to filter paragraphs with spans labeled "relationship."

Results: A total of 227,276 paragraphs that discussed sleeping were identified by the ADL model; of these, 8,871 (3.9%) also mentioned a partner. Across all conversations that mentioned both sleeping and a partner, the most common topics identified were sleep medication usage, narcolepsy journey, Xyrem/Xywav, falling asleep, medical diagnosis journey, and vivid dreaming. Of the most common sleep-related clinical topics identified, nighttime sleep disruptions were more likely to co-occur with the mention of a partner (OR [95% CI]; bad dreams, 2.8 [1.6-4.8]; night terrors, 2.2 [1.7-2.9]; rapid eye movement behavior disorder, 2.0 [1.3-3.0]; nightmares, 1.8 [1.5-2.1]; vivid dreams 1.4 [1.1-1.7]). The primary emotions expressed in paragraphs mentioning both sleep and a partner were fear (28.2%), anger (23.2%), and happiness (22.8%). In conversations that mentioned both sleep and a partner, the most associated sleep-related clinical topic and emotion (standardized pointwise mutual information squared [PMI2]) were sleep paralysis and fear (3.0). In paragraphs that discussed sleep and a partner, naps were associated with multiple emotions including frustration (2.6), love (2.5), anger (2.2), annoyance (1.7), and worry (1.6); sleepiness was associated with anger (1.9) and frustration (1.9); nightmares and night terrors were associated with fear (1.9 and 1.8, respectively).

Conclusion: These data suggest that nighttime sleep symptoms, including parasomnias, may be a source of concern within relationships of people with narcolepsy or IH. Sleepiness and bed sharing with a partner with narcolepsy or IH may cause relationship tension given the strong association with emotions with a negative connotation, such as anger and frustration.

MODELLING KEY DRIVERS OF INCREASED COSTS AND MORTALITY IN NARCOLEPSY

Sarah Bermingham[1], Dmitry Gultyaev[2], Emi Nazlazi[2], Qianyi Li[3]

[1] Takeda Pharmaceuticals USA., [2] Certara Germany GmbH, [3] Cencora

Introduction: While increased costs and mortality in people with narcolepsy are well-established, the underlying drivers of these outcomes remain underexplored. This study aimed to identify and quantify the probable causes of elevated direct costs, indirect costs, and mortality in people with narcolepsy versus controls.

Methods: We reviewed patient-reported consequences of narcolepsy, focusing on those impacting healthcare resource use, productivity, and mortality. Costs, mortality, and prevalence of each impact in the US general population were obtained from nationally representative data. Systematic and targeted literature reviews identified odds ratios for each impact in people with narcolepsy versus controls, selecting values from the most representative and rigorous studies. Few studies provided separate odds ratios for narcolepsy type 1 and type 2 compared with controls, and those that did generally reported no significant differences between the types. A model was developed to deterministically calculate average age-adjusted costs and mortality for an individual with narcolepsy compared with a control. Treatment-related costs were excluded.

Results: The annual incremental cost of narcolepsy was $18,735 (2024 US Dollars) per person. The largest contributor was productivity loss ($8,645/year), followed by healthcare costs associated with non-vehicular accidental injuries ($2,480/year), cardiovascular disease and events ($2,310/year), depression and anxiety ($2,110/year), headaches/migraines ($1,620/year), suicidal thinking and behavior ($1,050/year), and motor vehicle accidents ($520/year). Fatal cardiovascular events, non-vehicular accidental injuries, motor vehicle accidents, and suicide resulted in a 40% greater risk of mortality for people with narcolepsy compared with controls (average lifetime hazard ratio 1.4).

Conclusion: This study is the first to quantify increased costs and excess mortality in people with narcolepsy based on their probable causes. Our model results align with annual costs and mortality hazard ratios reported in previous database studies, while providing deeper insight into the specific contributors to narcolepsy's economic burden. Identifying the most costly and fatal aspects of narcolepsy is a critical step towards assessing the value of treatments that reduce these impacts. Understanding the cost of illness and mortality also helps inform policymakers about the severity and unmet needs of this underappreciated yet devastating disease.

CHARACTERIZING PATIENT-REPORTED COGNITIVE SYMPTOMS AND THEIR IMPACT ON DAILY LIFE IN NARCOLEPSY TYPE 1

Kiran Maski[1], Kathryn Pfeiffer[2], Meryl Brod[2], Robert Latzman[3], Sarah Bermingham[4], Paul Maruff[5], Brian Harel[3]

[1] Boston Children's Hospital, [2] The Brod Group, [3] Takeda Development Center Americas, Inc, [4] Takeda Development Center Americas, Inc., [5] Cogstate

Introduction: Narcolepsy type 1 (NT1) is a chronic, rare neurological disorder with a significant impact on daily life. It is characterized by a pentad of symptoms including excessive daytime sleepiness (EDS), cataplexy, disrupted nighttime sleep, hypnagogic and hypnopompic hallucinations, and sleep paralysis. Cognitive symptoms associated with narcolepsy are understudied in NT1 but have substantial impacts on daily life. This study investigated the nature of cognitive symptoms experienced by adults with NT1 and the impact on daily life using semi-structured interviews.
Methods: In-depth, qualitative interviews were conducted with adults diagnosed with NT1 in the USA. Participants were recruited through 1) a patient advocacy organization (via social media and the organization's website); 2) a professional market research organization; and 3) participant referrals. Individual interviews were conducted by telephone, followed a semi-structured guide and lasted ~90 minutes. The qualitative analysis was informed by an adapted grounded theory approach. Analyses identified key conceptual themes related to cognitive symptoms associated with NT1 in adults and their consequences for daily life.
Results: Of the 46 participants, 45 (98%) reported cognitive symptoms, with the most common being trouble remembering (89%, n=41) and difficulty with focus/sustained attention (87%, n=40). Most participants characterized cognitive symptoms as severe or moderate (79%, n=33/42) and reported symptoms occurring daily (73%, n=30/41). Of participants who rated the current impact of cognitive symptoms on their functioning/daily life, two-thirds (67%, n=22/33) reported that cognitive symptoms had a severe or moderate impact. Notably, 12/45 (27%) participants reported no improvement and 29/45 (64%) reported incomplete resolution of cognitive symptoms following drug treatments for NT1 symptoms, including EDS; 4/45 (9%) participants did not provide a response.
Conclusion: This investigation showed that cognitive symptoms among adults with NT1 are frequent, severe, and interfere with daily life activities. As such, the current pentad of narcolepsy symptoms represents an incomplete clinical picture. These findings suggest that cognitive symptoms should be considered a core feature of the disease. In many participants, cognitive symptoms persisted despite treatment. These data highlight a clear unmet need to assess cognitive function in people with NT1 and identify treatments that address NT1-associated cognitive symptoms.

USE OF THE PSYCHOMOTOR VIGILANCE TEST IN CLINICAL TRIALS OF CNS-ACTIVE DRUGS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Brian Harel[1], Paul Maruff[2], Kiran Maski[3], Gert Jan Lammers[4], Claudio Bassetti[5], Robert Latzman[1]

[1] Takeda Development Center Americas, Inc, [2] Cogstate, [3] Boston Children's Hospital, [4] Stichting Epilepsie Instellingen Nederland, [5] University Hospital, Bern

Introduction: People with central disorders of hypersomnolence (CDH) experience difficulties with sustained attention and associated difficulties in daily living. The Psychomotor Vigilance Test (PVT) is used widely to measure impairment in attention arising from disruption to sleep in healthy adults and in individuals with sleep/wake disorders. The PVT is therefore useful and relevant as an outcome for clinical trials of medicines designed to treat disorders in which there is a disruption to attentional processes, such as CDH. Interpretation of PVT clinical trial data for new medicines would be improved by the presence of a framework that aggregates the nature and magnitude of performance changes on the PVT in response to drugs that either depress or activate the central nervous system (CNS). We reviewed studies using PVT to assess the effects of CNS-active compounds on sustained attention in clinical trials, focusing on its utility in determining treatment efficacy and safety.
Methods: A systematic review and meta-analysis of 77 clinical trials that included the PVT as an outcome measure was conducted. These trials were conducted on healthy adults with and without sleep disruption, and in adults with diagnosed sleep disorders. Data were extracted from studies conducted after 2000, including placebo-controlled and experimental trials with CNS-active drugs.
Results: Among the 77 trials investigated, 84% (n=65) used PVT reaction time (RT) and 74% (n=57) used PVT lapses in attention (RT >500 ms) as the main outcome measures. Adults with sleep disorders showed significant impairment in both outcome measures compared with healthy adults. Sedative drugs increased lapses, while CNS-activating drugs improved both RT and lapses. Benchmark interventions, including modafinil and sleep deprivation, produced clinically meaningful changes in reaction time (≥38.4 ms) and lapses (≥3).
Conclusion: The PVT has been used widely to assess the effects of CNS-active compounds on sustained attention. Its ability to measure response speed and lapses in attention makes it valuable for evaluating drug effects on sustained attention, especially in CDH populations. The PVT's predictive validity and broad use across pharmaceutical, academic, and military trials underscores its importance in drug development and safety monitoring.

CLINICAL AND POLYSOMNOGRAPHIC CHARACTERISTICS OF PATIENTS WITH IDIOPATHIC HYPERSOMNIA AND MAJOR DEPRESSIVE DISORDER

Roger Rochart[1], Rena Jiang[1], Irene Chu[2], Hope Kincaid[2], Martina Vendrame[2]

[1] USF Morsani College of Medicine, [2] Lehigh Valley Health Network

Introduction: Idiopathic hypersomnia (IH) presents with debilitating daytime sleepiness. The pathophysiology of IH is poorly understood and there is lack of data concerning thoroughly documented comorbidities such as major depressive disorder (MDD), coupled with polysomnography (PSG) and multiple sleep latency test (MSLT) findings. We aimed to characterize clinical and PSG/MSLT characteristics of IH patients with and without MDD, seen within the Lehigh Valley Health Network.
Methods: We performed a chart review of all IH cases seen between 2000 and 2022, extracting presenting clinical features, comorbidities, PSG and MSLT findings. Descriptive statistics were generated for the entire sample and bivariate analyses were conducted to highlight differences between patients with MDD compared to those without.

Results: We included 142 patients diagnosed with IH, based on the International Classification of Sleep Disorders-3 criteria. Age at onset was 25.33±7.93 years and 119 (83.80%) were female. Average Epworth Sleepiness Scale (ESS) was 16.77±2.92. The most common presenting symptoms were sleep inertia [68(47.89%)], non-refreshing naps [48 (33.8%)], disrupted sleep [36(25.35%)]. MDD was the most frequent mood disorder [77(54.23%)]. Compared to patients without MDD, MDD patients had older age at onset (27.10±8.32 versus 23.23±6.94 years; p=0.003), lower ESS (15 versus 19; p< 0.0001), reported more frequently distrupted sleep [28(36.36%) versus 8(12.31%); 0.001], less non-refreshing naps [16(20.78%) versus 32(49.23%); p< 0.001] and less sleep inertia [30(38.96%) versus 38(58.46%); p=0.02]. Review of overnight PSG data among the whole cohort showed a median sleep efficiency of 90% (IQR:86%-95%), sleep latency of 13.50 minutes (IQR:6-33), REM latency of 122.5 minutes (IQR:79.50-183.50). On MSLT, average sleep latency was 5.21±2.08 minutes. Only 23 (16.20%) patients had sleep onset REM periods (SOREMP) on MSLT. Fewer patients with MDD [7 (9.09%)] had SOREMPs compared to patients without MDD [(16 (24.62%)] (p=0.0124). MDD patients had longer sleep latency [15.50 (7-36.50) versus 9.50 (4-22.50) minutes; p=0.002].
Conclusion: Our study highlights significant clinical and polysomnographic differences in IH patients with and without MDD. These findings underscore the importance of recognizing MDD as a comorbidity in IH, as it may influence clinical presentation and diagnostic features. Further research may elucidate underlying mechanisms and optimize management strategies for this subset of patients.

POSTURAL ORTHOSTATIC TACHYCARDIA SYNDROME, HYPERMOBILITY, AND HYPERSOMNIA: CHARACTERIZING AN EMERGING PHENOTYPE

Cosmo Fowler[1], Doo Choi[1], Komal Kaur[1], Briana Makadia[1], Donald Bliwise[1], Lynn Trotti[1]
[1] Emory University School of Medicine

Introduction: Hypermobility syndromes (including Ehlers-Danlos [EhD]) and postural orthostatic tachycardia syndrome (POTS) have each been associated with sleep disorders, as well as each other. We aimed to characterize the association of these diagnoses with hypersomnia as well as an overlap phenotype in which all three are present using a large, national electronic health record (EHR) database.
Methods: We queried the TriNetX U.S. Collaborative Network, an EHR and claims-derived database of >120 million patients from 69 healthcare organizations in the US. We searched for patients with diagnoses of either EhD (ICD-10-CM Q79.6) or hypermobility syndrome (M35.7) as well as POTS (G90.A) and hypersomnia (G47.1). We then utilized a commonplace index event (encounter for immunization, Z23) between 10/2015 – 10/2024 in patients with and without EhD/hypermobility and POTS to examine the risk of being diagnosed subsequently with hypersomnia, repeating this analysis after incorporating demographics into a 1:1 propensity matched model.
Results: There were 146,306 patients with a diagnosis of EhD/hypermobility, 75,366 with POTS, and 717,206 with hypersomnia within the dataset. Hypersomnia was associated with both EhD/hypermobility (4.9% prevalence vs 0.6% in non-EhD/hypermobility patients, X2 = 45,697, p< 0.001) and POTS (6.0% vs 0.6%, X2 = 36,719, p< 0.001), and there were 1,584 patients with all three diagnoses. This overlap population is 92% female and 86% Caucasian, with a mean age of 33 (SD 11, range 7–85). Using a commonplace index event (overall N = 15,219,962) and after propensity matching, EhD/hypermobility represented a significant risk for subsequent hypersomnia (RR 4.2, CI 3.8–4.7) and POTS (RR 63.4, CI 48.3–83.1), while POTS represented a significant risk for subsequent hypersomnia diagnosis (RR 3.7, CI 3.2–4.3) and EhD/hypermobility (RR 55.4, CI 42.4–72.4); all p< 0.001. The presence of EhD/hypermobility and POTS combined was associated with hypersomnia after matching (RR 6.5, CI 4.8–9.0, p< 0.001).
Conclusion: Our findings showed significant overlap between EhD/hypermobility and POTS diagnoses and hypersomnia, with the combination of both being more strongly associated with a future diagnosis of hypersomnia than either alone. This supports the hypothesis of a common disease entity, the characterization of which demands further study.

THE DIAGNOSTIC AND THERAPEUTIC VALUE OF TIME IN BED EXTENSION IN INSUFFICIENT SLEEP SYNDROME

Marco De Pieri[1], Anna Castelnovo[2], Silvia Miano[2], Mauro Manconi[3]
[1] hopitaux universitaires de Genève, [2] Ente ospedaliero cantonale, [3] Neurocenter of Southern Switzerland, Regional Hospital of Lugano

Introduction: Insufficient sleep syndrome (ISS) represents an emerging health concern but remains poorly defined as a diagnostic entity. In the present study, we aimed to clarify the longitudinal course of ISS and to identify prognostic factors by comparing remitting and non-remitting patients.
Methods: Fifty-five patients with ISS underwent a comprehensive clinical evaluation at baseline and during a follow-up visit. This evaluation included sleep symptoms, sleep logs, medications, and comorbidities. Additionally, actigraphy, video-polysomnography, and a multiple sleep latency test were conducted at baseline.
Results: During the follow-up visit, 69% of patients still met the criteria for a clinical diagnosis of ISS, experiencing symptoms such as daytime sleepiness, disrupted nighttime sleep, unrefreshing sleep, and sleep attacks. Comparing sleep patterns of remitters and non-remitters based on sleep diaries, we observed that remission is associated with not only an increase in total sleep time but also a more regular sleep schedule. This regularity includes a reduction in napping and a lesser difference in sleep timings between weekdays and weekends. However, comparing baseline clinical and instrumental data between remitters and non-remitters revealed no significant differences, hindering the use of these features as prognostic factors.
Conclusion: Given the low remission rate with standard treatment, we propose the following: (1) Criterion E (extension of total sleep time results in resolution of the symptoms of sleepiness) should be considered supportive rather than necessary; and (2) specific cognitive-behavioral therapy protocols targeting the cognitive factors underlying sleep-depriving behaviors are required, as single routine behavioral interventions are insufficient.

IMPACT OF AGE AT NARCOLEPSY ONSET ON SLEEP-ONSET REM PERIODS IN THE MULTIPLE SLEEP LATENCY TEST

Jun-Sang Sunwoo[1], Kwang Ik Yang[2]

[1] Kangbuk Samsung Hospital, [2] Sleep Disorders Center, Department of Neurology, Soonchunhyang University Cheonan Hospital, Soonchunhyang University College of Medicine

Introduction: This study aimed to investigate the effect of age at onset on the clinical characteristics and multiple sleep latency test (MSLT) findings in patients with narcolepsy.
Methods: We recruited 135 patients with narcolepsy who underwent MSLT and fulfilled the diagnostic criteria for narcolepsy type 1 (NT1) or type 2 (NT2). The age at onset of narcolepsy was defined as the age at which either excessive daytime sleepiness or cataplexy first occurred. We compared the clinical, PSG, and MSLT findings between the early- and late-onset groups. Correlation and multiple linear regression analyses were used to determine the effect of age at onset as a continuous variable. We also performed survival analyses to confirm the effect of age at onset on MSLT parameters. Statistical significance was defined as a two-tailed P-value of < 0.05.
Results: The mean age at onset was 18.3 ± 8.8 years and 79 (58.5%) patients were female. Seventy (51.9%) patients were diagnosed with NT1 and 65 (48.1%) were diagnosed with NT2. Patients with early onset had a higher rate of sleep-onset rapid eye movement periods (SOREMPs) than those with late onset in the first nap of the MSLT (81.9% vs. 63.3%, P = 0.031). However, the clinical symptoms of narcolepsy did not differ between the two age groups. In multiple linear regression analysis, age at onset was significantly associated with MSLT REM sleep latency (β = 0.057, 95% confidence interval [CI] 0.011-0.103, P = 0.015) after adjusting for covariates. Survival analysis confirmed that the early onset of narcolepsy (hazard ratio 2.340, 95% CI 1.396-3.920, P = 0.001) was associated with a higher probability of SOREMPs in the first nap trial of MSLT.
Conclusion: Younger age at the onset of narcolepsy was associated with shorter REM sleep latency and higher SOREMP probability on the MSLT. Furthermore, the effect of age at narcolepsy onset on the incidence of SOREMPs was most pronounced during the first nap of MSLT. Our results suggest that early onset of narcolepsy may be associated with great disease severity, specifically related to REM sleep dysregulation.

INCREASED SLEEP PROPENSITY WITHOUT A COMPLAINT OF EXCESSIVE DAYTIME SLEEPINESS IS PROTECTIVE OF INCIDENT HYPERTENSION

Slobodanka Pejovic[1], Alexandros Vgontzas[1], Nikolaos Athanasiou[1], Yun Li[2], Julio Fernandez-Mendoza[3], Edward Bixler[3]

[1] Sleep Research and Treatment Center, Penn State College of Medicine, [2] Shantou University Medical College, [3] Penn State College of Medicine

Introduction: Pathological sleepiness has been associated with significant medical morbidity in clinical samples. We have previously shown that physiological sleepiness (i.e., objective short sleep latencies) in otherwise healthy individuals is not associated with cardiovascular risks. The aim of this study was to examine whether physiological sleepiness in individuals without a complaint of excessive daytime sleepiness (EDS) is protective of incident hypertension.
Methods: From a random, general population sample of 1741 adults of the Penn State Cohort, 1395 were followed-up after 7.5 years and 659 (55% women, aged 49.72± 13.08) have neither hypertension nor complaint for EDS at baseline. All subjects underwent 8-hour polysomnography. Based on previous studies, physiological sleepiness was defined as a sleep latency (SL) ≤ 7 minutes. Hypertension was determined by a self-report of receiving treatment for high blood pressure. EDS was defined as the absence of a report of moderate-to-severe daytime sleepiness/drowsiness and/or irresistible sleep attacks. Binary logistic regression was performed while controlling for age, BMI, sex, race, smoking, alcohol use, caffeine use, diabetes, depression, total sleep time, wake time after sleep onset, OSA, follow-up duration and sampling weight.
Results: The incidence of hypertension was significantly lower in subjects with short SL (i.e., ≤ 7 minutes; 8.8%) as compared to those with intermediate SL (i.e., 8-30 minutes; 17.3%) and long SL (i.e., ≥ 30 minutes; 19.1%), respectively (both $p< 0.05$). There was a negative association between short sleep latency and incident hypertension after controlling for age, BMI, sex, race, smoking, alcohol use, caffeine use, diabetes, depression, total sleep time, wake time after sleep onset, OSA, follow-up duration and sampling weight. (OR=0.45; 95%CI=0.24-0.86; p=0.02).
Conclusion: This study confirms and expands our previous findings that physiologically sleepy individuals without a complaint of excessive daytime sleepiness are protected of hypertension risk. It appears that asymptomatic increased sleep propensity is not perceived as stressful or interfering with subjects' daily function and possibly is associated with lower activity of the stress system (i.e., sympathetic system and HPA axis). Additional studies are needed to explore further the psychological and physiological profile of these individuals.

DISCREPANCY BETWEEN CLINICAL PHENOTYPING AND ICSD-3 CRITERIA CONTRIBUTES TO MISDIAGNOSIS IN CENTRAL DISORDERS OF HYPERSOMNOLENCE

Jinu Johnson[1], Matheus Lima Diniz Araujo[2], James Bena[3], Noah Andrews[1], Katherine Beshears[1], Nancy Foldvary-Schaefer[2]

[1] Cleveland Clinic, [2] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [3] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH

Introduction: Central Disorders of Hypersomnolence (CDH) are classified primarily by polysomnography-multiple sleep latency test (PSG-MSLT). Lack of biomarkers, variable MSLT results in disorders other than narcolepsy type 1 (NT1) and inaccessibility of 24-hr PSG and actigraphy in most U.S. sleep centers contribute to misdiagnoses. We compared CDH diagnoses by sleep expert clinical phenotyping and ICSD-3 criteria to estimate the magnitude of potential misdiagnosis in a U.S. quaternary care sleep center.
Methods: This retrospective study included patients evaluated for hypersomnolence at Cleveland Clinic (January 2003

- August 2024). Patient with a clinical diagnosis of NT1, NT2, and IH based on sleep physician clinical history were included. ICSD-3 diagnoses were based on PSG/MSLT SOREMPs and MSLT mean sleep latency (MSL): narcolepsy: MSL< 8 min + >2SOREMPs; IH: MSL< 8 min + < 2SOREMPs. Those not meeting ICSD-3 criteria were considered undiagnosed. ICSD-3 diagnoses were analyzed between clinical groups using ANOVA, Kruskal-Wallis, and Pearson chi-square tests, followed by pairwise comparisons.

Results: Of 489 patients (33.6±13.6 yrs, 78.7% female), 72(14.7%) had NT1, 121(24.7%) NT2, and 296(60.5%) IH. More NT1 and NT2 patients had >2 SOREMPs than IH (NT1-81.9%, NT2-71.1%, IH-12.4%, p< 0.001). MSL was longer in IH than narcolepsy (IH-8.1±4., NT1-4.9±3.8, NT2-5.4±3.2 min, p< 0.001). Percentage agreement between ICSD-3 and clinical diagnoses was 100% for NT1, but lower for NT2 and IH (NT2-61.2%,IH-58.1%, p< 0.001). Among clinical NT1, 26.4% did not meet PSG-MSLT criteria. Among clinical NT2, 38.9% had different ICSD-3 diagnoses: 24% reclassified as IH and 14.9% were undiagnosed. Among clinical IH, 41.9% had different ICSD-3 diagnosis: 0.6% reclassified as NT2 and 41.2% were undiagnosed. Overall, 28.6% of CDH patients diagnosed based on clinical criteria were not diagnosed as CDH by ICSD-3 criteria due to lack of sleep laboratory findings.

Conclusion: This study showed diagnostic discrepancies between clinical phenotyping and ICSD-3 criteria for NT2 and IH, while NT1 diagnoses aligned. Over a quarter of clinically diagnosed patients remained undiagnosed by ICSD-3 criteria. These findings illustrate limitations of current diagnostic criteria and the need for to improve diagnostic accuracy in the evaluation of CDH.

INSIGHTS FROM PHYSICIAN NOTES INTO MANAGEMENT OF PATIENTS WITH NARCOLEPSY TYPE 2 AND IDIOPATHIC HYPERSOMNIA (IH)

Anne Morse[1], Phyllis Zee[2], Bonnie Bui[3], Katie Russell[3], Jeremy Adams[3], Amy Duhig[4], Stephen Crawford[4], Phani Veeranki[3], Yelena Pyatkevich[4], Dana Teltsch[4]

[1] Geisinger Commonwealth School of Medicine Geisinger Medical Center Janet Weis Children's Hospital,, [2] Northwestern University Feinberg School of Medicine, [3] Optum Life Sciences, [4] Takeda Development Center Americas, Inc.

Introduction: Narcolepsy and idiopathic hypersomnia (IH) are associated with diagnostic delays, comorbidities, and disease burden. Understanding how healthcare providers diagnose and treat patients could inform more timely and effective strategies for diagnosis and patient management. This study utilized physician-recorded electronic health record (EHR) clinical notes linked to claims data to understand patient management, symptoms and concerns, clinical features, and diagnostic journey of patients with narcolepsy type 2 (NT2) or IH in a large real-world US population.

Methods: Medical notes (n=400) for 70 patients sampled from a large cohort (n=51,548 patients) diagnosed with NT2 or IH were qualitatively reviewed utilizing Optum's Market Clarity integrated claims and EHR database based on data from January 01, 2014, to December 31, 2021. A grounded theory qualitative methodology has been applied to develop a schema of clinical terms and concepts and to summarize the frequencies of clinical terms. Classification categories included symptoms, diagnosis, testing and procedures, treatments, comorbidities, non-pharmacological management, and social/family/work factors. Patient narratives were described. Results were contextualized in the larger population.

Results: Patients median age was 39 years and 81% were female. Narcolepsy/IH-specific symptoms were documented for 70% of patients (excessive daytime sleepiness: 59%, disturbed nighttime sleep: 37%); 84% reported narcolepsy/IH-related symptoms (most commonly depression: 51% and anxiety: 46%), and 94% reported symptoms of any kind. Diagnostic/sleep evaluations were reported for 49% of patients, most commonly the multiple sleep latency test (36%) or polysomnography (30%). Treatments were recorded for 83% of patients; 77% with any narcolepsy-specific treatment (modafinil [31%], amphetamine-dextroamphetamine [26%], armodafinil [24%], methylphenidate HCI [20%], and oxybates [11%]); 53% with non-pharmacological measures, including exercise (30%), sleep hygiene (24%), weight management (23%), caffeine use (23%), and dietary management (21%). Social/family/work factors were rarely documented (overall: 16%, work productivity loss: 11%, and social support ≤4%), but documented more often for patients with treatment changes (overall: 26%; work productivity loss: 19%).

Conclusion: Physician notes of patients with NT2/IH inconsistently reported symptoms, diagnostic evaluations and treatments. Social/family/work factors were rarely reported. These findings are indicative of under-recognition of the full NT2/IH patient burden and highlight the need for improved patient management.

CORRELATION BETWEEN EPWORTH SLEEPINESS SCALE SCORES AND MEAN SLEEP LATENCIES: A MULTIPLE PATHOLOGY CROSS-SECTIONAL ANALYSIS

Ricardo Concepcion[1], Shaheryar Usman[1], Adrienne DaGue[1], Amira Dalmazio[1], Calli Bertschy[1], Lilit Sargsyan[1], Reeba Mathew[1], Ruckshanda Majid[2]

[1] University of Texas Health Science Center at Houston, [2] McGovern Medical School UT Health

Introduction: The correlation between the Epworth Sleepiness Scale (ESS) and mean sleep latency (MSL) on a Multiple Sleep Latency Test (MSLT) has been the subject of extensive research in sleep medicine. Higher ESS scores are often associated with shorter sleep latencies on MSLT. However, this finding has not been consistent in all clinical contexts. We performed a cross-sectional analysis of MSLT studies, testing this correlation while taking into consideration different final sleep diagnoses.

Methods: MSLTs performed at Memorial Hermann Sleep Disorders Center at Texas Medical Center between November 2020 and November 2024 were reviewed. Exclusion criteria included insufficient polysomnographic data quality or unavailable final report. Demographic and polysomnographic data were collected to include the MSLT findings and documentation of the final diagnosis. A correlation between the ESS scores and the MSLs was made with linear regression analysis (using a 95% confidence interval), first as an entire group followed by only those studies that met the criteria for narcolepsy (type 1 or 2).

Results: 33 studies were identified, and 22 studies were included for analysis. The average age was 25.7 years (SD +/- 11.4), comprising 23% males and 77% females. The average ESS score was 15.4 (SD +/- 4.9) and the average sleep time on the overnight PSG was 422 minutes (SD +/- 61.4). The prevalence of narcolepsy was 23%. The R2 value when comparing the ESS and MSL for the entire group was only 2%. When performing the same analysis on the studies that were diagnostic of narcolepsy, the R2 was 82% (p-value 0.03) demonstrating a strong correlation. The average ESS in this subgroup was 17.2 (SD +/- 4.9).
Conclusion: When patients are referred for an MSLT, their ESS score is typically known. We found that patients diagnosed with narcolepsy had a higher correlation between their ESS score and the mean sleep latency on the MSLT compared to those who did not get a narcolepsy diagnosis. Thus, the ESS score is a strong predictor of a positive diagnosis of narcolepsy on an MSLT.

POSTURAL ORTHOSTATIC TACHYCARDIA SYNDROME IN IDIOPATHIC HYPERSOMNIA

AnnaClaire Osei-Akoto[1], David Rye[1], Kendall Nichols[1], Mitchell Miglis[2], Lynn Trotti[1]
[1] Emory University School of Medicine, [2] Stanford University

Introduction: Idiopathic hypersomnia (IH) is a chronic neurologic sleep disorder causing excessive daytime sleepiness despite normal or prolonged sleep durations, often impairing daily functioning. Autonomic symptoms are common in people with IH. Postural orthostatic tachycardia syndrome (POTS), a form of autonomic dysfunction, is marked by symptomatic increased heart rate upon standing. This study aimed to investigate whether IH with comorbid POTS represents a distinct subtype of IH based on symptoms, signs, and treatment responses.
Methods: This retrospective study analyzed clinical data from IH patients who had (POTS+) or had not (POTS-) been diagnosed with POTS. We compared clinical, demographic, and sleep features between POTS+ and POTS−, employing Chi-square, Fisher's exact test, or t-tests, as indicated.
Results: Among 173 patients with idiopathic hypersomnia (IH), 75% were female, with a mean age of 43.1±15.3 years. Of these, 22 (12.7%) also had POTS. POTS+ patients were younger (38.3±10.7 vs. 43.8±15.8 years, p=0.04); gender distribution did not differ. At baseline, POTS+ patients had similar Epworth scores (16.3±4.9 for POTS+ vs 14.9±4.9 for POTS-, p=0.49), Functional Outcomes of Sleep scores (FOSQ, 9.4±4.0 vs 11.97±4.0, p=0.053), average weekday sleep durations (9.6±2.56 vs. 9.03±2.25 hours, p=0.46), and proportion with difficulty waking in the morning and cognitive symptoms. PSG sleep efficiency (89.3%±6.17% vs. 85.4%±10.63%, p=0.06), total sleep time (450.6±75.9 vs 424.2±80.9, p=0.27), and MSLT mean sleep latency (5.28± 2.53 vs 4.98±2.74, p=0.67) did not differ by group. Comorbidities such as Ehlers-Danlos syndrome (22.7% vs 1.3%, p=0.0004), fibromyalgia (22.7% vs 5.3%, p=0.01), and headaches (77.27% vs. 42.3%, p=0.002) were more common in POTS+, without significant differences for Hashimoto's or mood disorders. The POTS+ group was more likely to have side effects from amphetamine-dextroamphetamine (58.3% vs 16.1%, p=0.004) and methylphenidate (41.7% vs 11.9% p=0.03) but not modafinil, armodafinil, solriamfetol or oxybates.
Conclusion: People with IH and comorbid POTS have similar IH symptom severity and PSG/MSLT findings to those with IH without POTS. However, those with POTS are more likely to also have comorbid Ehlers-Danlos, fibromyalgia, and headache. The presence of POTS may signal an increased risk of side effects with traditional psychostimulants used for treating IH.

AI-ENABLED NARCOLEPSY TYPE-1 SCREENING WITH PPG: A PROOF-OF-CONCEPT STUDY

Chris Fernandez[1], Sam Rusk[1], Yoav Nygate[1], Tom Vanasse[1], Matt Sprague[1], Jan Wodnicki[1], Arturo Pina[2], Enrique Torres[2], John Bailey[2], Sidhartha Dasgupta[2], Omavi Bailey[2], Nathaniel Watson[3]

Introduction: While highly specific, the current diagnostic paradigm for type 1 narcolepsy (NT1), defined largely by sleep-onset REM period event (SOREMP) observations in PSGs and MSLTs, remains limited by its NT1 disorder sensitivity and procedural complexity. Machine learning methods have shown promise to accurately detect NT1 from PSG via comprehensive assessment of EEG biomarkers. Photoplethysmography (PPG), used for home sleep apnea testing, can determine sleep stages through machine learning without EEG. We explore whether such PPG-based sleep stages are robust enough to detect sleep architectural abnormalities specifically associated with NT1.
Methods: The dataset included a total of N=110 patients, N=35 positive NT1 patients and N=75 negative NT1 subjects. The negative NT1 patients were composed of N=61 confounding hypersomnolence disorders and N=14 negative controls. We evaluated four separate input data types, trained with stratified 10-fold cross-validation with supervised random forest machine learning (ML) models for NT1 detection. The following 4 input data types are features derived from ML models applied for automated sleep staging of EEG and PPG signals extracted respectively from overnight PSG: EEG-based sleep stage report indices (EEG-Stage), PPG-based sleep stage report indices (PPG-Stage), EEG-based hypnodensity derived features (EEG-Hypno), and PPG-based hypnodensity derived features (PPG-Hypno). To measure performance, we calculated the area under the receiver operating characteristic curve (ROC-AUC) for each model and performed a feature importance analysis for all models.
Results: ROC-AUC values were 0.889 and 0.843 for the EEG-Hypno and PPG-Hypno models, respectively. Furthermore, ROC-AUC values were 0.813 and 0.842 for the EEG-Stage and PPG-Stage models. Feature importance analyses for the EEG-Stage model revealed the highest-ranking features: sleep latency, total N3 time, N3 prevalence, total sleep time, and REM latency. Feature importance analysis for the PPG-Stage model revealed these highest-ranking important features comparatively: sleep latency, REM latency, total N3 time, and N3 prevalence.
Conclusion: ML methods automatically detected NT1 in PPG with comparable degrees of accuracy to EEG. The PPG sensor offers a simple and accessible modality in ecologically valid home settings. This method demonstrates potential extensions for screening of NT1 in HSATs, whereby patients with

NT1-associated sleep architectural characteristics may be flagged for further hypersomnolence disorders evaluation and testing.

IMPACT OF NARCOLEPSY ON MORTALITY AMONG PATIENTS WITH CARDIOVASCULAR DISEASE. A PROPENSITY SCORE MATCHED ANALYSIS

Jasmine Khatana[1], Rony Berbara[2], Vidya Krishnan[3]
[1] UH Cleveland Medical Center/ Case Western Reserve University, [2] UH Cleveland Medical Center, [3] The MetroHealth System

Introduction: Studies have shown patients with narcolepsy may be at increased risk of cardiovascular disease (CVD) and metabolic comorbidities, which in turn increase the risk of cardiovascular-related morbidity and mortality. However, there is limited data on the impact of narcolepsy on mortality among patients with cardiovascular disease.
Methods: We analyzed data from TrinetX database, a global federated health research network providing access to electronic medical across large healthcare organizations (HCOs). This report was run on the subset of 103 HCOs, a network called Research. We included all adult patients with a diagnosis of one of the following: ischemic heart disease, atherosclerotic heart disease, heart failure or cerebrovascular disease, and grouped them based on the presence or absence of narcolepsy. Groups were compared for comorbid conditions - diabetes mellitus, pulmonary hypertension, overweight and obesity, obstructive lung disease, sleep apnea, periodic limb movement disorders. A propensity score matching was done for age, sex and all of the comorbid conditions and then compared for mortality rates as an outcome variable.
Results: A total of 11,223,566 patients with CVD were included in this study, of which 15,281 patients had a diagnosis of narcolepsy. Patients with CVD and narcolepsy were significantly younger, more often female and had higher proportion of patients with all the comorbid conditions. After propensity score matching was done there were 14,789 patients in both groups for comparison. The adjusted mortality rate was significantly higher among patients with CVD and narcolepsy (15.16% vs 14.32%, P = 0.04).
Conclusion: Our study shows significant differences in co-morbidities in patients with CVD with and without narcolepsy, and with propensity matching, mortality is higher in the study patients with narcolepsy. Further analyses in this study will compare narcolepsy with and without cataplexy as well as the effects of medication use on mortality.

CHARACTERISTICS OF PATIENTS WITH A CO-MORBID NARCOLEPSY DIAGNOSIS ADMITTED TO U.S. HOSPITALS: 20-YEAR TREND

Younghoon Kwon[1], Leah Matthew[1], William Healy[2], Yeilim Cho[3], Hayden Leung[4], Ji Yoo[4], Yonsu Kim[5], Clara Farrehi[1]
[1] University of Washington, [2] Medical College of Georgia, [3] University of Washington, School of Medicine, Department of Psychiatry and Behavioral Sciences, [4] Kirk Kerkorian School of Medicine at UNLV, [5] School of Public Health, University of Nevada, Las Vegas

Introduction: Patients with narcolepsy are at risk for adverse health consequences, which may make them more vulnerable to hospital admissions. Moreover, narcolepsy can complicate the management of patients with other primary illnesses. There is scarce information about the characteristics of adult patients with narcolepsy who are admitted to hospital. The objective of the study was to describe a nationwide trend of patient characteristics and healthcare utilization of hospitalized adult patients with a comorbid narcolepsy.
Methods: We analyzed the National Inpatient Sample over 20-year period between 2002 and 2021. Adults (> 18 years) with diagnosis of narcolepsy were identified based on the ICD 9th/10th revisions. High-risk mortality was defined as the All-Patient Refined Diagnosis-Related Group (APR-DRG) Risk of Mortality ("rating of 3-4 subclasses). Total charges were the main measurement of health care utilizations and were adjusted by applying for the Consumer Price Index (CPI) rate since 2012. Overall trend of 5-year period (year 2002-2006, 2007-2011, 2012-2016, 2017-2021) over 20-year period was calculated by ANOVA.
Results: A total of 49,610 hospital admissions were identified over 20-year period. Mean age was 57.6 (17.5) years old and female patients consisted of 61%. The most common race/ethnic group was White (71%) followed by Others (15%), and Black (10%). Hispanics (2.8%) and Asians (0.5%) were underrepresented. Over the period of 20-year period, there was a trend of increasing number of hospitalized patients with comorbid narcolepsy (n=9215, 11807, 11071, 14679, p< 0.0001). Mean age decreased over time (58.8 years, 57.7, 57.6, 56.8, p< 0.0001). The proportion of female (58.1%, 60.2, 61.7, 62.1, p< 0.0001) and White race (57.7%, 65.3, 76.2, 79.7, p< 0.0001) patients with narcolepsy increased over time whereas Other race decreased over time (32.3%, 22.6, 9.2, 5.0, p< 0.0001). The proportion of high-risk mortality patients with narcolepsy fluctuated but generally increased (22.2%, 30.7, 22.8, 33.9). Mean total charges showed uptrends from ($20,583, 30469, 40905, 53318, p< 0.0001).
Conclusion: There is a trend of decreasing age, more female representation and a higher complexity of patients with narcolepsy admitted to US hospital over the past two decades. There appears to be underrepresentation of Hispanics and Asian races, implying underdiagnosis of narcolepsy.

OPTIMIZATION OF STANFORD CATAPLEXY QUESTIONNAIRE SCORING FOR NARCOLEPSY DETECTION

Giorgio Camillo Ricciardiello Mejia[1], Andreas Brink-Kjær[2], Emmanuel Mignot[3]
[1] Mignot Laboratory, [2] Technical University of Denmark, [3] Stanford University

Introduction: Narcolepsy Type 1 (NT1) is a chronic and disabling neurological disorder characterized by excessive daytime sleepiness and cataplexy—episodes of sudden loss of muscle tone triggered by emotions. Accurate diagnosis in large-scale studies remains challenging due to NT1's low prevalence (~30 per 100,000 adults) and reliance on resource-intensive clinical assessments. This study used XGBoost to increase specificity for a self-administered narcolepsy questionnaire developed at the Stanford Sleep Disorders Clinic, and that has been administrated to 180,000 participants in the UK Biobank.

Methods: We analyzed questionnaire responses from 1,358 adult participants (388 with narcolepsy cataplexy, 970 with other sleep disorders all recruited at the Stanford Sleep Clinic or by Stanford Staff), The questionnaire assessed demographics (age, sex), muscle weakness in specific body parts (jaw, knees, head, hands, speech), emotional triggers (laughter, anger, joking), and Epworth Sleepiness Scale (ESS) scores. An XGBoost classifier was trained and validated using 5-fold stratified cross-validation. To further reduce false positives and enhance specificity, a veto rule was applied during the validation phase: predictions of NT1 were vetoed when the DQB1*06:02 biomarker was negative, given its strong association with NT1.
Results: The study demonstrates high specificity (99.0%) and moderate sensitivity (82.5%) on the validation folds when excluding HLA biomarkers. Application of the HLA veto rule further improved specificity (99.7%) while maintaining the sensitivity (82.7%). At a prevalence of 30 per 100,000 adults, the Positive Predictive Value (PPV) improved from 2.4% to 7.6% before and after veto, respectively. Key features contributing to performance included laughing, head weakness, and joking as reported triggers for cataplexy and very high levels of ESS (≥17).
Conclusion: Our approach shows high specificity for a questionnaire screening tool on a validation set, which is critical for diagnosing narcolepsy given its low prevalence of approximately 0.03% in the general population. This approach provides a scalable and cost-effective screening tool for identifying NT1 cases in large-scale population samples. We anticipate that adding actigraphy and genome wide association polygenic risk score, available in 100,000 of these subjects in the UK biobank, will raise specificity to a level that will permit identification of the 30 cases within the 100,000 subjects.

IMPAIRED ATTENTION IN PEDIATRIC NARCOLEPSY TYPE 1 USING PSYCHOMOTOR VIGILANCE TASK

Elizabeth Montesano[1], Bo Zhang[1], Kiran Maski[1]
[1] Boston Children's Hospital

Introduction: Decreased attention is common in pediatric Narcolepsy Type 1 (NT1). However, objective data assessing attention dysfunction in this population are limited. The psychomotor vigilance task (PVT) has been used to measure attention in adults with central disorders of hypersomnolence but understudied in pediatric NT1. In this study, we compare PVT metrics between pediatric NT1 patients and healthy controls (HC) in the evening and morning with a between interval of nocturnal sleep measured by in-lab polysomnography (PSG). We hypothesized that attention dysfunction would be worse in NT1 vs HC in evening and morning and both sessions would be associated with self-reported sleepiness.
Methods: 28 pediatric NT1 participants (mean age 15.9) and 27 healthy controls (mean age 13.6) completed 3-minute PVT testing in the evening before PSG and upon awakening in the morning. Before each PVT, participants rated their sleepiness on 3-item visual analog scale. We compared PVT metrics between NT1 and HC, adjusting for age (including non-linear effects) and gender. Outcomes included mean 1/reaction time (RT), lapses (RT ≥ 500 ms), lapses355 (RT ≥ 355 ms), and slowest 10% 1/RT.
Results: NT1 participants showed reduced attention across various PVT metrics vs. HC. In the evening, mean 1/RT was significantly worse in NT1 participants (p =.008) but we found no significant group differences in lapses, lapses355, or slowest 10% 1/RT. In the morning, NT1 participants performed significantly worse than controls on mean 1/RT (p =.002), lapses355 (p <.001), and slowest 10% 1/RT (p =.004). Age but not gender significantly predicted all PVT measures (p <.01). Contrary to our hypothesis, none of the PVT measures were associated with self-reported sleepiness.
Conclusion: Pediatric NT1 participants exhibit objective and significantly impaired objective attention vs HC. Slower mean reactions times were evident in evening and morning but lapses and slowest reactions times were more evident in the morning. Given that self-reported sleepiness did not predict PVT outcomes, it is possible other narcolepsy features such as disrupted nighttime sleep play contributing roles. Overall, the PVT could be useful for assessing attention in children/adolescents with NT1 in clinical and school based settings.

EFFECTS OF ONCE-NIGHTLY SODIUM OXYBATE ON APNEA-HYPOPNEA INDEX: POST HOC ANALYSIS FROM THE REST-ON CLINICAL TRIAL

Richard Bogan[1], Bruce Corser[2], Thomas Stern[3], Akinyemi Ajayi[4], Brian Abaluck[5], Jennifer Gudeman[5]
[1] Bogan Sleep Consultants, [2] Sleep Management Institute, [3] Advanced Respiratory and Sleep Medicine, PLLC, [4] Florida Pediatric Research Institute, [5] Avadel Pharmaceuticals

Introduction: Sodium oxybate (SXB) is a central nervous system depressant used to treat narcolepsy and has the potential to cause respiratory depression. Registrational trials of SXB have generally excluded patients with respiratory depression, including those with an apnea hypopnea index (AHI) >15. This post hoc analysis of REST-ON evaluates the effect of once-nightly SXB (ON-SXB) compared to placebo on AHI in individuals with narcolepsy with either no sleep apnea or mild sleep apnea.
Methods: REST-ON (NCT02720744) was a phase 3, double-blind, placebo-controlled randomized clinical trial. Participants (age ≥16 years) with narcolepsy and AHI < 15 were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2–3, 6 g; weeks 4–8, 7.5 g; weeks 9–13, 9 g) or placebo. AHI was measured using polysomnography at baseline and weeks 3, 8, and 13, and analyzed post hoc. Adverse drug reactions (ADRs) were assessed at each visit.
Results: Respective mean (min, max) AHI values were similar for the ON-SXB (n=97) and placebo groups (n=93) at baseline (2.7 [0, 15] and 2.8 [0, 13]), week 3 (0.1 [0, 5] and 0.1 [0, 2]), and week 8 (0 [0, 0] and 0 [0, 0]). At week 13, mean (min, max) AHI values were 0 (0, 0) and 0.2 (0, 10) in the ON-SXB and placebo groups, respectively. Least squares mean (LSM) change from baseline in AHI with ON-SXB and placebo was –3.0 and –2.9, respectively, at week 3 (LSM difference [LSMD; 95% CI], –0.11 [–0.46 to 0.24]; P=0.522); –3.0 and –2.9, respectively, at week 8 (LSMD [95% CI], –0.11 [–0.46 to 0.23]; P=0.518); and –3.0 and –2.9, respectively, at week 13 (LSMD [95% CI], –0.12 [–0.46 to 0.23]; P=0.515). In the safety population, 1 (0.9%) and 1 (1.0%) participant in the ON SXB and placebo arms, respectively, experienced ADRs of sleep apnea, and 1 (0.9%) participant receiving ON-SXB reported snoring; all were mild or moderate in severity.

Conclusion: Treatment with ON-SXB was not associated with worsened AHI at any tested dose. ON-SXB was well-tolerated, as the reported respiratory-related ADRs were minimal, and mild or moderate in severity.

IMPACT OF AXS-12 ON SYMPTOM SEVERITY AND FUNCTIONAL IMPAIRMENT IN NARCOLEPSY: RESULTS FROM THE PHASE 3 SYMPHONY TRIAL

Michael Thorpy[1], Lois E. Krahn[2], Richard Bogan[3], Bruce Corser[4], Colin Shapiro[5], Dan Chen[6], Angad Chhabra[6], Eileen Leary[7], Herriot Tabuteau[6]

[1] Albert Einstein College of Medicine, [2] Mayo Clinic College of Medicine, Department of Psychiatry and Psychology, [3] Bogan Sleep Consultants, [4] Sleep Management Institute, [5] Toronto Western Hospital, Department of Psychiatry, Sleep and Alertness Clinic, Sleep Research Laboratory, [6] Axsome Therapeutics, Inc, [7] Axsome Therapeutics, Inc.

Introduction: Narcolepsy is a chronic neurologic condition associated with severe symptom burden, impaired functioning and reduced quality of life. Patients commonly report comorbid mood disorders. AXS-12 (reboxetine) is a selective norepinephrine reuptake inhibitor and cortical dopamine modulator under investigation for the treatment of narcolepsy. In the Phase 3 SYMPHONY trial, AXS-12 met the primary endpoint, a statistically significant reduction in weekly cataplexy attacks from baseline to Week 5 versus placebo. Here, we report secondary endpoints assessing symptom severity, daily functioning, and mood.
Methods: SYMPHONY was a randomized, double-blind, placebo-controlled trial in patients with narcolepsy type 1 (NT1). Participants (15-75 years) were randomized 1:1 to AXS-12 or placebo for 5 weeks. Stable, concurrent modafinil/armodafinil use was allowed. Secondary endpoints included: the Clinical Global Impression of Severity (CGI-S) for narcolepsy, the Functional Outcomes of Sleep Questionnaire short version (FOSQ-10), and the EuroQol 5-Dimension 5-Level (EQ-5D-5L) questionnaire anxiety/depression domain.
Results: Ninety participants were enrolled. At baseline, mean (SD) CGI-S for narcolepsy score was 5.2 (1.0) in the AXS-12 arm and 4.9 (1.0) in the placebo arm. AXS-12 led to a significant reduction versus placebo in CGI-S for narcolepsy at Week 5 (LS mean difference [95% CI]=0.72 [0.29, 1.16]; p=0.001). At baseline, mean FOSQ-10 total score was 11.1 (3.1) in the AXS-12 arm and 11.6 (3.2) in the placebo arm. AXS-12 led to a statistically significant improvement from baseline to Week 5 in FOSQ-10 total scores compared to placebo (1.66 [0.51, 2.82], p=0.005). At baseline, 47.8% of participants in the AXS-12 arm and 45.5% in the placebo arm reported anxiety/depression (EQ-5D-5L). A numerically greater proportion of participants achieved improvements on this domain with AXS-12 (55.0%) versus placebo (31.6%) at Week 5 (p=0.146).
Conclusion: AXS-12 demonstrated significant reductions in clinical impressions of narcolepsy symptom severity. Functional impairment due to EDS was also significantly reduced, in-line with previously reported improvement in clinician-rated assessments. Anxiety and depression-related symptoms showed trends favoring AXS-12. Combined with prior findings on cataplexy and cognitive improvements, these results highlight the potential of AXS-12 as a therapeutic option addressing multiple symptoms of narcolepsy which affect QoL and functioning.

RESIDUAL SYMPTOM BURDEN IN PATIENTS WITH NARCOLEPSY SATISFIED WITH TREATMENT: SUBGROUP ANALYSIS FROM THE CRESCENDO SURVEY

Michael Thorpy[1], Amy Kant[2], Keith Harper[2], Graham M.L. Eglit[3], Samantha Floam[3], Herriot Tabuteau[3]

[1] Albert Einstein College of Medicine, [2] Narcolepsy Network, [3] Axsome Therapeutics, Inc

Introduction: People living with narcolepsy type 1 (narcolepsy with cataplexy [NT1]) often experience breakthrough symptoms, including excessive daytime sleepiness (EDS), cataplexy, and cognitive difficulties, even when taking multiple medications. The CRESCENDO survey examined the patient experience in patients with NT1, providing a detailed characterization of symptom burden. Here we report a subgroup analysis of respondents reporting overall satisfaction with their current pharmacologic treatment to quantify residual symptoms in this population.
Methods: The CRESCENDO survey was conducted from October-December 2023 in adults diagnosed with NT1 who were currently taking an FDA-approved medication for the condition. The survey included assessments of symptom burden and impact on quality of life and was developed and executed in partnership with the patient advocacy organization Narcolepsy Network. A third-party research firm conducted the survey and ensured patient privacy. This subgroup analysis included respondents indicating satisfaction with their current narcolepsy treatment on a categorical scale.
Results: Of 203 respondents, 60.6% were taking multiple classes of narcolepsy medication. A majority (63.1%) reported satisfaction with their current treatment(s), 20.2% were neutral, and 16.7% were dissatisfied. Common reasons for satisfaction included symptom improvement (70%) and ability to complete more activities (37%). Of those satisfied, 71.9% reported breakthrough cataplexy (10.9% experienced attacks once per day or more, and 22.8% experienced attacks multiple times per week). Additionally, 53.3% reported that cataplexy burdens their professional lives, 49.3% their social lives, and 38.7% their day-to-day lives. Other commonly reported breakthrough symptoms were EDS (89.1%), brain fog (73.4%), and difficulty concentrating (71.9%). Depression was reported by 67.2% of satisfied respondents (Patient Health Questionnaire-8; score ≥5). Cognitive complaints were reported by 64.8% of participants (British Columbia Cognitive Complaints Inventory, score ≥5).
Conclusion: Respondents who reported overall satisfaction with their current NT1 treatment regime continued to experience substantial and diverse symptoms. These findings reveal a disconnect between patient-reported treatment satisfaction and the degree of symptom resolution, which may reflect limitations of current therapies, underreporting of ongoing symptoms, or diminished patient expectations. Overall, the results of this study suggest the need for enhanced assessment of residual symptoms and novel approaches to treating narcolepsy.

EFFECTS OF THE OREXIN 2 RECEPTOR AGONIST ALKS 2680 ON QEEG IN PATIENTS WITH NARCOLEPSY AND IDIOPATHIC HYPERSOMNIA

Meera Modi[1], Brendon Yee[2], Julia Chapman[3], Angela D'Rozario[2], Roman Rosipal[4], Leonardo Trejo[4], Ge Ruigt[4], Ronald Grunstein[5], Bhaskar Rege[1], Daniel Smith[1]

[1] Alkermes, Inc., [2] The Woolcock Institute of Medical Research, [3] CIRUS, Centre for Sleep and Chronobiology, Woolcock Institute of Medical Research, Macquarie University, [4] Pacific Development and Technology, LLC, [5] Woolcock Institute of Medical Research, Macquarie University CPC-RPAH Clinic, Royal Prince Alfred Hospital and University of Sydney, Sydney, Australia

Introduction: ALKS 2680 is a highly potent, orally bioavailable, and selective orexin 2 receptor agonist being developed as a once-daily treatment for narcolepsy and idiopathic hypersomnia (IH). Quantitative electroencephalography (qEEG) was conducted as an exploratory measure in a phase 1b study to evaluate the central pharmacodynamic effects of ALKS 2680 in patients with narcolepsy type 1 (NT1), narcolepsy type 2 (NT2), and IH.

Methods: In a randomized, double-blind, placebo-controlled study, single doses of ALKS 2680 (1, 3 and 8 mg for NT1; 5, 12 and 25 mg for NT2 or IH) and placebo were evaluated in a four-way crossover design following two-week washout from prior medications. At baseline and on dosing days, the Maintenance of Wakefulness Test (MWT) and Karolinska Sleepiness Scale (KSS) were administered at five post-dose timepoints. During each MWT assessment, three EEG epochs were extracted for oscillatory and fractal spectral qEEG analysis corresponding to test initiation, sleep onset, and test termination. Effects on baseline-corrected qEEG spectra were analyzed using a mixed-models repeated measures approach.

Results: In the combined cohort of patients with NT1 (N=10), NT2 (N=9), or IH (N=8), ALKS 2680 decreased amplitude in bands associated with sleepiness at the central midline region: oscillatory delta (least squares mean difference (LSMD), high dose vs placebo: −0.05μV/Hz; standard error [SE], 0.01; p< 0.001) and oscillatory theta (LSMD high dose vs placebo: −0.09μV/Hz; SE 0.02; p< 0.001). ALKS 2680 also increased amplitude in bands associated with wakefulness/vigilance: oscillatory beta3 (LMSD high dose vs placebo: 0.05μV/Hz; SE, 0.01; p< 0.001) and fractal gamma (LMSD high dose vs placebo: 0.03μV/Hz; SE, 0.01; p=0.001). The effects of ALKS 2680 on spectral parameters were maintained for up to 10 hours at the high dose. Decreased low frequency amplitude and increased high frequency amplitude was associated with higher sleep latency on MWT (eg. central midline delta×MWT: r=−0.359, p=0.001) and lower scores on the KSS (eg. frontal right beta3×KSS: r=−0.366, p< 0.001).

Conclusion: ALKS 2680 demonstrated statistically significant wake-promoting effects on qEEG spectral parameters in patients with NT1, NT2, and IH. These effects were correlated with objective and subjective improvements in wakefulness/alertness by ALKS 2680 (ie, MWT and KSS).

EFFECTIVENESS AND SAFETY OF LOW-SODIUM OXYBATE IN PARTICIPANTS WITH NARCOLEPSY: RESULTS FROM THE DUET STUDY

Logan Schneider[1], Chad Ruoff[2], David Plante[3], Deborah Nichols[4], Teresa Steininger[4], Douglas Fuller[4], M. Kirby[4], Sarah Akerman[4], Jessica Alexander[4], Marisa Whalen[4], Alyssa Cairns[5]

[1] Stanford University Center for Sleep Sciences and Medicine, [2] Mayo Clinic, [3] University of Wisconsin–Madison, [4] Jazz Pharmaceuticals, [5] Former employee of BioSerenity

Introduction: Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) is a phase 4, prospective, multicenter, single-arm, multiple-cohort, open-label study (NCT05875974) assessing the effectiveness of low-sodium oxybate (LXB; Xywav®) treatment on daytime and nighttime symptoms in participants with narcolepsy (type 1 [NT1] or 2 [NT2]) or idiopathic hypersomnia. Data presented are from the narcolepsy cohort.

Methods: DUET included a screening period (with 2-week washout for current oxybate users), 8-day baseline (BL) period, 2- to 8-week LXB titration period, 2-week stable-dose period, 8-day end-of treatment (EOT) period, and 2-week safety follow-up. The primary endpoint was change in Epworth Sleepiness Scale (ESS) score from BL to EOT. Key secondary endpoints for the narcolepsy cohort included change in polysomnography parameters: total shifts from deeper to lighter sleep stages, stage N3 sleep duration (minutes), and number of awakenings. Additional endpoints included Patient Global Impression of Change (PGIc)–overall narcolepsy disease. Primary and key secondary endpoints were controlled for multiplicity with sequential testing; other P-values are considered nominal.

Results: Fifty-five narcolepsy participants enrolled and were dosed with LXB (NT1, n=26; NT2, n=29); 13 transferred to another cohort and 34 were completers (NT1, n=16; NT2, n=18). Enrolled participants were mostly female (72.7%) and White (80.0%); mean (SD) age was 33.4 (12.9) years (NT1=34.6 [12.6]; NT2=32.4 [13.2]). For completers, least-squares mean (LSM) (SE) changes in ESS score were −7.7 (0.9), P<.0001, overall; NT1=−6.5 (1.4), P<.0001; NT2=−8.8 (1.3), P<.0001. Compared with BL, sleep architecture at EOT showed fewer deeper to lighter sleep stage shifts (LSM [SE]: −13.1 [2.9], P<.0001, overall; NT1=−13.9 [4.3], P=0.0029; NT2=−12.3 [4.1], P=0.0050); increased stage N3 sleep (minutes) (45.0 [8.8], P<.0001, overall; NT1=49.8 [13.0], P=0.0006; NT2=40.8 [12.3], P=0.0023); and fewer awakenings (−3.2 [0.9], P=0.0015, overall; NT1=−4.1 [1.4], P=0.0056; NT2=−2.3 [1.3], P=0.0771). Most participants (93.3%, n=30; NT1, 86.7%, n=15; NT2, 100%, n=15) reported improvement (very much, much, minimally) in overall narcolepsy disease on PGIc. Treatment-emergent adverse events were consistent with the known safety profile of LXB.

Conclusion: Participants with NT1 and NT2 taking open-label LXB showed improvements in daytime sleepiness (decreased ESS scores) and reduced symptom burden (improved PGIc), which paralleled improvements in sleep architecture and disruption.

CLINICALLY MEANINGFUL IMPROVEMENT IN DAYTIME SLEEPINESS WITH ON-SXB IN PEOPLE WITH NARCOLEPSY AND SEVERE SLEEPINESS

Richard Bogan[1], Thomas Roth[2], Michael Thorpy[3], Clete Kushida[4], Jennifer Gudeman[5]

[1] Bogan Sleep Consultants, [2] Sleep Disorders and Research Center, Henry Ford Health System, [3] Albert Einstein College of Medicine, [4] Stanford University School of Medicine, [5] Avadel Pharmaceuticals

Introduction: Efficacy of once-nightly sodium oxybate (ON-SXB; LUMRYZ™) for narcolepsy was demonstrated in the phase 3 REST-ON trial (NCT02720744). Efficacy on daytime sleepiness in REST-ON participants with the most severe sleepiness at baseline was analyzed post hoc.
Methods: Participants (≥16 years; narcolepsy type 1 [NT1] or NT2) were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2-3, 6 g; weeks 4-8, 7.5 g; weeks 9-13, 9 g) or placebo. Sleep latency on the Maintenance of Wakefulness Test (MWT) and Epworth Sleepiness Scale (ESS) scores were calculated in tertiles of participants from the modified intent-to-treat (mITT) population (randomized participants with ≥1 efficacy measurement after receiving 6-g dose) with lowest mean sleep latency on the MWT (MWT tertile) or highest ESS scores (ESS tertile) at baseline. Data are median (Q1, Q3) observed values.
Results: In the mITT population (ON-SXB, n=97; placebo, n=93), mean age for MWT tertile participants (ON-SXB, n=33; placebo, n=30) was 30.5 years (65.1% female, 76.2% NT1, 60.3% taking concomitant alerting agents), and for ESS tertile participants (ON-SXB, n=33; placebo, n=41), it was 32.4 years (63.5% female, 90.5% NT1, 37.8% taking concomitant alerting agents). Respective sleep latency on the MWT (min) for ON-SXB and placebo groups of MWT tertile participants was 1.5 (1.0, 2.3) and 2.0 (1.3, 2.5) at baseline and 7.0 (2.5, 15.0) and 4.9 (1.8, 8.3) at week 13 (9 g), and for ESS tertile participants was 4.7 (2.8, 7.5) and 4.6 (2.1, 6.6) at baseline and 11.5 (6.9, 21.7) and 5.0 (2.0, 13.0) at week 13 (9 g). Respective ESS scores for ON-SXB and placebo groups of MWT tertile participants were 16.0 (14.0, 19.0) and 19.0 (16.0, 20.0) at baseline and 10.0 (6.0, 16.5) and 16.0 (13.0, 19.0) at week 13 (9 g), and of ESS tertile participants were 21.0 (19.0, 22.0) and 21.0 (19.0, 22.0) at baseline and 9.0 (6.0, 19.5) and 18.0 (14.0, 22.0) at week 13 (9 g).
Conclusion: The most severely sleepy REST-ON participants at baseline experienced clinically meaningful improvement in daytime sleepiness with ON-SXB treatment, as ESS scores were at or below the normal threshold at the end of the study.

LONG-TERM SAFETY AND TOLERABILITY OF ONCE-NIGHTLY SODIUM OXYBATE: A POST HOC ANALYSIS FROM RESTORE

Sally Ibrahim[1], John Harsh[2], Bruce Corser[3], J. Douglas Hudson[4], Adrian Santamaria[5], Paula Schweitzer[6], Brian Abaluck[7], Jennifer Gudeman[7]

[1] University Hospitals Cleveland Medical Center and Case Western Reserve University, [2] Colorado Sleep Institute, [3] Sleep Management Institute, [4] FutureSearch Trials of Neurology, [5] Northwest Houston Neurology & Comprehensive Sleep Medicine Center, [6] Sleep Medicine & Research Center, St. Luke's Hospital, Chesterfield, MO, USA, [7] Avadel Pharmaceuticals

Introduction: Once-nightly sodium oxybate (ON-SXB; LUMRYZ™) is an extended-release formulation of sodium oxybate that eliminates the second, middle-of-the-night dose required by immediate-release twice-nightly oxybate (TN-OXB) formulations. RESTORE (NCT04451668) was an open-label/switch study evaluating the long-term safety/tolerability of ON-SXB in people with narcolepsy.
Methods: Participants ≥16 years of age with narcolepsy who had completed the phase 3 REST-ON trial, were on stable-dose TN-OXB (switch participants), or were oxybate-naïve were eligible for RESTORE. Switch participants' initial ON-SXB doses were equivalent/closest to their prior total nightly TN-OXB dose. After participants titrated their ON-SXB dose (±1.5 g/week; maximum, 9 g/night) with no tolerability issues for ≥3 months, participants entered the stable dosing period. Treatment-emergent adverse events (TEAEs) were recorded quarterly for switch participants in the safety population (all participants who received ≥1 dose of ON-SXB).
Results: A total of 130 switch participants were included in the safety population and received ON-SXB for a median (range) duration of 502.5 (8-1169) days during the >3-year study. Of these participants, 115 continued into the stable dosing period and were included in this analysis. Of the 115 who entered the stable dosing period, 73.9% (85/115) reported ≥1 TEAE. TEAEs reported by ≥3% of participants included COVID-19 (18.3%), nasopharyngitis (11.3%), nausea (10.4%), sinusitis (8.7%), fall (8.7%), headache (7.0%), enuresis (7.0%), cough (6.1%), upper respiratory tract infection (5.2%), urinary tract infection (5.2%), somnolence (4.3%), tremor (4.3%), vomiting (3.5%), dyspnea (3.5%), rash (3.5%), decreased appetite (3.5%), hypertension (3.5%), concussion (3.5%), and contusion (3.5%). Eight (7%) participants reported ≥1 serious TEAE (events, n=10); of these, 2 serious TEAEs were deemed related to ON-SXB (gastroesophageal reflux disease and cataplexy). Five participants (4.3%) experienced ≥1 TEAE that led to ON-SXB discontinuation (upper abdominal pain, fatigue, fall, dizziness, paresthesia, irritability, nightmare, and hypertension; n=1 [0.9%] each).
Conclusion: Reported AEs were consistent with the known AEs of oxybates. Only 4% of participants discontinued owing to a TEAE during the stable dosing period, underscoring the largely transient nature of AEs and the long-term tolerability of ON-SXB.

HYPNAGOGIC/HYPNOPOMPIC HALLUCINATION TYPES AMONG PARTICIPANTS WITH NARCOLEPSY TYPE 1 FROM THE PHASE 3 REST-ON TRIAL

Michael Thorpy[1], Jennifer Mundt[2], Sally Ibrahim[3], Clete Kushida[4], Maggie Lavender[5], Jennifer Gudeman[6], Thomas Roth[7]

[1] Albert Einstein College of Medicine, [2] University of Utah, [3] University Hospitals Cleveland Medical Center and Case Western Reserve University, [4] Stanford University School of Medicine, [5] Comprehensive Sleep Medicine Associates, [6] Avadel Pharmaceuticals, [7] Sleep Disorders and Research Center, Henry Ford Health System

Introduction: Limited information is available to quantify hypnagogic/hypnopompic hallucination (HH) events people with narcolepsy (PWN) may experience. This post hoc analysis from the phase 3 REST-ON trial evaluated individual HH types.
Methods: REST-ON (NCT02720744) participants (age ≥16 years) with narcolepsy were randomized 1:1 to once-nightly sodium oxybate (ON-SXB) (week 1, 4.5 g; weeks 2-3, 6 g; weeks 4-8, 7.5 g; weeks 9-13, 9 g) or placebo. HH events were assessed in participants with narcolepsy type 1. Modified intent-to-treat (mITT) population (≥1 efficacy measurement after 6-g dose) data were analyzed. Nocturnal HH types were evaluated via 6 yes/no questions and recorded in daily diaries. Daytime HHs were not assessed.
Results: In the mITT population with HH at baseline (n=112 [ON-SXB, n=55; placebo n=57]), baseline mean [SD] number of HH events/day was 0.60 [0.35] and 0.66 [0.35] in the ON-SXB and placebo groups, respectively. Respective mean change from baseline (95% CI) in HH events/day to weeks 3, 8, and 13 was −0.16 (−0.21, −0.11), −0.28 (−0.37, −0.19), and −0.29 (−0.40, −0.18) with ON-SXB (all P< 0.001) and −0.14 (−0.20, −0.08), −0.18 (−0.26, −0.10), and −0.24 (−0.33, −0.14) with placebo (all P< 0.001). Participants chose from the following HH types: 1) feeling that shadows or objects are moving/distorting (total number of events with ON-SXB and placebo: 1693 and 2133), 2) feeling another presence in the room (1362 and 1839), 3) feeling that you are about to be attacked (655 and 1232), 4) feeling that you are flying through the air (543 and 1351), 5) feeling that you will soon fall into a hole (448 and 914), and 6) feeling caught in a fire (123 and 152). Of 12,455 HH events, 7762 (62%) were hypnagogic, and 4683 (38%) were hypnopompic.
Conclusion: There were low baseline HH rates in REST-ON, and a strong placebo effect was observed. However, these data provide insight into the HH types participants experienced. Relevant to clinician-patient discussions, approximately half the number of events where participants felt like they were about to be attacked, flying through the air, and falling in a hole were reported with ON-SXB vs placebo.

IMPROVEMENT OF INDIVIDUAL EXCESSIVE DAYTIME SLEEPINESS SYMPTOMS WITH ONCE-NIGHTLY SODIUM OXYBATE FOR NARCOLEPSY

Heidy Merius[1], Michael Thorpy[2], Ellen Wermter[3], Clete Kushida[4], Brian Abaluck[5], Jennifer Gudeman[5]
[1] Stony Brook Medicine, [2] Albert Einstein College of Medicine, [3] Restorative Sleep Medicine, [4] Stanford University School of Medicine, [5] Avadel Pharmaceuticals

Introduction: The Epworth Sleepiness Scale (ESS) is a commonly used 8-item patient-reported outcome measure for excessive daytime sleepiness. While aggregate data are typically presented, individual domains vary in clinical significance. This post hoc analysis from the phase 3 REST-ON trial (NCT02720744) evaluated the efficacy of once-nightly sodium oxybate (ON-SXB; LUMRYZ™) on individual ESS domains.
Methods: Participants aged ≥16 years with narcolepsy were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2–3, 6 g; weeks 4–8, 7.5 g; weeks 9–13, 9 g) or placebo. ESS data from the modified intent-to-treat population (mITT; ≥1 efficacy measurement after receiving the 6-g dose) at weeks 3, 8, and 13 were analyzed.
Results: In the mITT population (ON-SXB, n=97; placebo, n=93), ON-SXB was associated with significant sleepiness improvements vs placebo for sitting and reading, watching TV, lying down to rest in the afternoon, and sitting quietly after lunch; all doses P< 0.01. ON-SXB was associated with significant sleepiness improvement vs placebo as a passenger in a car for an hour without a break (least squares mean difference [LSMD; 95% CI] in change from baseline: 6 g, –0.39 [–0.61 to –0.17]; 7.5 g, –0.59 [–0.85 to –0.32]; 9 g, –0.67 [–0.95 to –0.38]; all doses P< 0.001). Significant sleepiness improvements were observed with 7.5-g and 9-g ON-SXB when sitting inactive in public (LSMD vs placebo [95% CI]: 7.5 g, –0.34 [–0.61 to –0.07], P=0.014; 9 g, –0.44 [–0.71 to –0.18], P=0.001) and sitting and talking to someone (7.5 g, –0.29 [–0.47 to –0.11], P=0.002; 9 g, –0.24 [–0.44 to –0.04], P=0.018). Significant sleepiness improvement as a driver stopped in traffic was observed with 9-g ON-SXB (LSMD vs placebo [95% CI], –0.35 [–0.63 to –0.07]; P=0.015).
Conclusion: At all ON-SXB doses, participants had significant improvements vs placebo in sleepiness while completing routine activities. The greatest improvements in these activities were observed with the 9-g ON-SXB dose, including the domain for sleepiness as a driver stopped in traffic, a key safety concern. ON-SXB may be helpful in addressing safety challenges for people with narcolepsy.

CONSISTENT EFFICACY OF ONCE-NIGHTLY SODIUM OXYBATE ON DISRUPTED NIGHTTIME SLEEP IN PEOPLE WITH NARCOLEPSY

Yves Dauvilliers[1], Michael Thorpy[2], Thomas Roth[3], Clete Kushida[4], Anne Morse[5], John Harsh[6], Luis Ortiz[7], Jennifer Gudeman[8]
[1] Sleep-Wake Disorders Center, Department of Neurology, Gui-de-Chauliac Hospital, Institute for Neurosciences of Montpellier INM, INSERM, University of Montpellier,, [2] Albert Einstein College of Medicine, [3] Sleep Disorders and Research Center, Henry Ford Health System, [4] Stanford University School of Medicine, [5] Geisinger Commonwealth School of Medicine Geisinger Medical Center Janet Weis Children's Hospital,, [6] Colorado Sleep Institute, [7] Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, [8] Avadel Pharmaceuticals

Introduction: Once-nightly sodium oxybate (ON-SXB; LUMRYZ™) demonstrated efficacy in treating narcolepsy symptoms, including disrupted nighttime sleep (DNS), in the phase 3 REST-ON trial (NCT02720744). This post hoc analysis assessed ON-SXB efficacy on DNS across various participant subgroups.
Methods: Participants aged ≥16 years with narcolepsy type 1 (NT1) or 2 (NT2) were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2-3, 6 g; weeks 4-8, 7.5 g; weeks 9-13, 9 g) or placebo. Least squares mean differences (LSMDs) in changes from baseline for ON-SXB vs placebo for number of sleep stage shifts and nocturnal arousals as measured by polysomnography, as well as patient-reported sleep quality and refreshing nature of sleep, were compared among demographic (age, sex, race, body mass index [BMI] category), narcolepsy type (NT1/NT2), and concomitant alerting agent use subgroups from the modified intent-to-treat population (mITT;≥1 efficacy measurement after receiving the 6-g dose).

Results: In the mITT population (ON-SXB, n=97; placebo, n=93), LSMDs for ON-SXB vs placebo demonstrated significant improvements from baseline (P< 0.001) in number of sleep stage shifts at week 13 (9 g) across all participant subgroups, including age (< 35, ≥35 years), sex (female, male), race (white, non-white), BMI (low [< 25 kg/m2], high [≥25 kg/m2]), narcolepsy type (NT1, NT2), and alerting agent/no alerting agent use. LSMDs were significant in favor of ON-SXB 9 g vs placebo for change from baseline in number of nocturnal arousals (P< 0.05) in all subgroups, except age ≥35 years. At week 13, ON-SXB was associated with significant improvement from baseline (P< 0.05) in visual analogue scale (VAS) sleep quality compared with placebo across all subgroups, except non-white. All subgroups exhibited significant improvements (P≤0.01) in VAS refreshing nature of sleep with ON-SXB 9 g vs placebo, except NT2. Comparable trends were observed with the 6-g dose at week 3 and the 7.5-g dose at week 8.
Conclusion: While the trial was not powered to test for subgroup differences, these post hoc analyses demonstrate the robust, consistent efficacy of ON-SXB in treating DNS, including reducing nocturnal arousals and increasing refreshing nature of sleep, in patients with narcolepsy across various demographic and clinical characteristics.

EVALUATION OF CARDIAC SAFETY PROFILE OF ALKS 2680 IN HEALTHY SUBJECTS: CONCENTRATION-QTC RELATIONSHIP OF ALKS 2680

Jahnavi Kharidia[1], Borje Darpo[2], Sergey Yagoda[1], Alexandra Lovett[1], Hongqi Xue[2], Hailu Chen[1], Bhaskar Rege[1], Ishani Landry[1]
[1] Alkermes, Inc., [2] Clario

Introduction: ALKS 2680 is a highly potent, orally bioavailable, and selective orexin 2 receptor agonist being developed as a once-daily treatment for narcolepsy and idiopathic hypersomnia. Cardiac safety is an important consideration for drugs in clinical development. This cardiodynamic evaluation assessed the effects of ALKS 2680 on the corrected QT (QTc) interval using the Fridericia method (QTcF), and other electrocardiogram (ECG) parameters (heart rate [HR] and cardiac conduction [PR and QRS intervals]).
Methods: Single-ascending dose (SAD) data from 42 ALKS 2680-treated healthy volunteers (6 subjects in each of 7 dose cohorts ranging from 1 to 50 mg powder-in-capsule [PIC] and nanosuspension [NS] formulations) and 14 placebo subjects, and multiple-ascending dose (MAD) data from 23 ALKS 2680-treated healthy volunteers (5-6 subjects in each of 4 dose cohorts ranging from 3 to 25 mg PIC formulation) and 8 placebo subjects, were analyzed. Twelve-lead ECGs were extracted from Holter recordings at baseline and prespecified post-dose time points in the SAD (Day 1) and MAD (Day 10) cohorts. The primary analysis was based on concentration-QTc (C-QTc) modeling of the relationship between change-from-baseline QTcF and ALKS 2680 plasma concentrations using a linear mixed-effects modeling approach to exclude an effect on the QTc interval ≥10 ms. Other endpoints included HR and PR and QRS intervals.
Results: For the SAD and MAD cohorts, the by-timepoint analysis showed that the mean change-from-baseline HR followed the pattern observed on placebo for all doses. In the C-QTc analysis based on the pooled SAD and MAD cohorts, the estimated slope of the concentration-QTc relationship was negative (−0.113 [90% CI: −0.179 to −0.047] ms per ng/mL). An effect on placebo-corrected change-from-baseline QTcF exceeding 10 ms can be excluded within the full observed ALKS 2680 plasma concentration range up to ~94.4 ng/mL. No clinically relevant effects were observed in the by-timepoint analysis on placebo-corrected change-from-baseline PR and QRS intervals.
Conclusion: The high precision QT analysis confirms a lack of any effects of ALKS 2680 (up to 50 mg) on QTc prolongation, heart rate, or cardiac conduction.

THE OREXIN 2 RECEPTOR AGONIST ALKS 2680 IN PATIENTS WITH NARCOLEPSY OR IDIOPATHIC HYPERSOMNIA: A PHASE 1B STUDY

Ronald Grunstein[1], Brendon Yee[2], Julia Chapman[3], Jian Eu Tai[2], Sheila Sivam[4], Craig Hopkinson[5], Jandira Ramos[5], Derek Matthies[5], Shifang Liu[5], Sergey Yagoda[5], Bhaskar Rege[5]
[1] Woolcock Institute of Medical Research, Macquarie University CPC-RPAH Clinic, Royal Prince Alfred Hospital and University of Sydney, Sydney, Australia, [2] The Woolcock Institute of Medical Research, [3] CIRUS, Centre for Sleep and Chronobiology, Woolcock Institute of Medical Research, Macquarie University, [4] Woolcock Institute of Medical Research, [5] Alkermes, Inc.

Introduction: Targeting the orexin system may address symptoms across hypersomnolence disorders (narcolepsy type 1 [NT1], narcolepsy type 2 [NT2], idiopathic hypersomnia [IH]) with or without orexin deficiency. ALKS 2680 is a highly potent, orally bioavailable, and selective orexin 2 receptor agonist being developed as a once-daily treatment for narcolepsy and idiopathic hypersomnia.
Methods: Safety/tolerability and pharmacodynamics of ALKS 2680 were assessed in a randomized, double-blind, phase 1b study. Single doses of ALKS 2680 (1, 3, and 8mg for NT1; 5, 12, and 25mg for NT2 or IH) and matching placebo were administered in a 4-way randomized crossover design following 2-week washout from prior medications. Safety endpoints included treatment-emergent adverse events (TEAEs), vital signs, clinical laboratory assessments, and electrocardiograms (ECGs). Key pharmacodynamic assessment was mean sleep latency (MSL) on the Maintenance of Wakefulness Test (MWT).
Results: In patients with NT1 (N=10), NT2 (N=9), or IH (N=8), there were no serious adverse events and no patient discontinued due to a TEAE. All TEAEs were mild except 3 moderate events (NT1, nausea; NT2, pollakiuria; IH, pollakiuria), which occurred at the highest respective doses. Drug-related TEAEs occurring in >1 patient were insomnia, pollakiuria, salivary hypersecretion, decreased appetite, dizziness, and nausea in NT1 cohort, and insomnia, pollakiuria, and dizziness in NT2 and IH cohorts, respectively. For all cohorts, no clinically meaningful changes from baseline were identified in laboratory values, and no cardiovascular safety signals were identified in vital signs or ECGs. ALKS 2680 increased MWT MSL in a dose-dependent manner over 8h, as assessed by estimated least squares mean difference in change from baseline versus placebo (minutes) in patients with NT1 (1mg, 18.4; 3mg, 22.6; 8mg, 34.0; all p< 0.001), NT2 (5mg, 11.6; 12mg, 18.6; 25mg, 21.0; all p< 0.05), or IH (5mg, 8.1; 12mg, 11.1; 25mg, 17.7; all p< 0.05).

Conclusion: ALKS 2680 was generally well-tolerated and led to statistically significant, clinically meaningful improvements in MSL at all doses tested in patients with NT1, NT2, or IH, with MSL exceeding the average in healthy individuals at most doses. These results support the phase 2 clinical evaluation of ALKS 2680 in patients with NT1, NT2, and IH.

UNDERSTANDING PATH TO DIAGNOSIS, HCP RELATIONSHIPS, AND TREATMENT REGIMENS AMONG PEOPLE LIVING WITH NARCOLEPSY

Luis Ortiz[1], Heidy Merius[2], Maggie Lavender[3], Anne Morse[4], Beth Schneider[5], Dianna Cronin[5], Jennifer Gudeman[6]
[1] Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, [2] Stony Brook Medicine, [3] Comprehensive Sleep Medicine Associates, [4] Geisinger Commonwealth School of Medicine Geisinger Medical Center Janet Weis Children's Hospital,, [5] MyHealthTeam, [6] Avadel Pharmaceuticals

Introduction: Narcolepsy is a chronic, disabling hypersomnolence disorder requiring lifelong management. People with narcolepsy (PWN) often experience diagnostic delays and difficulties with quality care, including healthcare provider (HCP)- and treatment-related challenges. This survey assessed the path to diagnosis, HCP relationships, and treatment regimens among PWN from MyNarcolepsyTeam, a social network of >11,000 members.
Methods: MyNarcolepsyTeam members were invited to participate in a 36-question online survey fielded between April 10 and May 9, 2024. Eligible participants had a narcolepsy diagnosis, were age ≥21 years, and resided in the United States. Data were analyzed descriptively.
Results: Of 88 total respondents (female, 77%; age ≥50 years, 74%), 39% had narcolepsy type 1, 50% had narcolepsy type 2, and 11% were unsure. Most (81%) respondents saw ≥2 clinicians to receive a diagnosis; 36% visited ≥5 clinicians. 98% had undergone ≥1 sleep study, which was the most common diagnosis method (83%). Following diagnosis, 68% of respondents visited multiple HCPs to address narcolepsy symptoms. Of 82 respondents currently seeing an HCP, 56% were extremely/very satisfied with their clinician. Satisfaction was higher among respondents seeing sleep specialists vs non-sleep specialists (70% vs 38%). More respondents seeing sleep specialists vs non-sleep specialists reported discussions that address mental health (48% vs 31%) and long-term planning (38% vs 15%). Fifty percent of respondents currently seeing an HCP discussed the advantages and disadvantages of treatments with their HCP. Seventy-nine (90%) respondents were taking ≥1 medication to treat their symptoms; 67% took ≥2 medications. Current medications for narcolepsy most commonly included traditional stimulants (56%; [Adderall®, Ritalin®, etc.]) and antidepressants (38%). Nearly half of respondents (44%) found their treatment regimen extremely/very/somewhat challenging, of whom 83% were taking multiple medications. Reported treatment challenges included loss of efficacy, side effects, access barriers, and the complexity of medication regimens.
Conclusion: These findings highlight the challenges PWN face, emphasizing the need for expedited diagnosis and access to specialized healthcare. Despite greater satisfaction with care from sleep medicine specialists, there is a shortage in this field. This gap underscores the necessity for improved treatment regimens and enhanced discussions between PWN and HCPs to address mental health support and long-term planning.

OXYBATE AWARENESS, USAGE, AND EXPERIENCE AMONG PEOPLE WITH NARCOLEPSY: A MYNARCOLEPSYTEAM SURVEY ANALYSIS

Maggie Lavender[1], Heidy Merius[2], Beth Schneider[3], Dianna Cronin[3], Luis Ortiz[4], Anne Morse[5], Jennifer Gudeman[6]
[1] Comprehensive Sleep Medicine Associates, [2] Stony Brook Medicine, [3] MyHealthTeam, [4] Johns Hopkins Medical Institutions, Johns Hopkins All Children's Hospital, [5] Geisinger Commonwealth School of Medicine Geisinger Medical Center Janet Weis Children's Hospital,, [6] Avadel Pharmaceuticals

Introduction: Narcolepsy is characterized by excessive daytime sleepiness (EDS) and can occur with or without cataplexy. Oxybates are FDA-approved to treat EDS or cataplexy in people with narcolepsy. Immediate-release twice-nightly sodium oxybate (TN-SXB) and calcium, magnesium, potassium, and sodium oxybates (mixed-salt oxybates) are administered at bedtime and 2.5-4 hours later, whereas extended-release once-nightly SXB (ON-SXB; FT218) is administered once at bedtime. This study assessed oxybate awareness, usage, and experience among people with narcolepsy (PWN).
Methods: The MyNarcolepsyTeam survey was an anonymous, voluntary survey conducted from April 10 to May 9, 2024. Eligible participants were age ≥21 years, United States residents, and reported a narcolepsy diagnosis. The 36-item survey assessed respondents' demographics, symptom management, and relationships with healthcare providers (HCPs).
Results: Of 88 respondents, 77% were female, 75% were ≥50 years of age, and 39% and 50% had narcolepsy type (NT) 1 and NT2, respectively. Respondent brand awareness of oxybates was high (70%), with highest awareness for TN-SXB (55%), followed by mixed-salt oxybates (43%) and ON-SXB (23%). Of 82 respondents seeing an HCP, only 39% had discussed oxybates with their HCP. Current oxybate use was reported by 13% of respondents (15% of NT1 respondents; 7% of NT2 respondents), 82% of whom experienced symptom improvement within 2 weeks of starting oxybate treatment. Benefits of oxybate use included getting a better night's sleep (64%) and waking up refreshed (64%). Of 77 respondents not currently taking oxybates, 36% reported they did not know enough about oxybates. Of respondents who had previously taken an oxybate, 28% discontinued within 1 month of initiating treatment. The most commonly reported reason for discontinuing oxybate treatment was side effects (40% [age ≥60 years, 47%; age < 60 years, 27%]).
Conclusion: These results demonstrate that while respondents were moderately aware of oxybates, over one-third reported lacking enough information to consider starting oxybate treatment. Despite TN-SXB approval by the FDA in 2002, only 1:8 respondents were currently receiving oxybates. As narcolepsy medication regimens can be daunting, clinicians have the opportunity to counsel PWN about oxybate treatment options, including the potential for early symptom improvement and proactive side effect management to reduce discontinuation.

ARIPIPRAZOLE FOR TREATING POST-COVID-19 HYPERSOMNOLENCE IN ADOLESCENTS: A CASE SERIES

Yuta Sudo-Konno[1], Shigeru Chiba[1], Tatsuaki Okubo[2], Tsuyoshi Nemoto[1], Takaho Honaga[3], Kentaro Shirai[3], Emi Iwabuchi[2], Sho Takahashi[2], Hirokazu Tachikawa[4], Takashi Kanbayashi[1]

[1] International Institute for Integrative Sleep Medicine, Tsukuba Univ., [2] Ibaraki Prefectural Medical Center of Psychiatry, [3] International Institute for Integrative Sleep Medcine, [4] Institute of Medicine, University of Tsukuba

Introduction: Post-COVID-19 conditions, also known as long COVID, encompass a range of symptoms, including fatigue, dyspnea, and cognitive dysfunction, that persist for at least two months following three months after the onset of COVID-19. The WHO estimates that approximately 10–20% of individuals infected with COVID-19 develop post-COVID-19 conditions. Among these patients, it has been reported that around 80% experience sleep disturbances, such as insomnia, hypersomnolence, or circadian rhythm disorders. These disruptions in sleep duration, whether reduced or prolonged, can adversely affect subjective health and quality of life. In adolescents, such disturbances may contribute to school absenteeism and impair social adaptation, emphasizing the need for effective management strategies. Aripiprazole (APZ), commonly prescribed for schizophrenia, has recently been shown to improve hypersomnolence symptoms when used at low doses. In this study, we report a case series of 10 adolescents with post-COVID-19 hypersomnolence. Administration of low-dose APZ effectively reduced sleep duration, providing insights into its potential utility as a therapeutic option for hypersomnolence associated with post-COVID-19 conditions.
Methods: Ten adolescent patients with post-COVID-19 hypersomnolence who visited our institution between 2019 and December 2024 were included if their sleep duration was prolonged compared to their pre-infection baseline. All participants displayed sleep patterns resembling those observed in delayed sleep phase syndrome (DSPS). After obtaining informed consent from the patients and their guardians, low-dose APZ (0.5–2.0 mg) was prescribed. Patients maintained sleep diaries documenting bedtime, wake-up time, and total sleep duration both before and after the initiation of APZ treatment. Sleep parameters were subsequently analyzed for changes in total sleep duration and wake-up times using statistical methods. Adverse effects were monitored throughout the treatment period. The Ethics Committee of Ibaraki Prefectural Medical Center of Psychiatry approved this study.
Results: Low-dose APZ effectively reduced total sleep duration and advanced wake-up times in adolescents with post-COVID-19 hypersomnolence, enabling some patients to return to their previous lifestyles. No significant adverse effects were reported.
Conclusion: Low-dose APZ effectively managed post-COVID-19 hypersomnolence in adolescents by reducing total sleep duration and advancing wake-up times. These findings suggest APZ as a promising therapeutic option for post-COVID-19 hypersomnolence, particularly in adolescents, warranting further investigation in larger studies.

AMELIORATION OF SLEEP-RELATED EATING DISORDER AFTER SWITCHING FROM TWICE- TO ONCE-NIGHTLY OXYBATE

Lewis Kass[1]

[1] Westchester Pediatric Pulmonology & Sleep Medicine

Introduction: In a disproportionality analysis (Merino D, et al. J Clin Med. 2022;11:3890), sodium oxybate (SXB) treatment was associated with sleep-related eating disorder (SRED), a parasomnia characterized by somnambulism and compulsive eating. Immediate-release twice-nightly oxybate (TN-OXB) formulations (ie, SXB and calcium, magnesium, potassium, and sodium oxybates [mixed-salt oxybates]) are administered at bedtime and again 2.5-4 hours later. SRED coincides with the first dose of TN-OXB if patients remain awake. This retrospective, single-site analysis assessed the effect of switching from TN-OXB to extended-release once-nightly SXB (ON-SXB) on SRED among individuals with narcolepsy.
Methods: Retrospective chart review was conducted from a single clinical site. Data were collected from individuals with narcolepsy who experienced SRED while taking TN-OXB and were switched to ON-SXB from the time of switch to ON-SXB through currently available data. Patient demographics, medical history, oxybate treatment duration, dosage, and weight-related measures before and after the treatment switch were recorded. Data were described and analyzed descriptively.
Results: Of 8 individuals with narcolepsy who experienced SRED, the mean (SD) age was 21 (4.1) years, 6 (75%) were female, and 6 (75%) and 2 (25%) had narcolepsy type (NT) 1 and NT2, respectively. Before switching to ON-SXB, median (range) TN-OXB dose and mean (SD) treatment duration were 8.8 (4.8-10.5) g and 40.6 (21.1) months, respectively, with 3 individuals (37.5%) taking asymmetric doses. After switching to ON-SXB, median (range) ON-SXB dose was 9 (6-9) g. Sleep eating episodes were resolved in all individuals within 6 months of switching to ON-SXB. Five (63%) individuals experienced a reduction in BMI after switching to ON-SXB.
Conclusion: In this retrospective chart analysis, individuals with narcolepsy and SRED experienced positive clinical outcomes after switching from TN-OXB to ON-SXB. Individuals switching to an oxybate that did not require a middle-of-the-night dose had resolution of sleep eating, and nearly two-thirds experienced a reduction in BMI. SRED is an underappreciated challenge with TN-OXB dosing that may be ameliorated with a single, extended-release dose of SXB, as provided by ON-SXB.

Sleep Research Laboratory, [6] Axsome Therapeutics, Inc, [7] Axsome Therapeutics, Inc.

Introduction: AXS-12 (reboxetine) is a highly selective norepinephrine reuptake inhibitor and cortical dopamine modulator under development for narcolepsy. In the Phase 3 SYMPHONY trial, AXS-12 significantly reduced weekly cataplexy attacks from baseline to Week 5 versus placebo in patients with narcolepsy. Here we report the Phase 3 ENCORE trial, assessing long-term efficacy and safety of AXS-12 in participants who completed SYMPHONY.
Methods: ENCORE included a 24-week open-label extension (OLE) period, followed by a 3-week double-blind randomized-withdrawal (DBRW) period. During the OLE, participants received AXS-12 (5 mg once-daily for 1 week, twice-daily for 23 weeks). Following this, remaining participants were randomized 1:1 to continue twice-daily AXS-12 or switch to once-daily AXS-12 plus placebo for 1 week, then placebo twice-daily for 2 weeks. The primary endpoint was change in frequency of cataplexy attacks from randomization to DBRW Week 3. OLE efficacy outcomes included change in weekly frequency of cataplexy attacks, cataplexy response (≥50% reduction), and change in cataplexy-free days. Additional analyses are ongoing.
Results: ENCORE enrolled 68 participants; 42 completed the OLE and entered the DBRW (AXS-12, n=22; placebo, n=20). In SYMPHONY, baseline mean weekly frequency of cataplexy attacks was 31.5. At DBRW randomization, mean weekly frequency of cataplexy attacks was 4.2 (AXS-12) and 6.9 (placebo). Participants randomized to placebo experienced a mean increase of 10.29 weekly cataplexy attacks versus 1.32 for AXS-12, at end of DBRW (p=0.017). In the OLE, weekly frequency of cataplexy attacks decreased by 22.3 (71%) and 24.1 (77%) at 1 and 6 months, respectively. Cataplexy response was achieved by 72% and 82% at 1 and 6 months, respectively. Cataplexy-free days increased from 14.3% to 61% and 70% at 1 and 6 months, respectively. Common adverse events (AEs; ≥5%) during the OLE were nausea and tachycardia (both 5.9%); no new safety signals were detected. Discontinuations due to AEs occurred in 17.6% of participants in the OLE.
Conclusion: AXS-12 significantly reduced the frequency of cataplexy attacks during the DBRW. AXS-12 was well-tolerated and demonstrated maintenance of efficacy with long-term open-label use. These results align with SYMPHONY, supporting the positive therapeutic impact of AXS-12 for narcolepsy.

NARCOLEPSY TYPE 1 SYMPTOMS ACROSS PREGNANCY

Kelsey Biddle[1], Elizabeth Montesano[1], Thomas Scammell[2], Margaret Blattner[2]

[1] Harvard Medical School, [2] Beth Israel Deaconess Medical Center

Introduction: Narcolepsy type 1 (NT1) is a chronic neurological disorder characterized by excessive daytime sleepiness, cataplexy, and disrupted nighttime sleep, often requiring lifelong treatment. Little is known about how pregnancy impacts NT1, so individuals with NT1 face difficult decisions about continuing or discontinuing treatments during pregnancy, particularly given the uncertain risks and benefits for themselves and their fetuses. This study aims to address this knowledge gap by investigating the trajectory of NT1 symptoms and associated experiences during pregnancy, with the goal of informing future guidelines and improving shared decision-making for individuals with NT1 and their clinicians.
Methods: This mixed-methods study was designed to capture both quantitative and qualitative data on NT1 symptom trajectories and patient experiences around pregnancy. Eligible participants were adults with NT1 who gave birth within the past two years. Data collection included an online survey assessing symptom severity, social support, and treatment decisions during preconception, pregnancy, delivery, and postpartum. The survey included validated tools, such as the Narcolepsy Severity Scale (NSS), and custom items tailored to pregnancy contexts. A subset of participants also participated in semi-structured interviews. Quantitative data was analyzed using paired t-tests and one-way ANOVA, while qualitative data was analyzed thematically to provide additional insight into participants' experiences and priorities.
Results: Preliminary data from 16 women (mean age 33.8 ± 4.36 years) with NT1 revealed significant variability in symptom trajectory and medication use around pregnancy. Half reported improvement in their NT1 symptoms during pregnancy, while about 1/3 described worse symptoms. The most bothersome symptoms during pregnancy were disrupted nighttime sleep (94%), attention/concentration difficulties (94%), and daytime sleepiness (88%). While most (56%) participants took medications for at least part of their pregnancy, discontinuation was common, particularly in the first trimester.
Conclusion: This study provides the beginning of a comprehensive overview of NT1 symptom evolution and medication management patterns during pregnancy. These findings plus additional research will help shape future prospective studies tracking NT1 symptoms during pregnancy and guide clinical recommendations and support.

SAMELISANT (SUVN-G3031) ALLEVIATES EXCESSIVE DAYTIME SLEEPINESS IN NARCOLEPSY: RESULTS FROM A PHASE-2 STUDY

Ramakrishna Nirogi[1], Vinod Kumar Goyal[1], Jyothsna Ravula[1], Pradeep Jayarajan[1], Satish Jetta[1], Anil Shinde[1], Vijay Benade[1], Ramkumar Subramanian[1]

[1] Suven Life Sciences

Introduction: Narcolepsy is a chronic sleep disorder characterized by excessive daytime sleepiness (EDS), uncontrollable sleep attacks, cataplexy, hypnagogic hallucinations, and sleep paralysis. Current treatments for narcolepsy often come with significant limitations, such as side effects, limited efficacy, or the necessity of combining multiple therapies. Samelisant is a selective inverse agonist of histamine 3 receptors, showing promising potential as a novel treatment for this condition. In preclinical studies involving orexin knockout mice, Samelisant demonstrated wake-promoting effects and reduced cataplexy, underscoring its therapeutic potential. Samelisant safety/tolerability has been established in healthy subjects.
Methods: Samelisant was evaluated as monotherapy in a Phase 2 proof-of-concept study conducted in the USA and Canada to treat EDS in patients with narcolepsy (NCT04072380). The study

enrolled narcoleptic patients aged 18 to 65 years per ICSD-3 criteria, who had an Epworth Sleepiness Scale (ESS) score of ≥12 and a mean Maintenance of Wakefulness Test (MWT) time of < 12 minutes. A total of 190 patients were randomized into three treatment groups (placebo, Samelisant 2 mg, and Samelisant 4 mg) in a 1:1:1 ratio and received either placebo or Samelisant once daily for 14 days. The primary efficacy endpoint was the change in ESS score from Baseline to Day 14. Secondary and exploratory endpoints included changes in Clinical Global Impression – Severity, MWT and Patient Global Impression – Change scores from Baseline to Day 14. Safety was monitored throughout the study by the medical monitor and the data safety monitoring committee.

Results: Study evaluating Samelisant achieved primary efficacy endpoint demonstrating statistically significant ($p < 0.024$) and clinically meaningful reduction (-2.1 point) in ESS total score compared to placebo. Treatment with Samelisant resulted in significant improvement in EDS on scales assessed by both clinicians and patients. Samelisant was generally safe and well tolerated in narcolepsy patients and there were no serious events or death reported.

Conclusion: Samelisant holds promise as a monotherapy for treatment of EDS in narcolepsy, and a global Phase 3 study for the treatment of narcolepsy will be initiated in Q2 2025

ACTIGRAPHY-BASED ASSESSMENT OF THE IMPACT OF TAK-861 ON DAYTIME NAPPING IN PEOPLE WITH NARCOLEPSY TYPE 1

Raul Torres[1], Francesco Onorati[1], Melissa Naylor[1], Tina Olsson[1], Simerpal Gill[1], Yelena Pyatkevich[1], Sarah Bermingham[1], Dmitri Volfson[1]

[1] Takeda Development Center Americas, Inc.

Introduction: Excessive daytime sleepiness (EDS) is a hallmark symptom of narcolepsy that profoundly impacts daily life. Naps are a clinically meaningful indicator of EDS, and wrist-worn accelerometers offer a convenient and accurate measurement method. We aimed to develop and validate an objective actigraphy-based algorithm for detecting daytime naps in people with narcolepsy type 1 (NT1).

Methods: The Multi-Ethnic Study of Atherosclerosis (MESA) dataset included manually annotated naps from 2,237 participants with wrist-worn actigraphy devices across seven days. Using MESA data, we developed an algorithm that predicted sleep-wake epochs from activity counts, grouped these predictions into naps (sleep periods lasting ≥5min between 9AM and 9PM), then applied decision rules (pruning and fusion) to optimize agreement with manually annotated naps. Following validation, our algorithm was applied in a phase 0 non-interventional study of 16 participants with NT1 and 16 healthy sex- and age-matched controls (NCT04445129), and a phase 2 interventional study of orexin receptor 2-selective agonist TAK-861 in 112 participants with NT1 (NCT05687903). Algorithm-derived measures included the proportion of nap-free days and total minutes of daytime sleep on days with ≥1 nap.

Results: In MESA, our nap detection algorithm yielded high sensitivity (86.5%) and F1 area (84.6%), and nominal correlations ($R=-0.16$, $p < 0.001$; $R=0.15$, $p < 0.001$; n=2,237) between napping and self-reported sleepiness measured via Epworth Sleepiness Scale (ESS), suggesting sleepiness is weakly associated with less nap-free days and more daytime sleep. In the non-interventional trial, participants with NT1 had 11.5 fewer nap-free days ($p < 0.001$; n=16) in a 4-week period and slept 37.5 more minutes during the day ($p < 0.001$; n=16) than controls. In the interventional trial, relative to baseline, TAK-861-treated participants with NT1 experienced a statistically significant increase in nap-free days in a 4-week period and slept less time per day across TAK-861 dose groups (0.5mg/0.5mg: n=23, 2mg/2mg: n=21, 2mg/5mg: n=23, 7mg: n=23; all $p < 0.001$). No significant effects were observed with placebo (n=22).

Conclusion: We developed a highly sensitive and specific actigraphy-based nap-detection algorithm which identified two important nap-related findings: increased napping in untreated participants with NT1, and substantially reduced daytime napping in TAK-861-treated participants with NT1.

TREATMENT WITH AN OREXIN AGONIST REDUCES MICROSLEEPS AND IMPROVES WAKEFULNESS DURING MWT IN PEOPLE WITH NT1

Yishu Gong[1], Brian Tracey[1], Mads Olsen[1], Melissa Naylor[1], Tina Olsson[1], Emmanuel Mignot[2], Dmitri Volfson[1]

[1] Takeda Development Center Americas, Inc., [2] Stanford University

Introduction: The Maintenance of Wakefulness Test (MWT) is widely used in clinical trials to assess drug treatment effects on excessive daytime sleepiness (EDS). Sleep onset latency (SOL), the primary endpoint in MWT studies, measures the ability to stay awake until persistent sleep occurs; it does not provide insight into the quality of wakefulness prior to falling asleep. Here, we explored microsleeps, short periods of sleep (3-15 sec) prior to sleep onset during MWT as a biomarker for EDS following therapy using TAK-861, an oral orexin receptor 2-selective agonist developed for the treatment of narcolepsy type 1 (NT1) in a Phase 2 randomized, placebo-controlled trial (NCT05687903).

Methods: Participants with NT1 were randomized to receive TAK-861 (first dose at 8AM for all treatment arms; 0.5mg twice 3 hours apart; 2mg twice 3 hours apart; 2mg then 5mg 3 hours later; or 7mg once-daily) or placebo. The 4 MWT sessions consisted of a 40-minute wake trial at 10AM, 12PM, 2PM, and 4PM to assess fluctuations in sleepiness. MWTs were conducted at baseline and after 28 and 56 days after treatment, with microsleeps scored manually. Zero-inflated negative binomial mixed-effects models (with an offset term for SOL) and mixed-effects survival analysis were used to analyze microsleep rates and time-to-first microsleep, respectively. Pairwise contrasts with baseline within each treatment were performed, averaging over MWT sessions.

Results: MWT data were collected for 112 participants with NT1 (placebo: n=22, 0.5mg/0.5mg: n=23, 2mg/2mg: n=21, 2mg/5mg: n=23, 7mg: n=23). Microsleep rates (prior to falling asleep) decreased significantly by Week 4 and at Week 8 in all TAK-861 treatment groups relative to baseline (from 6 microsleeps per 10 min at baseline to < 2 per 10 min across all treatment groups). Additionally, all TAK-861 treatment groups experienced a prolonged time-to-first microsleep ($p < 0.005$ compared to baseline). Average microsleep duration (excluding participants with no

microsleep) showed no significant change in any arm. Placebo-treated participants showed minimal changes across sessions and visits.
Conclusion: TAK-861 significantly reduced microsleep rates and delayed the onset of the first microsleep, demonstrating its potential as an effective treatment for daytime sleepiness in participants with NT1.

EVALUATION OF THE NOVEL OREXIN 2 RECEPTOR AGONIST ALKS 2680 ON MEASURES OF AROUSAL CIRCUIT ACTIVATION IN RODENTS

Julie Brooks[1], Angelica Patino[1], Corey Puryear[1], Laura Tan[1], Brian Raymer[1]
[1] Alkermes, Inc.

Introduction: The orexin/hypocretin system acts as the master regulator of wakefulness by virtue of its connections to multiple downstream arousal neurotransmitter pathways. Thus, targeting the orexin system may provide novel treatment strategies for narcolepsy and related disorders. In this study, we characterized network engagement and functional activation induced in preclinical rodent models by ALKS 2680, a highly potent, orally bioavailable, and selective orexin 2 receptor agonist being developed as a once-daily treatment for narcolepsy and idiopathic hypersomnia.
Methods: Whole-cell patch-clamp techniques were used to measure changes in histamine neuron excitability following ALKS 2680 treatment in acute mouse brain slices conserving the tuberomammillary nucleus. Whole brain circuit activation mapping was quantified using cellular c-Fos activation following acute oral dosing in rats. Changes in cortical neurotransmission were measured using microdialysis in freely moving rats. Cortical activation and arousal states were quantified using electroencephalography (EEG) and electromyography (EMG) in rats.
Results: Bath application of ALKS 2680 onto acute brain slices resulted in a concentration-dependent depolarization of histamine neurons. The maximal change in membrane potential was similar to that produced by the synthetic orexin B peptide [Ala11,D-Leu15]-OX-B, however ALKS 2680 demonstrated greater potency. ALKS 2680 dose-dependently increased the number of c-Fos positive nuclei in OX2R expressing brain areas associated with arousal/wakefulness, cognition, and/or cataplexy. Notably, change in c-Fos activation was not observed in a brain area predominantly expressing orexin 1 receptors. Acute, oral administration of ALKS 2680 dose-dependently elevated extracellular prefrontal cortical acetylcholine and histamine concentrations. Finally, oral administration of ALKS 2680 resulted in a dose-dependent increase in an EEG profile consistent with wakefulness, including an increase in gamma power and suppression of slower frequency bands such as delta. In addition, sleep staging analysis revealed a significant increase in wakefulness relative to vehicle.
Conclusion: ALKS 2680 increased measures of cortical activation, engagement of vigilance circuitry, and consolidated wakefulness. These preclinical data support further investigation of ALKS 2680 for the treatment of narcolepsy and idiopathic hypersomnia, including cognition- and wakefulness-related symptoms.

DIAGNOSIS JOURNEY, SYMPTOMS, AND BURDEN OF IDIOPATHIC HYPERSOMNIA: PATIENT PERSPECTIVES FROM QUALITATIVE INTERVIEWS

Wilbur Williams[1], Meaghan O'Connor[2], Miranda Lauher-Charest[2], Laura Tesler Waldman[2], Michael Doane[1]
[1] Alkermes, Inc., [2] QualityMetric, an IQVIA business

Introduction: Idiopathic hypersomnia (IH) is a chronic neurological disorder characterized by excessive daytime sleepiness (EDS), among other symptoms. Studies assessing the burden of IH have largely relied on quantitative methods, providing limited insight into the patient experience. This study used qualitative interviews to understand aspects of this rare condition including diagnostic journey, symptoms, and disease burden.
Methods: Participants were recruited using purposive sampling. Trained qualitative researchers conducted each 60-minute individual interview. Interviewers used a concept elicitation approach with a semi-structured interview guide to elicit descriptions of patients' experiences. Interview transcripts were coded and analyzed using inductive and deductive approaches.
Results: Ten adults with IH were interviewed (mean age: 37 years). Most identified as female (80%) and employed (80%). All participants were White. At disease onset, initial symptoms included EDS (70%), fatigue (30%), and oversleeping (30%). In seeking a diagnosis, participants saw different healthcare professionals including sleep specialists, neurologists, psychiatrists, and primary care physicians. Half of the participants received an IH diagnosis >10 years after symptom onset. Prior to diagnosis, participants reported receiving other diagnoses, including depression, sleep apnea, and chronic fatigue syndrome. The most common symptoms participants with IH have experienced included cognitive impairments i.e. difficulties with thinking, memory, and concentration (100%), EDS (90%), and fatigue (90%). All or nearly all participants described that IH negatively impacted: work and school activities (e.g., trouble concentrating on tasks, forgetting information, falling asleep during meetings or conversations; 100%), mental health (e.g., depression, anxiety, embarrassment, lack of motivation; 100%), and instrumental activities of daily living (e.g., home maintenance, cooking/preparing meals, driving; 90%). Most participants also described negative impacts of IH on their relationships with family, friends, and romantic partners (e.g., reduced time spent with children, marital strain; 80%) and activities of daily living (e.g., eating, bathing, dressing/grooming, toileting; 70%).
Conclusion: This study provides patient-reported depictions of the often-challenging journey toward seeking an IH diagnosis, describes IH symptoms from patients' perspectives, and demonstrates the breadth of impact of IH on patients' lives. These results help to fill gaps in the literature by providing important insights into the IH patient experience.

RISING PRESSURE TO UNDERSTAND THE RISKS OF HYPERTENSION IN CHILDREN WITH NARCOLEPSY TYPE 1

Elizabeth Montesano[1], Maria E. Garcia[1], Shannon Lyon[1], Jennifer Worhach[1], Grace Wang[1], Bo Zhang[1], Joshua August[1], Kiran Maski[1]

[1] Boston Children's Hospital

Introduction: Most children/adolescents with Narcolepsy Type 1 (NT1) are treated with traditional stimulants based on U.S. claims data, yet the cardiovascular effects of these medications have not been investigated in this population. We compared vital signs in youth with NT1 before and after exposure to stimulants/wake promoting agents (WPAs) to test the hypotheses that these medications increase rates of elevated blood pressure (BP) and hypertension (HTN) and that body mass index (BMI) influences these outcomes.
Methods: In this retrospective study, we collected electronic medical data including vital signs and polysomnography/multiple sleep latency test (PSG/MSLT) results from 39 NT1 patients aged 7-18 at three points over 20-month period: baseline (drug-naïve/weaned), after initiating treatment, and after treatment optimization. We performed stepwise regression to determine predictors of baseline elevated BP/HTN. We used McNemar's test and generalized estimating equations to assess the effects of stimulant/WPA exposure on vital signs.
Results: The prevalence of elevated BP/HTN at baseline was 51% in our cohort and increased to 72% at the final visit when stimulants/WPA were optimized. BMI was not associated with elevated BP/HTN at baseline. Systolic and diastolic BP increased significantly with stimulant/WPA exposure (both $p < 0.05$), while heart rate (HR) showed a non-significant increase ($p = .08$). BMI was associated with increased systolic BP and HR across the three time points.
Conclusion: This study highlights potential cardiovascular risks associated with pediatric NT1, particularly in the context of treatment with stimulants/WPAs. We recommend close clinical monitoring of vital signs in clinical management of pediatric NT1 and advocate for prospective longitudinal research studies to better understand the cardiovascular risks of stimulants/WPAs in this population.

EFFECTIVENESS AND SAFETY OF LOW-SODIUM OXYBATE IN IDIOPATHIC HYPERSOMNIA PARTICIPANTS: RESULTS FROM THE DUET STUDY

David Plante[1], Alyssa Cairns[2], Logan Schneider[3], Deborah Nichols[4], Teresa Steininger[4], Douglas Fuller[4], M. Kirby[4], Sarah Akerman[4], Jessica Alexander[4], Marisa Whalen[4], Chad Ruoff[5]
[1] University of Wisconsin–Madison, [2] Former employee of BioSerenity, [3] Stanford University Center for Sleep Sciences and Medicine, [4] Jazz Pharmaceuticals, [5] Mayo Clinic

Introduction: Introduction: Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) is a phase 4, prospective, multicenter, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating the effectiveness of low-sodium oxybate (LXB, Xywav®) treatment on daytime and nighttime symptoms, including excessive daytime sleepiness (EDS) and polysomnography in participants with idiopathic hypersomnia (IH) or narcolepsy. Data presented are from the IH cohort.
Methods: DUET included screening (with 2-week washout for oxybate users), 8-day baseline (BL), 2- to 8-week LXB titration, 2-week stable-dose, 8-day end-of-treatment (EOT), and 2-week safety follow-up periods. The primary endpoint was change in Epworth Sleepiness Scale (ESS) score from BL to EOT. Secondary endpoints for the IH cohort included change in Idiopathic Hypersomnia Severity Scale (IHSS) total score, Patient Global Impression of Change (PGIc)−overall IH disease, PGIc−sleep inertia, and Patient Global Impression of Severity (PGIs)−sleep inertia. Exploratory endpoints included IHSS component scores (daytime functioning, sleep inertia). Primary and key secondary (IHSS total score) endpoints were controlled for multiplicity with sequential testing; all other P-values are considered nominal.
Results: Forty-six people with IH enrolled and were dosed with LXB; 40 were completers. Enrolled participants were mostly female (80.4%) and White (84.8%), with a mean (SD) age of 38.1 (11.8) years. For completers, BL mean (SD) ESS score and IHSS total score were 16.5 (2.7) and 32.9 (7.1), respectively; least-squares mean (LSM) (SE) changes from BL to EOT were −8.4 (0.7), P<.0001 and −15.5 (1.5), P<.0001. BL mean (SD) IHSS component scores for daytime functioning and sleep inertia were 17.7 (4.2) and 10.7 (3.1), respectively; LSM (SE) changes from BL to EOT were −8.8 (1.0), P<.0001 and −4.8 (0.4), P<.0001. At EOT, most participants reported improvement (very much, much, minimally) on PGIc−overall IH disease (94.6%) and PGIc−sleep inertia (81.1%). At BL, 25.0% of participants reported sleep inertia severity as very mild/mild/not present on PGIs–sleep inertia vs 59.0% at EOT. Treatment-emergent adverse events were consistent with the known safety profile of LXB.
Conclusion: People with IH taking open-label LXB showed improvements in EDS and sleep inertia (decreased ESS and IHSS component scores) and reported reduced multi-symptom burden (decreased IHSS total scores and improved PGIc/PGIs ratings).

SUBJECTIVE SLEEP QUALITY WITH LOW-SODIUM OXYBATE TREATMENT IN IDIOPATHIC HYPERSOMNIA: RESULTS FROM THE DUET STUDY

Richard Bogan[1], David Plante[2], Alyssa Cairns[3], Deborah Nichols[4], Teresa Steininger[4], Douglas Fuller[4], Sarah Akerman[4], Marisa Whalen[4], Nancy Foldvary-Schaefer[5]
[1] Bogan Sleep Consultants, [2] University of Wisconsin–Madison, [3] Former employee of BioSerenity, [4] Jazz Pharmaceuticals, [5] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH

Introduction: Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) is a phase 4, prospective, multicenter, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating the effectiveness of low-sodium oxybate (LXB, Xywav®) treatment on outcomes including sleep quality (using polysomnography [PSG] and self-reported questionnaires) in participants with idiopathic hypersomnia or narcolepsy. Data reported here are from the idiopathic hypersomnia cohort.
Methods: DUET included a screening period (with 2-week washout for current oxybate users), an 8-day baseline (BL) period, a 2- to 8-week LXB titration period, a 2-week stable-dose period (SDP), an 8-day end-of-treatment (EOT) period, and a 2-week safety follow-up. Participants underwent nocturnal PSG (ad libitum protocol) at BL and EOT. The Karolinska Sleepiness Scale

(KSS) was administered 90 minutes post-awakening from PSG to measure situational sleepiness (9-point scale; 1="extremely alert" to 9="extremely sleepy, can't keep awake"). Participants completed an electronic sleep diary (eDiary) daily during the BL and EOT periods, including questions regarding nightly sleep patterns, total sleep time (TST), sleep quality (5-point scale; "very good" to "very poor"), and how rested/refreshed the participant felt upon awakening (5-point scale; "very well" to "not at all"). Completion of ≥5 eDiary days during the 8-day assessment before PSG visits was required for analysis. eDiary and KSS data were analyzed in the completer set (enrolled participants who were dosed with LXB and completed SDP and PSG at EOT).

Results: Forty-six participants with idiopathic hypersomnia enrolled (completer set, n=40). Most were female (37/46; 80%) and White (39/46; 85%); mean (SD) age was 38.1 (11.8) years. Mean (SD) self-reported nocturnal TST at BL (n=36) and EOT (n=30) was 8.6 (2.0) and 8.4 (2.7) hours, respectively. The percent of participants rating their sleep quality as "very good"/"good" increased from 19.4% (BL) to 56.7% (EOT). The percent of participants with rested sleep ("very well"/"well"/"somewhat" rested) increased from 22.2% (BL) to 73.3% (EOT). Likewise, mean (SD) rating of self-reported sleepiness decreased from 5.7 (2.0) at BL to 3.5 (2.0) at EOT.

Conclusion: Following open-label LXB treatment, participants with idiopathic hypersomnia reported improvements in sleep quality and feeling more rested and less sleepy upon awakening.

SLEEP ARCHITECTURE WITH LOW-SODIUM OXYBATE TREATMENT IN IDIOPATHIC HYPERSOMNIA: RESULTS FROM THE DUET STUDY

Alyssa Cairns[1], Richard Bogan[2], Nancy Foldvary-Schaefer[3], Deborah Nichols[4], Teresa Steininger[4], Douglas Fuller[4], Sarah Akerman[4], Jessica Alexander[4], David Plante[5]

[1] Former employee of BioSerenity, [2] Bogan Sleep Consultants, [3] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [4] Jazz Pharmaceuticals, [5] University of Wisconsin–Madison

Introduction: Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) is a phase 4, prospective, multicenter, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating the effectiveness of low-sodium oxybate (LXB, Xywav®) treatment on outcomes including polysomnography (PSG)-based sleep architecture in participants with idiopathic hypersomnia or narcolepsy. This abstract will include results from the idiopathic hypersomnia cohort.

Methods: DUET included a screening period (2-week washout for current oxybate users), an 8-day baseline (BL) period, a 2- to 8-week LXB titration period, a 2-week stable-dose period (SDP), an 8-day end-of-treatment period (EOT), and a 2-week safety follow-up. Participants underwent nocturnal PSG using an ad libitum protocol at BL and EOT. PSGs were scheduled to allow a minimum of 10 hours in bed, unless the participant naturally awakened earlier; bedtime was determined by habitual bedtime. PSG recordings were centrally scored. Data were analyzed for participants in the idiopathic hypersomnia cohort completer set. P-values were uncontrolled for multiplicity and therefore considered nominal.

Results: Forty-six participants with idiopathic hypersomnia enrolled; 40 completed the study. Most were female (80%) and White (85%) with a mean±SD age of 38.1±11.8 years. Mean±SD total sleep time (TST) at BL and EOT was 467.5±111.9 and 413.4±97.9 minutes, respectively (LSM change [95% CI], –54.1 [–81.3, –26.9]; P=.0003). Mean±SD number of total shifts from deeper to lighter sleep stages at BL and EOT was 60.8±30.1 and 43.7±27.0, respectively (LSM [95% CI], –17.1 [–23.7, –10.5]; P<.0001). Mean±SD time spent in N1 at BL and EOT was 47.8±26.1 and 33.0±22.4 minutes (LSM [95% CI], –14.8 [–20.3, –9.3]; P<.0001), % of stage was 10.3% and 8.0% (P=.0017); in N2, 270.0±64.8 and 225.8±72.8 minutes (LSM [95% CI], –44.3 [–66.7, –21.9]; P=.0003), 58.5% and 54.2% (P=.0286); in N3, 51.9±35.3 and 92.5±53.5 minutes (LSM [95% CI], 40.6 [25.8, 55.4]; P<.0001), 11.2% and 22.8% (P<.0001); and in REM, 97.7±47.0 and 62.1±35.4 minutes (LSM [95% CI], –35.7 [–46.0, –25.3]; P<.0001), 20.0% and 15.0% (P<.0001).

Conclusion: Participants with idiopathic hypersomnia treated with open-label LXB demonstrated reduced TST on ad libitum polysomnography compared with baseline, increases in N3 sleep, and changes in sleep architecture.

SAFETY AND TOLERABILITY OF ONCE-NIGHTLY SODIUM OXYBATE: A POST HOC ANALYSIS FROM THE LONG-TERM RESTORE STUDY

Bruce Corser[1], John Harsh[2], J. Douglas Hudson[3], Sally Ibrahim[4], Adrian Santamaria[5], Paula Schweitzer[6], Danielle Burroughs[7], Brian Abaluck[7], Jennifer Gudeman[7]

[1] Sleep Management Institute, [2] Colorado Sleep Institute, [3] FutureSearch Trials of Neurology, [4] University Hospitals Cleveland Medical Center and Case Western Reserve University, [5] Northwest Houston Neurology & Comprehensive Sleep Medicine Center, [6] Sleep Medicine & Research Center, St. Luke's Hospital, Chesterfield, MO, USA, [7] Avadel Pharmaceuticals

Introduction: In the phase 3 REST-ON clinical trial, extended-release, once-nightly sodium oxybate (ON-SXB) demonstrated a safety profile consistent with the known oxybate safety profile, with adverse drug reactions (ADRs) primarily related to tolerability. The long-term safety and tolerability of ON-SXB were investigated in the open-label/switch study RESTORE (NCT04451668).

Methods: Participants in RESTORE were ≥16 years of age with narcolepsy type 1 or 2 who had completed the REST-ON trial (without starting another oxybate), were on immediate-release twice-nightly SXB (TN-SXB) for ≥1 month, or were oxybate naive. For participants who completed REST-ON but had not initiated TN-SXB or who were oxybate naive, ON-SXB was initiated at 4.5 g/night and increased weekly by 1.5 g/night as needed up to 9 g/night during a 1- to 2-month titration period. Participants then received ON-SXB until they could be transitioned to commercial therapy. This analysis included data from participants who completed REST-ON (without starting another oxybate) or who were oxybate naive and received ≥1 dose of ON-SXB (safety population). Safety data are reported as treatment-emergent adverse events (TEAEs; ie, any AE that occurs during treatment) and ADRs (ie, TEAEs considered drug-related).

Results: Of the 50 participants (mean age, 33 years; female, 60%; white, 80%; mean [range] ON-SXB treatment, 408.1 [8–1098] days) who were from REST-ON (n=15) or were oxybate naive (n=35), 76% (38/50) reported ≥1 TEAE; most were mild (n=18; 36%) or moderate (n=18; 36%) in severity. TEAEs occurring in ≥10% of participants included nausea (26%), COVID-19 (12%), somnolence (12%), dizziness (10%), vomiting (10%), sinusitis (10%), and tremor (10%). One (2%) participant reported ≥1 serious AE considered related to ON-SXB treatment (anxiety, delusional thoughts) that led to ON-SXB discontinuation. ADRs were reported by 56% (28/50) of participants. ADRs occurring in ≥10% of participants included nausea (24%), somnolence (12%), and dizziness (10%). Seven (14%) participants experienced ≥1 ADR that led to ON-SXB discontinuation; only nausea led to discontinuation in >1 participant (n=2).
Conclusion: These data from RESTORE demonstrate that REST-ON and oxybate-naive participants tolerated ON-SXB well, as TEAEs were primarily mild/moderate in severity. ADRs were aligned with the known safety profile of TN-SXB.

SUCCESSFUL TRANSITION FROM TWICE-NIGHTLY OXYBATES TO ONCE-NIGHTLY SODIUM OXYBATE: A POST HOC ANALYSIS FROM RESTORE

Adrian Santamaria[1], John Harsh[2], Bruce Corser[3], J. Douglas Hudson[4], Sally Ibrahim[5], Paula Schweitzer[6], Brian Abaluck[7], Jennifer Gudeman[7]

[1] Northwest Houston Neurology & Comprehensive Sleep Medicine Center, [2] Colorado Sleep Institute, [3] Sleep Management Institute, [4] FutureSearch Trials of Neurology, [5] University Hospitals Cleveland Medical Center and Case Western Reserve University, [6] Sleep Medicine & Research Center, St. Luke's Hospital, Chesterfield, MO, USA, [7] Avadel Pharmaceuticals

Introduction: Extended-release, once-nightly sodium oxybate (ON-SXB; LUMRYZ™) eliminates the middle-of-the-night dosing required with immediate-release, twice-nightly oxybates (TN-OXBs). RESTORE (NCT04451668) was an open label/switch study that assessed the safety and tolerability of ON-SXB in people with narcolepsy.
Methods: Participants with narcolepsy aged ≥16 years who had completed the phase 3 REST-ON trial, were on stable-dose TN-OXB (switch participants), or were oxybate-naïve were eligible. For switch participants, initial ON-SXB doses were equivalent or closest to their prior total nightly TN-OXB dose. Doses could be titrated at ±1.5g/week until stable dosing was achieved (minimum, 4.5g/night; maximum, 9g/night). Treatment-emergent adverse events (TEAEs) during the 8-week dose titration period were recorded weekly for switch participants in the safety population (ie, received ≥1 ON-SXB dose) who completed a nocturnal AE questionnaire.
Results: Safety data were collected for 99.2% (129/130) of switch participants. All TEAEs reported by ≥3% of switch participants occurred during weeks 1-3; no TEAEs ≥3% were reported during weeks 4-8. At week 1, TEAEs ≥3% included nausea (3.2%), vomiting (3.2%), decreased appetite (3.2%), and urinary retention (3.2%) with the 6-g dose, and headache (7.0%) and somnolence (4.7%) with 9g. At week 2, TEAEs ≥3% included nausea (3.2%), upper respiratory infection (3.2%), dizziness (3.2%), and hypertension (3.2%) with 6g. At week 3, TEAEs ≥3% included vomiting (3.2%), enuresis (3.2%), insomnia (3.2%), and somnambulism (3.2%) with 6g. No TEAEs ≥3% were reported with 4.5g during weeks 1-3, or with 7.5g or 9g during weeks 2-3. Most TEAEs were mild or moderate in severity. The only reported severe TEAE was dyskinesia (1.2%) with the 7.5-g dose. During the ≥3-year RESTORE study, only 5.4% of switch participants discontinued ON-SXB due to a TEAE.
Conclusion: For participants switching from stable-dose TN-OXB, ON-SXB was well tolerated during the 8-week titration period, with most TEAEs being of mild to moderate severity and consistent with the oxybate safety profile. By week 4, no TEAEs were reported by ≥3% of participants, suggesting resolution of many TEAEs during titration. Participants successfully switched to ON-SXB from their nearest or equivalent prior total nightly TN-OXB dose.

REAL-WORLD PATIENT INSIGHTS ON LOW-SODIUM OXYBATE FOR IDIOPATHIC HYPERSOMNIA: INTERIM RESULTS FROM LYRICAL

Caroleen Drachenberg[1], Jennifer Cline[2], Jennifer D'Souza[2], Christina Graham[2], Emily Kim[2], Meaghan Lawrence[2], Meagan Farrell[2], Grecia Sanchez[2], Donald Stull[2], Marisa Whalen[1], Jessica Alexander[1], Laura Herpel[3]

[1] Jazz Pharmaceuticals, [2] IQVIA, [3] Bogan Sleep Consultants

Introduction: Low-sodium oxybate (LXB; Xywav®) is approved by the US Food and Drug Administration to treat excessive daytime sleepiness or cataplexy in patients ≥7 years of age with narcolepsy and adults with idiopathic hypersomnia (IH). To better characterize the treatment experience, including symptoms and quality of life (QoL), a longitudinal mixed methods study (LYRICAL) explores real-world, patient-reported outcomes (PROs) among a US-based cohort of adults with narcolepsy or IH taking LXB.
Methods: This analysis focuses on interim enrollment data from participants with IH on LXB for ≥12 weeks (n=22). An ongoing online survey consisting of standardized PRO instruments and de novo questions is being administered at enrollment, weeks 12 and 24; qualitative interviews are being conducted in a subset of participants. Descriptive analyses were performed with Patient Global Impression of Change (PGIC) items, Epworth Sleepiness Scale (ESS), and Treatment Satisfaction Questionnaire for Medication version 9 (TSQM-9). Initial interview data (n=5) provided supporting evidence. No statistical testing was performed.
Results: At enrollment, the mean time on LXB for participants with IH was 61.4 weeks (standard deviation [SD]=37.5) with a mean nightly dosage of 6.9 grams (SD=2.3). Participants had a mean age of 30.2 years (SD=6.9), with the majority identifying as female (68.2%), White (45.5%) or Black/African American (36.4%); half (50.0%) were taking alerting agents. Nearly all participants (95.4%) reported improvements in IH symptoms compared to before LXB per overall PGIC. Symptom-specific PGIC items indicated improvements in nighttime sleep quality (72.7%), daytime sleepiness (86.4%), and sleep inertia (90.9%). ESS scores were in the mild range (mean=10.8; SD=4.7), with 50.0% reporting "normal" daytime sleepiness (≤10). Participants reported high global satisfaction (mean TSQM-9 score=69.8; SD=16.6); most participants (72.7%) reported being "Satisfied" to "Very satisfied" with symptom relief via LXB. Over 90.0% of participants reported improved QoL since starting LXB, per QoL-specific PGIC. During interviews, participants described

more complete symptom coverage with LXB compared to prior medications and improved day-to-day functioning.
Conclusion: The interim results of patient-reported data suggest improvements in multiple IH symptoms and quality of life compared to before starting LXB; and high global treatment satisfaction with LXB.

REFRESH: PROSPECTIVE, OBSERVATIONAL STUDY DESIGN OF ONCE-NIGHTLY SODIUM OXYBATE FOR NARCOLEPSY IN CLINICAL PRACTICE

Sarah Meskill[1], Gerard Meskill[1], Laura Herpel[2], Adrian Santamaria[3], Jeremy McConnell[4], Oktai Mamedov[5], Robyn Porpiglio[6], Eliot Friedman[7], Brian Abaluck[8], Jennifer Gudeman[8]

[1] Tricoastal Narcolepsy and Sleep Disorder Center, [2] Bogan Sleep Consultants, [3] Northwest Houston Neurology & Comprehensive Sleep Medicine Center, [4] Florida Sleep Specialists, [5] Comprehensive Sleep Center, [6] Ghaly Sleep Management Services, LLC, [7] Pulmonology Associates, [8] Avadel Pharmaceuticals

Introduction: Once-nightly sodium oxybate (ON-SXB; LUMRYZ™) is approved to treat excessive daytime sleepiness and cataplexy in adult and pediatric patients ≥7 years of age with narcolepsy. The REFRESH study assesses the clinical effectiveness, patient satisfaction, and safety of ON-SXB for the treatment of narcolepsy in a real-world setting.
Methods: REFRESH is a multicenter observational study with a targeted enrollment of approximately 60 participants. Inclusion criteria include age ≥18 years and a confirmed diagnosis of narcolepsy type 1 or 2. Individuals who are oxybate naïve or switching from twice-nightly oxybate (TN-OXB) to ON-SXB may participate. Exclusion criteria include prior or current use of ON-SXB, presence of a clinical or mental health condition contraindicated by ON-SXB labeling, or any mental or physical condition deemed exclusionary by the study clinician. Participants complete a baseline assessment before ON-SXB treatment initiation. Clinical assessments are conducted over 4 monthly clinic visits; between visits, participants complete self-assessments. The study assesses changes in Epworth Sleepiness Scale score, Narcolepsy Severity Scale symptom scores, Sheehan Disability Scale, Patient and Clinician Global Impression of Change, and vital signs, including blood pressure. Prior to starting ON-SXB, participants switching from TN-OXB are retrospectively asked how often they missed doses, how missed doses affect their narcolepsy symptoms and function, and if the twice-nightly dosing regimen of TN-OXB was associated with safety concerns. Partners of switch participants can participate to understand how twice-nightly dosing affected them.
Results: Study enrollment began in July 2024.
Conclusion: Understanding the real-world experience of individuals treated with ON-SXB can improve the care of people with narcolepsy in the future. In addition, understanding how treatment with ON-SXB compares with those who previously received TN-OXB is critical to optimizing decision-making for people with narcolepsy and their clinicians.

Introduction: Low-sodium oxybate (LXB; Xywav®) is approved by the US Food and Drug Administration to treat excessive daytime sleepiness (EDS) or cataplexy in patients ≥7 years of age with narcolepsy and adults with idiopathic hypersomnia. The longitudinal mixed methods study LYRICAL examines the real-world, treatment experience of US adults with narcolepsy or idiopathic hypersomnia taking LXB.
Methods: This analysis focuses on interim enrollment data from participants with narcolepsy on LXB for ≥12 weeks (n=33). An ongoing online survey consisting of standardized patient-reported outcome instruments and de novo questions is being administered at enrollment, weeks 12, and 24; interviews are being conducted among a subset of participants. Descriptive analyses were performed on Patient Global Impression of Change (PGIC) items, Epworth Sleepiness Scale (ESS), and Treatment Satisfaction Questionnaire for Medication version 9 (TSQM-9). Initial interview data (n=6) provided supporting evidence. No statistical testing was performed.
Results: At enrollment, the mean time on LXB for participants with narcolepsy was 98.2 weeks (standard deviation [SD]=64.8); mean total nightly dosage was 7.7 grams (SD=1.3); mean age was 32.7 years (SD=7.7). Participants were mostly female (93.9%), White (93.9%), and taking alerting agents (84.8%). All participants (100.0%) reported improvements on PGIC for overall narcolepsy symptoms after initiating LXB. Individual symptom-specific PGICs indicated similar improvements in nighttime sleep quality (93.8%), EDS (96.9%), and cataplexy (90.0%) since starting LXB. Mild levels of EDS were reported after initiating LXB (mean ESS score=11.2; SD=4.2). Participants reported high global satisfaction with LXB treatment (mean TSQM-9 score=72.7, SD=23.0); 75.7% of participants reported being "Satisfied" to "Very satisfied" with symptom relief provided by LXB and 60.6% were "Very" to "Extremely satisfied" with the amount of time needed to experience the effects of LXB. Over 90.0% of participants reported improved quality of life (QoL), per QoL-specific PGIC. Anecdotal interview data suggest high satisfaction with LXB, which may be attributed to reduced symptom burden and more comprehensive symptom coverage relative to prior medications.
Conclusion: Interim results of patient-reported data from the ongoing LYRICAL study suggest that participants with narcolepsy taking LXB experience symptom improvement, improved quality of life, and high global treatment satisfaction.

CORRELATION BETWEEN MAINTENANCE OF WAKEFULNESS TEST AND EPWORTH SLEEPINESS SCALE SCORES IN REST-ON

Thomas Roth[1], Sally Ibrahim[2], Anne Morse[3], Jennifer Gudeman[4], Yves Dauvilliers[5]

[1] Sleep Disorders and Research Center, Henry Ford Health System, [2] University Hospitals Cleveland Medical Center and Case Western Reserve University, [3] Geisinger Commonwealth School of Medicine Geisinger Medical Center Janet Weis Children's Hospital,, [4] Avadel Pharmaceuticals, [5] Sleep-Wake Disorders Center, Department of Neurology, Gui-de-Chauliac Hospital, Institute for Neurosciences of Montpellier INM, INSERM, University of Montpellier,

Introduction: Low-to-moderate strength correlations between Maintenance of Wakefulness Test (MWT) and Epworth Sleepiness Scale (ESS) scores have been reported in clinical trials in narcolepsy. This post hoc analysis of REST-ON (NCT02720744), which demonstrated the efficacy of once-nightly sodium oxybate (ON-SXB; LUMRYZ™) for narcolepsy, assessed the correlation between mean sleep latency (MSL) on the MWT and ESS scores.
Methods: REST-ON participants (age ≥16 years) with narcolepsy were randomized 1:1 to ON-SXB (week 1, 4.5 g; weeks 2-3, 6 g; weeks 4-8, 7.5 g; weeks 9-13, 9 g) or placebo. Pearson correlation coefficients assessed the relationship between MSL (min) on the MWT and ESS score by treatment arm in the modified intent-to-treat (mITT) population (≥1 efficacy measurement after receiving the 6-g dose) at baseline (pretreatment) and weeks 3 (6 g), 8 (7.5 g), and 13 (9 g).
Results: In the mITT population (ON-SXB, n=97; placebo, n=93), respective baseline MSL (SD) on the MWT and baseline mean (SD) ESS score was 5.0 (3.1) and 16.6 (3.8) for ON-SXB and 4.7 (2.6) and 17.5 (4.1) for placebo. At baseline, no correlation was observed between MSL on the MWT and ESS score for either arm (ON-SXB, r=0.015; placebo, r=–0.023). At weeks 3, 8, and 13, respective MSL (SD) was 13.1 (8.8), 14.5 (9.8), and 15.5 (9.8) minutes and respective ESS scores were 13.3 (5.9), 11.6 (6.1), and 10.4 (6.2) for ON-SXB; for placebo, MSL (SD) was 7.8 (5.9), 7.8 (6.3), and 9.4 (7.9) minutes, with ESS scores of 16.6 (4.6), 15.4 (5.3), and 14.9 (5.5). Moderate strength correlations between MSL on the MWT and ESS scores were observed in the ON-SXB arm (r=–0.419, –0.305, –0.394 at weeks 3, 8, 13, respectively). Weak correlations were observed in the placebo group (r=–0.193, –0.271, –0.181 at weeks 3, 8, 13, respectively).
Conclusion: After initiating ON-SXB treatment, the correlation between MWT and ESS scores strengthened, suggesting that improved wakefulness enhances awareness of sleepiness levels in people with narcolepsy.

SUBJECTIVE SLEEP QUALITY WITH LOW-SODIUM OXYBATE TREATMENT IN NARCOLEPSY: RESULTS FROM THE DUET STUDY

R Sangal[1], Emmanuel Mignot[2], Chad Ruoff[3], Deborah Nichols[4], Teresa Steininger[4], Douglas Fuller[4], M. Kirby[4], Marisa Whalen[4], Logan Schneider[5]

[1] Sleep & Attention Disorders Institute, [2] Stanford University, [3] Mayo Clinic, [4] Jazz Pharmaceuticals, [5] Stanford University Center for Sleep Sciences and Medicine

Introduction: Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) is a phase 4, prospective, multicenter, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating the effectiveness of low-sodium oxybate (LXB, Xywav®) treatment on outcomes including sleep quality (using polysomnography [PSG] and self-reported questionnaires) in participants with narcolepsy or idiopathic hypersomnia. Data reported here are from the narcolepsy cohort.
Methods: DUET included a screening period (with 2-week washout for current oxybate users), an 8-day baseline (BL) period, a 2- to 8-week LXB titration period, a 2-week stable-dose period (SDP), an 8-day end-of-treatment (EOT) period, and a 2-week safety follow-up. Participants underwent nocturnal PSG (ad libitum protocol) at BL and EOT. The Karolinska Sleepiness Scale (KSS) was administered 90 minutes post-awakening from PSG to measure situational sleepiness (9-point scale; 1="extremely alert" to 9="extremely sleepy, can't keep awake"). Participants completed an electronic sleep diary (eDiary) daily during the BL and EOT periods, including questions regarding nightly sleep patterns, total sleep time (TST), sleep quality (5-point scale; "very good" to "very poor"), and how rested/refreshed the participant felt upon awakening (5-point scale; "very well" to "not at all"). Completion of ≥5 eDiary days during the 8-day assessment before PSG visits was required for analysis. eDiary and KSS data were analyzed in the completer set (enrolled participants who were dosed with LXB and completed SDP and PSG at EOT).
Results: Fifty-five participants with narcolepsy (type 1, n=26; type 2, n=29) enrolled (completer set, n=34). Most were female (40/55; 73%) and White (44/55; 80%); mean (SD) age was 33.4 (12.9) years. Mean (SD) self-reported nocturnal TST at BL (n=32) and EOT (n=20) was 8.1 (1.6) and 8.3 (0.9) hours, respectively. The percent of participants rating their sleep quality as "very good"/"good" increased from 15.6% (BL) to 70.0% (EOT). The percent of participants with rested sleep ("very well"/"well"/"somewhat" rested) increased from 46.9% (BL) to 90.0% (EOT). Likewise, mean (SD) rating of self-reported sleepiness decreased from 5.1 (2.0) at BL to 3.8 (1.9) at EOT.
Conclusion: Following open-label LXB treatment, participants with narcolepsy reported improvements in sleep quality and feeling more rested and less sleepy upon awakening.

A PHASE 2A, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF ORX750 IN PATIENTS WITH NARCOLEPSY (TYPE 1 AND 2) AND IDIOPATHIC HYPERSOMNIA: STUDY DESIGN

Yves Dauvilliers[1], Guiseppe Plazzi[2], David Plante[3], Emmanuel Mignot[4], Thomas Roth[5], Amanda Sterkel[6], Deborah Hartman[6], Jennifer Kong[6], Mario Accardi[6], Saurabh Saha[6], Ellie Im[7]

Stanford University, [5] Sleep Disorders and Research Center, Henry Ford Health System, [6] Centessa Pharmaceuticals, [7] CENTESSA

Introduction: Narcolepsy types 1 (NT1) and 2 (NT2), and idiopathic hypersomnia (IH) are rare, debilitating central disorders of hypersomnolence characterized by excessive daytime sleepiness (EDS). None of the currently available therapies target the orexin system, which is a core element of wake-promoting circuitries and specifically, of NT1 pathology. ORX750 is a novel, investigational oral orexin-2 receptor (OX2R) agonist that demonstrated strong wake-promoting effects in acutely sleep-deprived healthy volunteers (ongoing phase 1 study). An ongoing phase 2a study, ORX750-0201 will evaluate the safety, tolerability, efficacy, and PK of ORX750 in NT1, NT2, and IH patients.
Methods: This phase 2a study is a randomized, double-blind, placebo-controlled, cross-over basket study with separate cohorts for NT1, NT2, and IH. Initial dosing will be 1 mg (NT1) and 2 mg (NT2 and IH) with sequential dose escalation/de-escalation between cohorts. Within dosing cohorts, participants will be randomized to one of two blinded treatment sequences and receive ORX750 for 4 weeks and placebo for 2 weeks (6-week treatment duration total) in a crossover design. Efficacy endpoints will include the Maintenance of Wakefulness Test (MWT), Epworth Sleepiness Scale (ESS), and weekly cataplexy rate (NT1 only). Other exploratory assessments include measures of overall symptom improvement, sleep, cognition, attention, memory, and general health.
Results: This study plans to complete 78 participants (n=18 NT1; n=24 NT2; n=36 IH), with three dose cohorts per disorder. This 6-week crossover study has >87.5 % power within each dosing cohort to detect a 15 min change in mean sleep latency on the MWT relative to placebo (two-sided α=0.05). The study initiated with participating sites in the US, Canada, and EU. Data for all three disorders are expected in 2025.
Conclusion: This study will evaluate the safety, tolerability, efficacy, and PK of multiple doses of ORX750 for the first time in patients with NT1, NT2, and IH with results informing future clinical studies.

SLEEP ARCHITECTURE WITH LOW-SODIUM OXYBATE TREATMENT IN NARCOLEPSY: RESULTS FROM THE DUET STUDY

Chad Ruoff[1], Logan Schneider[2], R Sangal[3], Deborah Nichols[4], Teresa Steininger[4], Douglas Fuller[4], M. Kirby[4], Jessica Alexander[4], Emmanuel Mignot[5]
[1] Mayo Clinic, [2] Stanford University Center for Sleep Sciences and Medicine, [3] Sleep & Attention Disorders Institute, [4] Jazz Pharmaceuticals, [5] Stanford University

Introduction: Jazz DUET (Develop hypersomnia Understanding by Evaluating low-sodium oxybate Treatment) is a phase 4, prospective, multicenter, single-arm, multiple-cohort, open-label study (NCT05875974) evaluating effectiveness of low-sodium oxybate (LXB, Xywav®) treatment on outcomes including polysomnography (PSG)-based sleep architecture in participants with idiopathic hypersomnia or narcolepsy (type 1 [NT1] or 2 [NT2]).
Methods: DUET included a screening period (2-week washout for current oxybate users), 8-day baseline (BL) period, 2- to 8-week LXB titration period, 2-week stable-dose period (SDP), 8-day end-of-treatment period (EOT), and 2-week safety follow-up. Participants underwent nocturnal PSG (ad libitum protocol) at BL and EOT. PSGs were scheduled to allow a minimum of 10 hours in bed, unless the participant naturally awakened earlier; bedtime was determined by habitual bedtime. PSG recordings were centrally scored. Data were analyzed for participants in the narcolepsy cohort completer set. Total shifts from deeper to lighter sleep stages was defined as N1/N2/N3/REM to wake and N2/N3/REM to N1. Key secondary endpoints (total stage shifts, N3 duration) were controlled for multiplicity with sequential testing; other P-values are considered nominal.
Results: Fifty-five participants with narcolepsy enrolled (NT1, n=26; NT2, n=29); 34 completed the study (NT1, n=16; NT2, n=18). Most were female (73%) and White (80%) (mean±SD age, 33.4±12.9 years). Mean±SD total sleep time (TST) at BL/EOT was 453.2±80.1/452.4±70.0 minutes (LSM change [95% CI]: –0.78 [–23.7, 22.1]; P=.9451). Mean±SD number of total shifts from deeper to lighter sleep stages at BL/EOT was 54.6±28.0/41.6±25.6 (LSM [95% CI]: –13.1 [–19.0, –7.1]; P<.0001 [controlled for multiplicity]). Mean±SD time spent in N1 at BL/EOT was 45.3±28.4/37.2±25.2 minutes (LSM [95% CI]: –8.1 [–14.9, –1.4]; P=.0196), % of stage was 10.4%/8.2% (P=.0037); in N2 was 241.8±61.2/243.3±76.1 minutes (LSM [95% CI]: 1.5 [–23.6, 26.6]; P=.9040), 53.1%/53.2% (P=.9869); in N3 was 61.1±34.8/106.1±69.5 minutes (LSM [95% CI]: 45.0 [27.0, 63.0]; P<.0001 [controlled for multiplicity]), 13.7%/24.0% (P<.0001); and in REM was 105.0±42.7/65.8±33.1 minutes (LSM [95% CI]: –39.2 [–50.8, –27.5]; P<.0001), 22.8%/14.7% (P<.0001).
Conclusion: Participants with narcolepsy taking open-label LXB showed negligible change in TST and N2, increased N3, decreased N1 and REM, and fewer shifts from deeper to lighter stages of sleep.

PHASE 1 CLINICAL DATA WITH OREXIN RECEPTOR 2 (OX2R) AGONIST, ORX750, IN ACUTELY SLEEP-DEPRIVED HEALTHY VOLUNTEERS

Deborah Hartman[1], Amanda Sterkel[1], Jennifer Kong[1], Emiliangelo Ratti[1], Mario Accardi[1], Saurabh Saha[1], Ellie Im[2]
[1] Centessa Pharmaceuticals, [2] CENTESSA

Introduction: ORX750 is a novel, investigational oral orexin receptor 2 (OX2R) agonist in development for the treatment of narcolepsy and idiopathic hypersomnia. Strong wake-promoting effects were observed in preclinical studies, supporting clinical investigation of ORX750. A first-in-human phase 1 study is ongoing to evaluate the safety and wake-promoting effects of single and multiple oral doses of ORX750.
Methods: Safety, tolerability, and pharmacokinetics of ORX750 were evaluated at single-ascending doses (SAD) and multiple-ascending doses (MAD) in a randomized, placebo-controlled study in healthy volunteers. Following the SAD study, wake-promoting effects were evaluated in placebo-controlled Proof of Concept (POC) cohorts with a single dose, two-way crossover design in acutely sleep-deprived subjects utilizing the Maintenance of Wakefulness Test (MWT).
Results: As of the data cut-off date of October 31, 2024, five SAD (total N=45 active, N=15 placebo), three POC (N=8, N=8, N=10), and 2 MAD cohorts (N=16 active, N=4 placebo) have

completed. Observed least squares (LS) mean (95% confidence interval [CI]) sleep onset latencies (minutes) in the MWT were 17.6 (12.1, 23.2), 32.0 (22.2, 41.8), and 33.6 (27.1, 40.1) at 1.0 mg, 2.5 mg, and 3.5 mg once daily (QD), respectively. Average LS mean (95% CI) difference from placebo for mean sleep latency was 8.1 (0.3,15.9), p=0.04 for 1.0mg, 15.2 (4.7, 25.8), p=0.01 for 2.5 mg, and 20.2 (15.2, 25.2), p< 0.0001 for 3.5 mg. Across SAD and MAD cohorts, treatment emergent adverse events were transient and mild in severity. This abstract will be supplemented with data from additional cohorts at the time of presentation.
Conclusion: ORX750 showed a favorable safety profile and clinically meaningful and statistically significant improvements on wakefulness in acutely sleep-deprived healthy volunteers. ORX750 was well tolerated, and normative wakefulness (>30 mins on the MWT) was achieved at the doses ≥ 2.5mg. These results support continued evaluation of ORX750 for the potential treatment of narcolepsy (type 1 and type 2) and idiopathic hypersomnia.

ASSESSING PATIENT PREFERENCE OF SOLRIAMFETOL FOLLOWING USAGE OF MODAFINIL/ARMODAFINIL: A SINGLE CENTER RETROSPECTIVE ANALYSIS

Grace Martin[1], Prisha Patel[1], Pratik Pohuja[1], Sarah Meskill[2], Gerard Meskill[2]

[1] Tricoastal Narcolepsy and Sleep Disorders Center, [2] Tricoastal Narcolepsy and Sleep Disorder Center

Introduction: Wakefulness promoting agents (WPA) are a class of drugs typically used for patients suffering from excessive daytime sleepiness to improve alertness. The most commonly utilized WPAs are modafinil/armodafinil ("modafinils"), and solriamfetol (trade name: Sunosi). The modafinils are similar in nature: modafinil is a racemic mixture of R and S isomers, while armodafinil is the isolated R isomer. The modafinils inhibit dopamine reuptake, while solriamfetol inhibits both dopamine and norepinephrine reuptake. Considering the difference in mechanisms and pharmacokinetic properties, more data are needed to assess the real world preferences of patients who are offered Sunosi while established on a modafinil product.
Methods: A manual chart review from 1/1/2024 to 6/1/2024 was conducted at a comprehensive sleep center in Sugar Land, TX to screen for patients with a diagnosis of obstructive sleep apnea, narcolepsy type 1, narcolepsy type 2, or idiopathic hypersomnia and who were on a modafinil product prior to switching to solriamfetol. Screening was conducted by using EMR software reporting to search for "Sunosi" in the impression and plan section of patient notes. Presence of inclusion criteria was confirmed manually. Patients who did not continue any WPA or were taking both a modafinil and solriamfetol were excluded.
Results: Sixty-two patients tried solriamfetol after being prescribed a modafinil product. Of these, 44 (71%) patients preferred solriamfeol, while 18 (29%) switched back to a modafinil. Of those who switched back, 12 (67%) reported superior benefit with the modafinil product, which 6 (33%) reported adverse events (2 citing anxiety, 1 each citing mood change, headache, anorexia, "felt funny").
Conclusion: Out of the patients that tried both a modafinil product and solriamfetol, most preferred solriamfetol. Additional analysis targeting patients naive to both agent types would be beneficial to eliminate sampling bias.

DOSAGE COMPARISON OF PATIENTS SWITCHING FROM TWICE NIGHTLY OXYBATE (TN-OXB) TO ONCE NIGHTLY OXYBATE (ON-OXB): A SINGLE CENTER COMPARATIVE ANALYSIS

Pratik Pohuja[1], Prisha Patel[1], Grace Martin[1], Gerard Meskill[2], Sarah Meskill[2]

[1] Tricoastal Narcolepsy and Sleep Disorders Center, [2] Tricoastal Narcolepsy and Sleep Disorder Center

Introduction: Narcolepsy is a chronic neurological condition associated with excessive daytime sleepiness (EDS), sleep fragmentation, and features of rapid eye movement (REM) dissociation. Sodium oxybate has been standard of care in narcolepsy management, starting with the FDA approval of TN-OXB in 2002. ON-OXB was FDA approved in 2023. As patients switch from TN-OXB to ON-OXB, it's becoming increasingly important to find the appropriate dose for switching patients to stabilize. However, there is little information published regarding dosing guidelines or real-world experience of patients switching from an established TN-OXB dose to ON-OXB.
Methods: In a comprehensive sleep center in Sugar Land, TX, a cohort of narcolepsy type 1 and 2 patients were studied from 6/1/2023 to 12/18/2024 to assess optimized ON-OXB dosing after switching from an established stable TN-OXB dose. Patient records were reviewed manually for dosages. The total amount of nightly oxybate and percentages of doses that increased, decreased, or remained the same were calculated.
Results: Twenty-three patients were found to have switched from TN-OXB and currently remain on ON-OXB. From these, 10 (43.5%) had an overall dose increase after switching, 4 (17.4%) had a dose decrease, and 9 (39.1%) had their total dose remain the same. Only 1 (4.3%) patient who was taking 9 grams of TN-OXB ended up on a lower dose of ON-OXB. The average total dosage went from 7.02 g nightly to 7.30 g nightly (mean difference 0.28; 95% CI -0.70-1.27).
Conclusion: The majority of patients (19 out of 23, 82.6%) who switched from TN-OXB to ON-OXB either maintained or increased their total nightly dosage of oxybate. These findings could provide dosing guidelines for the treatment of narcolepsy using oxybate therapy.

INM, INSERM, University of Montpellier,, [6] Harmony Biosciences Holdings, Inc.

Introduction: Pitolisant is FDA approved for the treatment of excessive daytime sleepiness (EDS) or cataplexy in adult patients with narcolepsy and for the treatment of EDS in pediatric patients ≥6 years with narcolepsy. Given the adjacency between IH and narcolepsy and pharmacological treatments for IH are limited, the efficacy of pitolisant is being evaluated in adult patients with IH.
Methods: The present analyses focused on a 4-week double-blind randomized withdrawal period (DBRWP) within a 12-week phase 3 clinical trial to evaluate the safety and efficacy of pitolisant in adult patients with IH (NCT05156047). Patients (213) initially received pitolisant for an 8-week open-label period (OLP) and then were assessed for their treatment response. Treatment responders (≥3-point reduction in their Epworth Sleepiness Scale [ESS] scores across the OLP) entered the DBRWP and were randomized to continue receiving dose-matched pitolisant or placebo. Primary and key-secondary efficacy measures included the ESS and the Idiopathic Hypersomnia Severity Scale (IHSS), respectively; change scores were evaluated from the end of the OLP to the end of the 4-week DBRWP for pitolisant compared with placebo.
Results: Among the 173/213 patients who completed the OLP (81.2%), 139 (80.3%) of them were considered treatment responders and entered the DBRWP (mean±SD age: 39.9±11.91 years; 78.6% female). During the DBRWP the LSM difference (95% CI) in total score between the pitolisant and placebo treatment groups was not statistically significant for the ESS (-0.85 [-2.24, 0.54]; P=0.228) and narrowly missed nominal statistical significance for the IHSS (-2.27 [-4.62, 0.08]; P=0.058). When statistically adjusting for the suspected placebo effect and suspected regression to the mean, there was a nominally statistically significant difference between pitolisant and placebo on the ESS (-1.51 [-2.84, -0.18] P=0.026) and the IHSS (-3.20 [-5.49, -0.90] P=0.006). No new safety signals were observed.
Conclusion: During the 4-week DBRWP, positive trends favoring pitolisant were observed on the ESS and IHSS; however, they did not reach prespecified statistical significance. Ad hoc analyses showed nominally statistically significant improvements in ESS and IHSS. Pitolisant may offer a favorable benefit-risk profile and could be a potential treatment option for patients with IH.

EFFECT OF PITOLISANT ON SYMPTOMS OF IDIOPATHIC HYPERSOMNIA DURING AN OPEN-LABEL PERIOD IN A PHASE 3 CLINICAL TRIAL

Bruce Corser[1], David Plante[2], Christopher Drake[3], Richard Bogan[4], Yves Dauvilliers[5], Salvatore Insana[6], David Seiden[6], George Nomikos[6], Michelle Manuel[6], Eric Bauer[6], Kumar Budur[6], Jeffrey Dayno[6]

[1] Sleep Management Institute, [2] University of Wisconsin-Madison, [3] Henry Ford Health System, [4] Bogan Sleep Consultants, [5] Sleep-Wake Disorders Center, Department of Neurology, Guide-Chauliac Hospital, Institute for Neurosciences of Montpellier INM, INSERM, University of Montpellier, [6] Harmony Biosciences Holdings, Inc.

Introduction: Idiopathic Hypersomnia (IH) is a rare and chronic neurological disorder. People with IH experience severe excessive daytime sleepiness (EDS), sleep inertia, and a multitude of adverse functional outcomes. Pharmacological treatments for IH are limited. Pitolisant is FDA approved for the treatment of EDS and cataplexy in adult patients and for excessive daytime sleepiness in pediatric patients ≥6 years with narcolepsy.
Methods: The present analyses focused on an eight-week open-label period (OLP) that was part of a twelve-week double-blind, placebo-controlled, randomized withdrawal phase 3 clinical trial to evaluate the safety and efficacy of pitolisant in adult patients with IH (NCT05156047). During the OLP, eligible participants were titrated with pitolisant for three weeks (8.9 mg, 17.8 mg, and 35.6 mg), then began a three-week flexible dose period, and concluded with a two-week stable dose period. Efficacy measures included the Epworth Sleepiness Scale (ESS), Sleep Inertia Questionnaire (SIQ), Functional Outcomes of Sleep Questionnaire (FOSQ-10), Patient-Reported Outcomes Measurement Information System, Sleep Related Impairment (PROMIS-SRI), Idiopathic Hypersomnia Severity Scale (IHSS), Patient Global Impression of Severity of EDS (PGI-S), and Clinician Global Impression of Severity of IH (CGI-S). Efficacy measures were evaluated for change from OLP baseline to the end of the eight-week OLP.
Results: Two hundred and thirteen patients (mean±SD age; 39.7±12.85 years; 79.3% female) were enrolled in the trial. There was a nominally statistically significant (P< 0.0001) group mean reduction in all efficacy measures from the OLP baseline to the end of the eight-week OLP (mean±SD): ESS (16.2±3.40, 8.7±5.04; delta=-7.6±5.12); SIQ (70.0±16.91, 52.8±19.86; delta=-18.0±19.14); FOSQ-10 (11.23±2.70, 13.72±3.56; delta=2.60±3.00); PROMIS-SRI (28.7±4.85, 21.6±6.58; delta=-7.2±6.36); IHSS (33.3±7.48, 25.8±9.44; delta=-7.7±7.94); PGI-S (3.8±0.72, 2.8±0.96; delta=-1.1±1.07); and CGI-S (3.7±0.60, 2.6±0.89; delta=-1.1±0.87). Among the 173 patients who completed the OLP (81.2%), 144 (83.2%) of them achieved a ≥3-point reduction on their ESS score, and 136 (78.6%) achieved a ≥4-point reduction on their IHSS score.
Conclusion: In an 8-week OLP of a phase 3 clinical trial in adult patients with IH, pitolisant demonstrated robust improvements in EDS, sleep inertia, and a multitude of functional outcomes. A large majority of patients exhibited clinically meaningful reductions in their EDS and IH symptoms.

Introduction: Pitolisant is being evaluated for use in adult patients with IH in two phase 3 clinical trials, a double-blind randomized withdrawal (DBRW) and an open-label extension (OLE). The present analyses focused on the safety and effectiveness of long-term administration of pitolisant in adult patients with IH across 13 months. The OLE study is ongoing.

Methods: Open-label data were integrated across two contiguous phase 3 clinical trials (DBRW: NCT05156047; OLE: NCT05458128). Safety measures included treatment-related treatment-emergent adverse events (TR-TEAEs). Effectiveness measures included the Epworth Sleepiness Scale (ESS); Idiopathic Hypersomnia Severity Scale (IHSS); Patient-Reported Outcomes Measurement Information System, Sleep Related Impairment-8a (PROMIS-SRI); Patient Sleep Inertia Questionnaire (SIQ); Functional Outcomes of Sleep Questionnaire (FOSQ-10); Patient Global Impression of Severity of EDS (PGI-S); and Clinician Global Impression of Severity of IH (CGI-S). Effectiveness measures were assessed at baseline, Month 2, Month 4, Month 10, and Month 16.

Results: The safety population included 213 patients who received at least one dose of pitolisant (mean±SD age, 39.7±12.85 years; 79.3% female). The median duration of pitolisant exposure was 39.14 weeks (range: 0.71-93.29 weeks) and the median maximum pitolisant dosage was 35.6 mg (median [range: 8.9-35.6 mg]). Among this population, 102 participants (47.9%) experienced a TR-TEAE; most frequent TR-TEAEs were headache (17.8%), insomnia (16.0%), and abnormal dreams (5.2%). The effectiveness population included 119 adult patients who enrolled in both trials (mean±SD age, 40.1±11.96 years; 79.8% female). Generally, the sample size remained stable across timepoints. All effectiveness measures demonstrated a nominally statistically significant reduction ($P< 0.0001$) from study baseline at every timepoint. Effectiveness measures are reported as baseline mean±SD, and change from baseline across all timepoints (range: lowest, highest change across endpoints [mean±SD]): ESS, 16.6±2.99 (-8.4±4.46, -9.7±4.69); IHSS, 33.7±7.10 (-9.8±7.56, -13.4±8.66); PROMIS-SRI, 64.16±4.89 (-8.35±7.26, -10.11±5.56); SIQ, 71.8±17.14 (-21.2±17.21, -24.9±18.91); FOSQ-10, 11.14±2.77 (3.31±2.99, 4.24±3.07); PGI-S, 3.9±0.74 (-1.2±0.99, -1.4±0.95); and CGI-S, 3.6±0.60 (-1.2±0.89, -1.3±0.78).

Conclusion: Pitolisant was well-tolerated, and the safety profile was consistent with the established safety profile for patients with narcolepsy. Pitolisant showed clinically meaningful and sustained improvements in multiple symptoms of IH across a >1-year dosing period.

SHIFT WORKER ADAPTATION SUBTYPES: K-MEANS CLUSTERING FOLLOWED BY CIRCADIAN RHYTHM AND STRESS REACTIVITY ANALYSES

Sung Hyun Kim[1], Ha Young Lee[2], Jeong Eun Jeon[2], Jin Hyuk Yoo[2], Minah Kim[2], Sun-Young Kim[3], Jiyoon Shin[4], Kyung Hwa Lee[2], Hong-Beom Shin[5], Seog Ju Kim[6], Yu Jin Lee[2]

Introduction: Shift work disrupts sleep and circadian rhythms, causing sleep and mood disturbances, and reduced quality of life. Symptom variability among shift workers remains insufficiently characterized. We aimed to classify adaptation subtypes in shift workers using K-means clustering based on psychiatric symptom scores. Subsequently, circadian rest/activity rhythms (RARs) and stress reactivity among these subgroups were examined.

Methods: 109 shift workers (93 females; mean age: 35.52 ± 10.54 years) completed self-report questionnaires, including the Beck Depression Inventory (BDI), Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS), and Ford Insomnia Response to Stress Test (FIRST). Actigraphy and sleep diary data were collected over 7-14 days to assess circadian RARs. K-means clustering used BDI, ISI, and ESS scores. Statistical analyses included ANOVA/Kruskal-Wallis, post-hoc tests, and ANCOVA adjusting for age, sex, and drinking.

Results: K-means clustering identified four distinct subtypes. Subtype 1 (well-adapted, n=40) showed the lowest BDI (3.27 ± 2.66), ISI (4.5 ± 2.09), and ESS (7.2 ± 2.79) scores. Subtype 2 (insomnia-predominant, n=28) represented high ISI (11.11 ± 2.62) but moderate BDI (5.00 ± 2.15) and ESS (8.86 ± 3.08). Subtype 3 (depression-predominant, n=28) presented high BDI (12.54 ± 2.96) but moderate ISI (9.29 ± 3.42) and ESS (8.61 ± 3.20). Subtype 4 (maladaptive, n=13) exhibited markedly high BDI (20.69 ± 3.85), ISI (15.69 ± 2.97), and ESS (12.15 ± 3.98). Significant differences in circadian RARs were observed between subtype 2 (insomnia-predominant) and subtype 3 (depression-predominant), with subtype 2 exhibiting lower RA (p=0.028) and higher L5 (p=0.015) than subtype 3. FIRST was lowest in subtype 1 (well-adapted) and highest in subtype 4 (maladaptive). Subtype 4 significantly differed from both subtype 1 (p=0.0023) and 2 (p=0.015). ANCOVA showed significant L5 (p=0.037) and FIRST (p=0.029) differences, while RA was approaching significance (p=0.063).

Conclusion: This study proposed four shift worker adaptation subtypes: well-adapted, insomnia-predominant, depression-predominant, and maladaptive, based on psychiatric and sleep-wake symptoms. Mood disturbances and insomnia emerged as key contributors to symptom heterogeneity. The shift worker subtypes in this study showed different characteristics in circadian RARs (RA and L5) and stress reactivity (FIRST), providing insights into individual differences in shift work tolerance.

SHIFT WORK DISORDER PREVALENCE AND ASSOCIATED CHARACTERISTICS USING THE MOBILE APPLICATION SLEEP BY CLEVELAND CLINIC™

Sikawat Thanaviratananich[1], Jinu Johnson[1], James Bena[2], Nancy Foldvary-Schaefer[3]

[1] Cleveland Clinic Foundation, [2] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [3] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH

Introduction: Shift Work Disorder (SWD) arises from recurring work schedules overlapping typical sleep times. SWD is associated with increased risks of medical and psychiatric disorders with estimated prevalence of 2-5%, likely to be underestimated. We studied the prevalence and associated characteristics of SWD using a mobile application developed to estimate sleep disorder risk in adults.

Methods: SLEEP by Cleveland Clinic™ is a free iOS/Android mobile application that evaluates sleep disorder risk including Cleveland Clinic Sleep Apnea Probability Score (Katzan, Sleep Med 2016), Insomnia Severity Index (ISI; Morin, Sleep 2011), 24-hr sleep duration, and SWD (Barger, Sleep 2012). Demographic, comorbidity and sleep disorder risks were compared between high-risk (HR) and low-risk (LR) SWD groups using Pearson chi-square and t-tests, where appropriate.

Results: There were 5,217 unique user downloads Nov 2019-Dec 2024. Of these 3,515 provided geographic information and 2,149 (61%) were Ohio residents. Among 445 users who completed SWD screening, 198 (44.5%) were HR and 247 (55.5%) LR. HR SWD users were younger (40 + 13 vs 44 + 14 yrs) and more likely to be female (69 vs 57%), both p=0.009, work full time (85 vs 71%; p< 0.001), work nights/rotating shifts (80 vs 67%; p=0.006) and work longer shifts (p< 0.001) without difference in race or BMI. HR SWD was associated with higher mental health disorder diagnoses (66% vs 38%, p=0.001), more alcoholic drinks/week (0.0 (0.0,2.0) vs 1.0(0.0,3.0; p=0.032)), and more sleep aid use (53 vs 40%; p=0.035), but were similar on caffeine and tobacco use. ISI was higher in HR SWD (18(14,21) vs 13(9,17); p< 0.001)) but habitual sleep duration was comparable. LR SWD had higher probability of OSA and moderate-severe OSA 57(23,80)/15(6,9) vs 36(11,72)/9(3,23; p=0.002).

Conclusion: Among users of a sleep screening mobile application who completed SWD screening, nearly half classified as HR SWD were more likely to work nights/rotating shifts, use alcohol and sleep aids, have mental health disorders and have higher insomnia severity, but lower risk of OSA. The application provides immediate accessibly to sleep disorder risk that can help identify SWD, insomnia and OSA among adults with smartphones.

SLEEP MEASUREMENT OF 3-SHIFT WORKERS AT A CHEMICAL PRODUCT FACTORY USING AN IN-HOME SLEEP EEG

Shigeru Chiba[1], Jaehoon Seol[1], Tsuyoshi Nemoto[1], Yuta Sudo-Konno[1], Toshio Kokubo[1], Masashi Yanagisawa[1], Takashi Kanbayashi[1]

[1] International Institute for Integrative Sleep Medicine, Tsukuba Univ.

Introduction: In Japan, over 12 million workers are engaged in night and shift work. Such irregular and long working hours may lead to reduced or fragmented sleep, as well as disruptions in circadian rhythms, which have been associated with an increased risk of sleep disorders, prostate cancer, and breast cancer. Previous research on shift workers' sleep has mainly relied on questionnaires or actigraphy, with limited studies utilizing electroencephalography (EEG) to analyze detailed sleep architecture.
Methods: Six shift workers aged 23–42 at a chemical plant in Osaka participated in this study. The plant follows a reverse-rotating schedule comprising four consecutive night shifts (22:50–7:00), followed by four afternoon shifts (14:50–23:00) and four morning shifts (6:50–15:00), with 1–2 rest days between shifts. Sleep was measured using a simplified EEG device developed at the University of Tsukuba. Each participant's sleep duration and sleep stages were recorded at least twice for each shift type and during rest days. Missing data due to sudden schedule changes were corrected through linear estimation. The study was approved by the ethical committee.
Results: The average sleep duration was 223 minutes on night shifts, 337 minutes on afternoon shifts, and 393 minutes on morning shifts. Regarding sleep stages, N2 and REM sleep were notably shorter on night shift days compared to other shifts, although no significant differences were observed for N1 or N3 stages. Additionally, Sleep Onset REM Periods (SOREMP), characterized by REM sleep occurring within 15 minutes of sleep onset, were observed in 50% (3/6) of participants.
Conclusion: Night shifts were associated with reduced N2 and REM sleep, suggesting that workers may compensate for these deficits on non-night shift days. The high occurrence of SOREMP further reflects REM sleep deprivation on night shift days.

AGE-RELATED DIFFERENCES IN HEART RATE AND VARIABILITY DURING SIMULATED JET LAG: EFFECTS OF BRIGHT LIGHT, EXERCISE, AND MELATONIN

Milin Patel[1], Kiyan Saissan[1], Natalie Mak[1], Shawn Youngstedt[2], Salma Patel[3]

[1] Sleep Medicine, The University of Arizona College of Medicine, [2] Arizona State University College of Health Innovation, [3] The University of Arizona

Introduction: Jet lag is a circadian rhythm disorder caused by misalignment of the body's internal clock with local time after traveling through multiple time zones. The effects of jet lag may intensify with age. This study evaluates age-related differences in heart rate and heart rate variability (HRV) during simulated jet lag and in response to interventions, including bright light, exercise, and melatonin.
Methods: Participants underwent a 5.5-day laboratory protocol with Holter monitoring. On Day 1, they followed a normal sleep schedule. On day 2, they adopted an ultra-short sleep-wake cycle (2 hours awake, 1 hour asleep) for 26 hours. On days 3-5, an 8-hour delay in the sleep-wake and light-dark schedules simulated westward travel. Participants were randomized into one of three groups: placebo, bright light (5,000 lux), or a combination of bright light, melatonin (0.5 mg), and exercise. Treatments were administered for three days, followed by a second 26-hour ultra-short sleep-wake cycle on Days 5-6. Heart rate and HRV were measured, and results were analyzed by age group (< 26 years and >26 years)
Results: 16 participants (86% male; mean age 28.4 ± 9.56 years) were randomized into placebo (N=5), bright light (N=7), or bright light + exercise + melatonin (N=3). In participants < 26 years, heart rate increased during the first ultra-short sleep period in the placebo group (72.66 ± 8.01; p=0.0157) but decreased with bright light treatment (64.36 ± 5.48; p=0.0425) compared to baseline (68.93 ± 10.8). HRV increased significantly in this group during treatment (1.83 ± 2.23 vs. 6.65 ± 1.54; p=0.0313). For participants >26 years, heart rate increased during the first ultra-short period in the placebo group (81.17 ± 9.70; p=0.0504) and decreased with bright light (77.49 ± 11.84; p=0.0754) compared to baseline (79.68 ± 11.92). No changes in HRV were observed in participants >26 years.
Conclusion: Bright light therapy increased HRV in participants < 26 years, while no such changes were observed in those >26 years. These results suggest age-specific differences in responses to circadian interventions and highlight the potential for targeted treatments to mitigate jet lag effects.

THE EFFECTS OF JET LAG AND CIRCADIAN ACCLIMATION OF PERFORMANCE, SLEEP, AND 6-SULFATOXYMELATONIN ON PSYCHOMOTOR VIGILANCE REACTION TIMES

Hayley Bartel[1], Natalie Mak[2], Shawn Youngstedt[3], Salma Patel[4]

[1] University of Arizona, [2] Sleep Medicine, The University of Arizona College of Medicine, [3] Arizona State University College of Health Innovation, [4] The University of Arizona

Introduction: Jet lag is a disruption of circadian rhythms caused by a mismatch between the body's internal clock and the local time, often resulting from travel across time zones or significant shifts in sleep patterns due to work or social obligations. This misalignment can influence hormonal balance and lead to various symptoms, including impaired mental health, reduced physical and cognitive performance, and poor sleep quality. This study aims to evaluate the effects of jet lag treatments on the psychomotor vigilance test.
Methods: After an 8-hour baseline sleep recording, participants followed a 26-hour protocol of 2 hours awake and 1 hour asleep. Subsequently, they underwent an 8-hour simulated time zone delay, maintained for three days. Participants were randomized into one of three treatment groups: (1) Dim Red Light + Placebo Capsules, (2) Bright Light Alone, or (3) Bright Light + Exercise + Melatonin. A final 26-hour protocol repeated the 2-hour wake and 1-hour sleep schedule. Psychomotor Vigilance Task (PVT) assessments were conducted every three hours, excluding sleep, with mean reaction time as the primary outcome measure.
Results: The study included 25 participants (19 males, 6 females; mean age 28.6 ± 9.48 years). Six participants received placebo, nine bright light alone, and ten bright light + exercise + melatonin. In the placebo group, mean reaction time was 256.031ms. The bright light alone group showed a non-significant increase of 4.576ms (p=0.719), while the bright light + exercise + melatonin group exhibited a non-significant decrease of 5.639ms (p=0.652). Across all groups, baseline mean reaction time was

233.249ms, increasing by 25.689ms during the treatment phase (p=5.63e-08), reflecting a significant effect of the simulated jet lag.
Conclusion: While the differences between treatment groups were not statistically significant, the overall treatment phase significantly impacted reaction times, highlighting the measurable effects of jet lag on cognitive performance. Further research is needed to determine the effectiveness of specific interventions.

ACTIGRAPHY DATA ANALYSIS OF LIGHT EXPOSURE AND SLEEP PATTERNS IN CANCER SURVIVORS USING A DATA SCIENCE APPROACH

Youngran Cha[1], Daniel Smith[1], Suzanne Dickerson[1]
[1] SUNY at Buffalo

Introduction: Sleep-wake disturbance affects 30%-75% of cancer survivors that significantly threatens to exacerbate fatigue, depression, treatment outcomes, disrupted circadian rhythms impacting quality of life. Thus, understanding the influence of light as an effective environmental cue to regulate circadian rhythms may give insight into improved sleep-wake cycles. Current literature on light therapy protocols is missing key information that could be understood by a Data Science approach. Actual light measurements such as daily light timing, intensity, and duration could be measured in waveform data using wrist-worn actigraphy. This data provides 1-minute epochs of data light measurements (light exposure, time, duration, intensity) to compare with sleep pattern variables (total sleep time, sleep efficiency, sleep onset latency, and wake after-sleep onset) which reflect sleep quality related to light exposure. This paper will explain the analytical approach to comprehensively analyze the relationship between light exposure indicators and sleep-wake patterns.
Methods: This study will comprise a retrospective secondary data analysis using baseline actigraphy data from a randomized controlled trial (RCT) (NCT 03810365). The dataset was collected between June 2019 and October 2022 using the actigraphy data from 132 cancer survivors for 7 consecutive days. The analysis includes dataset preparation of actigraphy data of rest-activity and light exposure in a sample of 7 days of data per patient. R programming will be used to transform raw light exposure data into usable information. The analysis of data includes using conditional inference trees and random forest plots to visualize the results and identify important factors in the model that will examine the relationship between light exposure and sleep outcomes. Extreme gradient boosting will be used for prediction of sleep outcomes. The impact of light exposure on sleep outcomes during the 1, 2, and 3 hours before bedtime, as well as the relationship between 24-hour continuous light exposure patterns and sleep outcomes, will also be analyzed.
Results: The paper will outline the procedures for preparing, cleaning data, and analysis.
Conclusion: This paper will explore a data science approach to understand the analysis method of evaluating light exposure and sleep outcomes. Future research could consider alternative light measurement tools to provide more reliable insights.

AGE-RELATED INCREASE OF CIRCANNUAL CORRELATION BETWEEN DAY LENGTH AND SEVERE SEIZURES

Marcus Ng[1], Ran Liu[2], Darion Toutant[1], Peter Bergin[3], Milena Pavlova[4]
[1] University of Manitoba, [2] University of Toronto, [3] Auckland District Health Board, [4] Brigham and Women's Hospital and Harvard Medical School

Introduction: Recent work at Earth's extreme poles in the northern and southern hemispheres has shown a significant correlation between increasing day length (i.e. solar time and severe seizures across the year with higher frequency during months of increasing day length). Age-wise, however, epilepsy prevalence is bimodal, peaking once in younger life and again in later life. It remains unknown whether the correlation between day length and seizure occurrence is uniform across the lifespan.
Methods: Secondary analysis of circannual severe seizure frequency from the Canadian Arctic (Kivalliq, Nunavut) in 2009-2020 (n=117) and New Zealand (Auckland) in 2015-2016 (n=361) dichotomized by age. Rayleigh's test was conducted to assess for a statistically significant departure from circular uniformity (e.g. representing equal likelihood occurrence throughout the year) for each age group (e.g. older vs. younger than x-years-old) at each site, over different dichotomized age thresholds (x=30, 35, 40, 45).
Results: At each site, there was a significant correlation between increasing day length and severe seizure occurrence for the "younger" age group at the 30, 35, 40, and 45-year-old age thresholds. The respective mean resultant lengths in Kivalliq were 0.33 (p=0.018), 0.31 (p=0.012), 0.25 (p=0.028), and 0.24 (p=0.022) averaging calendar directions from April 8-15. In Auckland, the mean resultant lengths were 0.18 (p=0.0005), 0.18 (p=0.0002), 0.19 (p< 0.0001), and 0.17 (p=0.0005) averaging calendar directions from July 15-24. In contrast, there were no significant correlations in the "older" age group at either site for any age threshold.
Conclusion: There were significant and reproducible correlations of severe seizures with increasing day length after the respective winter solstices of the northern and southern hemispheres in the younger patient cohorts of the Canadian Arctic and New Zealand. In contrast, these correlations were lost in each older patient cohort at each site. These findings demonstrate an inverse age-dependent increase in the circannual link between day length exposure and severe seizures, which may suggest that environmental influences on seizure expression are stronger in younger individuals but degrade with age; for example, possibly from selective degeneration of retino-geniculo-hypothalamic afferents reportedly more attuned to zeitgebers from twilight, moonlight, and the seasons.

AGE-DEPENDENT EFFECTS OF JET LAG ON VENTRICULAR DEPOLARIZATION: IMPACT OF BRIGHT LIGHT, MELATONIN, AND EXERCISE

Kiyan Saissan[1], Milin Patel[1], Natalie Mak[1], Shawn Youngstedt[2], Salma Patel[3]

[1] Sleep Medicine, The University of Arizona College of Medicine, [2] Arizona State University College of Health Innovation, [3] The University of Arizona

Introduction: Jet lag is a circadian rhythm disorder that disrupts the body's biological clock, with its effects potentially varying by age. This study investigates the influence of age on ventricular depolarization, measured by corrected QT interval (QTc) and QTc variability, in treatments designed to promote adjustment to jet lag.
Methods: Participants underwent a 5.5-day laboratory protocol with continuous Holter monitoring. On Day 1, participants followed a normal sleep schedule. On Day 2, they followed an ultra-short sleep-wake cycle (2 hours awake, 1 hour asleep) for 26 hours. Days 3–5 included an 8-hour delay in sleep-wake and light-dark schedules. Participants were randomized into three treatment groups: placebo, bright light (5,000 lux), or a combination of bright light, melatonin (0.5 mg), and exercise. Treatments were administered for three days, followed by a second 26-hour ultra-short sleep-wake cycle on Days 5–6. QTc intervals and QTc variability, calculated using Bazett's formula, were analyzed for participants aged < 26 and >26.
Results: Sixteen participants (86% male; mean age 28.4 ± 9.56 years) were randomized as follows: placebo (< 26 years, n=2; >26 years, n=3), bright light (< 26 years, n=4; >26 years, n=3), and bright light + melatonin + exercise (< 26 years, n=1; >26 years, n=2). In the placebo group, QTc intervals increased in participants aged < 26 from baseline to ultrashort 1 (401.5 ± 8.5 vs. 405.2 ± 8.2; p=0.0515), while QTc variability increased in participants aged >26 from ultrashort 1 to treatment (5.79 ± 0.78 vs. 6.57 ± 0.76; p=0.0355). In the bright light group, QTc intervals decreased in participants aged < 26 from ultrashort 1 to ultrashort 2 (391.78 ± 5 vs. 382.58 ± 5.27; p=0.0521), while QTc variability decreased in participants aged >26 from baseline to ultrashort 1 (7.233 ± 2.62 vs. 6.407 ± 2.57; p=0.032). No significant changes were observed in the bright light + melatonin + exercise group.
Conclusion: Jet lag increases QTc and QTc variability without treatment in both age groups. Bright light therapy reduces QTc and QTc variability, regardless of age. Therapeutic interventions for jet lag show promise but require further research to confirm these findings.

EFFECT OF CIRCADIAN RHYTHM ON COGNITIVE FUNCTION IN AMNESTIC MILD COGNITIVE IMPAIRMENT (AMCI) PATIENTS

Seong Jae Kim[1], Jung Hie Lee[2], Jae-Won Jang[3], Min Seo Choi[4], In Bum Suh[5]

[1] Department of Psychiatry, Chosun University School of Medicine, Gwangju, South Korea, [2] Department of Psychiatry, Gwanggyo Good Sleep Clinic, Suwon, South Korea, [3] Department of Neurology, Kangwon National University Hospital, Chunchon, South Korea, [4] Public Health & Health Policy, Jeju Institute of Public Health & Health Policy, Jeju, South Korea, [5] Department of Laboratory Medicine, Kangwon National University Hospital, Chunchon, South Korea

Introduction: Circadian disturbance has been implicated in accelerated aging and incident dementia. In particular, greater rest-activity rhythm(RAR) disturbance has been reported to be associated with larger cognitive decline in AD patients. However, the relationship between circadian rhythm disturbance and cognitive function in MCI patients is poorly understood. We aimed to compare circadian parameters between amnestic MCI(aMCI) patients and normal controls(NC), and to examine whether changes in circadian parameters can be related with cognitive function.
Methods: Participants over 50 years were recruited from Kangwon National University Hospital, and two public Dementia Care Centers. The Korean version of the Consortium to Establish a Registry for Alzheimer'sDisease(CERAD-K) was administered to eligible patients. The neuropsychological battery included verbal fluency, Word List Recall, Word List Recognition(WLR2), Constructional Recall(CR), and the Stroop Color-Word Test(SCWT). The diagnosis of aMCI was made according to Petersen's criteria. Actigraphy monitoring was conducted at home for five days. Nonparametric variables including the inter-daily stability(IS), intra-daily variability(IV) and relative amplitude(RA) were calculated for rest-activity rhythm (RAR). DLMO was determined from five hourly saliva samples obtained before sleep onset. Eighteen aMCI patients (76.6 ±6.1 years) and 21 NCs (70.4±6.7years) were finally analyzed. Generalized linear models(GLMs) were used to assess the effects of circadian parameters on cognitive functions.
Results: There were no significant differences in the RAR variables (IV, IS and RA), and the DLMO between the aMCI and NC groups. In GLMs, a significant group by RA interaction was observed on the scores of WLR2 (β =-9.22, p=.010). And there were significant main effects of IS on the scores of CR and SCWT (β =2.61, p=.027; β = 2.03, p=.049, respectively).
Conclusion: In our study, the regularity of RAR reflected improved non-verbal memory and executive function, regardless of cognitive impairment status. The robustness of RAR was implicated with increased verbal memory function. However, this relationship in aMCI patients, who are considered as preclinical AD, was found to be different from that of normal cognitive individuals.

A TWO-YEAR FOLLOW-UP STUDY ON THE COURSE OF AT-RISK DELAYED SLEEP-WAKE PHASE DISORDER IN THE YOUNG GENERATION

Yuichi Inoue[1], Sayaka Tomishima[2], Yoko Komada[3], Kosuke Tanioka[4], Isa Okajima[5]

[1] Department of Somnology, Tokyo Medical University, [2] Japan Somnology Center, Institute of Neuropsychiatry, [3] Institute for Liberal Arts, Institute of Science Tokyo, [4] Japan Somnology Center, Institute of Neuropsychiatry,Tokyo, Japan, [5] Department of Psychological Counseling, Faculty of Humanities, Tokyo Kasei University, Tokyo, Japan

Introduction: The prevalence of Delayed Sleep-Wake Phase Disorder (DSWPD) in the general population, especially among young people, and its impact on daytime functioning have been studied in various countries. However, there is currently a lack of longitudinal research examining the prognosis of DSWPD in a consistent population. This study investigated the progression of at-risk DSWPD in the young general population through follow-up surveys conducted at two-year intervals.
Methods: In 2019, 7,810 individuals responded to a web-based questionnaire, and in 2021, the same survey was completed by

2,375 participants, of whom 1,370 met the inclusion criteria. The survey assessed demographic variables, sleep habits, and daytime functioning, including the number of absent days in the preceding month, scores of the Biological Rhythms Interview of Assessment in Neuropsychiatry (BRIAN) evaluating DSWPD status, Work Limitation Questionnaire, SF-8, and Kessler Psychological Distress Scale (K6). Individuals were considered at risk for DSWPD if they had a BRIAN score of 40 or higher and four or more days absent per month.
Results: At follow-up, 1.9% of the population was at risk for DSWPD, with 14.5% of those initially at risk remaining, representing 0.5% of the total subject population. The persistently at-risk group showed higher absenteeism, while the newly onset group experienced similar work productivity and quality of life declines. Additionally, although the recovery group had reduced absenteeism to a level below the cutoff at follow-up, their sleep-wake schedule was still delayed, their BRIAN score was higher, and their K6 and productivity loss scores were worse than those in the persistently normal group.
Conclusion: Small but significant individuals were at risk for DSWPD at both time points. Small but significant individuals were at risk for DSWPD at both time points, however, the persistently at-risk group showed increased absenteeism. However, the persistently at-risk group exhibited increased absenteeism. Additionally, the newly onset group demonstrated poorer daytime functioning than healthy peers. These findings highlight the importance of continuous monitoring of DSWPD.

DIM LIGHT MELATONIN ONSET IN A DELAYED SLEEP-WAKE PHASE DISORDER COHORT: ONGOING CLINICAL TRIAL UPDATE

Caroline Johnson[1], Jennifer Brzezynski[1], Alexandra Bair[1], Sandra Smieszek[1], Haimeng Bai[1], Christos Polymeropoulos[1], Gunther Birznieks[1], Mihael Polymeropoulos[1]
[1] Vanda Pharmaceuticals Inc.

Introduction: We are conducting a double-blind, randomized, clinical study in Delayed Sleep-Wake Phase Disorder (DSWPD) participants with extensive clinical phenotyping. We evaluated screening Dim Light Melatonin Onset (DLMO) assessments in participants with a DSWPD diagnosis to determine the proportion of participants with and without a circadian delay.
Methods: Delayed DLMO is DLMO occurring after or within 30 minutes before desired bedtime, and after 21:30. Each DLMO assessment consisted of eight saliva collections performed at five, four, three, two, and one hour before bedtime, at planned bedtime, and one and three hours after bedtime. DLMO assessments were distributed to participants at Visit 1 (screening) and Visit 3 (treatment) with a questionnaire to record planned and actual collection times. The PROMIS Sleep Disturbance Questionnaire was also completed by participants at V1 to evaluate subjective levels of sleep difficulty, with higher scores indicating a greater sleep/wake disturbance. DLMO was defined as the clock time when the melatonin concentration exceeded the mean of three low consecutive values, plus twice the standard deviation of these points. Additionally, a sample for whole genome sequencing was collected.
Results: Fifty-six participants with DSWPD completed the screening DLMO assessment, 39 of which had a delayed DLMO (69.64%). Sub-analyses were conducted on these participants who had delayed DLMO. Within this subset, the average DLMO time was 00:17 (SD = 02:07) and the average PROMIS Sleep Disturbance Questionnaire score was higher compared to those without a delay (80.33 vs. 69.18, respectively). Of these 39 participants, 21 had a DLMO time after 00:00 (53.85%). Furthermore, we completed a linear regression analysis on DLMO time in a circadian gene set. The top scoring variant was 3' UTR rs10181401 in PER2, amongst others detected.
Conclusion: These initial data indicate that, on average, participants with DSWPD that completed the screening DLMO assessment had delayed DLMO. Further analyses show that more than half of this subset had significantly delayed DLMO (00:00 or later). This study is currently ongoing and blinded. Further data will be analyzed as more participants enroll. 'Phase typing' will be important in further understanding the underlying pathophysiology and in the treatment selection for patients with DSWPD.

NIGHT AND DAY: A SYSTEMIC REVIEW OF THE PAST 20 YEARS OF CRSWD RESEARCH

Ebelechiyem Okafor[1], Lovemore Kunorozva[2], Jacqueline M. Lane[3]
[1] Brigham & Women's Hospital, Division of Sleep and Circadian Disorders, [2] Harvard Medical School and Mass General Brigham, [3] Brigham and Women's Hospital

Introduction: Circadian rhythm sleep-wake disorders (CRSWDs) are a misalignment between a person's sleep period and the biosocial 24-hour cycle. Advanced sleep-wake disorder (ASWPD) and delayed sleep-wake disorder (DSWPD) are rare conditions mainly attributed to genetic and physiological factors. Diagnosis can be challenging due to a lack of access to resources, and symptoms of these disorders are often ignored or misdiagnosed as insomnia, with ~10% of insomnia patients having DSWPD. Treatment mainly consists of the use of melatonin and chronotherapy to reset the circadian clock, a process vulnerable to environmental factors.
Methods: This systematic review aimed to examine available research on diagnosing and treating ASWPD and DSWPD. The main goals were to: 1) Deliver a comprehensive overview of diagnostic methods and treatment tools 2) Examine study definitions of ASWPD and DSWPD 3) Evaluate the quality of studies 4) Identify current gaps in knowledge We used 5 main search phrases to identify and screen 1,805 records using the 2020 Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) through CADIMA. Our review identified 49 published articles, spanning 20 years of research. We then tested the capabilities of ChatGPT-4.0's Advanced Data Analysis to extract and summarize data.
Results: The majority of studies focused on DSWPD, with an equal percentage focusing on diagnosis and treatment. Most studies used the 2nd and 3rd editions of the International Classification of Sleep Disorders to base their definitions of ASWPD and DSWPD. The most popular diagnostic method was a combination of clinician-reviewed surveys, actigraphy, and DLMO used by 23.5% of studies. The most popular treatment approach was a combination of melatonin, phototherapy, and CBT used by 17.6% of studies. Finally, ChatGPT 4.0 was accurate about 80% of the time, more skilled in summarizing than extracting data.
Conclusion: This review identified a general set of diagnostic criteria for ASWPD and DSWPD, and a need for increased

studies of ASWPD and more diverse data across the lifespan. ChatGPT's expedited data extraction will be a beneficial asset in medical chart review, and with this veritable library of literature, aid in combating misdiagnosis by allowing for a systematic, more accessible way to diagnose and treat patients.

CLINICAL TRIAL OF SOLRIAMFETOL FOR EXCESSIVE SLEEPINESS RELATED TO EARLY MORNING SHIFT WORK DISORDER

Kirsi-Marja Zitting[1], Katherine Gilmore[2], Brandon Lockyer[3], Eileen Leary[4], Stuart Quan[1], Wei Wang[1], Nicolas Issa[5], Jonathan Williams[1], Jeanne Duffy[6], Charles Czeisler[7]
[1] Brigham and Women's Hospital, [2] Brigham and Womens Hospital, [3] Brigham & Women's Hospital, [4] Axsome Therapeutics, Inc., [5] Dana-Farber Cancer Institute, [6] Brigham & Women's Hospital, Harvard Medical School, [7] Harvard Medical School

Introduction: Shiftwork is common and in 10-43% of individuals it leads to a diagnosis of shift work disorder (SWD), characterized by excessive sleepiness accompanied by reduced sleep duration and/or insomnia. While more individuals work early morning shifts compared to overnight shifts, few studies have investigated this population. We aimed to evaluate the efficacy of solriamfetol for the treatment of excessive sleepiness during workdays in participants with SWD who work early-morning shifts.
Methods: We conducted a randomized, double-blind, placebo-controlled 4-week clinical trial in early morning shift workers (shift start 3-7AM). Participants had to report excessive daytime sleepiness and be at high risk for SWD as determined by a SWD questionnaire. Following screening and 2 weeks of baseline, participants were randomized into 4 weeks of placebo or solriamfetol (150mg taken after waking on workdays). The primary outcome was objective sleepiness measured by Maintenance of Wakefulness Test (MWT). Secondary outcomes included subjective sleepiness [measured by Karolinska Sleepiness Scale (KSS) and Epworth Sleepiness Scale (ESS)] and severity of illness [measured by Clinical Global Impression (CGI-Change) and Patient Global Impression (PGI-Change)]. Mixed-effects and logistic regression models were used to analyze the data.
Results: 74 participants completed study (median age 37 [28-46]; 27 females); 38 in the solriamfetol group and 36 in the placebo group. There was a significant difference between groups in the change in MWT sleep latency from baseline to end-of-treatment ($p< 0.0001$), with a greater increase in the solriamfetol group (12.5min, $p< 0.0001$) compared to placebo (3.1min, $p=0.0108$). There was a significant difference ($p=0.0001$) between the groups in the change in KSS and ESS scores, with a greater decrease in the solriamfetol group (KSS: -1.7, $p< 0.0001$; ESS: -7.2, $p< 0.0001$) compared to placebo (KSS: -0.5, $p=0.0167$; ESS: -2.4, $p=0.0044$). Finally, solriamfetol resulted in a higher percentage of participants showing improvement at end-of-treatment visit compared to placebo on CGI-Change (OR=4.4, $p=0.0014$) and on PGI-Change (OR=5.4, $p=0.0002$).
Conclusion: Solriamfetol significantly improved objective and subjective sleepiness and reduced the severity of illness compared to placebo in participants with SWD who work early-morning shifts. www.clinicaltrials.gov (NCT04788953).

ARIPIPRAZOLE (ABILIFY) AS A NEW TREATMENT FOR CIRCADIAN RHYTHM SLEEP-WAKE DISORDERS AND ITS MECHANISM OF ACTION

Takashi Kanbayashi[1], Shigeru Chiba[1], Ruoshi Li[2], Yuta Sudo-Konno[1], Tsuyoshi Nemoto[1], Arisa Hirano[2], Hideaki Ishido[3], Emiko Anegawa[4], Yuji Inotsume[5], Takeshi Sakurai[1]
[1] International Institute for Integrative Sleep Medicine, Tsukuba Univ., [2] International Institute for Integrative Sleep Medcine, Tsukuba Univ., [3] Hatsuishi Hospital, [4] Tsukuba White Dental Clinic, [5] Ishizaki Hospital

Introduction: circadian rhythm sleep-wake disorders (CRSWDs), especially delayed sleep-wake phase disorder (DSWPD), are common among young people and are a major problem in sleep medicine. They are usually treated with melatonin, bright light therapy, and lifestyle guidance, but nighttime sleep time is often extended, making them difficult to treat. We have reported that administration of 0.5-3 mg of aripiprazole to 12 patients with CRSWDs resulted in sleep onset time 1 hour earlier, sleep time 1.3 hours shorter, and wake time 2 hours earlier (Omori, 2018). However, the mechanism of action is unknown, which is a drawback in clinical application.
Methods: A total of 10 clinical reports of CRSWDs, DSWPD and non-24-hour sleep-wake disorder have been published in Japan, and a meta-analysis was performed. In vivo and ex vivo experiments were performed in mice to clarify the mechanism of action. The study was approved by the ethical committee.
Results: In a total of 45 cases, an average dose of 2.7 mg of aripiprazole resulted in 0.5 hours earlier sleep onset, 1.1 hours shorter sleep time, and 2.5 hours earlier wake-up time. In vivo study involved administering mice with aripiprazole through drinking water and subjecting them to a 6-hour advance jet lag. This administration led to the rapid re-entrainment of the shifted light-dark cycle (Li, 2023). Ex vivo experiments with suprachiasmatic nucleus (SCN) slice cultures have revealed that aripiprazole causes desynchronization of SCN neurons via the serotonin 1A receptor. The mathematical modeling suggests that mild disruption of SCN coupling by aripiprazole enhances photic entrainment without being so disruptive as to cause arrhythmicity.
Conclusion: A meta-analysis confirmed that aripiprazole is highly effective as a treatment option for CRSWDs. It was also confirmed that the mechanism of action is a direct effect on SCN. Melatonin as a therapeutic drug promotes sleep onset, but aripiprazole promotes early awakening, so it is expected that its effectiveness will be enhanced by using it in combination.

USE OF APPLE WATCH TO OPTIMIZE LIGHT THERAPY AND REDUCE CIRCADIAN MISALIGNMENT FOR NIGHT SHIFT WORKERS

Marleigh Treger[1], Anna Pockrass[2], Izza Peeran[2], Veronica Van Rossen[2], Elle Wernette[3], Christopher Drake[3], Olivia Walch[4], Philip Cheng[5]

[1] Henry Ford Health, [2] Henry Ford Sleep Research, [3] Henry Ford Health System, [4] Arcascope, [5] Henry Ford Health + Michigan State University Health Sciences

Introduction: Circadian misalignment can be alleviated with targeted light interventions. However, general "light at night" interventions do not account for shift workers' variable circadian phases. Recently, our lab validated Apple Watch (AW) as a noninvasive means of predicting circadian timing (i.e. dim light melatonin onset, DLMO). Here, we extend this by examining the clinical utility of AW in informing circadian interventions. We hypothesized the AW-informed group would result in higher rates of circadian alignment following treatment vs the control (non-personalized) group. We also compared the magnitude of phase shifts between these interventions.
Methods: Participants (N=46) were randomly assigned to either the AW or control group, and DLMO was measured before and after treatment. AW data (accelerometer and heart rate) was collected over 2 weeks and processed through a biomathematical model of the human circadian system to produce estimated DLMOs. Light therapy schedules were created from the corresponding phase response curves and implemented with light boxes and blue-blocker glasses (at-home or in-lab) to induce phase shifts. Participants in the control group followed a non-personalized light schedule (light from 18:00 and 21:00; light avoidance from 04:00 and 10:00). Circadian alignment was operationalized as DLMO between 02:00 and 14:00, and a relative risk ratio was used to compare the rate of circadian alignment between the two groups.
Results: The rate of circadian alignment post-treatment was 2.6 times higher in the AW group (56.8%) compared to the control group (22.2%). Additionally, those in the AW group achieved phase delays that were 8.5-times greater than the control group (AW group: delay of 2.5 hours ± 5.0 SD; control group: 0.3 hours ± 4.0 SD).
Conclusion: These findings support the use of AW to generate personalized light treatments. Accessible and effective circadian treatments are key to improving the safety of nightshift workers. In the future we aim to perform sensitivity analyses and compare the efficacy of personalized light interventions at-home versus in-lab, to establish the feasibility of prescribing personalized light therapy as an at-home treatment option.

USER EXPERIENCE OF A MOBILE APPLICATION TO REDUCE CIRCADIAN MISALIGNMENT IN NIGHT SHIFT WORKERS

Shruthi Ravindran[1], Marleigh Treger[2], Jonny Russell[3], Paige Coyne[1], Cameron McCray[1], Christopher Drake[4], Olivia Walch[5], Philip Cheng[6]

[1] Henry Ford Sleep Research, [2] Henry Ford Health, [3] Henry Ford Sleep Research Center, [4] Henry Ford Health System, [5] Arcascope, [6] Henry Ford Health + Michigan State University Health Sciences

Introduction: Around 80% of night shift workers experience circadian misalignment, leading to excessive sleepiness and decline of safety and work satisfaction. To address this, our team developed a mobile application, Arcashift, which tracks users' circadian rhythms and makes personalized activity recommendations (i.e. when to avoid light, when to exercise, etc.) based on user goals (i.e. wake up earlier). While the app was built with patient input and has been tested in randomized controlled trial settings, the real-world user experience is not yet well-established.
Methods: Night shift workers who habitually slept for less than 6 hours and presented with excessive sleepiness used Arcashift with premium access for 30 weeks (n = 28) in a hybrid type I effectiveness-implementation trial. Upon completion of the implementation period, participants completed a user feedback survey in which participants rated overall experience and ease of use on a 5-point scale ranging from negative to positive and completed 6 short answer questions.
Results: Among the users, 64% rated their overall experience as positive ("positive" or "somewhat positive") and 36% rated their experience as neutral. No users reported a negative ("negative" or "somewhat negative") experience. Eighty-two percent of users reported Arcashift was easy to use, whereas only 11% and 7% reported neutral and negative ease of use, respectively. Most liked features were the personalized recommendations (39%), the ease of inputting their work shifts and other obligations to the calendar (21%). The most common complaints were the app being unintuitive to use (11%) and the desire for more information about sleep in the app (14%). Other barriers included app glitches when entering shifts and other events into the calendar (7%).
Conclusion: Participants generally appreciate the individualized approach of Arcashift. The app was well received but modifications may be needed to further improve the user experience. Future directions include the information about improving sleep in Arcashift being made more accessible to the users of the app, as well as continuing to improve and providing great support to night shift workers in adapting to their schedules and decreasing their circadian misalignment.

FEASIBILITY AND ACCEPTABILITY OF SELF-DIRECTED, REMOTE DIM-LIGHT MELATONIN ONSET COLLECTION IN ADOLESCENTS

Jessica Love[1], Nicole Tacugue[2], Jakob Cherry[3], Joe Kossowsky[2], Jacqueline M. Lane[4]

[1] University of Wisconsin-Madison, Department of Psychology, [2] Department of Anesthesiology, Critical Care, and Pain Medicine, Boston Children's Hospital, [3] Division of Sleep and Circadian Disorders, Departments of Medicine and Neurology, Brigham and Women's Hospital, [4] Brigham and Women's Hospital

Introduction: Sleep dysregulation is highly prevalent in adolescents with chronic pain conditions and associated with poorer clinical outcomes, however, interactions between underlying circadian misalignments and pain in pediatric populations remain unclear. Melatonin serves as an effective biomarker of circadian dysregulation. Dim-light melatonin onset (DLMO) collections are the current gold standard method for measuring circadian rhythmicity by examining fluctuations in melatonin levels. Traditional DLMO collections conducted in external lab settings have limitations, including their inability to capture typical sleep patterns and restricted accessibility due to geographic, financial, and temporal barriers. We investigated the feasibility of a novel approach in which participants complete DLMO collections in an entirely self-directed manner using an at-home diagnostic kit.
Methods: Participants included adolescents with diagnosed chronic pain and healthy controls. The 3-week protocol involved sleep, activity, and light tracking; self-reported sleep diaries; a

survey determining morningness-eveningness chronotypes; one self-directed home DLMO collection with objective compliance measures; and a final instrument assessing participants' acceptability of study protocols. Main outcomes were feasibility and acceptability of self-directed remote DLMO collection.
Results: The study included adolescents with chronic pain (N=6, mean age=14.5, SD=2.74, 66.7% female) and healthy controls (N=6, mean age=13.3, SD=2.73, 50% female). Salivary DLMO times were successfully calculated using the Hockeystick method in 8 of 12 participants. On average, DLMO times were 2 hours and 32 minutes earlier than self-reported sleep onset times.
Conclusion: Our results demonstrate the feasibility and accuracy of self-directed, remote DLMO collections in adolescent populations. With further validation, this approach could enhance the measurement of endogenous circadian phases, allowing for more targeted sleep interventions to optimize clinical outcomes in pediatric patients with chronic pain.

FAST ASLEEP: EARLY TIME-RESTRICTED EATING ADVANCES SLEEP IN LATE SLEEPERS

Daniel Blum[1], Beatriz Hernandez[2], Jamie Zeitzer[2]
[1] NYU Shanghai, [2] Stanford University

Introduction: In a globally-connected society, habitually late sleep timing has become increasingly problematic. Late sleep timing is associated with adverse health outcomes including insulin resistance, depression, and impaired cognition. Exposure to morning light and limiting evening light can shift the timing of the suprachiasmatic nucleus, helping some individuals fall asleep earlier. However, with widespread nighttime use of devices like smartphones and tablets, completely avoiding light in the evening is challenging. One potential alternative approach to advancing sleep timing involves using early time-restricted eating (eTRE) to target the food-entrainable oscillator (FEO). This pilot randomized controlled trial (RCT) investigated whether eTRE could advance sleep timing in late sleepers.
Methods: Fifteen adults with habitual late sleep timing were randomized to eTRE or a sleep and nutrition hygiene control. The eTRE group adopted a 16-hour overnight fast aligned with a target wake time (e.g., fasting from 4 PM to 8 AM). All participants completed a 1-week baseline phase and a 2-week intervention phase, during which continuous actigraphy and daily sleep and nutrition diaries were maintained. Primary outcomes included changes in sleep onset, midpoint, and offset, measured via self-report and actigraphy. Total sleep time (TST) was a secondary outcome. Data were analyzed using linear mixed-effects modeling.
Results: Participants in the eTRE group showed significant advancements in sleep timing compared to controls. Self-reported sleep onset (56.1 minutes), midpoint (19.5 minutes), and offset (42.2 minutes) were earlier in the eTRE group. Actigraphy findings corroborated these results, with sleep onset, midpoint, and offset advancing by 66.5, 21.9, and 39.3 minutes, respectively. No significant differences in TST were observed between groups, though a trend toward increased TST in the eTRE group was noted.
Conclusion: A single 30-minute session on eTRE significantly advanced sleep timing in late sleepers. These findings suggest eTRE as a promising intervention for circadian misalignment. Future research with larger, diverse populations is warranted to validate these results and explore long-term effects.

DAILY MORNING BLUE LIGHT EXPOSURE AFFECTS POLYSOMNOGRAPHIC SLEEP IN A REAL-WORLD SETTING

William Killgore[1], Gabriela Franca[1], Lana Elali[1], Devin Hermes[1], Shivani Desai[1], Sean Hogan[1], Lindsey Hildebrand[1], Dale Russell[2], Michael Dretsch[3], Jeffrey Osgood[4], Michael Grandner[5], Sarah Green[1], Kathryn Kennedy[6], David Negelspach[6], Alisa Huskey[6]
[1] University of Arizona, [2] US Air Force, [3] Walter Reed Army Institute of Research-West, [4] Walter Reed Army Institute of Research, [5] University of Arizona College of Medicine, [6] The University of Arizona

Introduction: The circadian rhythm of sleep is particularly sensitive to ocular exposure to light, particularly blue wavelength light. Morning exposure to blue light typically phase advances the timing of sleep onset (i.e., one falls asleep earlier) while evening light exposure delays the onset of sleep. Despite its well-established effect on shifting the circadian timing of sleep, there have been no published placebo-controlled trials directly examining whether morning blue-wavelength light produces measurable changes in subsequent nighttime sleep architecture via polysomnography (PSG).
Methods: Thirty-six military participants (27 male; age=33.8, SD=6.9 years) meeting criteria for mild depression completed a 6-week counterbalanced, crossover, placebo-controlled clinical trial of blue (462 nm; active) versus red (661 nm; placebo) light using a commercially available eye-glass style device (AYO®) that was fitted with four LEDs at the appropriate wavelength. In a cross-over design, participants wore one device for 30-minutes each morning over a two-week treatment period, followed by a 2-week washout period, and a subsequent 2-week trial with the alternate intervention. Sleep was measured each night using an at-home ambulatory electroencephalographic sleep monitor (Dreem3®).
Results: Compared to red placebo light, daily morning blue light produced significant ($p<.05$) reductions in the duration of stage N1, N2, and N2%, and an increase in REM%, as well as decreased latency to stage N2 and REM sleep. There was also a trend level decline in microarousals with blue light. No differences were observed for N3, total sleep time, or WASO.
Conclusion: These data provide the first placebo-controlled evidence that a daily morning blue-wavelength light intervention produces significant changes in PSG sleep architecture in a real-world environment. Within a counterbalanced cross-over design, daily morning blue light reduced the amount of time spent later in non-restorative light stages of sleep and facilitated more rapid entry into restorative stages, including REM sleep. Moreover, blue light also reduced the latency to the first REM episode and increased the percent of time spent in REM. As prior work has emphasized the role of REM sleep in emotional processing, memory consolidation, and cognitive flexibility, these findings have implications for potentially managing sleep to facilitate cognitive and emotional health without pharmacologic interventions.

ADVANCING SLEEP TIMING AND IMPROVING SLEEP QUALITY IN ADOLESCENTS: RESULTS FROM A TRANS-C INTERVENTION

Brandon Pattillo[1], Sarah Kamhout[1], Isabella Wright[1], Kara Duraccio[1]

[1] Brigham Young University

Introduction: Most adolescents obtain insufficient sleep, which has been linked to negative mental and physical health outcomes. The purpose of this investigation was to examine the effectiveness of a sleep intervention known as the Transdiagnostic Intervention for Sleep and Circadian Dysfunction (TranS-C) in improving sleep and circadian outcomes adolescents experiencing circadian misalignment.

Methods: Adolescents with a self-reported sleep weekday bedtime of midnight or later (N = 31) completed a 6-week TranS-C sleep intervention in which they met with a sleep interventionist weekly for 40–50-minutes each week to implement behavioral sleep interventions. Sleep measurements (one-week of sleep monitoring via wrist-worn actigraphy and a sleep diary, a six-hour dim-light melatonin onset (DLMO) assessment, and a battery of sleep questionnaires (i.e., the Pittsburgh Sleep Quality Index (PSQI) and the Morningness/Eveningness Questionnaire (MEQ) occurred pre- and post-intervention. We ran a series of repeated-measure t-tests to evaluate changes in actigraphy measurements (averaged sleep duration, sleep onset latency (SOL), sleep midpoint, wake after sleep onset (WASO), sleep efficiency, and weekend/weekday sleep timing), DLMO, and in reported PSQI and MEQ total score.

Results: We observed significantly improved sleep quality (PSQI total scores) in adolescents following the intervention (p=.003; d=0.633). No significant changes were observed in actigraphy-derived sleep duration, SOL, sleep efficiency, or WASO (p>.05). On average, the adolescents' sleep midpoint shifted 30 minutes earlier across the week (p=.023; d=0.591), and average sleep onset also shifted about 30 minutes earlier across the week (p=0.044, d=0.498). Sleep onset for weekend sleep was, on average, 70 minutes earlier post-intervention (p=0.003, d=0.902), and weekend sleep offset was, on average, an hour earlier post-intervention (p=0.003, d=0.902). No significant changes were observed in DLMO or the MEQ total score (p>.05).

Conclusion: Although we failed to find significant support for increases in total sleep time, our findings support the effectiveness of TranS-C in improving the perception of sleep quality and in advancing sleep timing, particularly during the wekeend, among adolescents experiencing circadian misalignment. These findings suggest that TranS-C may serve as a helpful intervention target for adolescents who experience delayed sleep timing or perceive their sleep quality to be poor.

RECOGNIZING, DIAGNOSING, AND TREATING CIRCADIAN DISORDERS - LESSONS FROM A CIRCADIAN CLINIC

Jennifer Grom[1], Nisha Kantesaria[1], Chun-Yu Lee[1], Lawrence Epstein[2], Jeanne Duffy[3], Charles Czeisler[4], Milena Pavlova[2]

[1] Mass General Brigham, [2] Brigham and Women's Hospital and Harvard Medical School, [3] Brigham & Women's Hospital, Harvard Medical School, [4] Harvard Medical School

Introduction: Patients with circadian rhythm disorders (CRDs) are commonly misdiagnosed. Up to 22% of patients diagnosed with primary insomnia have been shown to have a bedtime out of phase with their circadian sleep time, suggesting a circadian etiology instead. Such misdiagnoses lead to expensive and unsuccessful medication trials with risk for significant morbidity. In contrast, first-line treatments for CRDs, such as timed melatonin and light exposure, are low risk and efficacious for CRD in controlled settings (Burke et al). However, there is currently a lack of effectiveness studies to reaffirm these CRD treatments are also useful in less-controlled, real-world, clinical care settings. We aim to describe patient characteristics and outcomes among patients treated at a circadian disorder specialty clinic over the last 7 years to offer insight on effectiveness of CRD treatments in clinical settings.

Methods: We conducted a retrospective descriptive analysis including patients treated for CRDs at the Brigham and Women's Faulkner Circadian Clinic from 2017 – 2024. CRD treatment protocols were based on national guidelines and implemented prior to study initiation. Diagnostic evaluation included clinical history, sleep diaries, actigraphy, and dim-light melatonin onset saliva testing when appropriate and financially attainable for patients. Descriptive statistics included frequency of comorbidities and medication use. Chi-squared tests were performed to assess the association between two categorical variables.

Results: Preliminary data from July 1, 2017-Aug 1, 2019 demonstrate 133 patients met inclusion criteria. Among them were 117 with Delayed Sleep Wake Phase Disorder (SWPD) 12 with Advanced SWPD, one with jet lag and 3 with a non-24 hour disorder. The mean number of visits was = 3.32, std(1.50). There was a significant difference in improvement of symptoms when instructions about melatonin timing and brand was given (X-squared = 22.863, df = 1, p-value = 1.74e-06).

Conclusion: Preliminary analysis suggests significant effectiveness of CRD treatments even after after adjusting for comorbidities and medication use.

CHARACTERISTICS OF RESTLESS LEG SYNDROME IN SHIFT WORKERS

Yun Ji Kim[1], Haein Kim[1], Yunsu Kim[1], Jihye Ahn[1], Hyewon Yeo[1], Seog Ju Kim[1]

[1] Samsung medical center

Introduction: Both shift work and restless leg syndrome (RLS) are common and can disrupt sleep and mood. However, the effects of shift work on RLS remain unclear. The current study aims to explore the prevalence, severity, and related sleep and mood symptoms of RLS in shift workers (SWs) compared to non-shift workers (NSWs).

Methods: This study recruited 4,562 SWs (age 36.98±9.84, 2,150 males and 2,422 females) and 2,093 NSWs (age 37.79±9.73, 999 males and 1,094 females). All participants completed online self-report questionnaires regarding RLS, sleep, and depression. The presence of RLS was screened using a single standard question for rapid screening of RLS. The severity of RLS was assessed using the International Restless Legs Syndrome Rating Scale (iRLS). Additionally, the Epworth Sleepiness Scale (ESS), Insomnia Severity Index (ISI), and short-term Center for Epidemiologic Studies Depression Scale (CES-D) were used to assess daytime sleepiness, insomnia, and depressive symptoms, respectively.

Results: Of participants, 1,255 (27.45%) of SWs and 548 (26.18%) of NSWs were screened as having RLS, with no significant differences in the prevalence of RLS between the groups. However, among those with RLS, SWs with RLS showed higher iRLS scores compared to NSWs with RLS after controlling for age and sex (SWs: 9.55±7.26, NSWs: 6.75±6.05, F=64.15, p< 0.01). In addition, SWs with RLS exhibited higher ISI scores (SWs: 11.81±6.27, NSWs: 9.54±5.95, F=46.09, p< 0.01), higher ESS scores (SWs: 8.77±4.06, NSWs: 8.22±3.94, F=4.80, p=0.03), and higher CES-D scores (SWs: 10.43±6.54, NSWs: 8.38±6.15, F=33.50, p< 0.01) than NSWs with RLS.

Conclusion: Although there was no significant difference in RLS prevalence between SWs and NSWs, SWs with RLS exhibited more severe RLS symptoms and RLS-related symptoms, such as insomnia, sleepiness, and depression, compared to NSWs with RLS. The current study suggests that shift work may exacerbate RLS severity and RLS-related sleep and mood symptoms, although it may not be associated with the onset of RLS.

ASSESSING RISK FACTORS FOR REM SLEEP BEHAVIOR DISORDER AMONG PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Emily Rivera[1], Vijaya Reddy[1], Sohail Dewain[1], Zihan Chen[2], Sapna Patel[1], Erika Renkyl[1], Maya Bellomo[3], Michelle Joo[3], Ahmed Ali[1], Michael Kappelman[4], Brian Koo[1]

[1] Yale School of Medicine, [2] Yale School of Public Health, [3] Yale College, [4] University of North Carolina

Introduction: REM Sleep Behavior Disorder (RBD) is a sleep disorder in which individuals act out their dreams and strongly predicts incident Parkinson's Disease (PD). Inflammatory Bowel Disease (IBD) is also associated with PD. Given the links among PD, RBD, and IBD, we assessed RBD prevalence in IBD and determined IBD factors associated with RBD. We hypothesized that RBD prevalence in IBD is greater than in age-sex matched controls.

Methods: 158 controls from the community and 462 IBD patients from IBD Partners, an IBD patient registry, completed online questionnaires to assess RBD symptoms, medical history, and IBD-related medical history. RBD was assessed using the validated RBD Single-Question Screen (RBD1Q). Also assessed were IBD severity using IBD disease duration, number of IBD-related hospitalizations, presence of IBD-related surgery, and Crohn's disease or simple clinical colitis activity indices. Logistic regression and generalized linear models were used for the outcome RBD1Q, while adjusting for age, sex, and race. Prevalence of RBD was assessed between groups using chi-squared testing.

Results: IBD and control participants were comparable in age; the IBD cohort had proportionally more women and more Caucasians. 462 IBD participants had a mean age of 57.1±10.9 years, 71.6% female and 95.2% Caucasian; 158 controls had a mean age of 57.4±11.7 years, 62.6% female, and 91.1% Caucasian. Among the IBD group, 14.1% had RBD, screening positively with the RBD1Q, compared to 5.1% of controls (p = 0.002). Logistic regression revealed that RBD was significantly associated with IBD after controlling for age, sex, and race (OR 3.2 [CI 1.48,6.82]; p=0.003). Among the IBD cohort, RBD was not associated with IBD type, IBD duration, or report of past gastrointestinal surgery. Males with RBD were more likely to report IBD-related hospitalizations (95.2%; p=0.004) than male IBD patients without RBD. RBD was not associated with IBD activity indices.

Conclusion: RBD is more prevalent in IBD patients than controls without IBD and may be related to IBD disease severity. Future studies are needed to determine if those with IBD and RBD on particular immunotherapies are at decreased risk for synucleinopathy phenoconversion.

PRODROMAL PARKINSONISM IN POST-9/11 VETERANS WITH PROBABLE REM SLEEP BEHAVIOR DISORDER: A PILOT STUDY

Melissa Jones[1], Taryn White[1], Dakota Broadway[1], George Jackson[1], Supriya Singh[2], Ruosha Li[3], Erik StLouis[4], Laura Marsh[1], Ricardo Jorge[1]

[1] Michael E. DeBakey VA Medical Center, [2] Baylor College of Medicine, [3] University of Texas Health Science Center at Houston, [4] Mayo Clinic

Introduction: Rapid eye movement (REM) sleep behavior disorder (RBD) is the single strongest predictor of Parkinson's disease (PD) risk. Given neurotrauma and psychiatric morbidity, the aging post-9/11 Veteran cohort is a target population for understanding probable RBD frequency and neuroprotection opportunities. We previously reported over 50% of post-9/11 Veterans screened positive for probable RBD. We aimed to examine frequencies of prodromal PD markers and polysomnography (PSG)-confirmed RBD in post-9/11 Veterans.

Methods: Veterans with probable RBD based on the single-question RBD screen (n=12) were recruited from the Translational Research Center for Traumatic Brain Injury (TBI) and Stress Disorders (TRACTS) Houston cohort. Participants were assessed for subthreshold parkinsonism (Unified Parkinson's Disease Rating Scale-III Motor score >3, excluding action tremor), olfactory loss (12-item Sniffin' Sticks), TBI exposures, autonomic symptoms, orthostasis, excessive daytime sleepiness, post-traumatic stress disorder (PTSD), and psychiatric comorbidities. PSG studies were conducted per American Academy of Sleep Medicine guidelines. A board-certified sleep physician confirmed the presence of REM sleep without atonia. We compared the frequency of prodromal marker positivity between participants with and without subthreshold parkinsonism.
Results: All 12 participants were male (6 [50%] Black, 3 [25%] Hispanic) with a mean (SD) age of 44.4 ± 6.7 years. PSG data (n=10) revealed REM sleep without atonia in 5 (50%), moderate obstructive sleep apnea (OSA) in 2 (20%), and severe OSA in 2 (20%) participants. Five (41.6%) participants had mild motor dysfunction suggestive of subthreshold parkinsonism on the UPDRS-III (M±SD score of 8.6 ± 5.9), while 7 participants had normal or low UPDRS-III ratings (2.3 ± 1.3; p=0.02). Veterans with subthreshold parkinsonism had lower Sniffin' Sticks scores than those without (M±SD 9.4 ± 2.07 vs. 11.29 ± 0.76; 95% CI: 0.01–3.76, p=0.049).
Conclusion: This pilot study suggests that motor and olfactory prodromal PD markers are frequent in post-9/11 Veterans with probable RBD. Larger prospective cohort studies are required to further quantify REM sleep without atonia and assess synuclein-specific biomarkers in this population.

EXPERT ANNOTATION OF FREE-TEXT DESCRIPTIONS OF DREAM ENACTMENT BEHAVIORS ASSOCIATED WITH REM SLEEP BEHAVIOR DISORDER

Melissa Jones[1], Arash Maghsoudi[2], Taryn White[1], Amir Sharafkhaneh[2], Javad Razjouyan[2], Carlos Schenck[3]
[1] Michael E. DeBakey VA Medical Center, [2] Baylor College of Medicine, [3] University of Minnesota Medical School

Introduction: We developed a database of free-text descriptions of dream enactment behavior (DEBs) from unstructured clinical notes of Veterans with electronic diagnoses of rapid eye movement sleep behavior disorder (RBD). We additionally examined characteristics of DEBs considered essential for the diagnosis of RBD according to expert consensus.
Methods: We randomly sampled electronic medical records of 200 Veterans with electronic medical records in the national Veterans Health Administration from 10/01/1999 – 09/30/2020; ≥2 electronic diagnoses of RBD (>30 days but < 390 days apart); and procedural codes for in-lab polysomnography within 6 months. DEB descriptions manually extracted from clinical notes were reviewed in expert consensus meetings and labeled as "essential" for RBD diagnosis, "supporting," or "unclear." Phrases were categorized according to DEB type (movements, vocalizations, consequences [e.g., descriptions of injuries], and dream content). Movements were further characterized as potentially violent or injurious, non-injurious, or unclear. Proportions were compared with Chi-square tests.
Results: Removal of 3 repeated phrases yielded 208 DEB descriptions for classification. Expert consensus labeled 124 (59.6%) phrases "essential," 71 (34.1%) "supporting," and 13 (6.25%) "unclear" for RBD diagnosis. Essential phrases included dream enactment variations (e.g., "acted out dreams"); hitting, punching, or kicking bedpartners, pets, and/or bedside objects; and other mentions of sleep-related injury or violence (e.g., "trying to strangle"). Supporting phrases described sleep-talking, thrashing, vivid dreams, nightmares, sleeping in separate beds, and non-descript behaviors. Excerpts describing sleep-related movements (121 [58.2%]) were more likely labeled as essential versus supporting or unclear (p=0.00). Conversely, descriptions of dream content (p=0.017) and vocalizations (p=0.012) were more likely to be considered supporting or unclear than essential. Potentially violent or injurious movements were also more likely to be labeled as essential than supporting or unclear (p=0.00).
Conclusion: Expert labeling emphasized the significance of sleep-related movements and associated injury risks for detecting RBD in free-text medical records. A natural language processing (NLP) algorithm that detects DEBs from free-text is needed to further characterize sleep-related violence and injury risks associated with DEBs according to demographics and comorbidities.

EYE BLINKING CHARACTERISTICS AS POTENTIAL BIOMARKERS IN ISOLATED REM SLEEP BEHAVIOR DISORDER DURING VISUOSPATIAL ATTENTION TASKS

Su Min Kim[1], Kang-Min Choi[1], Ki-Young Jung[2]
[1] Seoul National University Hospital, [2] Seoul National University

Introduction: Isolated REM sleep behavior disorder (iRBD) is a prodromal stage of alpha-synucleinopathies, including Parkinson's disease (PD), dementia with Lewy bodies (DLB), and multiple system atrophy (MSA). Although eye blinking characteristics were reported to be associated with the pathophysiology of PD, such as hypomimia, no studies have explored these features in the prodromal stage. This study aimed to investigate eye blinking characteristics in iRBD patients during Posner's cueing paradigm.
Methods: A total of 136 patients with video-polysomnography (v-PSG)-confirmed iRBD were enrolled (aged 67.1 years). Patients who developed synucleinopathies were classified as converters (iRBD-CV), while the others as non-converters (iRBD-NC). Fifty healthy controls (HCs) were also participated (aged 66.2 years). At baseline, all participants performed Posner's visuospatial cueing task, with cue-to-target interval (CTI; long-CTI or short-CTI) and the validity conditions set to 50%. During the tasks, 60-channel electroencephalogram (EEG) and two-channel electrooculogram (EOG) signals were recorded. After pre-processing, vertical EOG components were extracted through independent component analysis. The acquired components were robust-scaling normalized and then eye blinking events were automatically identified based on a thresholding approach from two temporal windows of interest (300-800 ms and 1300-1800 ms). In each window, we calculated blink latency to target stimuli (i.e., mean), synchrony (standard deviation), and rate. For group comparisons, independent t-tests

were performed in two steps: (i) iRBD vs. HC, (ii) iRBD-CV vs. iRBD-NC.
Results: iRBD exhibited delayed blink latency compared to HC in the second window for both long-CTI (1549 > 1529 ms, p = 0.017) and short-CTI (1543 ms > 1524 ms, p = 0.018). iRBD-CV (n = 31) exhibited a decreased blink rate compared to iRBD-NC in long-CTI (31.24% < 40.92%, p = 0.034), and a decreasing trend in short-CTI (26.90% < 34.37%, p = 0.080), which was more pronounced in PD-converters (n = 17, 26.19% and 21.75%, respectively). However, no significant group differences were observed in blink synchrony.
Conclusion: Delayed blink latency and decreased blink rate may be associated with the pathophysiology of the prodromal phase of synucleinopathies. Our results suggest that eye blink characteristics potentially serve as biomarkers reflecting the pathophysiology of iRBD and predicting their phenoconversion.

THE ASSESSMENT OF RMMA CLUSTERS AS A NOVEL DIAGNOSTIC APPROACH FOR SLEEP BRUXISM

Justyna Kanclerska[1], Dorian Nowacki[1], Weronika Frosztęga[1], Anna Wojakowska[1], Mieszko Więckiewicz[1], Katarzyna Madziarska[1], Helena Martynowicz[1]
[1] Wroclaw Medical University

Introduction: Sleep bruxism (SB) is a prevailing sleep-related movement disorder characterized by clenching and grinding of teeth, or thrusting and bracing of the mandible, that may occur without conscious awareness. It is also related to rhythmic masticatory muscle activity (RMMA) during sleep. Currently, polysomnography (PSG) is a gold standard for SB diagnosis. However, since this method is time-consuming, new approaches for diagnosing SB are currently under review. This study examines the potential of RMMA cluster analysis as an innovative and time-efficient diagnostic tool for SB in the future. Analyzing RMMA patterns, we determined specific profiles associated with SB episodes that could become a broadly used alternative to traditional diagnostic methods.
Methods: This study involved 200 Caucasian patients who were admitted to the Sleep Laboratory in Wroclaw University Hospital, Poland, for polysomnography examination as a diagnostic method for SB. Participants willingly agreed to attend the examination. The average age of the study group was 34.9 ±10.5 years. Before participation, all patients provided written informed consent, confirming their understanding of the objectives and procedures of the study, as well as potential risks and benefits.
Results: The findings of the study indicate that RMMA clusters are very specific for diagnosing sleep bruxism. When clusters are present, the diagnosis of bruxism is definitive (specificity 100%). However, the absence of clusters does not reliably exclude the presence of SB (false-negative diagnosis), possibly regarding tonic and phasic episodes and arousals. Therefore, diagnostic assessment through polysomnography and calculation of the bruxism episode index (BEI) is necessary. Cluster Index (AUC 0.77) and Cluster Event Index (AUC 0.8) were effective assessment tools for diagnosing bruxism. The Cluster Index is also useful for distinguishing severe bruxism (BEI >4) with a sensitivity of 71.9%, specificity of 87.4%, and accuracy of 80.5%.
Conclusion: RMMA cluster analysis shows notable promise as a specific and efficient diagnostic tool for SB. However, refining the method to address false-negatives through threshold values for tonic and phasic episodes is essential. This approach has the potential to streamline SB diagnosis and provide a basis for future research into its mechanisms and subtypes.

LONGITUDINAL CHANGES IN DIFFUSION TENSOR IMAGING ALONG THE PERIVASCULAR SPACE IN REM SLEEP BEHAVIOR DISORDER

WONCHUL SHIN[1], jung-Ick Byun[1], Seonmin Yoon[2], Kyungjin Hwang[3]
[1] KyungHee University Hospital at Gangdong, [2] Clearwater Hospital, [3] KyungHee University Hospital

Introduction: This study aimed to evaluated whether diffusion tensor image analysis along the perivascular space (DTI-ALPS) differed in isolated REM sleep behavior disorder (iRBD) patients who converted to neurodegenerative disease during follow-up and tracked DTI-ALPS changes longitudinally with repeated imaging.
Methods: Fifty patients diagnosed with iRBD by video-polysomnography (vPSG) at the Seoul National University Hospital who underwent MRI and were followed-up for at least 3 years, and 20 age- and sex- matched controls were included. DTI-ALPS index was calculated and compared between iRBD patients who converted (iRBD-C) or not (iRBD-NC), and the controls. Thirty of the iRBD patients and 5 of the controls underwent repeated imaging after mean duration of 40.9±10.1 months.
Results: The mean duration of RBD was 5.6±4.7 years from symptom onset and 14 of the patients were iRBD-C [to Parkinson's disease (n=10), Multiple system atrophy (n=3), or Dementia with Lewy bodies (n=1)] after 25.8±20.3 months from the baseline imaging. At baseline, significant difference was observed in baseline ALPS index between the controls, iRBD-C, and iRBD-NC (p=0.035), and post-hoc analysis revealed reduced ALPS index only in the iRBD-C group compared to the controls (post-hoc p=0.033). After longitudinal follow-up, iRBD patients showed significant decrease in ALPS index (baseline 1.38±0.17, follow-up 1.34±0.17, p=0.003). Compared to the controls at baseline, the ALPS index was lower only at follow-up (p=0.018), but not at the baseline (p=0.106).
Conclusion: Baseline DTI-ALPS index was associated with phenoconversion to alpha-synucleinopathy in iRBD patients during follow-up. Decreases in DTI-ALPS index on repeated imaging in iRBD may reflect neurodegenerative progression.

DREAM ENACTMENT BEHAVIOR IN VETERANS WITH PTSD: THE IMPACT OF SSRIS

William Wohlgemuth[1], Eric Geil[2], Daniella Marchetti[2], Douglas Wallace[3]
[1] Miami VA Medical Center, [2] Miami VA Sleep Center, [3] University of Miami

Introduction: Dream enactment behavior (DEB) has been reported among those with PTSD and a new parasomnia called

Trauma Associated Sleep Disorder has been proposed to characterize these sleep difficulties in trauma survivors. The most recent practice guidelines identified strong evidence for the use of SSRIs in veterans with PTSD. However, a condition referred to as 'serotonergic RBD' has been identified and may be secondary to use of these antidepressants.
Methods: Veterans at risk for sleep apnea at the Miami VA Sleep Center underwent a home sleep apnea test (HSAT) and completed questionnaires including demographics and the Munich Parasomnia Screening (MUPS). The frequency of dream enactment behavior was determined from two items on this scale regarding 'acting out dreams' and 'punching and kicking' during sleep. Electronic Medical Records were reviewed to obtain active medical and psychiatric diagnoses and active medication orders contemporaneous with the sleep evaluation. These data had a preponderance of veterans reporting no DEB (zero-inflated) so two-part regression model was used. The first logistic part identifies predictors of the susceptibility to DEB and the second linear part (which excludes those without DEB) identifies predictors of DEB severity.
Results: The study involved 607 veterans, predominantly male (84%) with mean age of 50 ± 14 years. Within this cohort, 49% were diagnosed with depression, and 33% with PTSD. Additionally, 44% of the cohort were prescribed antidepressants. No DEB was reported by 32.3% indicated and the other 67.7% reported DEB from "less than once a year" to "almost every night". PTSD was positively associated with DEB (p=0.001), but not antidepressants. All models controlled for depression, AHI, age and gender. With linear regression DEB severity was again predicted by PTSD but not antidepressants. When antidepressants were restricted to SSRIs, PTSD predicted DEB in the logistic model, but not SSRIs. However, both PTSD and SSRI use predicted DEB in the linear regression model.
Conclusion: These findings highlight the prevalence of DEB among veterans. Furthermore, PTSD strongly predicts the susceptibility to and the severity of the report of DEB. Also, antidepressant use, specifically SSRIs, appear to worsen the report of DEB in those with PTSD.

PREVALENCE AND INCIDENCE OF PERIODIC LIMB MOVEMENTS IN SLEEP IN SÃO PAULO: FINDINGS FROM THE EPISONO STUDY

Vanessa Cavalcante-Silva[1], Priscila Morelhão[2], Gabriel Pires[3], Priscila F Tempaku[4], Vânia D'Almeida[5], Sergio Tufik[3], Monica Andersen[6]
[1] Universidade Federal de São Paulo, [2] Sleep Institute, [3] Universidade de Federal de São Paulo, [4] Sleep Institute, Associação Fundo de Incentivo à Pesquisa, [5] UNIFESP - Universidade Federal de São Paulo, [6] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Periodic limb movement in sleep (PLMS) refers to repetitive, involuntary limb movements that occur during sleep. When these movements exceed 15 events per hour, they can significantly disrupt sleep quality and contribute to various health risks. Objective: This study aimed to examine the prevalence, incidence, and remission rates of PLMS in a population sample from São Paulo, one of the largest and most populous cities in the world.
Methods: The analysis utilized data from the 2007 EPISONO study, its 2015 follow-up, and the 2018 edition—the first 2 being part of a longitudinal investigation on sleep in a population sample representative of São Paulo, Brazil. PLMS prevalence rates were determined for 2007 and 2018, while incidence and remission rates were evaluated between 2007 and 2015.
Results: In 2007, the prevalence of PLMS was 9.02%, which increased to 15.60% by 2018. The incidence of new PLMS cases from 2007 to 2015 was 6.54%, with a remission rate of 50.82%. Aging significantly influenced the increase in both the prevalence and severity of PLMS over time.
Conclusion: This study demonstrated a rise in PLMS prevalence over a decade, which may be associated with aging demographics and shifts in lifestyle factors. These results underscore the need for continued research into the long-term health effects of PLMS and its contribution to sleep-related disorders.
Support (if any): This study was supported by the Associação Fundo de Incentivo à Pesquisa (AFIP), São Paulo, Brazil. MLA, ST and VDA are recipients of CNPq fellowships. PREVALENCE AND ASSOCIATED FACTORS OF INSOMNIA AND EXCESSIVE DAYTIME SLEEPINESS IN PATIENTS WITH PERIODIC LIMB MOVEMENTS IN SLEEP

Ramya Anbalagan[1], Bryn Morris[1], Sami Alrasheedi[1], Andras Bikov[1]
[1] Manchester University NHS Foundation Trust

Introduction: Excessive daytime sleepiness (EDS) and insomnia symptoms are commonly reported by patients with periodic limb movements in sleep (PLMS). However, the prevalence of symptoms and more importantly associated factors are not fully understood.
Methods: We analysed the demographics, clinical history and polysomnography (PSG) results of 95 patients (57% men, 50±13 years) who were diagnosed with PLMS based on PLMS index≥15/h. EDS was defined by an Epworth Sleepiness Scale (ESS≥11) and insomnia was defined in patients who reported either difficulties in falling asleep or maintaining sleep.
Results: Sixty-four percent reported EDS and 30% insomnia (18% sleep initiation and 19% sleep maintenance). Neither ESS, nor the presence of EDS correlated with demographics, comorbidities or PSG parameters. In contrast, patients with insomnia were likely to be females (75% vs. 34% in non-insomnia group, p< 0.01), more commonly complained about restless leg syndrome (64% vs. 23%, p< 0.01), less likely had diabetes (0% vs. 23%, p=0.03), had longer REM latency (212±103 mins vs. 150±102 mins, p=0.03) and lower proportion of N1 sleep (8.4±6.0% vs. 12.9±8.6%, p=0.05).
Conclusion: Whilst daytime sleepiness seems to be more common in patients with PLMS than the general population, it is not related to disease severity or other PSG parameters. On the other hand, insomnia, which was also commonly reported by our patients was related to some PSG features. Understanding factors associated with common symptoms in PLMS may help us to better tailor treatment for these patients.

THE CLINICAL IMPACT OF PERIODIC LIMB MOVEMENTS: UNDER-RECOGNITION IN SLEEP DISORDERED BREATHING AND ASSOCIATIONS WITH KEY OUTCOMES IN 493,085 PATIENTS

Yoel Green[1], Umaer Hanif[2], Katie Cederberg[1], Hyatt Moore[3], Ulysse Gimenez[2], Emmanuel Mignot[1]

[1] Stanford University, [2] BioSerenity, [3] InformAton LLC

Introduction: We evaluated PLMS in a large cohort, exploring their association with sleep disordered breathing (SDB) and apnea scoring, and associations with key clinical outcomes.
Methods: This retrospective analysis included 493,085 adults who completed polysomnography (PSG) and a sleep questionnaire. Data were collected from 240 sleep centers across 30 U.S. states (2004–2019). Periodic limb movement index (PLMI) was calculated from technician-scored PSGs. Subjective outcomes included medical comorbidities, depression, and insomnia, and objective outcomes included PSG measures. Multivariate analysis included significant variables identified in univariate analyses.
Results: The sample included 54.2% males, with a mean age of 54.6±14.4 years (range:18–107 years). PLMI was strongly negatively associated with SDB variables, suggesting under-recognition of PLMs in the presence of apnea. Therefore, we controlled for SDB (e.g., AHI, RDI) and demographic variables (i.e., age, sex, body mass index) in all additional analyses. Regarding self-reported outcomes, PLMI was associated with higher prevalence of depression (β= 0.14,$p< 0.001$), insomnia (β= 0.14,$p< 0.001$), heart attack (β=0.09,$p< 0.001$) and later awakening (β=0.15,$p< 0.001$). Multivariate analysis of self-reported outcomes confirmed independent associations with depression (β=0.09,$p< 0.001$), insomnia score (β=0.02,$p< 0.001$), later awakening (β=1.26,$p< 0.001$), and heart attack (β=0.07,$p< 0.001$). Regarding PSG outcomes, PLMI was associated with higher arousal index (β=0.22,$p< 0.001$), and greater N3 latency (β=0.10,$p< 0.001$), latency to persistent sleep (β=0.09,$p< 0.001$) and sleep onset latency (β=0.07,$p< 0.001$). Multivariate analysis revealed independent associations with arousal index (β=5.03,$p< 0.001$), latency to persistent sleep (β=0.06,$p< 0.001$) and N3 latency (β=0.03,$p< 0.001$).
Conclusion: PLMS may be under-recognized due to AHI scoring criteria and are clinically relevant, given associations with insomnia, depression, heart attack, later awakening, and arousal index. These findings highlight the need to reconsider scoring methods and further investigate PLMS as a clinical entity.

ELEVATED DOWNLOAD AND AHI IN CPAP THERAPY: A MARKER FOR PERIODIC LIMB MOVEMENTS IN SLEEP (PLMS)?

Arunima Jose[1], Jose Colon[2]

[1] Florida State University, [2] Lee Health

Introduction: Patients with periodic limb movements in sleep (PLMS) often present unique challenges in the management of obstructive sleep apnea (OSA). Anecdotal observations suggest that elevated download data and apnea-hypopnea indices (AHI) in patients using continuous positive airway pressure (CPAP) therapy may correlate with the presence of PLMS. This study aims to investigate the relationship between elevated download metrics on CPAP and confirmed PLMS diagnoses.
Methods: We conducted a retrospective analysis of 20 patients diagnosed with OSA and Statistical analyses were performed using chi-square. Inclusion criteria included the availability of detailed CPAP download data and polysomnography (PSG) ruling out PLMS. CPAP data were analyzed for average nightly usage, residual AHI, and percentage of flow limitations. Comparisons were made between patients with confirmed PLMS (PLMS+) and those without (PLMS-).
Results: Of the 50 patients analyzed, 14 patients were PLMS+. Statistical analyses were performed using chi-square, with a p-value of 0.002, indicating that the association between PLMS+ and PLMS- is statistically significant. Elevated download metrics were strongly predictive of PLMS diagnosis. Additionally, PLMS+ patients demonstrated greater CPAP pressure variability and lower subjective sleep quality scores compared to their PLMS- counterparts.
Conclusion: Elevated residual AHI and associated download metrics in patients undergoing CPAP therapy may serve as indirect markers for the presence of PLMS. These findings underscore the importance of comprehensive follow-up and PSG evaluations for patients presenting with suboptimal CPAP efficacy. Early identification of PLMS in this population could inform tailored therapeutic interventions, potentially improving sleep quality and overall treatment outcomes.

NEUROPHYSIOLOGY OF LARGE MUSCLE GROUP MOVEMENTS IN RLS: IMPLICATIONS FOR SLEEP ARCHITECTURE AND TREATMENT

Maria Mogavero[1], Patrizia Congiu[2], Giuseppe Lanza[3], Sara Marelli[1], Alessandra Castelnuovo[1], Monica Puligheddu[2], Oliviero Bruni[4], Luigi Ferini Strambi[1], Raffaele Ferri[3]

[1] Vita-Salute San Raffaele University and San Raffaele Scientific Institute, Division of Neuroscience, Sleep Disorders Center, Milan, Italy, [2] University of Cagliari, [3] Oasi Research Institute, [4] Sapienza University

Introduction: Recent evidence has highlighted Large Muscle Group Movements during sleep (LMM) as a distinct phenomenon in restless Legs Syndrome (RLS), with neurophysiological and neurobiological differences from periodic leg movements during sleep (PLMS). While LMM are correlated with sleep fragmentation and instability, their relationship with treatment outcomes remains unclear. This presentation aims to characterize LMM in RLS, investigate their impact on sleep neurophysiology, and evaluate their response to recommended therapies.
Methods: Two complementary retrospective analyses were conducted. The first included 100 drug-free RLS patients and 67 controls to evaluate the relationship between LMM and various sleep parameters. LMM, PLMS and other movement measures were assessed. The second study focused on 51 drug-free RLS patients randomized to dopamine agonists (DA), clonazepam (CLO), or placebo. Patients underwent baseline and post-treatment nocturnal polysomnography, with LMM and PLMS scored and changes analyzed using ANCOVA and paired t-tests.
Results: In the first study, RLS patients demonstrated significantly higher LMM and other movement measures than controls. LMM showed a negative correlation with total sleep time, sleep efficiency, and restorative sleep stages (N3 and R) and a

positive correlation with awakenings and lighter sleep stages (N1 and N2) in RLS patients. No significant correlation was found between LMM or PLMS and RLS severity. In the second study, DA significantly reduced PLMS but had minimal effect on LMM, apart from a small increase in LMM duration. CLO showed no significant impact on either LMM or PLMS. The placebo group exhibited a decrease in LMM index, likely reflecting a first-night effect. Persistent arousals and NREM instability were observed post-treatment, suggesting incomplete resolution of sleep disruptions despite reduced PLMS.
Conclusion: These findings underscore the complex interplay between motor activity and sleep neurophysiology in RLS. LMM are associated with sleep architecture fragmentation and arousals, reflecting their distinct neurophysiological basis compared to PLMS. Current therapeutic strategies, while effective for PLMS, fail to adequately address LMM or the broader sleep disturbances in RLS. Future research should prioritize the development of targeted therapies that address LMM and their detrimental impact on sleep, leveraging insights into the underlying neurotransmitter networks involved in RLS pathophysiology.

SEX-RELATED DIFFERENCES IN PERIODIC LEG MOVEMENTS ACROSS THE LIFESPAN AND IN THEIR RESPONSE TO TREATMENT IN RLS

Maria Mogavero[1], Giuseppe Lanza[2], Elena Antelmi[3], Bartolo Lanuzza[2], Oliviero Bruni[4], Sara Marelli[1], Alessandra Castelnuovo[1], Luigi Ferini Strambi[1], Raffaele Ferri[2]
[1] Vita-Salute San Raffaele University and San Raffaele Scientific Institute, Division of Neuroscience, Sleep Disorders Center, Milan, Italy, [2] Oasi Research Institute, [3] University of Verona, [4] Sapienza University

Introduction: Restless Legs Syndrome (RLS) and its associated motor manifestations, such as periodic leg movements during sleep (PLMS), exhibit significant sex-related differences in prevalence, progression, and treatment response. Epidemiological studies suggest a higher prevalence of RLS in women, but the underlying mechanisms remain unclear. This presentation combines two studies to explore: (1) sex differences in PLMS patterns across various age groups and hormonal stages, and (2) sex-specific responses to dopamine agonists (DA), pramipexole and ropinirole, in adult RLS patients.
Methods: In the first study, a retrospective analysis of 184 drug-free RLS patients (95 females, 89 males, ages 2–83 years) evaluated PLMS index and periodicity index via polysomnographic (PSG) recordings, stratified by age. The second study analyzed 41 drug-free adult RLS patients (26 treated with pramipexole, 15 with ropinirole) using baseline and post-treatment PSG. Treatment efficacy was assessed through changes in sleep parameters, movement indices, and a Visual Analogue Scale (VAS) for symptom severity.
Results: The first study revealed distinct age-related PLMS trends: women experienced a rapid PLMS increase before age 10, plateauing until menopause, followed by a sharp rise post-55 years. Men showed a more gradual PLMS increase, peaking after age 75. Periodicity index increased progressively in both sexes but remained slightly higher in women during midlife. These patterns aligned with hormonal shifts and autonomic nervous system modulation. In the second study, DA treatment reduced total leg movements, PLMS, and periodicity index in all patients, with greater reductions in women. Women exhibited higher sleep efficiency and lower wakefulness after sleep onset compared to men. The VAS scores improved across both sexes, though no sex differences were observed.
Conclusion: These findings underscore the complex interplay between sex, age, and neurophysiological factors in RLS. Hormonal changes and differential D3 receptor expression likely contribute to the observed disparities in PLMS progression and DA response. The results highlight the need for personalized, sex-specific approaches in RLS management, considering both lifespan dynamics and pharmacological nuances. Future guidelines should integrate these insights to optimize treatment efficacy and improve sleep outcomes for diverse demographic groups.

FIVE-YEAR OUTCOMES FROM THE NATIONAL RLS OPIOID REGISTRY: EFFICACY, STABILITY, AND TOLERABILITY

John Winkelman[1], Adysn Kilty[2], Benjamin Wipper[1], Jordana Zackon[3], Sylvie Adams[4]
[1] Harvard Medical School, [2] Mass General Hospital, [3] Tufts Medical School, [4] Boston University

Introduction: Opioids are effective in treating refractory or augmented restless legs syndrome (RLS) yet concerns about their long-term use in RLS are common. To investigate these concerns, the National RLS Opioid Registry tracks the long-term efficacy, dose stability, and tolerability of opioids for RLS.
Methods: This longitudinal, observational study initially interviewed and enrolled 500 participants prescribed opioids for RLS (median duration at baseline=2 years), from 44 US states and 4 countries. All participants had a history of therapeutic response to dopamine agonists and a majority experienced augmentation. Self-administered biannual surveys track opioid dosage, side effects, RLS severity, and other relevant factors. No clinical guidance or intervention is provided. Review of state-controlled substance records corroborate opioid dosing.
Results: At 5-years, 410 participants continue opioid treatment and study participation (7.0% lost to follow-up or withdrew, 3.6% died, 7.8% stopped opioids). Methadone (53.2%) and oxycodone (16.3%) are the most common opioids. Mean RLS severity (baseline IRLS=13.3; 5-year IRLS=13.1) and sleep disturbance (baseline ISI=10.6, 5-year ISI=9.6) were stable from baseline to 5-years. Median daily opioid dose increased slightly, to 36 MME (equivalent to methadone 9 mg or oxycodone 24 mg) from 30. Opioid doses increased in 51.0% of participants (median increase=15.0 MME) and decreased in 19.3% (median decrease=12.5 MME). Large dose increases (25-50 MME or >50 MME) occurred in 6.8% and 6.3% of participants, respectively. Several factors were predictors of such larger dose increases, including switching opioids to buprenorphine (OR=9.21, 95%CI [3.23-25.54]) or methadone (OR=4.39, 95%CI [1.95-9.68]), adding dopamine agonists (OR=4.55, 95%CI [1.46-12.94]), use of opioids for comorbid pain condition (OR=3.13, 95%CI [1.13-8.10]), higher baseline RLS severity (IRLS>20) (OR=2.79, 95%CI [1.17-6.60]), comorbid neuropathy (OR=2.79, 95%CI [1.14-6.62]), baseline sleep disturbance (ISI>7) (OR=2.42, 95%CI [1.18-5.4]), and under one year on opioids at baseline (OR=2.02, 95%CI [1.06-3.81]). 100% of participants who increased their dose by >25 MME had at least one predictor.

Conclusion: Low-dose opioids produced stable RLS symptoms over 5-years of follow-up. While 51.0% of participants increased their dose, most changes were small and larger dose increases were associated with specific risk factors.

TREATMENT OF RESTLESS LEGS SYNDROME AND PERIODIC LIMB MOVEMENT DISORDER: AN AASM CLINICAL PRACTICE GUIDELINE

John Winkelman[1], Joseph Andrew Berkowski[2], Lourdes DelRosso[3], Brian Koo[4], Matthew Scharf[5], Denise Sharon[6], Rochelle Zak[7], Uzma Kazmi[8], Yngve Falck-Ytter[9], Anita Shelgikar[10], Lynn Trotti[11], Arthur Walters[12]

[1] Massachusetts General Hospital and Harvard Medical School, [2] ReLACS Health, [3] UCSF, Fresno, [4] Yale University, [5] Rutgers Robert Wood Johnson Medical School, [6] University of Southern California, [7] UCSF Sleep Disorders Center, [8] American Academy of Sleep Medicine, [9] Case Western Reserve University, [10] University of Michigan Sleep Disorders Center, [11] Emory University School of Medicine, [12] Vanderbilt University Medical Center

Introduction: This guideline establishes clinical practice recommendations for the treatment of restless legs Syndrome (RLS) and periodic limb movement disorder (PLMD) in adults and pediatric patients. This clinical practice guideline updates the previously published American Academy of Sleep Medicine (AASM) practice parameter for the treatment of RLS and PLMD in adults.
Methods: The American Academy of Sleep Medicine (AASM) commissioned a task force of experts in sleep medicine to develop recommendations and assign strengths based on a systematic review of the literature and an assessment of the evidence using Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology. The task force provided a summary of the relevant literature and the certainty of evidence, the balance of benefits and harms, patient values and preferences, and resource use considerations that support the recommendations. The AASM Board of Directors approved the final recommendations.
Results: The following recommendations are intended as a guide for clinicians in choosing a specific treatment for RLS and PLMD in adults and children. Each recommendation statement is assigned a strength ("strong" or "conditional"). A "strong" recommendation (i.e., "The AASM recommends…") is one that clinicians should follow under most circumstances. A "conditional" recommendation (i.e., "The AASM suggests…") is one that requires that the clinician use clinical knowledge and experience, and to strongly consider the patient's values and preferences to determine the best course of action. Adult with RLS 1. In adults with RLS, the AASM recommends the use of gabapentin enacarbil over no gabapentin enacarbil (strong recommendation, moderate certainty of evidence) 2. In adults with RLS, the AASM recommends the use of gabapentin over no gabapentin (strong recommendation, moderate certainty of evidence). 3. In adults with RLS, the AASM recommends the use of pregabalin over no pregabalin (strong recommendation, moderate certainty of evidence). 4. In adults with RLS, the AASM recommends the use of IV ferric carboxymaltose over no IV ferric carboxymaltose in patients with appropriate iron status (see good practice statement for iron parameters) (strong recommendation, moderate certainty of evidence). 5. In adults with RLS, the AASM suggests the use of IV low molecular weight iron dextran over no IV low molecular weight iron dextran in patients with appropriate iron status (see good practice statement for iron parameters) (conditional recommendation, very low certainty of evidence). 6. In adults with RLS, the AASM suggests the use of IV ferumoxytol over no IV ferumoxytol in patients with appropriate iron status (see good practice statement for iron parameters) (conditional recommendation, very low certainty of evidence). 7. In adults with RLS, the AASM suggests the use of ferrous sulfate over no ferrous sulfate in patients with appropriate iron status (see good practice statement for iron parameters) (conditional recommendation, moderate certainty of evidence). 8. In adults with RLS, the AASM suggests the use of dipyridamole over no dipyridamole (conditional recommendation, low certainty of evidence). 9. In adults with RLS, the AASM suggests the use of extended-release oxycodone and other opioids over no opioids (conditional recommendation, moderate certainty of evidence). 10. In adults with RLS, the AASM suggests the use of bilateral high-frequency peroneal nerve stimulation over no peroneal nerve stimulation (conditional recommendation, moderate certainty of evidence). 11. In adults with RLS, the AASM suggests against the standard use of levodopa (conditional recommendation, very low certainty of evidence). 12. In adults with RLS, the AASM suggests against the standard use of pramipexole (conditional recommendation, moderate certainty of evidence). 13. In adults with RLS, the AASM suggests against the standard use of transdermal rotigotine (conditional recommendation, low certainty of evidence). 14. In adults with RLS, the AASM suggests against the standard use of ropinirole (conditional recommendation, moderate certainty of evidence). 15. In adults with RLS, the AASM suggests against the use of bupropion for the treatment of RLS (conditional recommendation, moderate certainty of evidence). 16. In adults with RLS, the AASM suggests against the use of carbamazepine (conditional recommendation, low certainty of evidence). 17. In adults with RLS, the AASM suggests against the use of clonazepam (conditional recommendation, very low certainty of evidence). 18. In adults with RLS, the AASM suggests against the use of valerian (conditional recommendation, very low certainty of evidence). 19. In adults with RLS, the AASM suggests against the use of valproic acid (conditional recommendation, low certainty of evidence). 20. In adults with RLS, the AASM recommends against the use of cabergoline (strong recommendation, moderate certainty of evidence). Special adult populations with RLS 21. In adults with RLS and end-stage renal disease (ESRD), the AASM suggests the use of gabapentin over no gabapentin (conditional recommendation, very low certainty of evidence). 22. In adults with RLS and ESRD, the AASM suggests the use of IV iron sucrose over no IV iron sucrose in patients with ferritin < 200 ng/mL and transferrin saturation < 20% (conditional recommendation, moderate certainty of evidence). 23. In adults with RLS and ESRD, the AASM suggests the use of vitamin C over no vitamin C (conditional recommendation, low certainty of evidence). 24. In adults with RLS and ESRD, the AASM suggests against the standard use of levodopa (conditional recommendation, low certainty of evidence). 25. In adults with RLS and ESRD, the AASM suggests against the standard use of rotigotine (conditional recommendation, very low certainty of evidence). Adults with PLMD 26. In adults with PLMD, the AASM suggests against the use of triazolam (conditional recommendation, very low certainty of

evidence). 27. In adults with PLMD, the AASM suggests against the use of valproic acid (conditional recommendation, very low certainty of evidence). Children with RLS 28. In children with RLS, the AASM suggests the use of ferrous sulfate over no ferrous sulfate in patients with appropriate iron status (see good practice statement for iron parameters) (conditional recommendation, very low certainty of evidence).
Conclusion: The treatment of RLS and PLMD should be based on a diagnosis established using ICSD-3 criteria and a comprehensive clinical history. The standard of care should be to provide one of the recommended interventions discussed within the guideline, taking into consideration the accessibility and resource requirements when deciding on the most appropriate treatment for a given patient. The treating clinician and the patient must make the ultimate judgment regarding any specific care.

EVALUATING THE RISK OF CENTRAL SLEEP APNEA ASSOCIATED WITH LOW-DOSE OPIOIDS FOR RESTLESS LEGS SYNDROME

Joseph Russo[1], John Winkelman[2], Adysn Kilty[1]
[1] Mass General Hospital, [2] Harvard Medical School

Introduction: Guideline based therapy for Restless Leg Syndrome (RLS) includes recommendation for low-dose opioid therapy which is often prescribed for patients with refractory and augmented symptoms. Although the respiratory effects of opioid use, including hypoventilation and development of central sleep apnea (CSA), are well-characterized, most of the evidence rests on opioid doses that are well in excess of that used for RLS. Our goal was to investigate the effect of low-dose opioids on polysomnography data in patients being treated for RLS.
Methods: A retrospective chart review of patients seen in our clinic was performed via database search to identify those with sleep studies performed both prior to low-dose opioid initiation and while on therapy. Positive Airway Pressure titration studies were excluded from analysis. Sleep study data with attention to total AHI, Non-REM AHI, Central AHI (cAHI), and oxygenation status were recorded along with pertinent medical history and medication history.
Results: Upon review of our database, 3 patients (2 male and 1 female) mean age 76.6 years at time of sleep study without and 79.7 years at time of study with low-dose (mean 15 MME/ day) opioid therapy met criteria. One patient identified had known history of atrial flutter. Time between sleep studies was on average 5.7 years while length of time on opioid therapy prior to second sleep study was 0.87 years. Total AHI and cAHI off opioids was noted to be mean (range)= 42 (17 – 58) and 8.3 (5.3 – 13.9) respectively, while on therapy 27.2 (15.8 – 47) and 13.9 (1.8 – 38). During NREM sleep total AHI 26.4 (6.7 – 55) and 27.3 (15.4-52). Percent of Total Sleep Time (%TST) with SPO2 < 90% was 14.3 off opioid therapy and 16.5 % while on opioid therapy.
Conclusion: To our knowledge this is the first case series reporting data on a population of patients taking low-dose opioids who have had polysomnography performed both before and after therapy initiation. This type of data is crucial to understanding the true risk of CSA in patients taking low dose opioid therapy for RLS symptoms. Further studies are warranted to investigate.

TONIC MOTOR ACTIVATION FOR TREATMENT OF PATIENTS WITH PAINFUL VERSUS PAINLESS RESTLESS LEGS SYNDROME

Elias Karroum[1], Jonathan Charlesworth[2], Haramandeep Singh[3], Mark Buchfuhrer[4]
[1] Department of Neurology, University of Virginia School of Medicine, [2] Noctrix Health, Inc., [3] Sleep Medicine Specialists of CA, [4] Stanford University School of Medicine

Introduction: Several studies characterized a more severe painful (versus painless) phenotype of restless legs syndrome (RLS). There is paucity of data comparing treatment of patients with painful and painless RLS. Bilateral high-frequency tonic motor activation (TOMAC) was recently approved for treatment of patients with medication-refractory RLS. The current study compared TOMAC efficacy in patients with painful and painless RLS.
Methods: Interim data were extracted for analysis from the THRIVE study, an ongoing multi-center post-market observational study assessing the long-term effectiveness and safety of the NTX100 TOMAC System for adult patients with RLS. Painful RLS classification was based on patients responding "Yes" to two consecutive questions at baseline: "Do you have unpleasant or uncomfortable feelings associated with the urge to move your legs?" and "Are these unpleasant or uncomfortable feelings painful?" Data collected at baseline included age, gender, RLS family history, age at RLS onset, RLS medications, augmentation severity, International RLS Severity Scale (IRLS), neuropathy diagnosis, and TOMAC titrated stimulation intensity. Primary endpoint was IRLS score change at 90-days. Secondary endpoints at 90-days included Clinical Global Impression-Improvement (CGI) score and CGI-responder rate. RLS medications change at 90-days was also evaluated.
Results: Data at 90-days were completed by 55 adult patients with medication-refractory and moderate-to-severe RLS (29 painful and 26 painless RLS). At baseline, painful (versus painless) RLS patients had more severe RLS symptoms (mean IRLS score: 28.8±5.2 versus 24.2±6.0; P=0.0034) and were more frequently treated with dopaminergic agents (65.5% versus 34.6%; P=0.0221). All other data at baseline were similar between the two groups. At 90-days, the mean change in IRLS score was not different between painful and painless RLS (-9.1±7.8 versus -7.7±7.0; P=0.5100). Mean CGI score (2.4 ±1.1 versus 2.5±0.9; P=0.6826), CGI-responder rate (65.5% versus 57.7%; P=0.5509), and RLS medications change at 90-days were also similar between the two groups.
Conclusion: This study reconfirms a more severe painful (versus painless) RLS phenotype. TOMAC efficacy was similar between the two RLS forms at 90-days. Whether TOMAC efficacy profile over a longer period is different between painful and painless RLS patients remains to be determined.

PHENOTYPIC CLASSIFICATION OF RESTLESS LEGS SYNDROME

Sungeun Hwang[1], Se Young Bang[2], Ki-Young Jung[3]
[1] Ewha Womans University Mokdong Hospital, [2] Seoul National University Hospital, [3] Seoul National University

Introduction: Restless legs syndrome (RLS) is diagnosed based on clinical features according to the IRLSSG diagnostic criteria. RLS exhibits significant heterogeneity among patients, complicating personalized management strategies. This study aimed to classify patients with RLS into phenotypic subgroups using unsupervised cluster analysis.
Methods: RLS patients who visited Seoul National University Hospital from 2014 to 2024 screened. Data on demographic and clinical characteristics, laboratory results, comorbidities, and sleep questionnaires were collected. Cluster analysis was performed to identify distinct phenotypes among patients with RLS.
Results: A total of 537 patients (mean age 60.4 ± 12.9 years; 64.2 female) were analyzed. The average onset age was 49.1 ± 15.4 years, and 173 patients (32.2%) had a family history of RLS. Cluster analysis identified five distinct phenotypes. Cluster 1: Late-onset female patients without a family history, with less severe RLS symptoms and mild sleep disturbances. Cluster 2: Female patients with longer disease duration and a family history, experiencing the most severe RLS symptoms and significant sleep disturbances. Cluster 3: Early-onset patients with moderate RLS severity and mild sleep disturbances. Cluster 4: Patients with longer disease duration but no family history. This cluster had the highest rate of augmentation (46.9%), with all patients requiring opioids for severe RLS symptoms. Cluster 5: Late-onset female patients without a family history, similar to Cluster 1, but characterized by lower education levels and occupation, with more severe RLS symptoms and sleep disturbances compared to Cluster 1.
Conclusion: This study identified five distinctive RLS phenotypes based on demographic, clinical, and sleep questionnaires. An individualized treatment approach tailored to these phenotypes may enhance the management of patients with RLS.

RESTLESS LEGS SYNDROME DURING PREGNANCY AND PUERPERIUM: DATA FROM THE LIFE-ON COHORT

Mauro Manconi[1], Andrea Maculano Estevens[2], Sandra Hackethal[1], Garbazza Corrado[2], Silvia Riccardi[1], Fabio Cirignotta[3], Susanna Mondini[2]
[1] Neurocenter of Southern Switzerland, Regional Hospital of Lugano, [2] Neurocenter of Southern Switzerland, [3] Bologbna University

Introduction: Pregnancy is a significant risk factor for the development of Restless Legs Syndrome. The natural course and impact of advancing pregnancy and the postpartum period on RLS prevalence and symptom severity is still scarcely studied. We aimed to elucidate the prevalence, trajectory, and inadequately understood factors such as cumulative incidence, severity, and risk factors of RLS throughout pregnancy and the postpartum.
Methods: We used data from the multicenter Life-ON Cohort Study which recruited 439 pregnant women in the 10-15 gestational week and followed them up until 12 months after delivery. Participants had 11 scheduled visits. RLS was assessed based on the five essential criteria proposed by the International RLS Study Group. Women meeting the diagnostic criteria were further evaluated using the International RLS Study Group Rating Scale (IRLS). All women received one full polysomnograpy performed at the second trimester of pregnancy.
Results: 26.03% of women (n=113, 95% CI 22.0–30.4%) met the diagnostic criteria for RLS. A previous history of RLS outside of pregnancy was found in 50.68% of women who reported RLS during the current pregnancy (OR = 2.717, 95% CI: 1.791–3.782) and 18.7% had a positive family history. During the entire follow-up period we found a cumulative incidence of 34.7%. Previous history of depression ((HR 2.03, 95%CI 1.003 – 4.09, p= 0.049), positive family history for RLS (HR 2.00 95%CI 0.92 – 4.35, p= 0.08) and previous RLS (HR 7.86, 95%CI 4.09 – 15.07, p= < 0.0001) were statistically significant risk factors to RLS. Around 20% of women experienced severe to very severe symptoms (IRLS >20 pts). A PLMS index > 15 was found in 26% of women.
Conclusion: RLS is a highly frequent complaint during pregnancy, with women who have a positive personal or family history for RLS being especially predisposed to develop manifest symptoms. The symptom severity remains relatively stable across pregnancy with a significant proportion (20%) warranting evaluation for a specific pharmacologic treatment. A screening approach and treatment of eligible women could greatly improve quality of life and reduce comorbidity during pregnancy.

ESTIMATION OF RESTLESS LEGS SYNDROME TREATMENT RESPONSE BASED ON WEARABLE MOVEMENT SENSORS

Stephanie Rigot[1], Leticia Camacho[1], Jatin Tekchandani[1], Sabrina Sifat[1], Viktoriia Kolotovska[1], Jonathan Charlesworth[2]
[1] Noctrix Health, [2] Noctrix Health, Inc.

Introduction: To enable remote management of restless legs syndrome (RLS) treatment, it would be helpful to have an objective indicator of RLS treatment response that could be passively measured over a period of weeks or months in the home. Wearable movement sensors could provide the basis for such an indicator. The tonic motor activation (TOMAC) system is a wearable therapy for refractory RLS that also has the capability to measure leg motion. Here, we aimed to classify RLS treatment response based on leg motion signals measured by the TOMAC system.
Methods: Twenty-seven individuals with RLS completed 456 TOMAC therapy sessions over 385 nights in-home. TOMAC therapy units were worn bilaterally over the head of the fibula from bedtime until wake. Participants activated 30-minute therapy sessions of TOMAC peroneal nerve stimulation to help them fall asleep when RLS symptoms were present. TOMAC units recorded accelerometer data for up to 3 hours prior to and one hour after the start of each therapy session. TOMAC response was grouped based on subjective ability to rapidly fall asleep (within 30 minutes) after starting TOMAC therapy. Accelerometer features included vector magnitude, discretized leg movements based on adapted AASM criteria, and positioning information. Cluster permutation tests were used to identify time-series differences between groups. One node decision trees were used to explore the predictive ability of individual accelerometer-based features to classify responders.
Results: There were reductions in TOMAC-recorded accelerometer signals for individuals who reported falling asleep within 30

minutes during TOMAC sessions compared to individuals who did not; these differences were significant ($p < 0.05$) for the time period from 15-33 minutes after TOMAC session start. During this significant time period, the leg movements per hour were 76.7% higher (130.6 vs 73.9 LM/hr) and the vector magnitude was 138% higher (0.081 vs 0.034 g) for individuals who were awake during TOMAC compared to those who reported they fell asleep.
Conclusion: Accelerometer signals recorded during in-home treatment of RLS contain information about response to treatment. This work motivates further development of predictive models to classify responders to RLS therapy.

REAL-WORLD OUTCOMES OF TONIC MOTOR ACTIVATION (TOMAC) FOR REFRACTORY RESTLESS LEGS SYNDROME (RLS)

Mark Buchfuhrer[1], Haramandeep Singh[2], Asim Roy[3], Joseph Ojile[4], Richard Bogan[5], Jessica Preciado[6], Jonathan Charlesworth[6]
[1] Stanford University School of Medicine, [2] Sleep Medicine Specialists of CA, [3] Ohio Sleep Medicine Institute, [4] Clayton Sleep Institute, LLC, [5] Bogan Sleep Consultants, [6] Noctrix Health, Inc.

Introduction: Tonic motor activation (TOMAC) is a noninvasive therapy that transmits bilateral high-frequency electrical stimulation to the peroneal nerves of the legs to treat refractory restless legs syndrome (RLS). TOMAC has previously been demonstrated as safe and efficacious in randomized controlled trials. Here, for the first time, we report real-world evidence from patients prescribed TOMAC.
Methods: We analyzed interim results from the THRIVE multicenter prospective observational post-market study of the NTX100 TOMAC System (Noctrix Health, Inc.). The intent-to-treat analysis population included all patients who were prescribed TOMAC, met the FDA indication of moderate-severe refractory RLS, and enrolled in the study prior to July 31, 2024. Baseline measures were assessed prior to starting TOMAC and interim outcomes were assessed at Day-90 relative to baseline. The primary efficacy endpoint was mean change to International RLS Study Group (IRLS) score and key secondary outcomes included clinical global impressions of improvement (CGI-I). The frequency and nature of adverse events and medication changes were assessed.
Results: The intent-to-treat population included 55 participants from 40 unique prescribers; mean age was 64.3 years (SD: 11.4), average duration of RLS symptoms was 27.6 years (SD: 16.6), and 62% were female. IRLS score improved from 26.6 at baseline to 18.1 at Day 90 of TOMAC treatment (Mean change: -8.5, SD: 7.4, 95% CI: -6.5 to -10.4). CGI-I responder rate was 62% and mean CGI-I score was 2.47 points (SD: 1.02, 95% CI: 2.20 to 2.74). Fourteen participants (25%) reduced RLS medication dose (average dose reduction: 62%) and four participants (7%) increased RLS medication dose. There were no serious or severe device-related adverse events.
Conclusion: These interim results suggest that TOMAC treatment is safe and effective in real-world treatment of refractory RLS.
Support (if any): The THRIVE study was sponsored by Noctrix Health, Inc.

OBSTRUCTIVE SLEEP APNEA AND PERIODIC LIMB MOVEMENTS OF SLEEP IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Viraj Jain[1], Harshil Modi[2], Moon Park[1], Eyad Almasri[2], Anil Ghimire[2], Lourdes DelRosso[3]
[1] UCSF Fresno, [2] UCSF Fresno, [3] UCSF, Fresno

Introduction: Chronic obstructive pulmonary disease (COPD) coexisting with obstructive sleep apnea, the overlap syndrome, can worsen nocturnal hypoxemia, disrupted sleep architecture, and adverse consequences. OSA is often comorbid with elevated Periodic limb movements of sleep (PLMS). Sleep parameters have not been investigated across OSA and PLMS subgroups in patients with and without COPD. This study seeks to examine differences in sleep architecture, respiratory indices, and ST between COPD and non-COPD patients, categorized by OSA and PLMS subgroups
Methods: This retrospective study included 711 participants, 48 with COPD and 663 without NoCOPD. Participants were categorized into four OSA/PLMS groups: Group 1 (no OSA/PLMS), Group 2 (OSA only), Group 3 (PLMS only), and Group 4 (OSA + PLMS). Sleep architecture metrics, respiratory indices, and ST were compared between groups using ANCOVA adjusted for age. Cumulative distribution function (CDF) plots were created to visualize ST distributions.
Results: The mean age of participants was 57.172 ± 17.926 years, with 316 males (44.4%). COPD patients were older than NoCOPD (62.583 ± 11.899 vs. 56.769 ± 18.211 years, $p < 0.001$). No significant differences in total sleep time (TST) were observed between COPD and NoCOPD (277.729 ± 94.902 vs. 300.249 ± 91.359 minutes, $p = 0.841$). However, ST was significantly higher in COPD across all OSA/PLMS groups. For Group 1, ST was 43.425 ± 110.800 minutes in COPD vs. 1.485 ± 5.332 minutes in NoCOPD ($p < 0.001$). In Group 4, ST was 62.735 ± 68.843 minutes in COPD vs. 14.822 ± 40.229 minutes in NoCOPD ($p = 0.003$). CDF plots revealed a greater cumulative burden of ST in COPD, particularly in Group 4.
Conclusion: COPD significantly exacerbates nocturnal hypoxemia, with the greatest ST observed in patients with comorbid OSA and PLMS. These findings demonstrate the added risk of elevated PLMS in patients with COPD and OSA, emphasizing the need for targeted therapeutic interventions to mitigate nocturnal oxygenation deficits in patients with these comorbidities.

PROTEOMIC PROFILING IN RESTLESS LEGS SYNDROME

Katie Cederberg[1], Jerome Rotter[2], Stephen Rich[3], Peter Ganz[4], Emmanuel Mignot[1]
[1] Stanford University, [2] Lundquist Institute, [3] University of Virginia, [4] University of California, San Francisco

Introduction: Restless legs syndrome(RLS) is a sensorimotor sleep disorder that affects up to 10% of people and significantly disrupts sleep, increases the risk of cardiovascular disease, hypertension, stroke, and causes overall poorer health. This project

leveraged large cohort studies using proteomics to replicate and extend our previous analyses in RLS.

Methods: The SomaScanv4 highly multiplexed aptamer assay profiled ~5K proteins from the Multi-Ethnic Study of Atherosclerosis(MESA) and the Stanford Technology Analytics and Genomics in Sleep study(STAGES). RLS was classified based on IRLSSG diagnostic criteria and individuals taking medication were excluded. Linear regression models were conducted to examine differentially expressed proteins(DEPs) in RLS(n=422) compared to controls(n=1,789). All models included log2-normalized relative protein expression as the dependent variable and important covariates (age, gender, BMI, sample storage time, blood draw time of day, study, and GWAS principal components). False discovery rate(FDR) was applied with an a-priori p-value of 0.05 to control for multiple testing.

Results: Linear regression analyses in MESA replicated our previous findings in STAGES with megalin(LRP2, p=0.026, Fold Change[FC]=1.41) and Cathepsin Z(CTSZ, p=0.013, FC=1.04) as upregulated in RLS; but significance diminished after FDR correction. Analyses in STAGES+MESA to extend our previous findings identified only megalin(q=0.045, FC=2.04) as significantly upregulated in RLS after FDR correction, which remained significant even after controlling for kidney function(Cystatin C), c-reactive protein, hypertension, and high cholesterol(q=0.031). Replication analysis of 464 DEPs identified in previous publications identified 11 proteins significant after FDR correction; 9 of which remained significant after controlling for kidney function(Cystatin C), c-reactive protein, hypertension, and high cholesterol, and included Megalin[LRP2], ANGL7[ANGPTL7], VIGLN[HDLBP], CHKB, FAM234B, TIGAR, ARF6, PTEN, FAM162A).

Conclusion: These large proteomic analyses confirmed Megalin as an independent protein overexpressed in people with RLS. Megalin(LRP2) is a large scavenger receptor that has major functions in the kidney but is also expressed in the brain, lung, placenta, and thyroid gland. It helps maintain iron homeostasis by promoting resorption of heme in the kidneys and mediates endocytosis of a variety of ligands, including proteins, heavy metals, hormones, and vitamins, notably vitamin D.

ADDITIVE AND SYNERGISTIC EFFECTS OF OBSTRUCTIVE SLEEP APNEA AND PERIODIC LIMB MOVEMENTS ON SLEEP PARAMETERS

Moon Park[1], Gulcin Benbir Senel[2], Harshil Modi[1], Viraj Jain[1], Lourdes DelRosso[3]

[1] UCSF Fresno, [2] IUC Cerrahpasa Faculty of Medicine, [3] UCSF, Fresno

Introduction: Obstructive Sleep Apnea (OSA) is associated with an increased index of periodic limb movements of sleep (PLMS), which independently can be associated with sleep fragmentation. However, when both conditions coexist, they can potentially have additive effects on sleep. There is limited data about their possible additive or synergistic effect on sleep parameters. This study explores the combined impact of OSA and PLMS, hypothesizing both conditions have an additive or synergistic effect on sleep parameters compared to each condition alone.

Methods: We conducted a retrospective analysis of 581 adults undergoing polysomnography at UCSF-Fresno. Subjects were categorized into three groups: OSA-only (AHI ≥ 5 and PLMI < 15), PLMS-only (PLMI ≥ 15 and AHI < 5), and OSA-PLMS (AHI ≥ 5 and PLMI ≥ 15). Sleep parameters were compared using Kruskal Wallis test and Jonckheere Terpstra. Linear regression models were used to compare whether effects were additive or synergistic.

Results: OSA-only group (291 subjects, 50.1%; mean age 54.6 ± 17.9 years; 46.4% male), PLMS-only (72 subjects, 12.4%; mean age 63.2 ± 17.1 years; 40.2% male), and both OSA and PLMS (218 subjects, 37.5%; mean age 61.8 ± 15.8 years; 52.2% male). Combined OSA and PLMS were associated with significant reductions in TST (coefficient: -117.09, $p < 0.001$) and N2 (-14.79, $p < 0.001$), N3 (-6.25, $p < 0.001$), and REM sleep (-5.62, $p < 0.001$), with synergistic impairments in sleep architecture compared to either condition alone. In contrast, WASO showed an additive effect (coefficient: 9.76, $p = 0.102$). The severity of OSA amplified these disruptions, particularly in NREM and REM sleep stages, with more pronounced effects observed when PLMS was present.

Conclusion: The combination of OSA and PLMS has a synergistic negative impact on sleep architecture, significantly reducing TST and deep sleep stages (N2, N3, and REM) compared to either condition alone. These effects are further amplified with increasing OSA severity, highlighting the compounded burden of coexisting sleep disorders. The findings underscore the importance of identifying and addressing PLMS in patients with OSA to optimize sleep quality and mitigate associated health risks.

PROFOUND POSTPARTUM SLEEP DISCONTINUITY IN FIRST-TIME MOTHERS

Teresa Lillis[1], Devon Hansen[2], Hans Van Dongen[2]
[1] Rush University Medical Center, [2] Washington State University

Introduction: Maternal sleep is disrupted during the postpartum period, but the nature and severity of sleep disruption has not been adequately documented. Studies of sleep duration have reported only modest sleep loss beyond the first week after giving birth, leaving first-time mothers poorly prepared for what kind of sleep disruption to expect. Using sleep data from first-time mothers' personal wearables (Fitbit), we examined sleep duration and the longest stretch of sleep (LSS) – a sleep consolidation metric commonly used for infant sleep – to quantify maternal sleep during the first 13 postpartum weeks.
Methods: N=41 first-time mothers (ages 26–43y) provided their sleep/wake wearable data from a full year before childbirth to the end of the first postpartum year. Sleep data were analyzed in 5min bins, using ≥10min consecutive sleep and wake as criteria for onset and offset of sleep periods, respectively. Off-wrist detection was based on absence of heart rate data. Daily sleep duration and LSS were calculated for each 24-hour day and compared between the first 13 postpartum weeks and the equivalent days of the prior year (preconception baseline).
Results: During postpartum week 1, daily sleep duration was 4.4±0.2h (mean±SEM) compared to 7.8±0.2h at preconception baseline. Daily LSS was 2.2±0.2h versus 5.6±0.2h preconception. 31.7% of participants went >24h without sleep. Across postpartum weeks 2-7, daily sleep duration increased to 6.7±0.1h versus 7.7±0.1h preconception. However, daily LSS stayed low at 3.2±0.1h versus 5.5±0.1h preconception. Across postpartum weeks 8-13, daily sleep duration was 7.3±0.1h versus 7.9±0.1h preconception. Yet, daily LSS was still reduced at 4.1±0.1h versus 5.6±0.1h preconception. All differences were significant ($F>29.8$, $P< 0.001$).
Conclusion: Sleep duration was greatly reduced during the first postpartum week, but gradually returned to near baseline levels thereafter. However, sleep consolidation, as captured by LSS, stayed considerably below preconception baseline throughout the first 13 postpartum weeks. This suggests that in postpartum weeks 2-13, sleep discontinuity – more so than sleep loss – contributed most prominently to first-time mothers' sleep disruption. Sleep discontinuity may be a risk factor and intervention target for postpartum depression and other postpartum-related health issues.

SIPPING, SLEEPING, AND SEX DIFFERENCES: ALCOHOL'S IMPACT ON POLYSOMNOGRAPHIC SLEEP AND SPECTRAL ACTIVITY IN OLDER ADULTS

Ashley Curtis[1], Mary Beth Miller[2], Amy Costa[1], Madison Musich[2], Chloe Rzeppa[1], Christina McCrae[1]
[1] University of South Florida, [2] University of Missouri

Introduction: Findings regarding the relationship between alcohol use and objective sleep are inconsistent and studies in aging populations are limited. Despite known sex differences in alcohol use and sleep health, sex differences in the alcohol/sleep relationship remain underexplored. This study examined sex differences in the association between alcohol use and polysomnographic-assessed sleep and spectral power in older adults.
Methods: Older adults (Mage=68.0±5.6; 38 women/26 men) completed overnight polysomnography (Sleep Profiler) and the Alcohol Use Disorder Identification Test consumption items. Multiple regressions examined whether alcohol use was independently or interactively (with sex) associated with objective sleep [total sleep time, sleep efficiency%, sleep onset latency, wake time after sleep onset], sleep architecture [N1%, N2%, N3%, rapid eye movement (REM)%], or frontal spectral power (Delta, Theta, Alpha, Sigma, Beta frequencies during N1, N2/N3, and REM), controlling for age, body mass index, and apnea-hypopnea index.
Results: Sex moderated associations between alcohol use and total sleep time (R-squared=.10, p=.01), N1% (R-squared=.12, p=.002) and all REM spectral power frequencies (R-squared ranged from.08 to.15, ps<.01). In women, greater alcohol consumption was associated with shorter total sleep time (B=-.53, p=.01), higher N1% (B=5.15, p=.03), and reduced REM spectral power across all frequencies (Bs ranged from -.08 to -.29, ps<.001). Additionally, greater alcohol use was associated with lower N1% in men (B=-6.83, p=.02).
Conclusion: Findings highlight potential sex-specific risks of alcohol use on objective sleep health and frontal cortical activity in older adults, with alcohol use linked to more time spent in lighter-staged sleep, shorter sleep duration, and reduced REM spectral power among women relative to men. Given the higher prevalence of insomnia disorder in women compared to men, and the risk of poor sleep health on other comorbidities, including cognitive decline, women who engage in heavy drinking may be an especially vulnerable population in need of prevention, intervention, and treatment. Prospective studies evaluating sex-specific mechanisms (circulating sex hormones, blunted fronto-cortical activity) that may contribute to associations between alcohol use and objective sleep are encouraged.
Support (if any): This research was made possible by awards (PI:Curtis) from the American Academy of Sleep Medicine Foundation.

HOUSEHOLD CHAOS AND PARENTAL SLEEP IN WORKING PARENTS AND PARENTS ON PARENTAL LEAVE

Maristella Lucchini[1], Daniela Macia[1], Liat Tikotzky[2], Sarah Berger[3], Natalie Barnett[1]
[1] Nanit Lab, [2] Ben-Gurion University of the Negev, [3] College of Staten Island, City University of New York

Introduction: While family chaos and its links to children's sleep are well-studied, little attention has been given to its associations with parents' sleep. The early months of life are a delicate transition, requiring significant adjustments to sleep and routines. Despite one study examining the relationship between household chaos and sleep outcomes for both infants and parents in the first year of life, the potential connection between family chaos and the critical transition from parental leave to returning to work remains unexplored. Similarly, limited studies address how parental leave policies affect parental sleep outcomes. This study seeks to fill these gaps by examining the interplay of family chaos, parental sleep, and the return to work.
Methods: Among Nanit users, we recruited 740 parents of infants 1-7 months (82% mothers). Fifty-nine percent of them had returned

to work, while 41% were still at home. The sample was fairly highly educated (45.5% College degree; 42% Postgraduate degree;11% Some college or less) and affluent (34.7% More than $200,000; 18.2% $150,000-$200,000; 22%; $100,000-$150,000; 8.8% $75,000-$100,000; 9.9% Less $75,000). Parents completed the PROMIS Sleep disturbances (SD) and Sleep Related Impairment (SRI) and the The Confusion, Hubbub, and Order Scale (CHAOS).
Results: Higher CHAOS scores were associated with more SD and SRI for parents (SD:β=0.3±0.03,p< 0.001; SRI:β=0.4±0.03,p< 0.001). CHAOS scores were higher in families with more children and for parents reporting going to work in the office compared to flexible locations, but it did not differ by education or household income. CHAOS, parental SD and SRI did not differ between parents who had returned to work and those who had not returned to work, even after controlling for infant age and parent gender.
Conclusion: More household CHAOS was significantly associated with worse reported parental sleep. CHAOS and parental sleep did not differ between parents who had returned to work and those who were on parental leave. This is the first study to analyze parental sleep and household CHAOS in the context of the parental leave transition, but more studies are needed to better understand this complex interplay, including longitudinal data and more diverse samples.

SUBSTANTIAL MATERNAL SLEEP DISRUPTION AS A POTENTIAL MEDIATOR OF INCREASED HEALTH RISK IN THE FIRST POSTPARTUM WEEK

Teresa Lillis[1], Natalie Williams[2], Devon Hansen[2], Hans Van Dongen[2]
[1] Rush University Medical Center, [2] Washington State University

Introduction: Maternal sleep disruption is common throughout the first postpartum year, and particularly severe in the first postpartum week. As nearly 75% of all pregnancy-related maternal deaths occur between postpartum days 1 and 7, maternal sleep disruption after birth could be a risk factor for maternal morbidity and mortality. Here, in a sample of first-time mothers, we quantified objectively measured sleep during the first 7 postpartum days.
Methods: N=41 first-time mothers (ages 26–43y) recorded their wrist activity (Fitbit) continuously across postpartum days 1-7. Sleep data were analyzed in 5min bins, using ≥10min consecutive sleep and wake as criteria for onset and offset of sleep periods, respectively. Sleep duration (including naps) and longest stretch of sleep (LSS) were calculated for each 24h day. Off-wrist detection was based on absence of heart rate data and controlled for in analyses.
Results: The incidence of acute total sleep deprivation (>24h without sleep) was 20% (n=8) on day 1, 20% (n=8) on day 2, and 10% (n=4) on days 3-7. Total 24h sleep duration ranged from a low of 2.7±2.2h (mean±SD) on day 1 to a high of 5.0±2.0h on day 7. LSS ranged from a low of 1.7±1.4h on day 1 to a high of 2.9±1.2h on day 7.
Conclusion: These results show that acute total sleep deprivation is common in new mothers after giving birth. The results also show severe chronic sleep restriction during the first postpartum week, with the average first-time mother in our sample obtaining no more than 5h total sleep duration per 24h and consolidated sleep periods shorter than 3h – much less even during the first few postpartum days. Our findings provide objective evidence of considerable maternal sleep disruption, making sleep disruption a plausible contributor to maternal health risks in the first postpartum week. Limitations of the study include that the sample was predominantly white, relatively affluent, and generally in good health. The sleep data nonetheless suggest that studies should investigate whether there is a causal relationship between maternal sleep disruption and health risks, and whether interventions to protect maternal sleep during the first postpartum week may improve health outcomes.

THE EFFECTS OF NOCTURIA ON SLEEP, MOOD AND QUALITY OF LIFE IN WOMEN

Daljinder Chalmers[1]
[1] Keele University

Introduction: Historically nocturia has received more attention as a men's health issue, despite the high prevalence in women as well. Nocturia in women has been thought of as a symptom of other disorders such as overactive bladder or global polyuria, though nocturia often occurs without daytime symptoms. The aim of the present study was to observe the impact of nocturia on women's health and wellbeing.
Methods: Participants (n-180) (75 % Caucasian) women with 21 % transitioning through the menopause aged 19 to 86, took part in a cross-sectional survey study consisting of the Pittsburgh Sleep Quality Index (PSQI), Groningen Sleep Quality Scale (GSQS), Nocturia Sleep Quality Scale (NSQS), 36-item Short-Form (SF-36) and the Hospital Anxiety and Depression Scale (HADS).
Results: Subjective sleep quality (M: 2.23, SD: 0.68), sleep disturbances (M: 1.34, SD: 0.54) and daytime dysfunction (M: 1.09, SD: 068) was notably higher in comparison to other component scores, global PSQI scores also indicated worse sleep quality (M: 7.69, SD: 3.40). Time to go to bed differed a great deal, participants took on average 30 minutes to fall asleep. Sleep quality was also observed to be poor (>5) as reported by the GSQS. Lost sleep time (M: 3.68, SD: 1.66) due to voiding at night and the impact of voiding (M: 6.25, SD: 1.50) at night was also observed to be noticeably higher using the NSQS. Dimensions (SF-36) aligned to physical components such as physical function (M: 27.11, SD: 4.41), physical problems (M: 2.84, SD: 1.57), and energy and vitality (M: 46.15, SD: 20.18) have extremely low mean scores. Participants also reported high anxiety scores (M: 8.77, SD: 4.32) on the HADS.
Conclusion: The findings show the importance of considering individuals sleep, QoL and psychological well-being as well as acknowledging their clinical diagnosis. In clinical practice, administering a simple sleep questionnaire should become routine as part of the clinical assessment of the patient's disease and will also help in improving the patient's overall condition.

HOW DO SLEEP PATTERNS RELATE TO LOW SEXUAL FUNCTION IN WOMEN? A STUDY FROM THE EPISONO DATABASE

Larissa Fonseca[1], Isabela Ishikura[1], Allan Porcacchia[1], Helena Hachul[1], Sergio Tufik[1], Monica Andersen[2]

[1] Universidade Federal de São Paulo, [2] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Sleep disorders are highly prevalent among women, with nearly 47% reporting complaints related to sleeping less than 6 hours per night. These disturbances not only affect overall well-being, but are also associated with sexual dysfunction, which impacts over 40% of women. Despite the coexistence of these conditions, their relationship remains underexplored, particularly in women at reproductive age. Our study aimed to investigate objective sleep pattern in women at reproductive age and its association with sexual function.
Methods: We included a total of 76 women participants from the 4th edition of the epidemiological sleep study (EPISONO), conducted in São Paulo, Brazil, between 2018 and 2019. The participants responded the Female Sexual Function Index (FSFI) and underwent a full-night type 1 polysomnography to assess their sexual function and sleep parameters, respectively. Based on FSFI scores, the women were distributed into 2 groups: low and preserved sexual function.
Results: Considering low sexual function as the dependent variable, the results of the generalized linear model revealed that women with low sexual function exhibited a higher percentage of N2 sleep phase and a lower percentage of N1 sleep phase compared to those with preserved sexual function.
Conclusion: Our findings suggest that NREM sleep, particularly N2 sleep phase, may play a distinct role in sexual health, becoming relevant to investigate the mechanisms beyond the interaction of sleep and sexual function.

THE SLEEP-HORMONE CONNECTION: SNOOZZZE COHORT INSIGHTS INTO MENOPAUSAL HORMONE THERAPY AND SLEEP ARCHITECTURE IN OLDER WOMEN

Gabriela Parra[1], Pamela DeYoung[1], Brynn Norby[1], Kathryn Macaulay[2], Lana McGinnis[1], Stephanie White[1], Steven Luu[1], Christopher Schmickl[1], Atul Malhotra[1], Janna Raphelson[1]
[1] University of California, San Diego, [2] UC San Diego Health

Introduction: Obstructive sleep apnea(OSA) prevalence increases in women with aging, particularly after age 50yrs with menopause in association with loss of estrogen and progesterone. Therefore, we hypothesized that women over 50yrs on menopausal hormone therapy(HT) have a lower AHI4% and better sleep architecture(e.g.higher sleep efficiency) than those not on HT.
Methods: Using San Diego Multi-Outcome OSA Endophenotype(SNOOzzzE) cohort, results were obtained for women over age 50yrs to assess sleep characteristics. The SNOOzzzE cohort includes 3,319 consecutive adults who underwent a clinical polysomnography(PSG) after being referred to UCSD sleep clinics between 1/2017-12/2019(IRB #182136). HT status was determined by manual search of medical record medication lists. Independent sample t-tests were performed to assess differences($P < 0.05$) for multiple PSG parameters including AHI4%, sleep efficiency, and percent time per sleep stage.
Results: Of the 1297 women over 50yrs, 28 were found to be on HT. Women on HT were slightly younger(age (M)= 62±6.5yrs(SD)) than those not on HT(M= 63.4±8.9yrs). AHI4% was not significantly different between the two groups, but trended lower in HT group(M=14.3±23.5/h vs. 18.9±24.0/h). Sleep efficiency(SE) was significantly higher in women on HT(M= 77.9±11.3%) than those not on HT (M=71.3±18.1%,$p < 0.001$) percent N1 sleep was lower in women on HT(M= 5.9±4.1%) than those not(M= 10.6±11.3%, $p=0.003$). Sleep latency trended lower in women on HT(M= 25.0±25.4 vs M=32.2±41.1 min). AHI3% in REM sleep was significantly lower in women on HT (M=24.38± 24.92/h vs M=33.91± 25.02/h).
Conclusion: Although our study is underpowered, HT may be associated with improvement in SE, lower %stage 1 sleep, improved sleep latency, and lower AHI3% in REM Sleep. Medical records collect limited information on menstrual history, menopausal status, and HT treatments. Due to limited available information in this analysis, results may be confounded by age and other factors, which we hope to address in future analyses. Furthermore, we acknowledge possibility of confounding by indication, healthy user effect and selection bias. Nonetheless, our results suggest real differences in the sleep of older women on HT and more research on the sleep-hormone interaction is needed.

INFANT MILK TYPE AFFECTS MATERNAL SLEEP CONTINUITY IN FIRST-TIME MOTHERS

Teresa Lillis[1], Devon Hansen[2], Hans Van Dongen[2]
[1] Rush University Medical Center, [2] Washington State University

Introduction: Postpartum maternal sleep is disrupted, even after stabilizing following the first three months. Evidence suggests that breastfeeding women wake more often during the night than those who use infant formula, while sleep duration is similar. Here we investigated the effects of breastmilk versus formula feeding on maternal sleep across postpartum weeks 14-52.
Methods: N=41 first-time mothers (26-43y) recorded their sleep (Fitbit) and reported infant milk type – breastmilk or formula – with 16 participants also logging daily infant feeding events (mobile app). Daily sleep duration and continuity (LSS: longest stretch of sleep) were assessed by 24h day. Effects of milk type were analyzed with mixed-effects ANCOVA, controlling for general trends across days.
Results: Mean daily sleep duration was 7.4h throughout postpartum weeks 14-52, whereas LSS increased from 4.3h to 5.3h. In week 14, 64.7% of participants fed breastmilk, 17.1% formula, and 18.2% mixed. By week 52, 47.2% fed breastmilk, 43.5% formula, and 9.3% mixed. Milk type did not affect sleep duration ($F=2.6$, $P=0.11$), but those feeding breastmilk had 0.4h shorter LSS than those feeding formula or mixed ($F=10.2$, $P=0.001$). Among those logging feeding events, milk

type did not affect sleep duration (F=0.8, P=0.38), but LSS was shorter by 6.2min per feeding event for breastmilk compared to formula (F=12.0, P< 0.001). There were no significant relationships with breastmilk pumping, breastfeeding versus breastmilk bottle feeding, infant weight gain, or infant sleep training. On average there were 9.1 daily feeding events for exclusive breastmilk feeding, compared to 7.3 for formula or mixed (F=10.9, P=0.001).
Conclusion: In this predominantly white and relatively affluent sample, maternal sleep duration in postpartum weeks 14-52 did not vary by infant milk type. However, participants who fed their babies formula had fewer daily feeding events and greater sleep continuity than participants who exclusively fed their babies breastmilk. As there was no effect of breastfeeding versus breastmilk bottle feeding, use of infant formula per se may have led to increased maternal sleep continuity. Whether a difference in infant sleep continuity is involved remains to be investigated. Regardless, current recommendations of exclusive breastmilk feeding may come at a cost to maternal sleep.

ASSOCIATIONS BETWEEN SLEEP AND AFFECT IN MIDLIFE WOMEN: THE IMPORTANCE OF METHODOLOGICAL RIGOR

Shelby Wood[1], Rebecca Thurston[2], Yue-Fang Chang[2], Pauline Maki[1]
[1] University of Illinois Chicago, [2] University of Pittsburgh

Introduction: In midlife women, sleep difficulties are associated with prolonged mood states like depression. Sleep difficulties may also associate with positive and negative emotions ("affect") that can change rapidly over minutes and hours. Here we examined day-to-day bidirectional associations of actigraphy-assessed sleep measures with positive (PA; energetic, interested/involved) and negative affect (NA; angry/irritated, nervous/anxious, stressed) in midlife women. We compared those findings to results obtained from the same sample using more typical, but less rigorous methods (e.g., questionnaire-based sleep, cross-sectional associations).
Methods: Participants from the MsBrain I study completed: a) the Pittsburgh Sleep Quality Index (PSQI; total sleep time, TST; sleep efficiency, SE; sleep disturbance); b) sleep assessment via wrist actigraphy over 72-hours (TST; SE; wake after sleep onset, WASO); and c) ecological momentary assessment (EMA) of PA and NA over 72-hours. Multiple linear regression models evaluated cross-sectional associations of sleep (72-hour average actigraphy, PSQI) with PA and NA (72-hour average). Mixed-effects models evaluated day-to-day bidirectional associations between sleep (actigraphy) and affect.
Results: Participants included 247 postmenopausal women (mean age=59.2 years, 80.1% White). In cross-sectional analyses, actigraphy-assessed longer TST (p=.009) and greater WASO (p<.001) were associated with lower PA. PSQI measures were unrelated to affect. In day-to-day bidirectional associations using actigraphy and EMA, moderate TST (p=.035), higher SE (p=.017), and lower WASO (p=.001) were associated with higher next day PA; conversely, higher PA was associated with shorter next night TST (p=.029). Sleep was not significantly related to NA.
Conclusion: In cross-sectional analyses, questionnaire-based sleep measures were not associated with affect while worse actigraphy-assessed sleep measures were associated with lower PA. Day-to-day analyses indicated bidirectionality of associations between sleep and affect such that better sleep predicted higher next day PA yet higher PA predicted shorter next night sleep. Therefore, cross-sectional associations do not fully capture the dynamic, bidirectional associations between sleep and affect observed on a day-to-day basis and findings underscore the importance of rigorous methods for assessing sleep and affect in midlife women.
Support (if any): This research was supported by the National Institutes of Health, National Institute on Aging (grant numbers: RF1AG053504 and R01AG053504 to Thurston and Maki).

SLEEP DISORDERS AND POLYSOMNOGRAPHIC FINDINGS IN TRANSGENDER PATIENTS ON HORMONAL THERAPY: A DESCRIPTIVE REVIEW

Marc Daou[1], Kimberly Campbell[1], Robert Thomas[1]
[1] Beth Israel Deaconess Medical Center

Introduction: Cisgender men and women exhibit notable differences in objective and subjective sleep quality. Sleep differences are influenced by sex steroids (estrogen, progesterone, testosterone), though mechanisms remain unclear. Gender-affirming hormonal therapy (GAHT) impacts sleep in transgender individuals, with transgender males (TM) showing increased snoring and phase delays, and transgender females (TF) reporting phase advancement and, in some cases, OSA resolution. Limited data on transgender populations highlight the need for targeted research into their unique sleep challenges.
Methods: Patients seen at Beth Israel Deaconess Medical Center's sleep and neurology clinics (2018–2024) were selected using ICD-10 codes: F64.0, F64.1, F64.2, F64.8, F64.9, F64.89, and Z87.890. Chart reviews assessed sleep diagnoses, medications, and results from in-laboratory and home-based sleep studies. Statistical analyses (descriptive metrics, t-tests) were performed using STATA-18.
Results: Thirty-six patients were included (7 TF, 29 TM), with 34 (27 TM, 7 TF) on GAHT. Non-restful sleep and obstructive sleep apnea (OSA) were the most common diagnoses, affecting 26 patients (22 TM, 4 TF). Complex sleep apnea occurred only in TM (10 patients). Insomnia and delayed sleep phase disorders were diagnosed in 16 (13 TM, 3 TF) and 8 (7 TM, 1 TF), respectively. Rarer diagnoses included hypersomnia, sleep-wake cycle instability, and one case of Klein-Levin syndrome in a TF patient following GAHT. Polysomnograms (PSG) were available for 23 patients (4 TF, 19 TM), and home sleep tests (HST) for 16 patients (1 TF, 15 TM). No significant differences were seen between transtypes in PSG and HST results. Sleep stage analysis revealed a mild decrease in N3 (10%) and REM sleep (16%) across all PSG, with no transtypic differences. Compared to cisgender controls, transgender patients had significantly longer total sleep time (298 vs. 416 minutes, p < 0.0001).
Conclusion: Transgender individuals, particularly those on GAHT, experience diverse sleep challenges, including circadian rhythm disorders, OSA, periodic breathing, and insomnia. Although no significant differences in objective measures were observed in our study, the small sample size underscores the need for further research to better inform clinical practice.

SLEEP DISORDERS IN MENOPAUSAL WOMEN IN A COLOMBIAN COMMUNITY

OSCAR MEDINA[1], Andres Sanchez[2], Harold Torres[2], Jorge Mejia[2], Nora Sanchez[3], Jesus Solano[2], Jose Sanchez[2]

[1] UNIVERSIDAD SIMON BOLIVAR, [2] UNIVERSIDAD DE SANTANDER, [3] Universidad de Los Andes

Introduction: During menopause, women experience symptoms related to hormonal changes, which can lead to sleep disorders such as insomnia, hypersomnia and restless legs syndrome. The aim of this study was to determine the prevalence of sleep disorders associated with menopause in a community in Colombia.
Methods: Observational, descriptive, cross-sectional study. All women with menopause who attended the Avanzar clinic in Floridablanca, Colombia from January to April 2024 were invited to participate. After signing the informed consent, the Athens (cut point 4), Epworth (cut point 6) and International Restless Legs Scale (cut point 10) questionnaires were applied. Statistical analysis was performed with SPSS 22 and significance was considered to be less than 0.05. Chi-square was used for categorical variables and Pearson correlation for numerical variables. The study was approved by the ethics committee of the University of Santander.
Results: 118 women were included. Mean age 62.45 years (SD: 5.93; min: 49 and max: 79). Mean age at menopause onset was 49.48 years (SD: 2.85; min: 44 and max: 60). 39.83% presented menopause between 44 and 49 years of age and 60.17% at 50 or more years. 93.22% presented insomnia (Athens ẋ: 9.31; SD: 4.13; min: 0 and max: 19), 77.97% daytime sleepiness (Epworth ẋ: 7.95; SD: 2.23; min:1 max:14) and 9.32% restless legs syndrome (RLS ẋ: 5.68; SD: 6.69; min:0 max:27). It could be seen that the younger the age of menopause onset the higher the Athens score (P=NS), the lower the Epworth score (P=NS) and the higher the RLS score (P=NS). The higher the Athens score, the higher the Epworth score (Pearson 0.39: P< 0.0001); and the higher the SPI score, the higher the Epworth score (Pearson 0.31: P=0.001). No significance was found in any other variable or in the medical comorbidities studied.
Conclusion: There is a high prevalence of insomnia, daytime sleepiness and RLS in menopausal patients, which seems to be higher in those who start menopause at an earlier age. Insomnia and restless legs syndrome appears to worsen daytime sleepiness. Measures should be taken to avoid sleep complications and comorbidities in this group of patients.

THE DISPROPORTIONATE BURDEN OF OSA IN WOMEN IN THE UNITED STATES: A CALL FOR IMPROVED AWARENESS AND DIAGNOSIS

Elroy Boers[1], Meredith Barrett[2], Adam Benjafield[2], Leanne Kaye[2], Peter Cistulli[3], Jean-Louis Pepin[4], Alison Wimms[2], Jeff Armitstead[2], Kimberly Sterling[2], Atul Malhotra[5]

[1] ResMed, [2] ResMed Science Center, [3] University of Sydney, [4] Grenoble Alpes University, [5] University of California, San Diego

Introduction: While obstructive sleep apnea (OSA) is widely recognized as a condition that predominantly impacts men, the burden on women is significant, yet often under-appreciated. Given increased attention on understanding gender differences in chronic diseases, especially related to menopausal changes (e.g., body weight and hormones), it is critical to better understand how the burden of OSA develops over time in women. Therefore, we sought to estimate the prevalence of OSA by gender across the United States (US) through the year 2050.
Methods: A dynamic open cohort population Markov model was developed to simulate population dynamics from 2020 to 2050. Population growth, OSA development, BMI trajectories, all-cause mortality, and OSA and BMI-related mortality were derived from literature estimates and modeled across subgroups of age, sex, and BMI trends in 5-year increments. OSA prevalence was calibrated for subgroups by age, sex and BMI, and distributions of OSA severity grades were modeled based on sex, apnea hypopnea index (AHI) and BMI. OSA prevalence (AHI >5) was projected among those aged 30-69 years.
Results: The burden of OSA across the US is expected to rise significantly by 2050, with total cases projected to increase by 34.7%, from 56.9 million in 2020 to 76.6 million by 2050. The prevalence of OSA is estimated to increase for both males and females, but the rise is notably more pronounced among women, with the number of female OSA cases projected to grow by 64.4%, from 18.9 million in 2020 to 30.4 million in 2050, while male cases are expected to increase by 19.0%, from 38.0 million to 46.2 million.
Conclusion: Our modeling study projects a significant increase in OSA prevalence across the US through 2050, with a disproportionate rise in the burden among women. This data serves as a call to action to increase awareness in primary healthcare settings, particularly regarding peri-menopausal and post-menopausal women who face weight gain and hormonal changes that increase OSA risk. The findings highlight the need for efficient and accurate diagnostic tools which are appropriate for characteristics of female OSA, along with optimal treatment pathways for female patients.

EFFECT OF A NONHORMONAL SLEEP SUPPLEMENT ON SLEEP QUALITY IN PERI- AND POSTMENOPAUSAL FEMALES: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

Stephen Carbonneau[1], Alyssa Dweck[1], Trisha VanDusseldorp[1], Vincent Mysliwiec[2], Matthew Stratton[3], Michaela Alesi[1], Laura Mason[1], Will Mykytiuk[1], James Komorowski[1]

[1] Bonafide Health, [2] The University of Texas Health Science Center, [3] University of South Alabama

Introduction: Sleep disturbances are common during menopause due to hormonal changes. This clinical trial evaluated the safety and efficacy of a nonhormonal sleep supplement (NSS) containing S-adenosyl-methionine, propyl gallate, gamma-aminobutyric acid, magnesium glycinate, and theanine on sleep and sleep quality in peri- and postmenopausal females with impaired sleep.
Methods: A randomized, double-blind, placebo-controlled trial was conducted over three weeks in peri- and postmenopausal females aged 40–65 years with moderate-to-severe sleep disturbances [T-score ≥ 60 on the Patient-Reported Outcomes Measurement Information System Sleep Disturbance

(PROMIS-SD)]. Participants were randomly assigned to NSS or placebo (PLB) 60 minutes before bedtime each night for three weeks. A repeated measures analysis of variance (RMANOVA) was conducted to assess changes between conditions in total sleep time (TST) as measured by daily diaries, PROMIS-SD score, sleep quality visual analog scales (VAS), and safety, between baseline and Wks 1, 2, and 3.
Results: A total of 127 females completed the trial (NSS [n=65]: 54.1±8.7 yr; PLB [n=62]: 54.4±5.6 yr). All improvements were statistically significant (p≤0.05) compared to PLB. TST increased with NSS supplementation, on average, at Wk2 (NSS +21.6 min [+5.6%] vs PLB -17.1 min [-4.3%]) and Wk3 (NSS +40.9 min [+10.7%] vs PLB -15.0 min [-3.8%]). PROMIS-SD scores improved progressively over three weeks (Wk1: NSS -15.9% vs PLB -10.6%; Wk2: NSS -20.0% vs PLB -12.1%; Wk3: NSS -28.3% vs PLB -10.3%). Improvements were observed in several VAS measures over the course of the study. Ease of returning to sleep showed consistent improvement (Wk1: NSS -30.9% vs PLB -13.1%; Wk2: NSS -35.1% vs PLB -14.6%; Wk3: NSS -42.9% vs PLB -18.4%). Sleep quality demonstrated significant improvements at Wk2 (NSS -34.0% vs PLB -19.8%) and Wk3 (NSS -41.2% vs PLB -14.4%). Sleep satisfaction showed marked improvement by Wk3 (NSS -43.5% vs PLB -16.3%).
Conclusion: NSS clinically and significantly improved TST and significantly improved sleep quality in peri- and postmenopausal females with moderate-to-severe sleep disturbances. Additionally, NSS demonstrated rapid efficacy and a favorable safety profile, supporting its use as a potential option for enhancing sleep quality in peri- and postmenopausal females.

SOMATIC SYMPTOMATOLOGY AND SLEEP-RELATED DAYTIME DYSFUNCTION POST-MILD TRAUMATIC BRAIN INJURY: EXPLORING GENDER SPECIFIC ASSOCIATIONS

Nekabari Yakpogoro[1], Alisa Huskey[1], Kathryn Kennedy[1], Michael Grandner[2], William Killgore[1]
[1] The University of Arizona, [2] University of Arizona College of Medicine

Introduction: Somatization is the manifestation of physical symptoms such as, pain or weakness, and is linked to impaired daytime functioning from poor sleep quality. Pre-injury somatization has been linked to higher concussion symptom scores and prolonged recovery, with worse effects in females. We hypothesized that somatization would be associated with sleep-related daytime dysfunction in women, but not men.
Methods: Participants included healthy adults (n=30) and individuals with mild traumatic brain injury (mTBI; n=150). Measures were collected from 113 adults (72 females; M age=23.79, SD=6.90, and 41 males; M age=26.88, SD=8.51) at five timepoints following injury (2-weeks, 1-month, 3-months, 6-months, 12-months). Daytime dysfunction was measured using a subscale of the Pittsburgh Sleep Quality Index (higher scores indicated greater sleep-related dysfunction). Somatization was assessed using the Personality Assessment Inventory. Multivariate regression and Pearson correlation analyses were used to examine the relationship between somatization and daytime dysfunction for the group and separately for males and females, controlling for age and time since injury.
Results: Somatization accounted for 62.3% of the variance in sleep-related daytime dysfunction at two-weeks (R2=0.62,F(2,7)=8.42) post-injury. When evaluated separately by sex, somatization predicted sleep-related daytime dysfunction in females (β=1.11, p=0.04) but not males (β=0.31, p=0.51). At one-month, somatization accounted for 21.9% of the variance in daytime dysfunction (R2=0.219,F(2,18)=3.80). After Bonferroni correction (p=0.042), males trended toward significance (β=1.041, p=0.083) but not females (β=0.57, p=0.33). There were no significant correlations at three-months. At six-months, somatization accounted for 49.5% of the variance in daytime dysfunction (R2=0.495,F(2,17)=10.30). Somatization predicted daytime dysfunction for both females (β=1.540, p< 0.001) and males (β=1.686, p< 0.001). There were no significant correlations at twelve-months post-injury.
Conclusion: Somatization was strongly associated with sleep-related daytime dysfunction, with notable sex differences at various points following injury. Early post-injury, females with somatization experienced greater sleep-related daytime dysfunction while males demonstrated stronger correlations over time. These findings suggest that females may show the strongest association between sleep-related dysfunction and somatization early in the course of injury, but these effects may be more apparent later in men.

EXCESSIVE DAYTIME SLEEPINESS AND ALL-CAUSE MORTALITY IN FEMALE VETERANS: A RETROSPECTIVE COHORT ANALYSIS

Arash Maghsoudi[1], Kalli McWhinney[1], Mehrnaz Azarian[1], Amin Ramezani[1], Javad Razjouyan[1], Amir Sharafkhaneh[1]
[1] Baylor College of Medicine

Introduction: Excessive Daytime Sleepiness (EDS) has been associated with all-cause mortality in previous studies, which primarily focused on male populations. This study aims to examine the presence of this relationship in a large cohort of female Veterans.
Methods: We conducted a retrospective analysis of Veterans' medical records from 1999 to 2022, focusing on individuals with sleep-related ICD-9/10 codes or those who received clinical sleep services. Using a validated natural language processing (NLP) pipeline, we extracted Epworth Sleepiness Scale (ESS) data from clinical notes. ESS scores were categorized as normal (0–10) and high (11–24). The cohort was further stratified into three age groups: young (< 50 years), middle-aged (≥50 to < 65 years), and older adults (≥65 years). Logistic regression models were used to estimate odds ratios (ORs) for all-cause mortality, with the normal ESS group serving as the reference. Results were adjusted for age, race, ethnicity, Body Mass Index (BMI), and Charlson Comorbidity Index (CCI).
Results: ESS data were extracted for 40,250 female Veterans (mean age: 48.08 ± 12.08 years; mean BMI: 32.9 ± 6.7 kg/m²; 54.9% White; 15.4% with CCI ≥2). Cardiovascular, metabolic, neurologic, and renal comorbidities were more common in the normal ESS group compared to the high ESS group. In the overall cohort, the adjusted odds ratio (aOR) for all-cause mortality in the high ESS group compared to the normal ESS group was not statistically significant. However, when stratified by age, middle-aged females in the high ESS group had significantly higher

odds of all-cause mortality (aOR: 1.16; 95% CI: 1.03–1.31). No significant associations were observed in the younger or older age groups.
Conclusion: EDS is significantly associated with higher odds of all-cause mortality in middle-aged females but not in other age groups. Further studies are warranted to explore potential mechanisms, including sex-specific responses to sleepiness and the role of age in this association.

VASOMOTOR SYMPTOMS AND SLEEP QUALITY AMONG MIDLIFE WOMEN OF MIDDLE EASTERN AND NORTH AFRICAN ANCESTRY

Ahmad Sukhon[1], Hadi Ismail[2], Safa Sankari[3], Abdulghani Sankari[4], Hrayr Attarian[5], Galit Dunietz[1]
[1] University of Michigan, [2] University of Cincinnati, [3] University of Michigan, Dearborn, [4] Wayen State University- School of Medicine, [5] Northwestern University Feinberg School of Medicine

Introduction: Vasomotor symptoms (VMS) are common disturbances associated with menopause, affecting nearly 80% of midlife women. These symptoms, i.e., hot flashes and night sweats, have been infrequently studied in relation to sleep quality of women from diverse racial and ethnic background. We therefore examined associations between VMS and sleep quality in a unique sample of women from Middle Eastern and North African (MENA) ancestry.
Methods: This cross-sectional study enrolled 101 women (40-60y) of MENA ancestry, most of whom live in Michigan. These women provided demographic, lifestyle, sleep, and health information through structured interviews with validated questionnaires, including the Menopause Rating Scale (MRS), Pittsburgh Sleep Quality Index (PSQI), Patient Health Questionnaire (PHQ-9), and GAD-7 anxiety scale. We used the first item in the MRS to collect data on the frequency of VMS: "Which of the following symptoms apply to you at this time? Hot flashes, sweating (episodes of sweating)". Likert scale responses were: none, mild, moderate, severe, extremely severe. Women reporting moderate to extremely severe VMS frequency were classified as having VMS. Sleep quality was evaluated with the PSQI assessing their quantity, sleepiness, sleep disturbances, efficiency, quality, latency, and sleep medication use. An overall sleep quality score>5 defined poor sleep quality, and a score< 5 indicated good sleep quality. We implemented logistic regression models to estimate the association between VMS and sleep quality adjusting for BMI, depressive symptoms, and anxiety. All data analyses were conducted using JASP, Version 0.19.1 (University of Amsterdam).
Results: The median age of women was 47y (IQR=8) and median BMI was 27.5 kg/cm2 (IQR=7.2). Most women (>60%) experienced poor sleep quality and 36% reported moderate-to-severe hot flashes. The presence of hot flashes was associated with poor sleep quality, after adjusting for BMI, anxiety, and depressive symptoms. Specifically, women who reported moderate-to-severe hot flashes had 4-fold likelihood to experience poor sleep quality (OR= 3.99, 95% CI 1.01, 15.69).
Conclusion: Women in midlife who experience hot flashes are vulnerable to poor sleep quality, independent of depression and anxiety. Future studies are warranted to determine whether menopause hormone therapy benefits sleep quality.

SLEEP QUALITY AND MENTAL HEALTH IN LATE PREGNANCY: IMPACTS ON MATERNAL AND FETAL OUTCOMES

Giovanni Scuracchio Baccalá[1], Sérgio Stein[2], Taysa Gomes[2], Rafaela Dotta[2], Augusto Boccagini[2], Victor Vicentim[2], Cláudia A. Stefane[1], Paulo A. Mei[1]
[1] Federal University of São Carlos, [2] São Leopoldo Mandic

Introduction: Pregnancy induces significant physiological changes, particularly during the perinatal period. Sleep disorders in late pregnancy are associated with poorer physical and mental health outcomes during puerperium. This study aimed to assess the sleep quality of postpartum women and its correlation with maternal and neonatal health outcomes.
Methods: A prospective cross-sectional study included 67 postpartum women admitted for labor at a public maternity hospital in São Paulo, Brazil, from June 2019 to February 2020. Participants with pre-existing sleep disorders, severe comorbidities, or substantial obstetric complications were excluded. Data collection involved self-designed questions and validated tools: the Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), and Hospital Anxiety and Depression Scale (HADS). Data were analyzed using IBM SPSS 25.0, with significance threshold set at $p \leq 0.05$.
Results: Participants' ages ranged from 14 to 46 years (M = 26.9, SD = 6.4). Poor sleep quality (PSQI ≥ 5) was reported in 89.6% (M = 9, SD = 2.2), and excessive daytime sleepiness (ESS > 10) in 76.1% (M = 11, SD = 4.4). Symptoms suggestive of anxiety (HADS-A > 8) and depression (HADS-D > 8) were observed in 31.3% and 17.9% of participants, respectively. Anxiety was significantly associated with low birth weight (< 2.500g, regardless of gestational age at birth) ($t(65) = -2.93$, $p < 0.005$), as was depression ($t(65) = -2.59$,$p < 0.01$). Poor sleep quality (PSQI > 5) showed a trend toward significance with low birth weight ($t(65) = -1.9$, $p = 0.062$).
Conclusion: Anxiety and depressive symptoms were significantly associated with low birth weight, while poor sleep quality showed a trend toward significance. Although these associations may be influenced by confounding factors, they suggest potential pathways through which maternal mental health and sleep disturbances may impact fetal development. These findings underscore the need for targeted interventions to improve maternal sleep and mental health during the perinatal period.

IMPACT OF BODY MASS INDEX (BMI) AND POSITION ON OBSTRUCTIVE SLEEP APNEA (OSA) IN POSTMENOPAUSAL WOMEN

Unjung Cho[1], Chang-Hoon Lee[2], Rachel Immen[3], Mark Eric Dyken[4], KyoungBin Im[1]
[1] UC Irvine, [2] Seoul National University Hospital, [3] Carle, [4] University of Iowa Hospitals and Clinics

Introduction: Obstructive sleep apnea (OSA) is influenced by age, body mass index (BMI), and sex, with postmenopausal women showing increase in OSA. The role of BMI in postmenopausal women remains poorly understood. This study investigates how BMI affects supine AHI in postmenopausal women compared to men and premenopausal women.
Methods: 846 subjects ≥18 years (383, 45.3%, males and 463, 54.7%, females) with polysomnograms at the University of Iowa Hospitals and Clinics from July 2011 to June 2012, were categorized into four groups: men < 55 years (YM, n = 187), men ≥55 years (OM, n = 264), premenopausal women (YW, women < 55, n = 197), and postmenopausal women (OW, women ≥55, n = 257) and placed into BMI categories: normal (< 25 kg/m²), overweight (25–30 kg/m²), obese (30–40 kg/m²), and morbidly obese (≥40 kg/m²). Supine AHIs were analyzed across groups to assess the impact of BMI on OSA severity. Linear regression, analysis of covariance (ANCOVA), and Tukey's HSD test were performed for analysis.
Results: The supine AHI values for each BMI group were: men < 55 years: 3.2, 10.1, 18.1, 21.0; men ≥55 years: 9.5, 13.9, 23.2, 29.4; premenopausal women (women < 55): 1.1, 2.9, 7.0, 12.0; and postmenopausal women (women ≥55): 13.2, 14.8, 17.3, 15.5. Using linear regression model, slopes of supine AHI value for BMI changes were as the following for each group (YM 0.65, OM 0.29, YW 0.24, OW -0.05). Multiple regression model showed much attenuated effect of BMI on supine AHI in postmenopausal women compared to all other groups (p = 0.023 compared to the reference group OM). YM group showed stronger effect of BMI on supine AHI than OM (p =0.024).
Conclusion: BMI's effect on Supine AHI differs across groups with the postmenopausal women showing significantly attenuated relationship between BMI and supine AHI. This underscores the importance of considering non-BMI factors, such as age- and sex-related physiological changes in postmenopausal women to improve the effectiveness of treatments like positional therapy and CPAP. Further studies are warranted to investigate the underlying mechanisms and develop targeted interventions for postmenopausal women with OSA.

SLEEP QUALITY, RACE AND PREGNANCY OUTCOMES

Coral Li[1], Louise O'Brien[2]
[1] Michigan Medicine, [2] University of Michigan

Introduction: Poor sleep quality is common during pregnancy and linked with adverse pregnancy outcomes. African-Americans have worse perinatal outcomes compared to Caucasians; data are limited on whether sleep quality differs between racial backgrounds. We examined predictors and frequency of poor sleep quality between Caucasian and African-American women and its association with adverse outcomes.
Methods: Third trimester pregnant participants were recruited from an academic medical center and screened for sleep disruption including snoring, sleep duration, restless leg syndrome (RLS) and the General Sleep Disturbance Scale (GSDS). Sleep quality was ascertained by the GSDS sleep quality domain on the GSDS and poor sleep quality was defined as a score of at least 3. Demographic and delivery information were abstracted from medical records. Participants were included if they were either African-American or Caucasian.
Results: Overall, 976 Caucasians and 224 African-Americans were enrolled. Poor sleep quality was found to be similarly common in each racial group (74.3% vs. 74.0% respectively). In regression models, variables that explained poor sleep quality differed by race, with poor sleep quality in Caucasians explained by presence of RLS (aOR 1.7, 95%CI 1.8-2.3), higher BMI, (aOR 1.03, 95%CI 1.01-1.06) and prior pregnancy loss, (aOR 1.2, 95%CI 1.0-1.4). However, in African-Americans it was explained only by gestational age (aOR 1.09, 95%CI 1.02-1.17). While poor sleep quality was associated with depressive symptoms in both racial groups, it had a stronger association in African-Americans compared to Caucasians (aOR 4.6 vs. 1.7). In Caucasians, poor sleep quality was independently associated with induction of labor (aOR 1.4, 95%CI 1.0-2.0) which was not observed in African-Americans. In addition, Caucasian women with poor sleep quality had increased frequency of gestational hypertension (3.1% to 5.6%) whereas the frequency did not change in African-Americans (3.5% to 3.7%). Conversely, African-Americans with poor sleep quality had an increase in pre-eclampsia diagnoses (17.9% to 22.6%) while Caucasians did not (12.1% to 12.9%).
Conclusion: Our findings suggest that while the frequency of poor sleep quality is the same between Caucasians and African-Americans, explanatory variables differ and associations with pregnancy outcomes may differ by race. Such differences should be considered when addressing perinatal health.

OBJECTIVE AND SUBJECTIVE SLEEP QUALITY ACROSS THE MENSTRUAL CYCLE IN TRANSDIAGNOSTIC PSYCHIATRIC OUTPATIENTS WITH SUICIDALITY

Anisha Nagpal[1], Katja Schmalenberger[1], Fiona Baker[2], Tory Eisenlohr-Moul[1]
[1] University of Illinois at Chicago, [2] SRI International

Introduction: Most studies on sleep across the menstrual cycle use small, healthy samples in laboratory settings with infrequent measurements. Longitudinal evidence shows sleep quality worsens perimenstrually, predicting increases in affective symptoms. However, no studies have examined nightly objective and subjective sleep in high-risk psychiatric outpatients with suicidal ideation.
Methods: Across 1–3 cycles, 56 psychiatric outpatients with past-month suicidal ideation wore Oura® rings to measure nightly sleep metrics (total sleep time(TST), wakefulness after sleep onset(WASO), sleep efficiency(SE%), sleep midpoint(SM), sleep onset latency(SOL), percentage of light sleep(N1N2%), percentage of deep sleep(N3%), and percentage of REM sleep(REM%)) (n=3591). Participants (N=142) also completed daily subjective sleep ratings (overall sleep quality, slept too much, trouble sleeping, feeling lethargic/tired) (n=9775). Ovulation was verified via LH-tests and basal body temperature. Percent luteal/follicular phase elapsed (cycle-time) was used to predict sleep outcomes via generalized additive mixed models.
Results: Intraclass correlations (ICCs) showed significant within-person variability in objective sleep outcomes (SOL=0.086 to SM=0.329) and high trait stability for sleep stages (REM%=0.516 to N3%=0.697). Subjective sleep ICCs ranged from 0.315 (slept more) to 0.362 (lethargic/tired), with ~two-thirds of variance being within-person. Cycle-time predicted nonlinear trends

in SE% (F=2.38,p=0.056), slept more (F=4.66,p<.001), trouble sleeping (F=5.51,p<.001), lethargy/tired (F=9.09,p<.001), N1N2% (F=3.06,p<.01), N3% (F=3.91,p<.01), and REM% (F=2.20,p=0.09). Significant random slopes of cycle-time for SE% (p<.01), WASO (p=.07), sleep quality (p<.01), trouble sleeping (p<.01), lethargy/tired (p<.01), and REM% (p<.05) indicate substantial individual differences in degree of cyclical change. A significant interaction between weekend status and cycle-time was observed for REM%, though the main nonlinear trend of cycle-time remained marginally significant (p=0.08). While cycle-time showed significant nonlinear effects on sleep outcomes, it accounted for only 1.85–8.21% of model-explained variance, suggesting most outcome variance stems from unmeasured individual differences.

Conclusion: Menstrual cycle time has significant nonlinear effects on sleep outcomes in psychiatric outpatients. The small percentage of variance explained by cycle-time suggests that other factors, such as individual traits or external influences (e.g. substance use, acute stressors), play a larger role in shaping sleep outcomes. Future research should focus on how trait indices of sleep outcomes moderate cyclical symptom changes among patients with affective sensitivity to the menstrual cycle.

SEX DIFFERENCES IN THE INTERPLAY BETWEEN PHYSICAL ACTIVITY, SLEEP QUALITY, AND SUBJECTIVE COGNITIVE COMPLAINTS AMONG ADULTS AND OLDER ADULTS

Priscilla Amofa-Ho[1], Melanie Stearns[1], Ashley Curtis[1], Kevin McGovney[2], Amy Costa[1], Mary Beth Miller[3], Uma Nair[1], Christina McCrae[1]

[1] University of South Florida, [2] University of Missouri (Department of Psychology), [3] University of Missouri

Introduction: Subjective cognitive complaints (SCC) are associated with future cognitive decline and increased risk of dementia among adults and older adults. Sedentary lifestyle and poor sleep are risk factors for dementia with a complex association with SCC. However, there are limited explorations of sex differences in the interaction between sleep and SCC. Likewise, physical activity's [PA] effect on this association is poorly understood. The current analysis examined whether PA moderated the relationship between SCC and sleep and if this relationship was further moderated by sex (i.e., 3-way interaction).

Methods: Adults (N=732, Mage=59.80, 53%-female) reported their average sleep quality, sleep onset latency, and total sleep time over the past month using the Pittsburgh Sleep Quality Index (PSQI) as part of online data collection study. They also completed the International Physical Activity Questionnaire (total weekly minutes; proxy for PA) and Everyday Memory Questionnaire-20-Item Revised (EMQ; total score; proxy for SCC). SPSS PROCESS evaluated interactions between sex, SCC, and PA on sleep, controlling for age, race, and educational attainment.

Results: PA moderated the relationship between SCC and sleep quality for males [F(1,337)=4.65, p=.032], such that less PA was associated with worse sleep quality for men with lowest SCC (t=7.06, p<.001), intermediate SCC (t=7.15, p<.001), and highest SCC (t=6.45, p<.001). PA moderated the relationship between SCC and sleep quality for females [F(1,318)=4.50, p=.035], such that greater PA was associated with worse sleep quality for women with lowest SCC (t=5.41, p<.001), intermediate SCC (t=6.64, p<.001), and highest SCC (t=8.10, p<.001). A 3-way interaction (PA x SCC x sex) occurred for sleep quality [F(1,721)=9.30, p=.002].

Conclusion: In a community sample of adults, poor sleep quality was associated with greater subjective cognitive complaints, with physical activity moderating the association differently between males and females. Differences in social factors (socioeconomic, lifestyle, responsibilities at home) could explain the sex differences. Behavioral sleep interventions may benefit from addressing and optimizing the ideal level of physical activity, which may differ for men and women. Longitudinal data and objective measures of sleep will be imperative to understand this complex relationship and inform interventions.

EXPLORING SEX-SPECIFIC DIFFERENCES BETWEEN STRESS, SLEEP, AND CHRONOTYPE IN ASIAN AMERICAN ADULTS

Jasmine Niazi[1], Melanie Stearns[1], Ashley Curtis[1], Kevin McGovney[2], Amy Costa[1], Mary Beth Miller[3], Uma Nair[1], Christina McCrae[1]

[1] University of South Florida, [2] University of Missouri (Department of Psychology), [3] University of Missouri

Introduction: Sex differences in stress, sleep, and chronotype (morning-eveningness) are essential for understanding sleep health disparities across diverse populations due to their significant impact on physical and mental health outcomes. However, existing studies are limited by insufficient representation of Asian Americans, furthering the need to investigate unique gender and ethnic differences that may influence health disparities. Therefore, we aim to examine sex differences in stress, sleep, and chronotype among Asian American men and women.

Methods: Asian American adults (N=51, Mage=54.41, 41%-female) reported their average sleep onset latency (SOL), total sleep time (TST), and sleep quality using the Pittsburgh Sleep Quality Index over the past month as part of an online data collection. They also completed the Morning Eveningness Questionnaire and Perceived Stress Scale. SPSS t-tests evaluated how variables differed for Asian American men and women.

Results: Asian American women reported less TST in hours (M=6.19+\-2.06) than Asian American men (M=7.30+\-1.26, p=.021). Results trended toward significance, where Asian American women reported greater WASO in minutes (M=38.29+\-60.78, p=.097) and preference for mornings (M=58.29+\-9.19, p=.074) than Asian American men (M=15.61+\-13.64, M=51.33+\-12.80). There was no significant difference in SOL or stress between the two groups.

Conclusion: Asian American women reported sleeping less than Asian American men, suggesting Asian American women may be at particular risk for experiencing sleep health disparities. This might be due to gender expectations of Asian women fulfilling cultural and familial obligations and duties, such as caregiving, alongside other roles, such as academics and professional work. Thus, behavioral sleep interventions might benefit from cultural tailoring to incorporate the unique cultural practices, social factors, and gender expectations of Asian cultures.

The current study is limited by its small sample size, and future studies should utilize larger samples and longitudinal and experimental methodologies to elucidate sex differences further.

EFFECT OF A NONHORMONAL SLEEP SUPPLEMENT ON DAYTIME FUNCTIONING IN MENOPAUSAL FEMALES: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

Stephen Carbonneau[1], Alyssa Dweck[1], Trisha VanDusseldorp[1], Vincent Mysliwiec[2], Matthew Stratton[3], Michaela Alesi[1], Laura Mason[1], Will Mykytiuk[1], James Komorowski[1]
[1] Bonafide Health, [2] The University of Texas Health Science Center, [3] University of South Alabama

Introduction: Menopause significantly impacts females' well-being, often causing severe sleep disturbances driven by hormonal fluctuations. These disturbances impair daytime functioning in up to 26% of females, leading to symptoms such as daytime sleepiness, morning grogginess, and fatigue. This clinical trial evaluated the safety and efficacy of a nonhormonal sleep supplement (NSS) containing s-adenosyl methionine, propyl gallate, gamma-aminobutyric acid, magnesium glycinate, and theanine on daytime functioning in peri- and postmenopausal females with menopause-related sleep disturbances.
Methods: A randomized, double-blind, placebo-controlled trial was performed in females aged 40–65 with moderate-to-severe sleep disturbances [T-score ≥ 60 on the Patient-Reported Outcomes Measurement Information System Sleep Disturbance (PROMIS-SD)]. Participants were randomly assigned to NSS or placebo (PLB) 60 minutes before bedtime for three weeks. Repeated measures analysis of variance (RMANOVA) evaluated changes in PROMIS Sleep-Related Impairment (SRI), daytime functioning Visual Analog Scales (VAS), and safety at baseline and Wks 1, 2, and 3.
Results: The groups included 65 NSS and 62 PLB participants (NSS: 54.1±8.7 yr; PLB: 54.4±5.6 yr; 127 completed the trial). Compared to PLB, all NSS improvements were statistically significant ($p \leq 0.05$). Overall daytime functioning (PROMIS SRI) improved with NSS at Wk1 (-13.0% vs PLB -8.8%), Wk2 (-16.7% vs PLB -10.5%), and Wk3 (-18.6% vs PLB -10.3%). Improvements were observed in several VAS measures over the course of the study. Morning ease improved at Wk2 (-42.4% vs PLB -12.9%) and Wk3 (-47.7% vs PLB -28.4%). Morning grogginess showed marked improvement at Wk2 (-33.6% vs PLB -8.5%) and Wk3 (-41.8% vs PLB -2.8%). Daytime sleepiness improved at Wk2 (-20.0% vs PLB -0.7%) and Wk3 (-49.3% vs PLB -6.4%). Restfulness and rejuvenation improved at Wk3 (-30.3% vs PLB -7.7%).
Conclusion: NSS significantly improved daytime functioning, morning ease, and morning grogginess in peri- and postmenopausal females with moderate-to-severe sleep disturbances. Additional improvements were observed in daytime sleepiness and restfulness. This study demonstrates NSS as a potential therapy for enhancing daytime functioning in menopausal females with sleep disturbances.

DEVELOPMENT OF A CULTURALLY TAILORED SLEEP INTERVENTION FOR MIDLIFE AFRICAN AMERICAN WOMEN: A SCOPING REVIEW

Sueyeon Lee[1], Natalie Watson-Singleton[2], Karen Saban[1], linda Janusek[1]
[1] Loyola University Chicago, [2] Spelman College

Introduction: Sleep disturbances are prevalent among African American women (AAW), particularly during midlife. These women experience unique challenges, including earlier menopause, greater vasomotor symptoms, more depressive symptoms, and poorer sleep quality and quantity than White women. Given the cultural and psychosocial factors influencing AAW's sleep health, it is crucial to develop culturally tailored sleep interventions that address their unique needs.
Methods: This scoping review examines (1) sleep in midlife AAW, (2) factors contributing to their sleep disturbances, (3) previous culturally tailored sleep interventions evaluated in this population, and (4) strategies for developing culturally tailored sleep interventions for midlife AAW. CINAHL, PubMed, and PsycINFO were searched for relevant sources.
Results: Midlife AAW experience worse sleep quantity and quality, both objective and subjective, than White women. Factors contributing to midlife AAW's sleep disturbances include vasomotor symptoms, racism-related stress, various stressors and psychological factors, the superwoman/strong Black woman schema, and environmental factors. A very few studies have applied culturally tailored sleep interventions involving midlife AAW, including sleep health education delivered by peer educators. Recommendations for developing and evaluating a culturally tailored sleep intervention for midlife AAW include the following: (1) use linguistically and culturally tailored methods for recruitment and content, (2) incorporate cultural concepts and values such as religious beliefs and spirituality, (3) address population-specific sleep barriers such as racism-related stress, (4) involve family members, (5) involve community facilitators, and (6) implement interventions in culturally familiar settings, such as churches.
Conclusion: The sleep challenges faced by midlife AAW warrant culturally sensitive, tailored interventions. Incorporating cultural values, addressing specific barriers such as stress, and involving family and community members have potential to enhance the effectiveness of such interventions. Future research should continue to explore and refine these approaches to improve sleep health outcomes for AAW and promote their overall well-being.

SLEEP DISTURBANCE AND SYMPTOM BURDEN IN WOMEN WITH SARCOIDOSIS

Catherine Lange[1], Laura Koth[1]
[1] University of California, San Francisco

Introduction: Sarcoidosis is a systemic inflammatory disease with many symptoms, including sleep disturbance, fatigue, dyspnea, and pain. This study aims to address the relationship between sleep disturbances and symptom burden in women with sarcoidosis.

Methods: We used data from the UCSF Sarcoidosis Research Program longitudinal cohort which enrolled participants with pulmonary sarcoidosis and unaffected healthy controls. We collected demographic and clinical characteristics. Sleep disturbance was assessed using General Sleep Disturbance Scale (GSDS), depression with the Patient Health Questionnaire-9 (PHQ9), fatigue with the Fatigue Assessment Scale (FAS), cognitive difficulties with the Multiple Sclerosis Neuropsychological Questionnaire, and shortness of breath with the San Diego Shortness of Breath Questionnaire.
Results: The cohort consisted of 55 men and 72 women. Women had a higher mean score for sleep disturbances compared to men (45.4 +/- 22.8 vs 37.5 +/- 22.8, p = 0.043). Compared to men, women were more likely to report waking after sleep onset (48/72 women vs 26/55 men, p = 0.028) and early awakening (35/72 women vs 15/40 men, p = 0.015). Across women with sarcoidosis and healthy controls, unadjusted analyses revealed that current immunosuppressant usage (p = 0.020) and sarcoidosis diagnosis (p = 0.021) were associated with occasional or frequent sleep disturbance. Only two of the participants with occasional sleep disturbances also had obstructive sleep apnea. Of the women with sarcoidosis 31% (17/54) reported clinically significant sleep disturbances as defined by the DSMV (GSDS score > 63). 59% (32/54) of women reported occasional or frequent sleep disturbance (GSDS score > 42), and 89 % (48/54) of women with sarcoidosis reported some form of sleep disturbance (GSDS score > 21). Occasional or frequent sleep disturbances (scores>42) in women with sarcoidosis were positively correlated with depression, shortness of breath, and fatigue (p < 0.001), as well as cognitive difficulties (p = 0.002)
Conclusion: Women experienced higher sleep disturbances than men and were more likely to report waking after sleep onset and early awakening. 89% of women with sarcoidosis reported some form of sleep disturbance, which correlated with high fatigue scores, depressive symptoms, cognitive difficulties, and shortness of breath.

THE ASSOCIATION OF OBSTRUCTIVE SLEEP APNEA WITH MARKERS OF ACCELERATED AGING: A SYSTEMATIC REVIEW AND META-ANALYSIS

Calvin Chang[1], Joshua Hicks[1], Zahra Izadi[1], Arshdeep Marwaha[2], AJ Hirsch Allen[3], Mohammadreza Hajipour[1], Najib Ayas[4]
[1] University of British Columbia, [2] University of Sakatchewan, [3] The University of British Columbia, [4] UBC

Introduction: There is differing susceptibility to age-related health complications. A variety of circulating biomarkers of biological aging have been developed. Obstructive sleep apnea (OSA) is a prevalent sleep disorder that may contribute to premature aging, possibly through pathways involving intermittent hypoxia, sleep fragmentation, oxidative stress, and inflammation. The aim of this study was to systematically review and summarize the literature with respect to the relationship between OSA and circulating markers of premature aging.
Methods: Following the 2020 PRISMA guidelines, five electronic databases (MEDLINE, Embase, CINAHL, Cochrane, PsycINFO) were searched from inception to October 2024. Eligibility criteria included full manuscript English studies on adult humans with OSA (apnea-hypopnea index ≥ 5) that evaluated a circulating marker of aging. Quality assessments were conducted using standard methods. A random-effects meta-analysis was conducted on each marker. Studies investigating multiple markers at the same time were corrected using robust variation estimation (RVE).
Results: Twenty-five studies (8396 participants) were included in our review. Four studies investigated two markers simultaneously. Biomarkers included telomere length (TL, n=17), mitochondrial DNA (mtDNA, n=4), epigenetic age acceleration (EAA, n=2), sirtuins (SIRT, n=4), cyclin-dependent kinase inhibitor 2A (P16) (n=1), and autophagy protein 5 (ATG5) (n=1). Meta analyses were conducted on 15 studies that had a mean with standard deviation. There was significant association between OSA and shorter TL (unadjusted mean (95%CI) = -0.405 (-0.606, -0.203), p=0.0019). SIRT levels were lower in OSA participants; however, the meta-analysis was only borderline significant after RVE (mean (95%CI) = - 1.93 (-4.74, 0.879), p=0.09). MtDNA (mean (95%CI) = 0.669 (-1.29, 2.63), p=0.144) studies yielded mixed results. OSA was linked to increased EAA. The sole P16 and ATG5 studies demonstrated greater premature aging in OSA.
Conclusion: This systematic review highlighted a variety of markers of premature aging that may be impacted by OSA. Some markers were referenced in much higher frequency than others (TL), and thus had stronger evidence. OSA is greatly underdiagnosed, but the presence of OSA likely has an important role in premature aging. Further research is needed to understand the effects of OSA on biological aging, and assess whether these are associated with more robust age-related clinical outcomes.

AN HERBAL SUPPLEMENT IMPROVES RESTORATIVE SLEEP AND SLEEP QUALITY, ELEVATES MOOD, AND INCREASES TOTAL SLEEP TIME

Dawna Salter[1], Jennifer Murphy[1], Raviteja Yarlagadda[2], Koteshwara Veeragandham[3]
[1] PLT Health Solutions Division of Innovation and Clinical Research, [2] Samishta Hospital & Research Institute Department of Orthopaedics, [3] Renova Neelima Hospital Department of Orthopaedics

Introduction: Boswellia serrata (Indian Frankincense) and Zingiber Officinale (Ginger) are therapeutic botanicals used widely in traditional Indian medicine. This randomized, double-blind, placebo-controlled trial assessed the effects of B. Serrata gum resin and Z. Officinale rhizome extracts (BSG) on musculoskeletal pain, restorative sleep, sleep quality, sleep parameters, mood, and inflammatory biomarkers.
Methods: Sixty (23M/37F) healthy volunteers aged 40-70 (mean 52 ± 8) with a BMI of 20-29.9 kg/m2 (mean 25.1 ± 2.1) and self-reported poor sleep due to mild musculoskeletal pain were randomized to receive 300 mg BSG or Placebo (PLA) daily for 28 days. Daytime and nighttime pain was assessed weekly by a visual analog scale (VAS). Restorative sleep and sleep quality measures were evaluated using the Restorative Sleep (RSQ) and Leeds Sleep Evaluation (LSEQ) Questionnaires. Mood changes were assessed through the Profile of Mood States Questionnaire (POMS-SF) and self-reported sleep parameters were tracked through the Consensus Sleep Diary (CSD). Inflammatory biomarkers were also assessed.
Results: There was a significant (p< 0.001) time x treatment interaction for daytime pain, nighttime pain, RSQ, each of the four domains of the LSEQ (getting to sleep, quality of sleep, ease of waking up, behavior following waking), and POMS-SF. Planned

group comparisons indicated BSG improved restorative sleep and pain scores compared to PLA on days 7, 14, and 28 ($p< 0.05$), while each LSEQ domain and the overall mood disturbance score improved compared to PLA on days 14 and 28 ($p< 0.05$). Serum TNF-α was significantly lower with BSG than PLA on day 28 ($p< 0.01$). Pearson's Chi2 analysis of the CSD demonstrated that 28 days of BSG significantly ($p< 0.001$) improved the likelihood of improving total sleep time by at least 45 minutes. A secondary analysis of the women-only cohort also demonstrated significant ($p< 0.05$) improvements in pain, RSQ, LSEQ, and POMS-SF.
Conclusion: Daily BSG supplementation decreased pain and improved restorative sleep after one week, while sleep quality and mood improved after 14 days in all subjects and the women-only cohort. BSG increased total sleep time and decreased serum TNF-α in healthy adults with self-reported poor sleep secondary to mild-to-moderate musculoskeletal pain.

THE ASSOCIATION OF INSOMNIA WITH CIRCULATING BIOMARKERS OF ACCELERATED AGING: A SYSTEMATIC REVIEW

Joshua Hicks[1], Calvin Chang[1], Zahra Izadi[1], Arshdeep Marwaha[2], AJ Hirsch Allen[3], Mohammadreza Hajipour[1], Najib Ayas[4]
[1] University of British Columbia, [2] University of Sakatchewan, [3] The University of British Columbia, [4] UBC

Introduction: Insomnia is a prevalent sleep disorder defined by difficulty initiating or maintaining sleep or waking up earlier than intended. Studies suggest that insomnia may contribute to premature biological aging and increase susceptibility to age-related health complications. Various circulating biomarkers of biological aging have been used to assess the aging processes; increased biological age compared to chronologic age indicates premature biological aging. This study aims to systematically review and summarize the literature with respect to the relationship between insomnia and circulating biomarkers of premature aging.
Methods: Following the 2020 PRISMA guidelines, five electronic databases (MEDLINE, Embase, CINAHL, Cochrane, PsycINFO) were searched from inception to October 2024. Eligibility criteria included full manuscript English studies on adult humans with insomnia that evaluated a circulating marker of aging. We only included studies that assessed insomnia symptoms and severity with validated sleep surveys or by the Diagnostic and Statistical Manual of Mental Disorders. Quality assessments were conducted using standard methods.
Results: Twenty-two studies (17422 participants) were included in our analysis: biomarkers included telomere length (TL, n=17 studies), epigenetic age acceleration (EAA, n=3), mitochondrial DNA (MtDNA, n=1) and klotho (n=1), a protein involved in the aging process. Several studies (N=13) found insomnia was associated with reduced TL, with greater reductions in more severe insomnia, as indicated by higher survey scores. Additionally, there was a positive correlation between the number of insomnia symptoms and the degree of EAA. Single studies on MtDNA copy number and klotho showed lower values in insomnia. One study found longer TL in insomnia that was not significant. However, despite promising associations, the findings are undermined by the variety of surveys (five surveys) used and subsequent definitions of the control and exposure group.
Conclusion: Insomnia is associated with increased biomarkers of premature aging, such as reduced TL and EAA. Although the data is suggestive, the inconsistency and breadth of methodological approaches limits the conclusions that can be made. This underscores the need for further research in this area, including the study of additional markers not included in our review (e.g. sirtuin levels, autophagic activity), and the association of these markers with robust age-related clinical outcomes.

EXAMINATION OF SAVORING, SAVORING BELIEFS, AND MULTIDIMENSIONAL SLEEP HEALTH IN ADULTS WHO ARE AGE 65 YEARS AND OLDER

Caitlan Tighe[1], Hailey Dorazio[1], Grace Lynch[1], Christina Sacco[1], Brooke Sullivan[1], Declan Miles[1]
[1] Providence College

Introduction: Savoring is an approach to positive emotion regulation that involves thinking about and appreciating positive experiences. Few studies have examined associations of savoring with sleep; those that have focused on sleep-related impairment and sleep disturbance without assessing associations with multidimensional sleep health. The current study expands on the existing literature by evaluating the association of savoring beliefs with multidimensional sleep health and estimating the frequency of engagement in savoring in a sample of adults who are age 65 years and older.
Methods: Study aims were assessed using a cross-sectional survey. Recruitment and study procedures occurred online. The sample included 148 adults who were 65-82 years old (M=69.6, SD=4.1); 63.5% identified as women, 36.5% as men. Participants completed self-report questionnaires assessing sociodemographic characteristics, perceived health status, and engagement in savoring during the past 30 days; savoring beliefs (i.e., perceived savoring ability) were assessed via the Savoring Beliefs Inventory and multidimensional sleep health via the RU_SATED V4.0 questionnaire. Hierarchical regression was used to test the association of savoring beliefs with multidimensional sleep health; gender, age, and self-rated health status were included in the model as covariates. Frequency counts were used to estimate engagement in savoring.
Results: Adjusting for gender, age, and self-rated health status, savoring beliefs were positively associated with multidimensional sleep health ($\beta=.24$, $p=.003$). Approximately 75% of participants reported engagement in savoring during the day at least some days in the past 30 days, and approximately 39% reported savoring before attempting to initiate sleep at least some days.
Conclusion: In this sample of adults aged 65 years and older, higher perceived savoring abilities were significantly associated with better subjective, multidimensional sleep health. Most of the sample reported some extent of engagement in daytime savoring, with comparatively fewer people reporting savoring before sleep on a regular basis. This study adds to the growing literature linking positive psychological constructs with sleep health. Future directions for this research may include conducting prospective, microlongitudinal studies to evaluate daily, temporal associations of savoring and sleep health, and experimental studies to evaluate the effect of savoring on sleep health.

SLEEP AND COGNITIVE TRAJECTORIES AMONG OLDER ADULTS WITH SUBJECTIVE COGNITIVE DECLINE: THE ROLE OF AGE

Jing Huang[1], Nancy Perrin[2], Sarah Szanton[2], Adam Spira[3], Chakra Budhathoki[2], George Rebok[1], Junxin Li[2]

[1] Johns Hopkins University, [2] Johns Hopkins University School of Nursing, [3] Johns Hopkins Bloomberg School of Public Health

Introduction: Growing evidence indicates that subjective cognitive decline (SCD), characterized by self-reported cognitive deterioration without measurable cognitive impairment, may be an early indicator of Alzheimer's disease. The impact of sleep disturbance on cognitive decline in individuals with SCD, and the extent to which this differs across age groups, remains unknown. This study investigated the association between baseline sleep disturbance and a 10-year trajectory of cognitive performance in individuals with SCD and examined if this association differed between age groups (50–64 years and ≥65 years).

Methods: Using six waves (2010–2020) of the Health and Retirement Study, we included individuals aged ≥50 years who were cognitively unimpaired with SCD at baseline and had ≥3 waves of cognitive function data (n = 1,372). Sleep disturbance was assessed using the modified Jenkins Sleep Scale, while global cognitive function was measured with the 27-point Modified Telephone Interview for Cognitive Status (TICS-M). Latent growth curve modeling was employed to examine the associations between sleep disturbance and cognitive trajectories, controlling for sociodemographic and health factors. To explore potential age-related differences, an interaction term between sleep disturbance and age group was included in the model. Subgroup analyses were conducted when the interaction term was statistically significant.

Results: Results showed that sleep disturbance was not significantly associated with cognitive change rate in SCD individuals overall. However, a significant sleep disturbance by age group interaction was observed, when added to the model (estimate = -0.05, 95%CI: -0.08, -0.01). Further subgroup analyses revealed that in those aged 50–64 years (n = 814), baseline sleep disturbance was not significantly associated with cognitive change (estimate = 0.02, 95%CI: -0.01, 0.04). In contrast, among those aged ≥65 years (n = 558), poorer sleep at baseline was associated with accelerated cognitive decline (estimate = -0.04, 95%CI: -0.07, -0.01).

Conclusion: These findings suggest that sleep disturbance may impact cognitive decline more with advancing age in individuals with SCD, underscoring the importance of sleep health for older adults. Future research could investigate the potential of sleep interventions to mitigate further cognitive decline in older adults with SCD.

ENHANCING COGNITIVE HEALTH THROUGH SLEEP-BAND THERAPIES: A CALL TO ACTION FOR ADVOCACY AND REIMBURSEMENT PATHWAYS

George Duval[1]

[1] AI-Mednavigators

Introduction: Mild cognitive impairment (MCI) and age-related cognitive decline present significant challenges for aging populations. Slow-wave sleep (SWS) has been shown to play a crucial role in cognitive health, particularly in memory consolidation and brain repair. Emerging technologies, such as sleep-bands utilizing closed-loop acoustic stimulation, have demonstrated potential in enhancing SWS. However, the integration of sleep studies into diagnostic frameworks for MCI and the lack of reimbursement pathways for sleep-band therapies hinder their clinical adoption and accessibility.

Methods: This work synthesizes evidence from recent peer-reviewed studies on the efficacy of acoustic stimulation technologies in enhancing SWS. Policy analysis was conducted to evaluate existing reimbursement frameworks for sleep-related devices, such as CPAP, and their adaptability for sleep-band therapies. Additionally, actionable steps for clinicians, researchers, and policymakers were proposed to address current barriers to implementation.

Results: Current studies highlight the clinical potential of sleep-band technologies in improving SWS and mitigating cognitive decline in aging populations. Despite these promising results, the absence of established reimbursement models and limited integration of sleep studies into MCI diagnostic protocols remain critical barriers. Lessons from CPAP reimbursement pathways suggest a viable framework for developing similar pathways for sleep-bands, emphasizing clinical validation, regulatory alignment, and stakeholder engagement.

Conclusion: Sleep-band therapies represent a promising intervention for enhancing SWS and addressing cognitive decline in aging populations. To realize their potential, advocacy is needed to include sleep studies in MCI diagnostic protocols and establish reimbursement pathways similar to those for CPAP devices. Collaborative efforts among clinicians, policymakers, and researchers are essential to advancing these goals and improving access to sleep-band therapies.

SLEEPLESS GOODBYE: UNDERSTANDING BEREAVED DEMENTIA CAREGIVER SLEEP QUALITY THROUGH A TELEPHONIC SURVEY

Yingyan Huang[1], Megan Petrov[1], Julie Fleury[1], Zachary Baker[1]

[1] Edson College of Nursing and Health Innovation, Arizona State University

Introduction: Dementia is a leading cause of death among older adults (65+) in the U.S. Caring for a person with dementia worsens family caregivers' sleep quality, which may persist following bereavement. Few studies have explored post-death sleep quality in bereaved dementia caregivers. Caregiving characteristics and psychological resources of bereaved dementia caregivers may influence their post-death sleep quality differently. This study aimed to characterize post-death sleep quality, examining independent associations of caregiving characteristics (i.e., age, sex, relationship types) and psychological resources (i.e., coping styles) with post-death sleep quality in bereaved dementia caregivers.

Methods: A cross-sectional phone survey included 581 bereaved dementia caregivers. Post-death restless sleep was measured using the following item: "During the past week, your sleep was restless", and the responses were coded as "Yes" or "No".

Pre-death sleep duration was measured in hours using the following question: "On a typical care day in the month before [Care Recipient] died, how much time per day and night did you spend asleep?" Restoration-oriented and loss-oriented coping styles were assessed with the Dual Coping Inventory. Regression models estimated the associations between age, sex, relationship type to the deceased (e.g., spouse, child), coping styles, and post-death sleep quality, controlling for pre-death sleep duration.
Results: Most bereaved dementia caregivers (n=389; 67.8%), with an average time since death of 4.6 years, reported short pre-death sleep duration (< 7 hours). Approximately half (n=259; 44.6%) reported post-death restless sleep within the past week. Sex and relationship type were not associated with post-death sleep quality. In the unadjusted model, a one-unit increase in loss-oriented coping style was associated with an increased likelihood (OR: 1.74; 95% CI:1.32-2.30) of restless sleep. In adjusted (controlling for sex, family relationship type, coping styles, and pre-death sleep duration) models, a one-unit increase in loss-oriented coping style was associated with an increased likelihood (OR: 1.47; 95% CI: 1.07-2.02) of restless sleep.
Conclusion: Restless sleep among bereaved dementia caregivers was common, particularly those using more loss-oriented coping strategies. Empirical studies using representative samples can help validate these findings. Qualitative work is also warranted to better understand subjective sleep experiences, which might help inform interventions to improve sleep.

RECIPROCAL ASSOCIATIONS BETWEEN DAILY SLEEP AND PAIN AMONG INDIVIDUALS WITH RHEUMATOID ARTHRITIS

Christina Mu[1], Katie Stone[2], Fei Jiang[3], Aric Prather[4], Patricia Katz[5]
[1] University of California, San Francisco, [2] California Pacific Medical Center Research Institute, [3] Department of Epidemiology and Biostatistics, University of California, San Francisco, [4] Department of Psychiatry and Behavioral Sciences, University of California San Francisco, [5] Department of Medicine, Division of Rheumatology, University of California San Francisco

Introduction: Rheumatoid arthritis (RA) is a chronic autoimmune condition characterized by joint pain. Self-reported poor sleep is common in RA. This study examined the potential reciprocal relationship between sleep health and pain in RA.
Methods: Participants completed four waves of data collection with approximately 6 months between visits. 118 participants completed at least one wave of data collection with 7-day daily diary collecting multidimensional information on sleep (e.g., timing, perceived sufficiency) and pain severity (e.g., night, morning). A linear mixed-effects model was used to examine the associations between sleep (the primary predictor) and the next-day pain (outcome). Fully adjusted models controlled for age, sex, race, education, marital status, health covariates (e.g., depression), and medication use. Statistical significance was defined as p-value<.05.
Results: The sample mean age was 57.9 years and 87.3% were female. Overall, those with more severe average pain for the day, night pain, morning pain, and joint stiffness had longer sleep onset latency, more nighttime awakenings, and lower perceived sleep sufficiency (feeling rested). This between-person effect remained significant when examining the inverse of the relationship, such that those with longer sleep onset latency, nighttime awakenings, and lower sleep sufficiency had more average pain for the day, night pain, morning pain, and joint stiffness. Turning to the daily associations, experiencing night pain, morning pain, and joint stiffness were associated with longer sleep onset latency, more nighttime awakenings, and lower sleep sufficiency the following night's sleep. Average pain for the day was associated with lower sleep sufficiency and this association was reciprocal. Inversely, earlier bedtime and later waketime were associated with more night pain and joint stiffness the following day.
Conclusion: Findings highlight the daily and temporal relationship between sleep and pain. Average pain for the day and sleep sufficiency were found to have a reciprocal relationship, yet this relationship was not observed for sleep timing, sleep onset latency, and nighttime awakenings.
Support (if any): This research was supported by the National Institute of Arthritis and Musculoskeletal and Skin Diseases (Award No. R01-AR072040).

TOTAL SLEEP TIME MODULATES THE ASSOCIATION BETWEEN SLEEP EFFICIENCY AND MORTALITY: INSIGHTS FROM BIG DATA

Arash Maghsoudi[1], Amir Sharafkhaneh[1], Javad Razjouyan[1]
[1] Baylor College of Medicine

Introduction: Sleep efficiency (SE) and total sleep time (TST) are crucial parameters for sleep quality and quantity and affect health outcomes. Previous studies suggest an association between poor sleep metrics and increased mortality. This study explores how TST modulates the relationship between SE and survival using a large-scale polysomnography (PSG) dataset.
Methods: We analyzed PSG data of 134,225 patients from the VA Corporate Data Warehouse (CDW) spanning 1999–2024. A large language model (LLM), with >95% accuracy, was employed via prompting to extract TST and SE. We used unsupervised k-mean clustering method on SE and TST to identify the optimal number of clusters, i.e. five strata: high TST & high SE (high-high); low TST & low SE (low-low); low TST & high SE (low-high); intermediate TST & intermediate SE (mid-mid); and intermediate TST and low SE (mid-low). We compared the mortality rate among these strata.
Results: The low-low cluster (TST, 105.0 minutes; SE, 33.3%), had the highest mortality rate (33%) and the high-high cluster (TST, 400.8 minutes; SE, 89.5%) had the lowest mortality rate (12%). Additionally, when comparing the low-low and low-high clusters, the one with lower SE showed a higher mortality rate (33% vs 21%). Comparing mid-low to low-high clusters showed higher mortality rate in the former (25% vs 21%). The Charlson Comorbidity Index (CCI) exhibited a direct negative relationship with SE, with higher CCI values associated with lower SE, namely, average CCI of 0.9 for SE of 89.5% (high-high cluster), and 1.9 for SE of 33.3% (low-low cluster).
Conclusion: We confirmed that higher TST and SE associated longevity. Among those with decreased TST, diminishing SE is associated with increased mortality. As TST declines, the importance of SE in modulating mortality will be highlighted. Further analysis is warranted to assess the interactions of medical interventions in the interplay of TST and SE.

VALIDATION OF SELF-REPORTED SLEEP DURATION USING THE METHOD OF TRIADS AMONG OLDER ADULTS WITH SLEEP DISTURBANCES

Emily Xu[1], Gawon Cho[2], Anne Chen[2], Jarett Talarcyzk[2], Margaret Dolye[2], Brienne Miner[2]

[1] Yale School of Medicine, [2] Yale University

Introduction: Self-reported measures of sleep duration (SD) may not be accurate, especially among older adults. However, comparisons of self-report with actigraphy or polysomnography (PSG) alone may have limitations, as actigraphy is not a direct measure of sleep, and PSG may be skewed by the "first night effect." Thus, we employed the method of triads, an estimation technique using sleep diaries and two additional objective measures, to robustly assess the validity of SD collected by sleep diary.
Methods: Seventy community-living adults ≥55 years with symptoms of insomnia and/or daytime sleepiness ≥once/week completed an 8-day home-based protocol with 7 days of sleep diary (done electronically using daily email reminders or on paper per participant preference), 7 nights of EEG-headband (Beacon Biosignals), 7 days and nights of wrist actigraphy (Philips Respironics), and one night of home-based PSG (NOX Medical). SD measures from the sleep diary, EEG-headband, and actigraphy were averaged over 7 days, while SD from PSG represented one night of measurement. The method of triads, a technique in factor and path analysis, was used to estimate validity coefficients (VC), which represent the correlation between an individual measure and the "true" latent SD value in a triangular comparison. We constructed two triads among: 1) sleep diary-, actigraphy-, and PSG-measured SD; and 2) EEG-headband-, actigraphy-, and PSG-measured SD. Bootstrapping was used to calculate 95% confidence intervals.
Results: Mean age was 73 years ±9 years, 59% were women, and 27% were minority race/ethnicity. Pairwise correlations between sleep diary-reported SD and actigraphy or PSG were low (r< 0.30). In the first triad, the VC for sleep diary-reported SD was 0.35 (95% CI 0.08-0.70); in comparison, VCs for actigraphy (0.74, 0.30-1.3) and PSG (0.75, 0.33-1.9) showed stronger performance when compared to latent SD. In the second triad, VCs for EEG-headband, actigraphy, and PSG were 0.67 (0.28-0.90), 0.71 (0.44-1.0), and 0.78 (0.52-1.1), respectively.
Conclusion: Sleep diary-reported average SD is a weak measure of latent SD when validated in a triangular comparison with actigraphy and PSG. Future work examining the association of SD with adverse outcomes among older adults with sleep disturbances should use objective measures to evaluate SD.

COGNITIVE BEHAVIORAL THERAPY FOR MILD COGNITIVE IMPAIRMENT IN OLDER ADULTS

Akiko Noda[1], Kunihiro Iwamoto[2], Masato Okuda[1], Fumihiko Yasuma[3]

[1] Chubu University Graduate School of Life and Health Sciences, [2] Nagoya University Graduate School of Medicine, [3] Chubu University

Introduction: Mild cognitive impairment (MCI) is a transitional state from normal cognition to dementia. Identifying predictors of dementia in individuals with MCI is of great interest. The prevalence of MCI in adults older than 60 years increases with age and a lower level of education. Sleep fragmentation, insufficient sleep, and irregular sleep–wake rhythm can increase levels of beta-amyloid and phosphorylated tau levels. Given the relationships between sleep and cognitive function, it is important to examine the efficacy of non-pharmacological cognitive behavioral therapy for insomnia (CBT-I) as the first step in insomnia. We investigated the effects of CBT-I on cognitive function in older adults.
Methods: Twenty volunteers aged 60 years or older (mean age 70.1 ± 4.7 years) with suspected MCI using Touch Panel-type Dementia Assessment Scale (TDAS) were included in this study. Participants taking tranquilizers or hypnotic medications and those with moderate-to-severe sleep disordered breathing (SDB) were excluded. Cognitive function was assessed using the Mini-Mental State Examination (MMSE), Wisconsin Card Sorting Test (WCST), and N-back tasks. To assess the severity of SDB at home, we used a portable device to perform (SAS-2100, NIHON KODEN, Tokyo, Japan) the home sleep apnea test. Sleep complaints were evaluated using the Pittsburgh Sleep Quality Index (PSQI). CBT-I involved three components. The first was to discuss sleep hygiene recommendations, such as avoiding caffeine before bedtime and avoiding napping. The second was informing and supporting individuals to change their bedroom and bedtime activities, such as going to bed only when sleepy. The third component was sleep restriction therapy. The Chubu University Ethics Review Committee approved the study protocol. We obtained written informed consent from each participant after fully explanation of the protocol.
Results: Ten participants were enrolled in the CBT-I group and 10 in the control group. The CBT-I group showed significant improvement in the percentage of correct answers on the 2-back tasks, WCST category achievement, TDAS score, and PSQI, however, the control group did not.
Conclusion: CBT-I may positively affect cognitive function in older adults with MCI. Our findings suggest that the appropriate management with CBT-I should thus be considered as a non-pharmacological adjunct for MCI.

ASSESSING SLEEP QUALITY IN A PILOT SAMPLE OF CHRONIC PAIN PATIENTS: A COMPARATIVE STUDY OF PSQI AND OURA© RING MEASURES

Soamy Montesino Goicolea[1], Pedro Valdes-Hernandez[1], Eric C. Porges[1], Cameron Smith[1], Olga Nin[1], Yenisel Cruz-Almeida[1]

[1] University of Florida

Introduction: This study focuses on two critical aspects of health and well-being in middle-aged and older individuals: sleep quality and pain. It compares two contrasting yet complementary methods of evaluating sleep quality. The first is the Pittsburgh Sleep Quality Index (PSQI), a validated self-reported measure commonly used in sleep research. The second is the OURA© Ring, a wearable technology that collects objective sleep data. By integrating subjective and objective measures, this research aims to provide a more comprehensive understanding of sleep quality, particularly in individuals experiencing chronic musculoskeletal pain.

Methods: The study analyzed baseline and post-intervention data from 33 adults with chronic musculoskeletal pain (pain >4/10 for ≥3 months) and self-reported sleep disturbances (PSQI >5). Participants completed pain and sleep questionnaires and experimental pain assessment. Objective sleep measures, including sleep duration, latency, and efficiency, were collected over 30 days using the OURA© ring. PSQI and OURA© outputs were compared to identify equivalent sleep components (C1–C5). Data analysis included Pearson's and Spearman's correlations, with partial correlations conducted and significance set at $p < 0.05$ after correction for multiple comparisons.
Results: The analysis revealed significant correlations between several PSQI components and their OURA©-derived equivalents. PSQI component 2 (C2) showed a strong positive correlation with OURA© sleep latency ($r = 0.797$, $p = 0.008$), while PSQI questions 2, 3–1, and 4 demonstrated moderate to strong correlations with their OURA© counterparts ($r = 0.50–0.83$, $p \leq 0.049$). Sleep duration (C3) correlated strongly with its equivalent ($r = 0.66$, $p = 0.002$), but sleep latency over 30 minutes (PSQI5a), sleep efficiency (C4), and sleep disturbances (C5) showed no significant correlations. Total PSQI and component C2 also correlated moderately with pain measures, including WOMAC, MPQ, and GCPS ($r = 0.45–0.58$, $p \leq 0.026$).
Conclusion: These results emphasize the need to integrate subjective and objective measures for a comprehensive assessment of sleep quality. Discrepancies, particularly in sleep latency and disturbances, highlight the limitations of the PSQI. Further research is needed to refine sleep evaluation methods in aging populations with chronic pain.

PREVALENCE OF OBSTRUCTIVE SLEEP APNEA IN THE ELDERLY ACROSS THE UNITED STATES THROUGH 2050

Elroy Boers[1], Meredith Barrett[2], Adam Benjafield[2], Leanne Kaye[2], Atul Malhotra[3], Jean-Louis Pepin[4], Alison Wimms[2], Jeff Armitstead[2], Kimberly Sterling[2], Peter Cistulli[5]

Introduction: Chronic conditions such as cardiovascular disease, diabetes, and chronic obstructive pulmonary disease are associated with obstructive sleep apnea (OSA). These conditions are more prevalent in older adults, who may be at heightened risk for OSA. Studies on OSA prevalence have primarily focused on individuals aged up to 70 years, leaving a significant gap in data regarding the population >70 years. Therefore, it is crucial to assess the prevalence of OSA in this group. We aimed to estimate the prevalence of OSA among older adults across the United States through 2050.
Methods: A dynamic open-cohort Markov model was constructed to simulate changes in population structure from 2020 to 2050. Parameters for population growth, the progression of OSA, body mass index (BMI) trajectories, all-cause mortality, and mortality linked to OSA and BMI were based on estimates from existing literature and were modeled across various subgroups categorized by age, sex, and BMI trends, updated every five years. OSA prevalence was adjusted according to age, sex, and BMI subgroups. The projection of OSA prevalence (defined as AHI >5) was focused on individuals aged 70-85 years.
Results: From 2020 to 2050, the prevalence of OSA in older adults is projected to increase substantially. The overall prevalence of OSA with AHI ≥ 5 is expected to rise by 136%, from 11.9 (33%) million cases in 2020 to 28.2 (53.7%) million cases in 2050. For older females, the prevalence of OSA (AHI ≥ 5) will see an increase of 159%, from 4.7 million (23% of females 70-85 years) cases in 2020 to 12.1 million (45.0%) cases in 2050. For older males, the increase will be more moderate than for females, with a rise of 121%, from 7.3 million (45.7%) cases in 2020 to 16.1 million (63.4%) cases in 2050.
Conclusion: The prevalence of OSA in older adults is expected to rise significantly through 2050, with the most pronounced increase among older females. The potential clinical implications of these findings highlight the need for targeted healthcare strategies in the United States to address the anticipated growth in OSA burden in the aging population.

IMPACT OF SEX, AGE, AND ETHNICITY ON SLEEP PARAMETERS AND DISORDERS: A POLYSOMNOGRAPHIC ANALYSIS

Harshil Modi[1], Moon Park[1], Viraj Jain[1], Lourdes DelRosso[2]
[1] UCSF Fresno, [2] UCSF, Fresno

Introduction: Sleep patterns and disorders, such as obstructive sleep apnea (OSA) and periodic limb movements of sleep index (PLMI), vary by age, sex, and ethnicity. Despite research on these disorders, the interaction of demographic factors like age, sex, and ethnicity on sleep architecture and disorder severity remains underexplored. This study investigates sex, age, and ethnicity-based differences in sleep parameters and severity of apnea-hypopnea index (AHI) and PLMI.
Methods: This retrospective analysis utilized polysomnography data from 711 adults (mean age 56.9 ± 17.2 years, 53% female). Participants were stratified by age (18–40, 41–50, 51–60, 61–70, and >70 years), sex, and ethnicity. Ethnic groups included White, Black, Hispanic, Asian, and Other. All the polysomnographic parameters were analyzed. Pearson correlation coefficients were calculated to examine the relationship between age and adjusted sleep parameters Logistic regression models adjusted for AHI and PLMI to evaluate demographic influences on sleep outcomes.
Results: Women exhibited shorter Rem Latency (-4,981 ± 4,823 ms vs. -3,724 ± 5,014 ms; $p = 0.004$) and higher WASO (-2,802 ± 2,569 ms vs. -1,953 ± 2,434 ms; $p = 0.010$) compared to men, particularly in the 41–60 age group. Age was positively correlated with WASO ($r = 0.16$; $p < 0.001$) and negatively with Sleep efficiency ($r = -0.25$; $p < 0.001$) and TST ($r = -0.26$; $p < 0.001$). Ethnic differences were notable: The mean AHI (Apnea-Hypopnea Index) varied by ethnicity, with the highest observed in Blacks (mean AHI = 23.20, SD = 27.80), followed by Hispanics (mean AHI = 20.02, SD = 25.11), while Whites had a mean AHI of 14.80 (SD = 17.71). PLMI (Periodic Limb Movement Index) was highest among Whites (mean PLMI = 22.28, SD = 30.80)

and Asians (mean PLMI = 18.11, SD = 36.48), while Blacks had the lowest mean PLMI (mean PLMI = 11.69, SD = 14.09).
Conclusion: Sex and ethnicity significantly influence RL, WASO, and PLMI, while age predicts SE and TST declines. OSA severity was worse in Blacks and Hispanics, while PLMI was worse in whites. These findings emphasize the need for tailored clinical approaches addressing demographic-specific sleep disparities.

IDENTIFYING SOCIOECONOMIC, BEHAVIORAL, AND HEALTH PROFILES AND THEIR ASSOCIATION WITH SLEEP HEALTH DISPARITIES: A CLUSTERED ANALYTIC APPROACH

Astrid Zamora[1], Velarie Ansu Baidoo[2], Erica Jansen[3]
[1] Stanford University School of Medicine, [2] University of Miami Miller School of Medicine, [3] University of Michigan School of Public Health

Introduction: Sleep health is influenced by socioeconomic, behavioral, and health factors, yet limited research has explored how distinct subgroups based on shared characteristics are associated with sleep health outcomes. This study aimed to identify and explore clusters of individuals based on socioeconomic, behavioral, and health profiles and examine sleep health disparities across clusters.
Methods: NHANES 2017-2018 (N=5,811) data were analyzed using K-means clustering to classify participants into subgroups based on socioeconomic, behavioral, and health factors. Variables included income-to-poverty ratio, education, marital status, household size, food insecurity, smoking and alcohol consumption, BMI, and depression. Variables were standardized, and K-means clustering was performed with a maximum of three clusters. Sleep health was assessed across five dimensions—regularity, timing, duration, satisfaction, and alertness—and summarized into a composite score (0–5), with scores ≥3 classified as "good" sleep health. Weighted logistic regression models examined associations between cluster membership and sleep health, adjusting for age, gender, and race/ethnicity.
Results: The mean age was 47.2 years (SE=0.6), with 51.7% female. Three clusters were identified: cluster 1 (23.6%), the "disadvantaged and high health risk" group, had lower income, education, larger households, and higher food insecurity; this group also had higher BMI, depression, and were more likely to smoke and drink. Cluster 2 (58.4%), the "moderately advantaged and healthier" group, had higher education, moderate income, household sizes, lower depression, a more moderate BMI, and fewer smokers and drinkers. Cluster 3 (17.9%), the "advantaged and low health risk" group, had higher income, education, smaller households, and lower food insecurity; this group also had lower BMI, minimal depression, and were least likely to smoke or drink. Compared to cluster 2 (ref. group), cluster 1 had 74% higher odds of poor sleep health (95% CI: 1.53, 1.97; p< 0.0001), while cluster 3 had 80% higher odds (95% CI: 1.34, 2.34; p=0.0004).
Conclusion: This study identified subgroups with distinct socioeconomic, behavioral, and health profiles linked to sleep health. Interestingly, the more advantaged cluster had worse sleep health than the moderately advantaged cluster. Future research should replicate these findings with longitudinal data to explore causal relationships.

SUBJECTIVE VS OBJECTIVE SLEEP MEASURES AMONG OLDER ADULTS WITH TRAUMATIC BRAIN INJURY

Claire Pfaeffle[1], Lauren Masino[1], Christine Johnston[1], Emerson Wickwire[1], Jennifer Albrecht[1]
[1] University of Maryland Baltimore

Introduction: Traumatic brain injury (TBI) is a common fall-related injury among older adults that increases risk for sleep complaints. Subjective and objective sleep measures ensure a comprehensive account of sleep, yet there is limited data on the concordance between subjective and objective measurements of sleep in this population. The purpose of this study was to compare subjective and objective measures of sleep in older adults with TBI.
Methods: Adults aged 65 and older treated for TBI within 72 hours of injury at a single trauma center who provided informed consent were included. Assessments were conducted starting at 2-weeks post injury. Subjective sleep was assessed via a standardized sleep diary completed daily for one week. Objective sleep was assessed via actigraphy (Phillips Actiwatch Spectrum Plus®), with participants wearing the device on their non-dominant hand for one week. This study focused on study participants with complete subjective and objective data at the 2-week assessment. We compared subjective and objective mean values of total sleep time (TST), sleep efficiency (SE), time to bed (TTB), wake time (WT), wake after sleep onset (WASO), and sleep onset latency (SOL) and tested differences between groups using Student's t-tests.
Results: Participants included 46 older adults (74.5 [SD 7.9] years). Subjective and objective measures of TST differed significantly (subjective TST mean 7.7 hrs. (SD 1.6) vs. objective TST mean 6.7 hrs. (SD 1.8), p <.01). The measure of SE also differed significantly (subjective SE mean 84.7% (SD 10.8) vs. objective SE mean 73.9% (SD 17.2), p <.001). There was no statistically significant difference for TTB, WT, SOL, or WASO.
Conclusion: Among older adults with TBI, significant subjective-objective discrepancies were observed based on self-report sleep diaries and actigraphy over one week. Notably participants reported less TST and lower SE than what was observed via actigraphy. These findings support consensus recommendations for multimethod assessments of sleep among individuals with TBI.

INFLAMMATION, NEURODEGENERATION, AND SLEEP IN AGING: A STUDY IN COGNITIVELY HEALTHY OLDER ADULTS

Natalie Pandher[1], Leslie Yack[1], Esther Li[1], Brianne Bettcher[2], Rowan Saloner[1], Kaitlin Casaletto[1], Lea Grinberg[1], Thomas Neylan[1], Joel Kramer[1], Christine Walsh[1]
[1] University of California, San Francisco, [2] University of Colorado

Introduction: A lower Ab42/40 ratio has been linked with shorter sleep duration and disrupted NonREM stage 3 sleep (N3), but

it is unclear how it relates to sleep efficiency (SE). The association of inflammatory markers and sleep, having relied on actigraphy or single-night EEG, is also mixed. Interleukin 6 (IL-6) is increased with decreased N3, increased wake after sleep onset (WASO), and daytime sleepiness. In men, IL-6 is lower with higher total sleep time. In women, IL-6 is lower with fewer nighttime arousals, and TNF-α is lower with more N3 sleep. Using multi-night frontal EEG, we hypothesize that a) lower Ab42/40 ratio is associated with poorer sleep efficiency, and b) increased IL-6 is linked to less N3 in men and more WASO in women.
Methods: 23 cognitively unimpaired older males (M=76.2, SD=5.8 yrs) and 26 females (M=73.6, SD=5.6 yrs) used multi-night frontal EEG sleep-monitoring devices (Zeo, Inc; ABM, Inc) and had quantified plasma IL-6, TNF-α, and Ab42/40. Data were analyzed with Pearson correlations, partial correlations, and ANOVAs where appropriate using SPSS.
Results: Lower Ab42/40 was associated with lower SE (R2=0.483, beta=.586, t=2.190, p=.05, n=15) and increased WASO (R2=0.520, beta=-.546, t=-2.121, p=.06, n=15). In males, higher levels of plasma IL-6 and TNF-α were linked to less time in N3 (IL-6: r=-4.23, p=0.045; TNF-α: r=-3.8, p=0.07). Higher plasma IL-6 was also associated with increased nighttime awakenings in males (r=0.411, p=0.05). We did not identify any significant relationships in women.
Conclusion: Our findings suggest that a lower Ab42/40 ratio is associated with decreased sleep efficiency and increased wake after sleep onset in cognitively unimpaired older adults. Additionally, elevated IL-6 levels were associated with reduced N3 sleep and more nighttime arousals in males but not females. While no sex differences were observed in the relationship between Ab42/40 and sleep, this data highlights the potential role of inflammation, particularly IL-6, in modulating sleep architecture and cognitive function in older adults. These results underscore the need for further investigation into the sex-specific mechanisms underlying sleep disturbances and their impact on aging and neurodegeneration.

COMPARING THE MMSE AND SMARTPHONE-BASED ECOLOGICAL MOMENTARY COGNITIVE TESTING OF COGNITIVE FUNCTION IN RELATION TO SLEEP IN PERSONS WITH DEMENTIA

Jessie Song[1], Raeanne Moore[2], Mary-Lynn Brecht[3], Diviya Khullar[4], Brent Mausbach[2], Jennifer Martin[5], Yeonsu Song[6]
[1] University of California, Los Angeles, School of Nursing, [2] University of California, San Diego, [3] University of California Los Angeles, [4] University of California, Los Angeles, [5] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles, [6] School of Nursing, University of California Los Angeles

Introduction: Poor sleep is linked to cognitive decline in older adults, particularly in people living with dementia (PLWD). As dementia progresses, sleep quality often worsens, underscoring the need for ongoing monitoring of both sleep and cognitive function. This study examined the associations between cognitive function (assessed both at a single time point and daily) and sleep in PLWD.
Methods: Seventy-three PLWD participated in ecological momentary cognitive testing (EMCT) via web links sent to their caregivers' smartphones three times/day over seven days, using the NeuroUX platform (Quick Tap 1 [QT1], Quick Tap 2 [QT2], or Matching Pairs [MP]). Baseline data were analyzed as part of an ongoing clinical trial (NCT05452031) testing a dyadic sleep intervention for PLWD and their caregivers. PLWD also completed the Mini-Mental State Examination [MMSE]. Sleep was assessed via daily ecological momentary assessment [EMA] diaries, completed by caregivers. Cognitive measures included median total scores [TS], median reaction times [RT], intra-individual variability [SD], and within-day variability for the three EMCTs, along with total MMSE scores. Sleep quality was assessed using a daily "good sleep" variable across seven days, indicating no difficulty falling or staying asleep (1=good sleep, 0=poor sleep). Pearson correlation analyses were performed.
Results: Of the 73 PLWD, 66 had at least one valid EMCT during the seven days and 43 had valid data for all seven days. The mean MMSE score was 15.05 (SD 8.92), and the mean "good sleep" score was 0.59 (SD 0.37). A lower SD of the median RT across all days was significantly associated with better sleep (r=-0.25, p=0.047), while other metrics (median TS, median RT) were not related to sleep. The association between cognitive performance and sleep was stronger in the evening than in the morning or afternoon, although the difference was not statistically significant. MMSE scores were not significantly correlated with sleep.
Conclusion: Daily variability in cognitive performance on the QT1 EMCT is significantly associated with subjective sleep quality, while MMSE scores are not. By leveraging smartphone-based cognitive assessments, caregivers and healthcare providers can gain real-time insights into the relationship between sleep quality and fluctuations in cognitive performance.

ASSOCIATION BETWEEN INFLAMMATORY MARKERS AND SLEEP QUALITY IN FAMILY CAREGIVERS OF PEOPLE LIVING WITH DEMENTIA

Diviya Khullar[1], Anna Papazyan[2], Cathy Alessi[3], Jennifer Martin[4], Yeonsu Song[5]
[1] University of California, Los Angeles,, [2] University of California, Los Angeles, [3] VA Geriatric, Research, Education and Clinical Center, VA Greater Los Angeles Healthcare System, [4] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System, [5] School of Nursing, University of California Los Angeles

Introduction: Family caregivers of adults with dementia often report poor sleep quality due to the demands of caregiving. Poor sleep, due to shorter sleep duration and/or disturbed sleep, has been linked to inflammatory processes. Previous research has identified elevated levels of C-reactive protein (CRP), tumor necrosis factor alpha (TNF-□), and interleukin-6 (IL-6) as significant markers of poor sleep. Additionally, interleukin-10 (IL-10) and interferon-gamma (IFN-□) are involved in inflammatory processes that may impact sleep but have not been evaluated in caregivers. This pilot study aimed to examine the relationship between sleep quality and inflammatory markers in family caregivers of people living with dementia (PLWD).
Methods: Data were collected from 18 caregivers enrolled in a dyadic behavioral sleep study involving PLWD and their family caregivers (NCT05102565). Plasma samples from caregivers

were analyzed for inflammatory markers, including CRP, IL-6, IL-10, TNF-□, and IFN-□. The Pittsburgh Sleep Quality Index (PSQI) global score was used to assess sleep quality. Spearman correlations coefficients (□) were calculated, with a significance threshold of $p < 0.20$, given the pilot nature of the study.
Results: Among the 18 caregivers, the mean PSQI score was 6.6□ 3.6. IL-6 showed a slight positive correlation with the PSQI score (□□ =0.18, p=0.025). Both IL-10 and IFN-□ were significantly associated with PSQI global scores (□□ =0.28, p=0.03 for IL-10 and □ □ =0.27, p=0.001 for IFN-□). CRP levels showed a minimum positive correlation with the PSQI score (□=0.07, p=0.19). A slight negative correlation was observed between PSQI scores and TNF-□ □ levels (□=-0.10, p< 0.01).
Conclusion: In this pilot study, higher PSQI scores were associated with elevated levels of IL-6, IL-10, IFN-□, and CRP levels, suggesting a link between poor sleep quality and increased immune and inflammatory marker levers in caregivers. The negative correlation observed between PSQI and TNF-□ is contrary to what is noted in literature reviews; however, this is due to the small sample size. Larger studies are needed to confirm these findings and further explore the health implications of poor sleep among caregivers of PLWD.

AGE-RELATED PATTERNS IN SLEEP DURATION ACROSS THE ADULT LIFESPAN IN THE U.S.: INSIGHTS FROM A LARGE-SCALE STUDY USING WEARABLE TECHNOLOGY

Eunjin Lee[1], Eric Zhou[2], Eun Yeon Joo[3], Hyun Gi Ahn[4], Aly Suh[5]
[1] Sungshin Women University, [2] Harvard Medical School, [3] Department of Neurology, Neuroscience Center, Samsung Medical Center, Sungkyunkwan University School of Medicine,, [4] Samsung Electronics Co., Ltd, Suwon, Republic of Korea, [5] Sungshin Women's University

Introduction: Sleep duration is known to evolve as we age, yet large-scale studies characterizing this across the lifespan are limited and are often reliant upon self-report data, which can be biased by a number of factors (e.g., social desirability, research participation). We leveraged wearable technology to collect information on sleep duration at the population level to assess sleep duration and variability across adulthood.
Methods: Data was analyzed from 274,128 adults (ages 20–69 years) in the U.S. who wore a consumer wearable device (Samsung Galaxy Watch). The longest continuous nighttime sleep period(18:00 to 6:00) was used for analyses, with data filtered to only include those with at least 20 weekdays and 8 weekends of tracked sleep over the past 3 months. Descriptive statistics examined sleep duration and variability, while t-tests compared differences across age groups (by decade) and between weekday/weekend sleep (social jetlag).
Results: Adult sleep durations across the lifespan were: 20-29 years ($\bar{x}$=7hours 42minutes, SD=47 minutes), 30-39 years($\bar{x}$=7hours 35minutes, SD = 49minutes), 40-49 years($\bar{x}$=7hours 32 minutes, SD =51minutes), 50-59 years($\bar{x}$=7 hours 34 minutes, SD = 52minutes), and 60-69 years ($\bar{x}$=7hours 45minutes, SD=56minutes). During weekdays, 40-49 years recorded the shortest average sleep duration ($\bar{x}$=7hours 33 minutes, SD=50.75), compared to 60-69 years ($\bar{x}$=7hours 45minutes, SD=56.36, p< 0.001). Social jetlag was observed across all age groups, with those between 40-49 years exhibiting the greatest difference between weekday vs. weekend sleep (Δ=34 minutes more on weekends), while those between 60-69 years experienced the smallest difference (Δ=20minutes more on weekends). Similarly, sleep variability, measured by the standard deviation of sleep duration, was highest in the 40-49 age group and lowest in the 60-69 group, suggesting middle-aged adults have more irregular sleep patterns due to work and family obligations.
Conclusion: These findings provide data describing typical sleep durations across the lifespan. In contrast to common clinical guidance, older adults appear not to sleep less than younger adults. Adults between 40-49 years are likely to face challenges with insufficient sleep during the weekdays, possibly reflecting the considerable work and childrearing responsibilities of this age group.

INVESTIGATING THE CORRESPONDENCE BETWEEN SELF-REPORTED AND SMART-BED SLEEP HEALTH THROUGH NOVEL FOUR-DIMENSIONAL GRAPHICAL MODELING TECHNIQUES

Meredith Wallace[1], Margaret Kuzemchak[1], Lan Yu[1], Daniel Buysse[2], Rachel Conlon[2]
[1] University of Pittsburgh, [2] University of Pittsburgh School of Medicine

Introduction: The self-reported Ru-SATED questionnaire measures overall subjective sleep health. Although psychometrically valid, the extent to which it corresponds to objective sleep health is unknown. Our particular interest is in the objectively-measured sleep Amount, Regularity, and Timing (ART), which are most directly amenable to objective measurement and behavioral intervention. We used novel modeling and graphical methods to investigate how self-reported multidimensional sleep health relates to the ART of sleep, as measured with a smart-bed.
Methods: The analytic sample included N=2,625 Sleep Number®bed users who completed the Ru-SATED 4.0 scale, which measures multidimensional sleep health in the past month. Participants had 7-28 days of smart-bed data in the previous month (Mean[SD] age = 52.0[16.1], 55.3% female, 79.2% White, 5.8% Black). From the smart-bed data, we computed the average duration of restful sleep (Amount), standard deviation (SD) of sleep midpoint (Regularity), and average sleep midpoint (Timing). We extended Response Surface Modeling principles to explore how complex combinations of smart-bed ART data related to Ru-SATED. Novel graphical techniques were used to illustrate this four-dimensional relationship.
Results: The ART of smart-bed data explained 10% of the variance in Ru-SATED scores. The highest Ru-SATED scores (i.e., best subjective sleep health) were observed in those with the combination of longer objective restful time (≥5 hours), low midpoint variability (< 1 hour SD), and a midpoint between 1:00-5:00AM (i.e., all but the most extreme early/late midpoint). The lowest Ru-SATED scores (i.e., worst sleep health) were observed in those with the combination of high midpoint variability (> 3 hours SD) and either long/late (>5 hours, > 5:00AM) or short/early sleep (< 5 hours, < 12:00AM).

Conclusion: The smart-bed-measured Amount, Regularity and Timing of sleep corresponded to self-reported Ru-SATED scores, further establishing the validity of Ru-SATED. Ru-SATED was associated with the combination of objective sleep measures, rather than any single measure, and was effectively visualized using innovative four-dimensional graphic techniques. This further validates the conceptualization of sleep health as a multidimensional construct and may assist with presenting clinically relevant information regarding patient sleep health patterns and goals.

AGE, SLEEP AND INFLAMMATION: A CORRELATIONAL STUDY

Dominique Lorrain[1], Denis Bélisle[1]

[1] Université de Sherbrooke

Introduction: This correlational study explores the relationship between sleep and inflammation in aged individuals. Cytokines are involved in various central nervous system processes, including wakefulness, appetite, mood regulation, sexual behaviors, and thermoregulation. Sleep disorders commonly associated with aging, such as insomnia, circadian disruptions, sleep apnea, and periodic leg movements, might have significant biological impacts on the inflammatory system and immune functions. Aging is also associated with increased levels of some inflammatory markers.

Methods: 77 individuals (women: 51, men: 26) aged 60–87 years (mean age 69.8 ± 6.1 years) were recruited from the community. None were using psychoactive drugs. Participants underwent three nights of polysomnographic sleep recording in the laboratory: the first night served for adaptation and sleep disorder assessment, while nights two and three were for experimentation. A 19-channel EEG montage was used with additional sensors for eye movements, muscle activity, respiration, and leg movements. Fasting, resting venous blood was drawn in the morning upon awakening for further measurement of cytokine receptors IL-1α, IL-1β, IL-1RA, IL-6, IL-8, IL-10, TNFα and sTNFR1 in serum (Milliplex). Questionnaires assessed health (SF-36), sleep quality (PSQI), anxiety (BAI), and depressive symptoms (BDI, POMS).

Results: Periodic Leg Movement during Sleep (PLMS) was correlated to four inflammation markers (IL10 (.361), IL6 (.307), IL1B (.264) IL1A (.227)), the most of any other sleep variables, clearly indicating that PLMS is associated with a prolonged state of inflammation. sTNFR1 was the biomarker most associated with other variables (Micro-arousal (-.375), AHI (Apnea Hypopnea Index:.278), #Arousal (-.261), Stage1 (-.238), POMS (.401)). The first three variables are sleep disrupters and Stage1 augments when there is less of deeper sleep states, it seems counterintuitive that they would consistently negatively correlate with an anti-inflammatory marker. AHI was further correlated with IL1RA (.277).

Conclusion: Correlations are modest but many and significant, pointing toward a definite role of sleep in inflammatory processes. The signaling relevance of biomarkers, being pro, anti or both, depending on circumstances, remains ambiguous.

INSOMNIA SYMPTOMS AND PHYSICAL FUNCTION IN OLDER VETERANS DURING AND AFTER VA REHABILITATION: A FEASIBILITY STUDY

Julia Boyle[1], Michael Perlis[2], Patricia Bamonti[1], Jonathan Bean[3], Kelly O'Malley[4], Jane Driver[4], Michael Grandner[5], Jennifer Moye[3]

[1] Office of Research and Development & New England GRECC, VA Boston Healthcare System, [2] Department of Psychiatry, University of Pennsylvania, [3] New England GRECC, VA Boston Healthcare System, [4] Geriatrics and Extended Care, VA Boston Healthcare System, [5] Department of Psychiatry, College of Medicine, University of Arizona

Introduction: Older adults admitted to subacute rehabilitation are at a critical window in the recovery of physical function, yet older Veterans are susceptible to sleep difficulties which may impact this recovery. This study aimed to determine the feasibility of evaluating sleep and physical function in older Veterans at admission, discharge, and 1-month post-discharge from subacute rehabilitation using patient-reported, actigraphy, and performance-based measures.

Methods: Veterans aged 60+ were approached within 1 week of admission to VA Boston's subacute rehabilitation. Each participant completed the Insomnia Severity Index(ISI)(clinically meaningful difference[CMD]=6), the Activity Measure for Post-Acute Care(AM-PAC)(CMD=4), and two performance measures (gait speed; chair stands) at admission, discharge, and 1-month follow-up. All participants completed wrist-worn ActiGraph GT3X+ accelerometer for 1 week at admission. Descriptive and frequency analyses were used to identify completion rates and preliminary descriptive data at three time points.

Results: Thirty-six Veterans were approached for participation; 20 refused with 8 declining due to concerns about wearing the actigraph and 5 declining due rehabilitation demands. Sixteen participants(Mean age=75±6.4years; 100%male; 94%White) completed actigraphy and all self-reported measures at admission; of these, 14(88%) completed measures at discharge and 12(75%) at 1-month post-discharge. Most Veterans(88%) were unable to complete gait speed or chair stands at all time points due to functional difficulties during admission and/or could not be assessed face-to-face due to travel difficulties post-discharge. Veterans were lost to follow-up due to rehospitalization(n=3) or patient death(n=1). For the 12 Veterans with complete data, AM-PAC scores improved from admission(Mean=49.9±8.1) to discharge(Mean=54.2±6.1), with minimal changes post-discharge (Mean=53.2±10.8)(overall 41.6% met/exceeded CMD=+4). Conversely, ISI scores improved from admission (Mean=10.8±7.3) to discharge (Mean=6.2±5.8)(25% met/exceeded CMD=-6) but worsened again 1-month post-discharge (Mean=10.6±7.4)(33.3% met/exceeded CMD=+6).

Conclusion: It is feasible to assess insomnia and physical function through self-reported measures in older Veterans during and after subacute rehabilitation. Performance and actigraphy-based measures were less feasible/barriers to participation in this environment given recovery demands, lower functional status, and face-to-face difficulties post-discharge. Veterans may benefit from targeted behavioral sleep interventions during this transitional period and such interventions may confer additional benefits regarding daytime function.

HOW AGE SHAPES THE NIGHT: A CROSS-SECTIONAL DIVE INTO SLEEP ARCHITECTURE

Shaheryar Usman[1], Ricardo Concepcion[1], Amira Dalmazio[1], Adrienne DaGue[1], Calli Bertschy[1], Lilit Sargsyan[1], Reeba Mathew[1], Ruckshanda Majid[2]

[1] University of Texas Health Science Center at Houston, [2] McGovern Medical School UT Health

Introduction: Delta (N3) or slow-wave sleep, essential for restorative processes, is believed to decline with age, potentially impacting sleep quality and cognition. Previous studies on this relationship have shown inconsistent results. We performed a cross-sectional analysis to examine age-related changes in sleep architecture across adult age groups.
Methods: Baseline adult PSG studies performed between July 1 and December 7, 2024, at Memorial Hermann Texas Medical Center, were reviewed. We excluded titration studies due to their potential impact on sleep architecture. Total sleep time (TST) and sleep stage distribution, with a focus on N3, were analyzed across three age groups: Group 1 (18–30 years) Group 2 (31–60 years), and Group 3 (>60 years), using ANOVA and linear regression analysis (95% confidence intervals when applicable).
Results: A total of 159 studies were reviewed. The average ages for Group 1 (12 subjects), Group 2 (82 subjects), and Group 3 (65 subjects) were 23.8 ± 4, 47.7 ± 8.2, and 68.8 ± 6.8 years, respectively. The TST was lowest in Group 3 (246 minutes, $p < 0.05$), as was the sleep efficiency (63%, $p = 0.0003$). Sleep latencies did not differ between groups. When comparing the sleep stages (percentage means), only stage N1 was statistically different (longest in Group 3, $p = 0.0008$) representing 15.8% of TST. In addition to demonstrating an increase in N1 with age ($R^2 = 3.3\%$, $p = 0.02$), linear regression analyses also demonstrated a decrease in N3 with age ($R^2 = 2.5\%$, $p = 0.046$). The respiratory disturbance index (RDI) using AASM V.3 criteria, increased across the groups (18.5, 23.7, 36.9 events/hour respectively, $p = 0.002$).
Conclusion: This study demonstrates age-related changes in sleep architecture, which include reduced TST, lower sleep efficiency, a higher proportion of N1 and decreased total N3 sleep with age. The observed increase in RDI is consistent with our current understanding of the relationship between age and obstructive sleep apnea. These alterations in sleep patterns may have far-reaching consequences. Larger population studies investigating the impact of such sleep architectural changes on cognitive functioning, memory consolidation, and overall health in adults are needed.

PERCEPTIONS OF SLEEP AND PHYSICAL ABILITIES IN OLDER VETERANS DURING VA SUBACUTE REHABILITATION: PRELIMINARY FINDINGS FROM A FEASIBILITY STUDY

Angelica Boeve[1], Jennifer Moye[2], Michael Perlis[3], Patricia Bamonti[4], Jonathan Bean[2], Kelly O'Malley[5], Jane Driver[5], Michael Grandner[6], Julia Boyle[4]

[1] Sleep Medicine, Minneapolis VA Healthcare System, [2] New England GRECC, VA Boston Healthcare System, [3] Department of Psychiatry, University of Pennsylvania, [4] Office of Research and Development & New England GRECC, VA Boston Healthcare System, [5] Geriatrics and Extended Care, VA Boston Healthcare System, [6] Department of Psychiatry, College of Medicine, University of Arizona

Introduction: Poor sleep raises the risk for physical functioning difficulties and safety concerns, such as falls, in older adult populations. However, there is insufficient literature on sleep in older Veterans receiving care in VA inpatient rehabilitation settings during and after hospitalization. Furthermore, we do not sufficiently understand Veterans' perceptions of the importance of their sleep and physical abilities during this recovery process. The present analysis assessed older Veterans' perceptions of sleep, physical ability, and interest in pursuing non-pharmacological sleep interventions after completing their treatment at a VA subacute rehabilitation unit.
Methods: Veterans aged 60+ were approached ≤1 week prior to discharge from VA Boston's subacute rehabilitation. Veterans completed a brief semi-structured interview. Using frequency analyses, we determined how many Veterans believed their sleep and physical abilities were important to their recovery, believed their sleep impacts their physical abilities, how many were interested in non-pharmacological sleep interventions, when this intervention should occur, and how many believed this sleep intervention should include physical activities.
Results: Fourteen Veterans (Mean age=75.4±6.6 years; 100% male; 93% White) completed the brief semi-structured interviews prior to discharge. All Veterans (100%) reported that their sleep and physical abilities were important to their overall recovery and that their sleep impacts their physical abilities. Most (71%) expressed interest in a non-pharmacological intervention to help them sleep. Veterans shared that the intervention should occur during (50%), after (7.1%) or both during and after (29%) subacute rehabilitation. The majority (71%) reported that physical activity should be incorporated into the sleep intervention.
Conclusion: This analysis highlighted Veterans' perception regarding the importance of their sleep and physical functioning, particularly as it relates to their physical recovery process. This data also demonstrates a high level of Veteran interest in receiving non-pharmacological sleep interventions to promote their recovery. A natural next step would be to develop and study an intervention to support Veterans' sleep and physical abilities during and/or after their discharge from subacute rehabilitation.

SLEEP, CIRCADIAN RHYTHMS, AND COGNITIVE FRAILTY IN OLDER CHINESE IMMIGRANTS: PROTOCOL FOR AN OBSERVATIONAL STUDY

Ruixue Cai[1], Chenlu Gao[1], Zhong Liu[2], Lei Gao[1], Kun Hu[1], Peng Li[1]

[1] Massachusetts General Hospital/ Harvard Medical School, [2] Massachusetts General Hospital

Introduction: Immigrant workers are integral members of the American society. While efforts have been made to support their health needs, the challenge of caring for their aging parents has

often been overlooked. These aging parents, whose lives are closely tied to their adult children, are referred to as the 'zeroth generation' immigrants. Compared with first-generation immigrants, these 'zeroth generation' immigrants may experience even higher rates of sleep and circadian rhythm disturbances, due to factors linked to immigration and acculturation. This observational study aims to examine the relationships of sleep and circadian rhythms with frailty and cognition among older Chinese immigrants in the US.

Methods: We plan to recruit Chinese immigrants aged ≥65 years old to complete a series of tests and questionnaires. Specifically, we will assess participants' general cognitive abilities (Mini-Mental State Exam), episodic memory (word list recall, story recall task), working memory (digit span test), and executive function (Trail making task, Stroop test). Grip strength and walking speed will be tested to assess frailty. Participants will also wear an actigraphy device and complete sleep diaries for 10 consecutive days. Questionnaires will collect demographic information, lifestyle, chronotype, living conditions, language experience, education and employment history, immigration and travel history, medical history and medication use, frailty, sleep quality, sleepiness, migration-acculturative stress, depressive symptoms, and subjective cognitive decline.

Results: We anticipate enrolling 200 participants, balanced by immigration generation and sex, in the first phase of the study. We anticipate that the zeroth-generation participants experience poorer sleep and circadian health, including lower sleep quality, shorter sleep duration, increased daytime sleepiness, and greater rest-activity rhythm disturbances, as well as higher frailty prevalence and worse cognitive performance than their first-generation immigrant peers. Additionally, we expect that heightened acculturative stress mediates the associations between sleep and circadian health, with frailty and cognition, particularly in the zeroth-generation immigrants.

Conclusion: This study will provide new insights into the sleep and circadian health challenges faced by the zeroth-generation Chinese immigrants and their impact on frailty and cognitive aging. Findings will inform interventions and policies to promote health equity, addressing the specific needs of this vulnerable demographic.

A RANDOMIZED, TRIPLE-BLIND, PLACEBO CONTROLLED TRIAL INVESTIGATING A STANDARDIZED CORN LEAF EXTRACT ON SLEEP IN HEALTHY ADULTS WITH SLEEP DIFFICULTIES

Mesfin Yimam[1], Qi Jia[1], Katarina M. Doma[2], Abdelrahman Zamzam[2], David C. Crowley[2], Najla Guthrie[2], Erin Lewis[3]

[1] Unigen Inc., [2] KGK Science Inc., [3] KGK Science Inc

Introduction: Difficulties falling and/or staying asleep affects over one quarter of American adults. Current management strategies include prescription sleep aids; however, long-term use is associated with adverse effects and natural alternatives may provide safer and more effective relief. UP165, a standardized corn leaf extract (CLE), has shown to bind melatonin receptors, increase melatonin synthesis and increase total sleep time (TST) and deep sleep in rodents and in a pilot clinical trial. Therefore, this study investigated the safety and efficacy of CLE on sleep quality in a healthy population.

Methods: This clinical trial enrolled 80 healthy adults (18-65 years; n=40/group) with difficulties falling and/or staying asleep. Participants were assigned to CLE or placebo for 28 days. Following a 7-day run-in period, objective (actigraphy with electroencephalogram) and subjective (Pittsburgh Sleep Quality Index; PSQI) sleep measures, were assessed at baseline (Day 0), and Days 14 and 28, with safety assessed at screening and Day 28.

Results: At Day 14, there was an increase in rapid eye movement (REM) (6.4 vs. -3.2 min; p=0.042) and decrease in awake duration (-17.9 vs. 17.0 min; p=0.021) for participants supplemented with CLE compared to those on placebo. At Day 28, there were increases in TST (35.2 vs. -16.9 min), REM (8.3 vs. -4.4 min) and light sleep time (30.8 vs. -12.4 min) for the CLE group compared to the placebo group ($p < 0.05$). Compared to placebo, participants supplemented with CLE demonstrated significantly shorter sleep onset latency and less sleep fragmentation by Day 14. CLE improved sleep efficiency and increased sleep maintenance on both Days 14 and 28. The PSQI sleep latency score decreased from baseline at Days 14 and 28 for the CLE group whereas the Placebo group decreased at Day 28 only ($p < 0.05$). Post-hoc analysis supported these findings with a significant increase of 35.7 min in non-REM sleep at Day 28 for participants supplemented with CLE compared to a decrease of 10.6 min for those on placebo. Supplementation with CLE was safe and well tolerated.

Conclusion: The current study suggests supplementation with CLE may improve sleep parameters in a healthy population with sleep difficulties.

SLEEP HEALTH COMPOSITE SCORE FOR QUALITY, DURATION, AND EFFICIENCY CORRELATED WITH BIOMARKER HOMA-IR AND COGNITIVE DECLINE IN MIDDLE-AGED ADULTS

Carleara Weiss[1], Jihnhee Yu[2]

[1] University at Buffalo School of Nursing, [2] University at Buffalo School of Public Health and Health Professions

Introduction: Biomarker studies have evidenced the relationship between sleep, cognitive function, and dementia. Along with traditional biomarkers such as phosphorylated tau and amyloid beta, metabolic function markers such as the homeostasis model assessment of insulin resistance (HOMA-IR) have been associated with sleep and cognitive function.

Methods: A cross-sectional analysis of the Midlife in the United States Survey (MIDUS) using the MIDUS 2 Biomarker Project (204-2009) cohort with data from 1255 respondents. The project included biological assessments and subjective measures of sleep and cognitive function. We used a Random Forest Regression and linear regression models to predict HOMA-IR association with sleep and cognitive function. HOMA-IR was tested with a fasting blood draw. Sleep Health components were calculated with the Pittsburgh Sleep Quality Index (satisfaction/quality), daytime dysfunction (alertness), timing (usual bedtime), efficiency (habitual sleep efficiency), and duration (sleep duration). Cognitive function with the Mood and Symptom Questionnaire (MASQ) Cognition control.

Results: Participants were middle-aged (mean 57.32) female (56.8%) recruited from three sites. The random forest regression

model (RFRM) accuracy explains 23% variability of HOMA-IR (R-squared= 0.23, mean square error=12.32). The importance of each predictor was assessed using % Mean Decrease in Accuracy (%IncMSE) with a higher value indicating a higher impact of the covariate on model accuracy.) Sleep efficiency (6.52%IncMSE), Sleep duration (5.28%IncMSE), and Sleep quality (3.21%IncMSE) were the most important covariates. Sleep quality had a significant negative correlation with HOMA-IR ($p< 0.001$) and Cognitive Control ($p=0.04$) in linear regression model.
Conclusion: Poor scores in sleep health components efficiency, duration, and quality significantly predicted the biomarker HOMA-IR in a sample of middle-aged adults. Poor sleep quality correlated with worse HOMA-IR levels and lower cognitive control. Future studies should investigate the interplay between insulin resistance, sleep health, and cognitive impairment.

NEIGHBORHOOD DEPRIVATION AND SLEEP HEALTH AMONG MIDDLE-AGED PRIMARY CARE PATIENTS

Britney Sun[1], Morgan Bonham[1], Fangyu Yeh[1], Laura Curtis[1], Julia Benavente[1], Patrick Cecil[1], Prophecy Agyare[1], Rodolfo Zuleta[1], Michael Wolf[1], Minjee Kim[1]
[1] Northwestern University Feinberg School of Medicine

Introduction: Poor sleep health, including short sleep duration, is linked to adverse health outcomes. While studies have investigated individual determinants of sleep health disparities, the role of structural determinants such as neighborhood deprivation is less explored, especially in middle-aged adults. The objective of this study was to examine the relationship between neighborhood deprivation and self-reported sleep health among middle-aged primary care patients.
Methods: This interim analysis of the Health Literacy and Cognitive Function among Middle-Aged Adults (MidCog) study included English-speaking adults aged 35-64 recruited from an academic general internal medicine practice and 7 federally qualified health centers in the Chicagoland area. Neighborhood deprivation was assessed using the 2021 Area Deprivation Index (ADI) linked to census blocks, categorized into terciles, with the highest tercile indicating the greatest deprivation. Multidimensional sleep health was measured using the RU-SATED questionnaire, while short sleep duration (< 6 hours) was derived from the Ultra-short Munich ChronoType Questionnaire. We examined the associations of neighborhood deprivation with sleep health and short sleep duration using univariate and multivariable regression models, adjusting for a priori covariates of age, sex, number of chronic conditions, and depressive symptoms (defined as PROMIS Depression T-score > 55).
Results: A total of 709 participants were included in the analysis (mean age 52.3 ± 8.1; 62% female; 45% non-Hispanic White, 38% non-Hispanic Black, 8% Hispanic; 55% with ≥ 2 chronic conditions). The median sleep health score was 8 (IQR: 6-10), and 7.5% of participants reported short sleep duration. Compared to the least deprived neighborhoods, living in more deprived neighborhoods was significantly associated with poorer sleep health (high ADI: aβ [95% CI] = -1.52 [-2.01, -1.02], $p< 0.001$; moderate ADI: aβ [95% CI] = -0.74 [-1.22, -0.26], $p=0.002$) and higher risk of short sleep (high ADI: adjusted relative risk (aRR) [95% CI] = 3.44 [1.37, 8.62], $p=0.008$; moderate ADI: aRR [95% CI] = 3.85 [1.60, 9.26], $p=0.003$), after adjusting for covariates.
Conclusion: In this sample of middle-aged primary care patients, neighborhood deprivation was associated with poorer sleep health and insufficient sleep duration, which may contribute to neighborhood-level inequities in long-term health outcomes.

RACE AND SEX-SPECIFIC ASSOCIATIONS OF EXCESSIVE DAYTIME SLEEPINESS AND SUBJECTIVE COGNITIVE DECLINE IN A SAMPLE OF COMMUNITY-DWELLING OLDER-ADULTS

Anthony Briggs[1], Joshua Gills[1], Mark Bernard[1], Luisa F. Figueredo[2], Joanna Dominguez[1], Elizabeth Weisgerber[1], Fatou Barry[3], Elena Valkanova[4], Arlener Turner[5], Girardin Jean-Louis[6], Ricardo Osorio[2], Omonigho Michael Bubu[2]
[1] NYU Grossman School of Medicine, [2] Department of Psychiatry, New York University Grossman School of Medicine, [3] NYU, [4] University of South Florida, [5] University of Miami School of medicine, [6] University of Miami Miller School of Medicine

Introduction: Excessive daytime sleepiness (EDS) may serve as an early and potentially reversible risk factor for cognitive decline. Subjective cognitive decline (SCD) is a self-perceived decrease in cognitive abilities without any measurable evidence of objective cognitive impairment. SCD is associated with Alzheimer's disease (AD) biomarkers. We examined the association between EDS and SCD in a diverse sample of community dwelling older adults stratified by sex and race.
Methods: Cross-sectional analysis of data from 186 community-dwelling healthy older-adults (n = 103 whites, n = 83 blacks) participating in various NYU studies on sleep, aging and memory. EDS and SCD were characterized using the Epworth Sleepiness Scale (ESS) and Cognitive Change Index (CCI) questionnaire, respectively. AD biomarkers were assessed in plasma and included ptau181, and aβ42. Linear mixed effects models controlling for age, sex, race, aβ42, and ptau181, examined a main association of ESS with CCI values. Interactions between ESS*race, and ESS*sex on CCI were also examined.
Results: Participants were on average 72.7±6.5y of age, 68.8% female, 44.6% Black/African American, had 16.6±2.2y of education, had an ESS of 4.2±3.7) (score range: 0 – 24; ≥11 is suggestive of EDS), and 407.0±85.6 minutes of total seep time. Mean (SD) for CCI was 27.8 (8.69) [no complaints 20 and maximum complaints 100). In adjusted main effect models, ESS, Sex and Race were independently associated with CCI β[95% CI};β[ESS] =1.17 [-0.69-1.27], $p < 0.001$); β[Sex] =6.24 [-6.34 – 3.64], $p < 0.01$), and β[Race] =-3.64 [-0.22 – 0.20], $p < 0.05$), respectively. Males and Whites were more likely to report subjective cognitive concerns relative to females and Black/African Americans, respectively. Race by ESS interaction with CCI was significant, β [Race*ESS] = -1.37 [-0.08-0.14], $p <.05$). Blacks with lower ESS values were less likely to report subjective memory concerns. We found no sex by ESS interactions.
Conclusion: In this non-sleepy, cognitively healthy diverse sample of community dwelling older adults, EDS scores were associated with SCD. Race and sex-specific associations were also observed, thus suggesting that EDS scores may represent an early marker of cognitive decline and useful for examining racial and sex differences in early onset AD risk

FOOD INSECURITY AND SLEEP AMONG COLLEGE STUDENTS IN A PUBLIC UNIVERSITY SYSTEM

Suzanna Martinez[1], Sonali Singh[1], Sevan Kalaydjian[2], Michael Grandner[3]

[1] UCSF School of Medicine, [2] UC Irvine, [3] University of Arizona College of Medicine

Introduction: Recent studies have documented alarmingly high levels of food insecurity (FI) among college students, with FI being associated with insufficient sleep. College campuses have quickly responded by establishing campus food pantries. It is unknown whether food pantries can improve sleep while experiencing food insecurity.
Methods: Online survey data were collected from a cross-sectional sample of 1,599 college students who used Basic Needs Centers in the 10-campus UC system. Students were asked to report their number of visits to a food pantry in the past month, and to rate their sleep sufficiency (never to always). Demographic characteristics were obtained from institutional data. Using a multiple variable regression, we examined food insecurity and campus food pantry use (at least 1/mo) in relation to sleep sufficiency controlling for demographic factors.
Results: Students on average were 23.44 years old (SD= 35.67), and 70% female. Almost one third (28%) had "enough sleep to feel rested" in the last 3 months. Of students who used the CFP, 20% used it 1-3 times in the last month, and 29% used at least 4 times. Preliminary results show that food insecurity was related to obtaining less sufficient sleep (β= -18.1, $p < 0.001$).
Conclusion: Food insecurity was associated with obtaining insufficient sleep among students attending a state university system, whereas CFP use showed no association. These findings highlight the critical need address to food insecurity as a factor that may hinder sufficient sleep.

PREDICTED AGE FROM SLEEP AND ACTIGRAPHY FEATURES: INSIGHTS FROM MACHINE LEARNING REGRESSION

Sebastian Moguilner[1], Shahab Haghayegh[2], Kun Hu[3]

[1] Harvard Medical School, [2] Massachusetts General Hospital/ Harvard Medical School, [3] Massachusetts General Hospital/ Harvard Medical School

Introduction: Advanced wearable technologies allow non-invasive ambulatory monitoring of physiological outputs/functions, including movement, sleep, and heart rate, all of which are changing with aging. The goal of this study is to test whether these ambulatory physiological measures can be integrated to better predict age using machine learning.
Methods: We analyzed the datasets of 22 healthy male adults between 20-40 years old (chronological age) in the Multilevel Monitoring of Activity and Sleep in Healthy People (MMASH) database. Using movement, sleep, and heart rate features derived from an accelerometer, inclinometer, and PPG sensors. A Lasso regression model was used to predict chronological age. The model was trained on standardized features over 1,000 bootstrap iterations (each sampling 90% of the data for training with replacement) to provide robust chronological age estimates in test sets.
Results: The Lasso regression model achieved high performance in predicting age ($p < 0.001$) with an averaged R-squared value of 0.502 that is compared to the values achieved using brain activity data (fMRI) in large, diverse populations. The most important features that predicted age include (1) vector movement derived from raw acceleration data expressed in Newton-meter, (2) sleep efficiency (percentage of sleep time on total sleep in bed), (3) mean heart rate, (4) maximum heart rate across the 24 h, and (5) time duration of standing.
Conclusion: This study demonstrates the effectiveness of machine learning regression in predicting age using ambulatory data from wearables. The performance should be validated in larger populations across a wider age range and in females.

COMMON INADEQUATE SLEEP HEALTH BEHAVIORS AND ITS IMPACT ON INSOMNIA SYMPTOMS IN A NON-CLINICAL POPULATION IN KOREA

Jee Hyun Kim[1], Inho Yoon[2], Dongyeop Kim[3], Hye Ah Lee[4]

[1] Ewha Womans University Seoul Hospital, Ewha Womans University College of Medicine, [2] Department of Neurology, Ewha Womans University Seoul Hospital, [3] Department of Neurology, Ewha Womans University Seoul Hospital, Ewha Womans University College of Medicine, [4] Clinical Trial Center, Mokdong Hospital, Ewha Womans University

Introduction: This study examined the sleep hygiene status and inadequate sleep health behaviors in a non-clinical population in Korea, using the Korean Sleep Hygiene Practice Scale (SHPS-K) to investigate common inadequate sleep behaviors in different age groups and sex.
Methods: We recruited non-clinical adults (aged 18-65) without a history of neurologic, psychiatric, or medical disorders and diagnosed sleep disorders. An online survey was done using the SHPS-K, Pittsburgh Sleep Quality Index (PSQI-K), Insomnia Severity Index (ISI-K), and Epworth Sleepiness Scale (KESS). 484 participants were enrolled (242 women, mean age of 43.8 □ 12.77 years). The detailed answers for each item of the SHPS-K were analyzed between age groups, sex, and groups with and without insomnia symptoms (ISIS-K □ 15). Using receiver operating characteristic analysis in different age groups, we also determined the cutoff values that could identify poor sleepers with insomnia symptoms (PSQI-K > 5 and ISI-K □ 15).
Results: The average total SHPS-K score was 71.2, with no sex difference. Mean ISI-K, PSQI-K, and KESS were not different between sex and age groups. The older participants had lower SHPS-K than the younger groups, with a significant trend for ages ($p < 0.001$). This trend was significant in both men and women. The most frequent inadequate sleep hygiene behaviors were doing irrelevant activities in bed, lack of regular exercise, sleep-in on weekends, staying in bed after waking up in the morning, lack of exposure to light during the day, and inconsistent bedtime. Men had poorer eating and drinking behaviors and complained of noise or light more than women. Women had poorer sleep scheduling and timing behaviors than men. Young adults with insomnia symptoms showed the highest SHPS-K than other age groups with insomnia ($p < 0.001$).

Conclusion: This study showed that sleep-disturbing behaviors were different between age groups and sex. The group with insomnia symptoms showed worse sleep hygiene practices. Furthermore, young adults had significantly worse sleep hygiene than middle-aged or older adults. Sleep hygiene education could contribute differentially to improving sleep quality in non-clinical populations.

MULTIDIMENSIONAL SLEEP HEALTH PROFILES BASED ON RU-SATED SCORES REPLICATE ACROSS TWO INDEPENDENT SAMPLES

Rachel Conlon[1], Margaret Kuzemchak[2], Lan Yu[2], Daniel Buysse[1], Meredith Wallace[2]

[1] University of Pittsburgh School of Medicine, [2] University of Pittsburgh

Introduction: Multidimensional sleep health patterns relate to general health and functioning. We developed the Ru-SATED 4.0 Multidimensional Sleep Health (MDSH) Scale, a self-reported measure of individuals' Regularity, Satisfaction, Alertness, Timing, Efficiency, and Duration of sleep over the past month. In the present study, we applied clustering techniques in two separate samples to uncover subgroups of participants with similar MDSH profiles.
Methods: The Ru-SATED 4.0 Scale was completed by participants recruited via: (1) YouGov.com (n=1,998; age=18-95y; Mage=49.6±17.2y; 53.1% women; 66.1% White, 10.7% Black, 11.9% Latinx, 7.5% Multiple racial/ethnic identities), and (2) the Sleep Science Panel from the Sleep Number Corporation (n=2,830; age=19-90y; Mage=52.8±16.5y; 54.6% women; 79.3% White, 6.2% Black, 4.0% Latinx, 5.9% Multiple racial/ethnic identities). Each Ru-SATED dimension was dichotomized into "good" (scores of "often" or "always") and "poor" (scores of "never," "rarely," or "sometimes"). Latent class analysis was used to identify subgroups with similar MDSH patterns in each sample. Secondary sleep measures related to duration, timing, and efficiency were calculated from the Pittsburgh Sleep Quality Index self-report questionnaire among YouGov participants and objective bed data from the past 7-28 days among Sleep Science Panel participants, and used in analyses to compare classes.
Results: In both the YouGov and Sleep Science Panel datasets, a 4-class model fit the data best, revealing the following classes: (1) "Great sleep across dimensions," (2) "Poor sleep across dimensions," (3) "Short, irregular, yet satisfying sleep," and (4) "Low sleep efficiency, low satisfaction." Membership in each class ranged from 10%–41% among YouGov participants and 21%–31% among Sleep Science Panel participants. Post-hoc ANOVAs confirmed significant differences among the 4 groups on secondary measures of sleep duration, timing, and efficiency in both samples (ps< 0.01).
Conclusion: These findings support distinct underlying groups based on Ru-SATED self-reported MDSH patterns, which were replicated across two independent samples of adults in the U.S, and confirmed by self-report and objective sleep data. Future research is warranted to understand how these sleep health profiles relate to other aspects of health and may support efforts to increase access to personalized, high-quality sleep medicine.

EXPLORING THE FREQUENCY AND IMPACT OF OBSTRUCTIVE SLEEP APNEA ON QUALITY OF LIFE IN CHILDREN WITH CYSTIC FIBROSIS: A PROSPECTIVE OBSERVATIONAL STUDY

Elizabeth Osei-Kuffuor[1], Aarti Shakkottai[2]

[1] UT southwestern, [2] University of Texas Southwestern

Introduction:: Obstructive sleep, a disorder characterized by recurrent episodes of partial or complete upper airway obstruction during sleep, has been associated with poor quality of life (QoL) among other detrimental sequelae. Cystic fibrosis (CF) is a chronic, life-limiting genetic condition that affects multiple organ systems including the respiratory and gastrointestinal system. Emerging data suggest OSA is common among children with CF however, the impact of comorbid OSA on their QoL is still unknown.
Methods: In this single-center, prospective observational study, children aged 2-8 years with CF and /or their caregivers were asked to complete a validated OSA screening tool and two disease-specific QoL measures
Results: Forty-two children with CF participated in our study. The mean age of the participants was 8.8 years with a standard deviation of 4.34. There was a slight male predominance at 52%. 12% of our participants were non-White and 6.4 % identified as Hispanic. 30.8% of the participants had public insurance. 50% of the participants were on highly effective modulator therapy (HEMT). 80.95% of our participants had a normal BMI and 11% were overweight/obese (overweight >/= 85%, obese >/=95%). Lung function was normal, on average, in our participants. 15% of the participants were found to be at high-risk sleep for OSA (proportion of positive responses >=0.33 on Pediatric Sleep Questionnaire-Sleep Disordered Breathing Disorder ScaleThe participants generally reported good quality of life (QoL), with an average score of 30.2 on the OSA-18. However, the average scaled score on the CF Questionnaire-Revised (CFQ-R) was 78.7, placing their QoL within the moderate range (scores between 60 and 80). Among those at high risk for OSA, the mean CFQ-R score was 75.1 and the mean OSA-18 was 50.6. The correlation coefficient between PSQ-SRBD and OSA-18 was 0.586 with a P value of 0.001 and that between PSQ-SRBD and CFQ-R was 0.130 with a P value of 0.51.
Conclusion: There appears to be an increased frequency of OSA symptoms among children with CF as compared to the general population. Having symptoms seems to adversely affect QoL in these patients. Larger studies are needed to further explore this relationship.

SLEEP-RELATED BREATHING DISORDERS IN SURGICALLY CORRECTED SINGLE VENTRICLE CONGENITAL HEART DISEASE PATIENTS

Jacob Pesachov[1], Danny Del Cid-Linares[1], Andrew Cheng[1], Iris Perez[1]

[1] Children's Hospital Los Angeles

Introduction: Sleep-related breathing disorders (SRBD) are increasingly recognized as significant comorbidities in pediatric patients with single ventricle congenital heart disease (SVCHD) who have undergone surgical correction. The impact of SRBD in these patients remains poorly understood. This study investigates the prevalence of SRBD in patients who have undergone the Fontan procedure.
Methods: We conducted a retrospective chart review of 54 pediatric patients with SVCHD who had undergone the Fontan procedure and had polysomnography (PSG) between 2000 and 2024. Data was abstracted from patients' most recent PSGs and included demographic characteristics, apnea-hypopnea indices (oAHI and CAI), end-tidal CO2 (ETCO2), and oxygen saturation metrics.
Results: The cohort's mean age at the time of PSG was 7.4 years ±4.8, with 67% male. 29/54 patients (54%) had OSA. 18/54 PSGs were performed pre- Fontan; 5 of which had PSG post Fontan. 36 patients (67%) had PSG post-Fontan only. Pre-Fontan cohort had 7 mild OSA, 1 moderate OSA and 1 severe OSA. Post-Fontan cohort including those who had pre-Fontan PSG had 17 mild OSA, 5 moderate OSA and 3 severe OSA. There was improvement in oAHI in 3/5 patients who had pre and post Fontan PSG. 2/54 patients had CSA (CAI ≥ 5/hr.) and none met criteria for hypoventilation (ETCO2 >50 mmHg for >25% of total sleep time). The average oxygen saturation (SpO2) was 89% ± 6.8.; average SpO2 nadir was 80.8% ± 7.9. SpO2 nadir of < 87% was seen in 61% of patients.
Conclusion: There was a high prevalence of SRBD in pediatric patients with SVCHD patients' post-surgical correction. Most patients demonstrated mild OSA. Our data suggest that early screening for SRBD in this population is essential.

UNDERSTANDING CEREBRAL HEMODYNAMICS IN PEDIATRIC OBSTRUCTIVE SLEEP APNEA WITH NEAR-INFRARED SPECTROSCOPY

Young Kim[1], Emily Yu[1], Lucy Block[1], Eileen Danieu[1], Patrick Sorenson[1], Timothy Quang[1], Brian Hill[1], Ashura Buckley[1], Bruce Tromberg[1]

[1] National Institutes of Health

Introduction: Pediatric obstructive sleep apnea (POSA) is concerning due to its links with cardiovascular, metabolic, and developmental health risks. While polysomnography (PSG) is the gold standard for diagnosing POSA, traditional OSA markers, like the apnea-hypopnea index (AHI), are not tailored to pediatric populations and do not fully address the impact of OSA on brain health. Understanding the effects of POSA on the brain is crucial for identifying potential neurocognitive impairments and long-term consequences. Near-infrared spectroscopy (NIRS) techniques can provide cerebral hemodynamics non-invasively by using light to probe tissue oxygenation. Cerebral hemodynamic oscillations, linked to autoregulatory mechanisms such as vasomotion and the glymphatic system, could enhance our understanding of POSA's cerebral effects.
Methods: We assessed the feasibility of measuring cerebral hemodynamics with a smartphone-compatible NIRS device in 60 pediatric patients (ages 3-12) with normal and affected sleep. Participants underwent a routine PSG sleep study with NIRS probes placed on the forehead and forearm. We calculated and compared metrics including respiratory rate (RR), heart rate (HR), and area under the curve (AUC) for very-low (VLFO) and low-frequency oscillations (LFO) across patients with different apnea severities from the NIRS data.
Results: NIRS-derived values of HR and RR were representative of PSG-measured values (r = 0.916 ± 0.05). Increased

severity of sleep apnea, as measured by AHI, was associated with stronger LFOs and VLFOs (r = 0.187, p=0.28; r =.35, p=0.038). These frequency ranges are known to be linked with compensatory mechanisms for vasomotion and autoregulation of cerebral blood flow. Higher AHI scores correlated with a more pronounced presence of these oscillations, suggesting that disrupted sleep patterns in pediatric obstructive sleep apnea may impact cerebral hemodynamics.
Conclusion: This study demonstrates the feasibility of assessing cerebral hemodynamics with a portable, smartphone-compatible NIRS in pediatric sleep disorder patients, offering insights into the cerebral effects of pediatric obstructive sleep apnea. These findings suggest that NIRS could be a valuable, accessible adjunct for investigating the physiological impacts of sleep apnea in children, with potential for wider clinical application.

ADHD AND VIGILANT ATTENTION AMONG SLEEP-DISORDERED BREATHING CHILDREN

Qinye Zhu[1], Hiroo Wada[1], Yuito Ueda[1], Yoshihito Kameda[1], Ai Ikeda[2], Takeshi Tanigawa[1]
[1] Department of Public Health, Juntendo University Graduate School of Medicine, [2] Juntendo University

Introduction: This study aimed to investigate the associations between vigilant attention and ADHD symptom and emotional and behavioral characteristics among children at high risk for sleep-disordered breathing (SDB).
Methods: Data were collected from 808 children (61.6% boys) identified as being at high risk for (SDB based on parent-reported symptoms, including snoring, apnea, or struggling to breathe during sleep. A type-3 portable sleep monitor was used to measure the oxygen desaturation index (ODI). ADHD symptoms, including inattention and hyperactivity-impulsivity, were assessed using the ADHD Rating Scale-IV. Emotional and behavioral characteristics were evaluated using parent-reported questionnaires. Vigilant attention was measured using a 10-minute Psychomotor Vigilance Test (PVT), focusing on response speed, lapses, and false starts. Generalized linear models were employed to analyze the relationships between ADHD symptoms, emotional and behavioral characteristics, and PVT metrics, adjusting for covariates such as grade, BMI z-score, ODI, hay fever, nasal congestion, and sleep duration.
Results: Among boys, inattention was significantly associated with slower response speed (β = -0.02, p = 0.01), increased lapses (β = 0.03, p = 0.02), and more false starts (β = 0.01, p = 0.02). Hyperactivity-impulsivity was linked to increased lapses (β = 0.024, p = 0.02) and more false starts (β = 0.02, p < 0.001). For girls, inattention was associated with increased lapses (β = 0.04, p = 0.01), while hyperactivity-impulsivity was linked to a higher number of false starts (β = 0.04, p < 0.01). Emotional and behavioral characteristics, such as situational anxiety, being easily frightened, and restlessness, were associated with slower response speed (β = -0.22, p < 0.01; β = -0.15, p = 0.02; β = -0.16, p = 0.03) and increased lapses (β = 0.01, p < 0.01; β = 0.18, p = 0.02; β = 0.48, p = 0.02) in boys. For girls, deliberation was linked to faster response speed (β = 0.28, p < 0.01) and fewer false starts (β = -0.05, p = 0.01).
Conclusion: The findings highlight sex differences in how ADHD symptoms and emotional-behavioral characteristics relate to vigilant attention in children at risk for SDB, emphasizing the need for sex-specific approaches in assessment and management.

SLEEP-DISORDERED BREATHING IN CHILDREN AND ADOLESCENTS WITH NOCTURNAL ENURESIS

Laura Miller[1], Adam Cieciuch[1], Isaac Nakamura[1], Monir Hossain[1], Narong Simakajornboon[1]
[1] Cincinnati Children's Hospital Medical Center

Introduction: Nocturnal enuresis (NE) is a common pediatric condition. Previous studies have shown the association between OSA and NE. The underlying mechanism may be related to disruptions of sleep and increased sympathetic activation which may impair arousal from sleep. However, it is unclear whether primary or secondary NE is more likely to be associated with OSA. Therefore, this study aimed to investigate this issue.
Methods: We conducted a retrospective study of pediatric patients with NE who were referred to our sleep center and underwent diagnostic study at Cincinnati Children's Hospital from January 2005 to September 2024. Patients were divided by NE type and age group (< 12 and ≥12 years old). Exclusion criteria included tracheostomy, ventilator dependence, and neurogenic bladder. OSA was defined by obstructive AHI >1.5/hr. Statistical comparisons between primary and secondary NE were performed by Chi-square for categorical variables and by Mann-Whitney test for continuous variables.
Results: 138 patients, aged 4-20 years old, met criteria for entry into analysis; 64.1% had primary NE, 35.9% had secondary NE. There was no difference in the age between primary[P] and secondary[S] NE (10.4±3.7 yo [P] vs 9.5±3.6 yo [S]; P=NS). For prevalence of OSA, there were no differences in the prevalence of OSA (61.9%[P] vs 60.0%[S]; P=NS) and percentage of mild, moderate and severe OSA between the two groups. For PSG parameters, there were no differences in the sleep efficiency, percentage of sleep stages (N1, N2, N3, REM), AHI or obstructive AHI (6.5±19.2/hr[P] vs 4.6±8.7/hr[S]; P=NS) between primary and secondary NE. Sub-group analysis of children (< 12) and adolescents (≥12) revealed no significant differences in the prevalence of OSA and PSG parameters in either age group.
Conclusion: Our study shows a high prevalence of OSA in our cohort of patients with NE who were referred to pediatric sleep clinics. Interestingly, there were no significant differences in the prevalence and severity of OSA between primary and secondary NE in both children and adolescents. These findings emphasize the need for comprehensive screening of OSA in both primary and secondary NE. Further studies are needed to assess the impact of OSA treatment on outcomes in children with NE.

DISCREPANCIES IN CAREGIVER-REPORTED AND LABORATORY-ASSESSED EARLY CHILDHOOD SLEEP PROBLEMS

Brizhay Davis[1], Gabriel Steinberg[2], Eberechukwu Uwah[1], Olivia Cicalese[1], Wanjiku Njoroge[1], Tiffani Johnson[3], Darko Stefanovski[4], Arun Handa[1], Ignacio Tapia[5], Rebecca Waller[2], Jodi Mindell[6], Ariel Williamson[7]

[1] Children's Hospital of Philadelphia, [2] University of Pennsylvania, [3] Department of Emergency Medicine, University of California-Davis, [4] University of Pennsylvania School of Veterinary Medicine, [5] University of Miami Miller School of Medicine, [6] Saint Joseph's Univeersity, [7] The Ballmer Institute for Children's Behavioral Health, University of Oregon

Introduction: Sleep disordered breathing (SDB) and insufficient sleep are common in early childhood and linked to neurobehavioral functioning, highlighting the importance of screening for these sleep problems. However, few studies have examined variation in multi-method evaluations of these concerns. This study compared caregiver-reported symptoms of child SDB and sleep duration to subsequent polysomnography (PSG) and actigraphy.
Methods: Data from 95 3-5-year-olds (43% boys, 49% Black, 51% Non-Latine White; 96% maternal caregiver) were drawn from a larger study. Caregivers reported on symptoms of child SDB using the Pediatric Sleep Questionnaire (PSQ) and on insufficient sleep using the Brief Child Sleep Questionnaire (BCSQ). Preschoolers were initially categorized into 4 groups based on measure cut-offs and sleep duration guidelines: (A) SDB only (PSQ score □0.33 clinical cut-off, total 24-hour sleep duration >=10 hours); (B) insufficient sleep only (PSQ < 0.33, total sleep duration < 10 hours); (C) both SDB and insufficient sleep (PSQ □0.33, total sleep duration < 10 hours); (D) no sleep problems. Children then completed PSG scored according to diagnostic guidelines and # nights/weeks of actigraphy scored using validated procedures with daily sleep diaries.
Results: Based on initial caregiver-report, 29 (31%) preschoolers had SDB only (A); 10 (11%) had insufficient sleep only (B); 13 (14%) had both SDB and insufficient sleep (C); and 43 (45%) had no sleep problems (D). After PSG/actigraphy, 62% were reassigned from their initial caregiver-reported group. Twenty-one percent were reassigned based on PSG results only, 27% reassigned based on actigraphy only, and 14% reassigned based on both actigraphy and PSG. Initially, based on caregiver-report, the largest group (45%) were the no sleep problem group (D). However, after PSG and actigraphy, the no sleep problem group (D) only reflected 21% of the sample. Importantly, after PSG and actigraphy, the group reflecting co-occurring SDB and insufficient sleep (C) increased from 14% to 38% of the sample.
Conclusion: Early childhood sleep-disordered breathing and insufficient sleep may be underrecognized when based on caregiver report compared to more objective measures. Additional multi-method studies with early childhood samples may be needed to re-evaluate caregiver report-based clinical cutoffs for sleep issues in young children.

IT RUNS IN THE FAMILY: A REVIEW OF OBSTRUCTIVE SLEEP APNEA IN PEDIATRICS' AND THE PREVALENCE OF SUCH IN BIOLOGICAL FAMILY

Emily Ethridge[1], April Scribner[1], Kristi Pruss[1], Supryia Jambhekar[1], Beverly Spray[1], Denise Willis[1]
[1] Arkansas Children's Hospital

Introduction: While previous studies have established a familial link to obstructive sleep apnea (OSA), prevalence of family members using positive airway pressure (PAP) for OSA among children who also require PAP is unclear. This study explored the relationship between children requiring PAP and family members who also utilize PAP, as well as the association of obesity.
Methods: Caregivers of children utilizing PAP therapy were invited to complete a family history questionnaire. Adopted children or those with unknown familial history were excluded. Statistical analysis assessed the relationship between children with OSA on PAP therapy and familial PAP usage. The correlation of PAP use, BMI, and self-reported weight status of relatives were also explored.
Results: These are limited results. We are conducting further analysis on the data to examine OSA in other family members and explore correlations of PAP use and obesity across groups. Data from 200 children with OSA were analyzed. The majority were male (63.5%) and 45.5% identified as White, non-Hispanic. The mean age was 10.4 years (SD=5.4). The mean BMI percentile was 89.2 (SD=21.3), and the median apnea-hypopnea index was 17.7 per hour (IQR: 10.7-36.5). Average PAP adherence (> 4 hours/night) in this group of children was 55.9% (SD = 33.3). Of the 200 children, 57 (28.5%) indicated that the father had OSA and 42 (21.0%) reported the mother had OSA. Additionally, 17 (8.5%) children had a sibling with OSA. Parental PAP adherence (>4hours/night) was 55.9% in fathers and 70.3% in mothers. Self-reported parental weight indicated that 30.0% of fathers and 40.5% of mothers were extremely overweight. Most parents reported nightly PAP use.
Conclusion: Based on very limited analyses, we conclude that a significant number of children with OSA have a parent with OSA. A large number of parents of children with OSA report being extremely overweight. While children wear PAP about half of the time, fathers and mothers reported slightly higher adherence rates. We are in the process of continuing further analyses to provide a clearer understanding of familial patterns of OSA and PAP usage.

Chan School of Public Health, [9] Department of Occupational and Environmental Health, University of Iowa College of Public Health, [10] Division of Allergy and Immunology, Boston Children's Hospital, Harvard Medical

School, [11] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Exposure to allergens has been shown to trigger inflammatory pathways contributing to sleep-disordered breathing (SBD) and fragmented sleep, specifically in children with atopic diseases. However, little is known about the relationship between indoor allergen exposure and sleep symptoms in children in the general population, or how several inflammatory-related health factors, such as asthma, allergic rhinitis, or obesity, contribute to this relationship. We investigated the associations between high indoor allergen concentrations, sleep quality dimensions, and SDB in children ages 6-12 years old living in predominantly low-income neighborhoods.
Methods: Bedroom dust aeroallergens were collected in participants' bedrooms. Outcomes were caregiver-reported sleep-related daytime impairment and sleep disturbance (pediatric PROMIS instruments), symptoms of SDB (AHI/ODI), and actigraphy based short sleep (< 8 hours) duration and poor sleep continuity (sleep fragmentation > 75th percentile). Logistic regression was used to examine associations between aeroallergens and sleep disturbances, adjusting age, sex, race, ethnicity, maternal education.
Results: The sample included 256 children (age 9.5 years; 41% Hispanic, 29% Black, 22% White, 8% Other; 43% female) with 27% reported maternal education attainment of a high school or less. 38% lived in disadvantaged neighborhoods (neighborhood Child Opportunity Index < 40). Mouse (Musm1), cat (Feld1), and dog (Canf1) allergens were detected in 81%, 72%, and 53% of households, respectively. Elevated mouse allergen exposure (>0.55 µg/g-75th percentile) was associated with a 2.6-fold (95%CI:1.34, 5.03) increased adjusted odds for sleep-related daytime impairment (PROMIS T-score > 55). This association persisted after adjustment for health factors (asthma, allergic rhinitis, obesity, and environmental tobacco smoke exposure), neighborhood disadvantage, and SDB. There was attenuation of this association with poor sleep consolidation and frequent awakenings. There were no associations with the other sleep outcomes or exposures.
Conclusion: Our results reveal that elevated mouse exposure was associated with increased sleep-related daytime impairment symptoms in children living in predominantly low-income neighborhoods. The mechanisms that link this association are not clear, however poor sleep quality explained some of this relationship. Strategies to reduce household exposure and improve air quality should be tested as approaches for reducing health disparities.

UNHEALTHY NEIGHBORHOOD CHARACTERISTICS AND OZONE EXPOSURE MAY INCREASE ADOLESCENT OSA

Hannah Pham[1], Clarissa Camarena[1], Julie Ryu[2], Kelan Tantisira[2], Rakesh Bhattacharjee[3], Jeremy Landeo Gutierrez[2]
[1] UC San Diego, [2] University of California San Diego, [3] University of California, San Diego

Introduction: The impact of modifiable exposures at the neighborhood level on adolescent obstructive sleep apnea (OSA) is not well understood. Publicly available tools that quantify environmental exposures can be leveraged to study their influence on OSA. Hypothesis: adolescents with moderate-severe OSA undergoing polysomnography (PSG) more likely reside in neighborhoods with less healthy characteristics, based on the Healthy Places Index (HPI) criteria.
Methods: Retrospective review of 11 to 18 years olds who underwent PSG at Rady Children's Hospital (October 2016-April 2022). Exclusion criteria: craniofacial, chromosomal, and neuromuscular disorders. Age, sex, BMI percentile (BMIp) were obtained. Moderate-Severe OSA was defined as OAHI>5 events/hour. The HPI Percentiles (HPIp) is a tool developed by the Public Health Alliance of California that provides zip-code based data of social and environmental factors of health. Statistical analyses included chi-square, parametric, and non-parametric tests. Logistic regression was used to model the odds of moderate-severe OSA and relevant predictor variables (HPI, ozone, and PM 2.5).
Results: 1745 adolescents with a mean age of 14.1±2.1 years were included, 56.1% were males. 58.2% Hispanic, 24.1% Non-Hispanic(NH)-Whites, 4.3% NH-Asians/Pacific Islander, 4.2% NH-Blacks/African American, and 6.6% NH-Other. Adolescents with moderate-severe OSA had higher age (mean 14.42 [2.13] vs mean 13.98 [2.12], p-value< 0.05), higher proportion of male sex (67.7% vs 49.1%, p-value< 0.001), and higher BMIp (median 98.60 [94.35-99.40] vs median 93.40 [71.25-98.30], p-value< 0.05) compared to adolescents with no-to-mild OSA. Furthermore, adolescents with moderate-severe OSA reside in neighborhoods with lower HPIp (mean 0.42 [0.24] vs 0.48 [0.23], p-value< 0.05) and higher ozone percentiles (median 0.64 [0.47-0.70] vs 0.61 [0.44-0.68], p-value< 0.05) with greater proportion in the upper tertile of ozone levels (37.8% vs 30.5%, p-value< 0.05). On logistic regression analysis, each 1 percentile increment in HPI was associated with 1% decreased odds (OR:0.98,0.99) of mod-severe OSA, and residing in a zip-code in the upper tertile exposure to ozone was associated with 28% excess odds of moderate-severe OSA, after adjusting for age, sex, and BMIp.
Conclusion: In a sleep laboratory population, adolescents with severe-moderate OSA more likely resided in overall less healthy communities and with higher ozone exposures.

DECREASED CHILDHOOD OPPORTUNITY IS ASSOCIATED WITH HIGHER OSA SEVERITY AMONG ADOLESCENTS UNDERGOING POLYSOMNOGRAPHY

Clarissa Camarena[1], Hannah Pham[1], Julie Ryu[2], Kelan Tantisira[2], Rakesh Bhattacharjee[3], Jeremy Landeo Gutierrez[2]
[1] UC San Diego, [2] University of California San Diego, [3] University of California, San Diego

Introduction: Adolescent Obstructive Sleep Apnea (OSA) and its relation to neighborhood childhood opportunity has not been explored. The Child Opportunity Index (COI) measures children's neighborhood-level conditions and resources. We hypothesize that Moderate-Severe OSA in adolescents undergoing polysomnography (PSG) is higher in those residing in neighborhoods with lower opportunity (COI).
Methods: Retrospective review of adolescents 11 to 18 years old who underwent PSG at Rady Children's Hospital between October 2016 and April 2022. Exclusion criteria: craniofacial and chromosomal anomalies, and neuromuscular disorders. Age, sex, body mass index (BMI) percentile were obtained.

Moderate-Severe OSA was defined as OAHI>5 events/hour. Statistical analyses included chi-square tests, two sample t tests and non-parametric tests. Logistic regression was used for analysis of Moderate-Severe OSA and relevant predictor variables (COI z-scores and its subsets: education (ED), health and environment (HE), social and economic (SE).
Results: 1745 adolescents were included. Adolescents with Moderate-Severe OSA were older compared to the No-Mild OSA group (14.4 vs 13.9, p-value < 0.001) and were a higher proportion of male sex (67.7% vs 32.3%, p-value < 0.001). The cumulative COI z-scores were lower in the Moderate-Severe OSA group compared to the No-to-Mild OSA group (-0.001 [0.02] vs 0.004 [0.02], p-value <.05). Those with moderate-severe OSA had a lower COI SE z-score (-0.03 [0.11] vs -0.004 [0.12], p-value <.05), lower COI HE z-score (0.022 vs 0.026, p-value <.001) and lower COI ED z-score (0.002 [0.06] vs 0.019 [0.07], p-value <.05) compared to the No-to-Mild OSA group. Logistic regression identified that each 0.01 z-score increase in COI global, COI-SE, COI-HE and COI-ED were associated with an OR=0.93(0.89, 0.98), OR=0.99(0.98, 0.99), OR=0.93(0.89, 0.98) and an OR=0.98(0.96, 0.99) of moderate-severe OSA, respectively, after adjusting for age, sex and BMI.
Conclusion: In a sleep laboratory adolescent population, we identified higher rates of Moderate-Severe OSA in those residing in neighborhoods with lower Child Opportunity Index scores, and across all three domains of the COI tool. Future studies should further identify drivers of increased OSA in the neighborhood levels.

CLINICAL PROFILE OF CHILDREN WITH VERY SEVERE OBSTRUCTIVE SLEEP APNEA

Haania Rizwan[1], Noman Baig[2], Nada Youssef[2], Alan Schwartz[2], Pranshu Adavadkar[2]

[1] The Aga Khan University, [2] University of Illinois at Chicago

Introduction: There is a dearth of literature on very severe obstructive sleep apnea (OSA) (apnea-hypopnea index [AHI] ≥ 75/h) in the pediatric population. We aim to describe the demographics, clinical presentation, and treatment outcomes of this cohort.
Methods: This IRB-approved retrospective cohort study involved a chart review of all pediatric patients who had an AHI ≥ 75/h on PSG performed between September 2014 and January 2024 at a single urban academic institution. Data on demographics, clinical features, and treatment outcomes were collected. Descriptive and correlation analyses were performed to characterize this cohort and explore the relationship between clinical variables and AHI, and treatment outcomes.
Results: The cohort included 32 children (mean age 11.8 years, 75% male, 46.9% African American, 31.3% Hispanic). Common comorbidities were obesity (90.6%, mean BMI 96.5th percentile), asthma (40.6%), and atopic disorders (28.1%). Only 6 were syndromic. Snoring was the most prevalent symptom (96.9%) followed by excessive daytime sleepiness and witnessed apnea (78.1% each). Most had high Mallampati scores of 3/4 (83.3%) and tonsillar hypertrophy 3/4 (62.5%), though 6 had absent tonsils. The mean AHI was 95.6/h (98.2/h supine, 79.4/h non-supine), oxygen nadir was 65.3%, and SpO2< 90% was for 67.1min. Seven had a central apnea index >5/h, 2 met criteria for sleep-related hypoventilation, and 8 had periodic limb movements of sleep index >5/h. Most clinical features were not associated with higher AHI or response to adenotonsillectomy. Fourteen received adenotonsillectomy, 3 CPAP, 8 both, and 7 no therapy due to lack of follow-up. Adenotonsillectomy improved PSG parameters with a mean AHI reduction of 73.3/h.
Conclusion: Our study demonstrates that the majority of children with very severe OSA were non-syndromic, mostly obese, and from ethnic minorities, suggesting the need for a proactive approach and lower threshold for OSA evaluation in this cohort. Clinical features have limited utility in predicting the severity of OSA in this extreme group. Lack of treatment due to loss to follow-up in such severe OSA cases highlights the need for closer follow-up. Further studies are needed to examine factors contributing to the disproportionate prevalence of severe OSA among ethnically minority children.

ASSOCIATION WITH SEVERITY OBSTRUCTIVE APNEA (OSA) WITH ELEVATED BLOOD PRESSURE AMONGST A PEDIATRIC POPULATION

Powen Hsueh[1], Julie Ryu[2], Rakesh Bhattacharjee[3]

[1] Southwest Healthcare Medical Education Consortium/ Temecula Valley Hospital, [2] University of California San Diego, [3] Division of Pulmonary Medicine, Department of Pediatrics, University of California San Diego/Rady Children's Hospital

Introduction: The prevalence of pediatric hypertension has risen from 1.1% in 2004 to 6% in 2019, driven largely by increasing childhood obesity. As obesity is a key risk factor for obstructive sleep apnea (OSA), we hypothesize that OSA in children is associated with elevated blood pressure in a pediatric sleep clinic population.
Methods: Retrospective chart review of pediatric patients who underwent polysomnography and evaluation at Rady Children's Hospital between January 2019 and December 2024. Demographic data included sex, age, BMI, ethnicity, and systolic (SBP) and diastolic (DBP) blood pressure percentiles(%). Polysomnography determined the obstructive apnea-hypopnea index (OAHI), with OSA severity classified as follows: no OSA (OAHI < 1/hour), mild OSA (OAHI 1–5/hour), moderate OSA (OAHI 5–10/hour), and severe OSA (OAHI >10/hour). Exclusion criteria included craniofacial, cardiac, pulmonary, and neuromuscular abnormalities. Blood pressure percentiles were calculated based on NHLBI pediatric blood pressure guidelines, with hypertension defined as SBP or DBP at or above the 95th percentile for age, sex, and height.
Results: 484pediatricsubjects(meanage:10.8±4.3years,37.6%female) were evaluated. Ethnicity distribution included 214(44.3%) non-Hispanicand261(53.9%)Hispanic.Mean±SDSBP%andDBP%byOSA severity were as follows: no OSA(n=45): 0.786±0.236/0.677±0.225; mild OSA(n=229): 0.792±0.232/0.700±0.214; moderate OSA(n=106): 0.801±0.208/0.725±0.222; and severe OSA(n=104): 0.893±0.151/0.772±0.222. SBP% was significantly higher in severe OSA compared to all other severities (p< 0.05), while DBP% was significantly higher in severe OSA compared to mild OSA (p< 0.05) and borderline compared to no OSA (p=0.07). Only SBP% significantly correlated with OAHI (p< 0.05). The OAHI trended higher in children with hypertensive BP measurements compared to those without (8.89±15.5 vs. 5.96±10.6, p=0.063). Multivariate regression

analysis, adjusted for age and BMI, revealed that OAHI was not significantly associated with either SBP% or DBP%.
Conclusion: The findings demonstrate that BP increases with OSA severity in a pediatric sleep clinic population. While the association between OAHI and BP was not independent of age and BMI, children with severe OSA are more likely to have elevated BP and a trend toward hypertension, emphasizing the need for targeted BP screening and management in children with greater OSA severity.

POLYSOMNOGRAPHY, COMORBIDITIES, AND PERIOPERATIVE COMPLICATIONS IN PEDIATRIC TONSILLECTOMY AND ADENOIDECTOMY

Megan Wilson[1], Baylee Polzin[1], Lilah Kahloon[1], Keenya Frazier[1], Rory Young[2], Elizabeth Cash[3], Egambaram Senthilvel[4], Swapna Chandran[3]

[1] University of Louisville School of Medicine, [2] University of Louisville School of Medicine/Department of Otolaryngology, [3] University of Louisville Department of Otolaryngology, [4] University of Louisville Department of Pediatrics, Division of Sleep Medicine

Introduction: Obstructive sleep apnea (OSA) is the most common indication for adenotonsillectomy (T&A) in the pediatric population. Though polysomnography (PSG) is the gold standard for OSA diagnosis, the role PSG findings, patient comorbidities, and their interactions play in predicting perioperative events remains unclear. The aim of this study is to evaluate the correlation between preoperative PSG findings, patient comorbidities and specific perioperative events.
Methods: This was a single center retrospective study involving children under 18 years of age undergoing T&A. Bivariate correlation and one/two-way ANOVA analyses were conducted.
Results: A total of 207 patients were included, with a mean age of 6.32 years, 62.4% male, and 33.3% obese. Elevated AHI correlated with increased ICU time (r=0.310,p< 0.001) and prolonged return to PO intake (r=0.320,p< 0.001), with no significant association with time requiring supplemental O2 (r=0.156,p=0.058) or time requiring mechanical ventilation(r=0.104,p=0.156). Lower SaO2 nadir correlated with increased ICU time, supplemental O2 time, and prolonged return to PO intake (r=-0.322,-0.340,and -0.448, p< 0.001), but not time requiring mechanical ventilation (r=-0.14,p=0.864). ANOVA and descriptive statistics revealed prolonged return to PO intake was associated with the obese BMI class (F(3,140)=2.723,p=0.047), neuromuscular disorders (F(1,142)=7.629,p=0.007), and developmental delay (F(1,142)=7.200,p=0.008). Increased ICU time was associated with neuromuscular disorders (F(1,151)=7.221,p=0.008), cardiac risk factors i.e. structural heart disease (F(1,151)=10.307,p=0.002), and developmental delay (F(1,151)=8.245,p=0.005). Increased supplemental O2 time was associated with neuromuscular disorders (F(1,147)=14.887,p< 0.001), cardiac risk factors (F(1,147)=8.811,p=0.003) and developmental delay (F(1,147)=4.443,p=0.037). Increased time requiring mechanical ventilation was associated with the underweight BMI class (F(3,152)=8.026, p< 0.001). Two-way ANOVA showed elevated BMI class/cardiac risk factors produced a combined effect on time to PO intake (F=4.278,p=0.041), and neuromuscular disorders/cardiac risk factors produced a combined effect on supplemental O2 time (F=4.844,p=0.030).
Conclusion: Prolonged return to PO intake was significantly associated with elevated AHI, decreased SaO2 nadir, obese BMI class, neuromuscular disorders, and developmental delay. Increased time in the ICU was significantly associated with elevated AHI, decreased SaO2 nadir, neuromuscular disorders, developmental delay, and cardiac risk factors. Prolonged time requiring supplemental O2 was significantly associated with lower SaO2 nadir, neuromuscular disorders, developmental delay, and cardiac risk factors.

C-GASP SURVEY STUDY CORRELATES PEDIATRIC SLEEP / BEHAVIORAL DISORDERS WITH NARROW MAXILLARY TRANSVERSE 2ND PRIMARY INTER-MOLAR DISTANCE (BOGUE-INDEX)

Jerald Simmons[1], Kevin Boyd[2], William Harrel[3], Loria Nahatis[4], Sam Sadeghian[5], Mariana Burnier[1], Ashley Paige[1], Jeffrey Black[6], Benjamin Black[6], Steve Carstensen[7], Matthew Pingel[8]

[1] Comprehensive Sleep Medicine Associates, [2] Dentistry for Children, [3] Harrell Orthodontics/TMJD/Dental Sleep Medicine, [4] dental, [5] REST Technologies, Inc., [6] Sleep Education Consortium, [7] Center for TMJ & Sleep Solutions, [8] Granville Pediatric Dentistry

Introduction: There is growing evidence suggesting a relationship between childhood malocclusion compromising upper airway dynamics and poor sleep, daytime dysfunction, ADHD behaviors and daytime sleepiness. To date, literature is limited of studies supporting specific anatomic deficiencies (malocclusion phenotypes) in children as a contributing cause. Furthermore, screening tools that can be simply implemented on a large scale are lacking to identify those children at risk. The Children's Airway Screening Taskforce (CAST) sanctioned by the American Dental Association to address this issue developed the Children's General Airway Screening Protocol (C-GASP) which utilizes a 5 question survey as a frontline instrument for screening which is undergoing validation.
Methods: The 5 question C-GASP instrument addresses Air Pathway, Breathing Sounds, Sleep Activities, Morning Conditions and Daytime Function. Responses are entered digitally by guardians of sequential patients ages 2-12 presenting for routine dental / oral health care. Following completion of data entry, dental staff obtain specific oral metrics, which include a transverse measurement of the maxillary 2nd primary molar (A to J) distance known as the Bogue Index.
Results: To date 210 assessments have been completed. Of these 58 have C-GASP scores of 0 (normal group) and 152 have C-GASP Scores >0 (abnormal group), of which 31 has C-GASP Scores of 4 or 5. Only those with maxillary transverse molar (A to J) primary teeth measures available were included for this analysis. 36 normal Ave age 5.56 yrs (SD 2.5) 62% F, 21 abnormal w C-GASP >3, age 5.24 (SD 1.8) 38% F. T-Test between these groups demonstrated a t-statiscic:-2.99, p 0.0042.
Conclusion: These findings provide support that a narrow maxillary arch in children is associated with poor clinical conditions affecting sleep and daytime function. Observations described by E.A. Bogue, MD, DDS in the 1920's are now being supported by these findings. Further data acquisition is underway to provide validation of the C-GASP screening intake tool that can ultimately be implemented globally for screening children 2 to

12 to identify risk of OSA, allowing opportunity for corrective interventions.

IMPACT OF SICKLE CELL DISEASE MODIFYING THERAPIES ON PEDIATRIC SLEEP

Michelle Yoo[1], Shasha Bai[1], Tracy Huang[2], Grace Kalmus[3], Lindsey Abel[3], Carlton Dampier[1], Kirshma Khemani[1], Roberta Leu[1], Devon Greene[4], Snehal Vala[1], Benjamin Kopp[1]

[1] Emory University School of Medicine, [2] Emory University, [3] Children's Healthcare of Atlanta, [4] University of Tennessee College of Medicine

Introduction: Children with sickle cell disease (SCD) have a higher prevalence of sleep disturbances, adenotonsillar hypertrophy, and obstructive sleep apnea (OSA) than the general population. Disease-modifying therapies such as hydroxyurea, voxelotor, and crizanlizumab aim to prevent pain crisis and reduce complications of SCD. The impact of these disease modifying therapies on OSA and nocturnal hypoxemia remains unclear. We hypothesized that in children with SCD, those on disease modifying therapies will have higher nocturnal oxygen saturation, improved sleep quality, decreased prevalence and degree of OSA.

Methods: This was a retrospective chart review of 1125 polysomnogram (PSG) records from January 01, 2013 to July 31, 2023 from children with SCD aged 1-18 years at Children's Healthcare of Atlanta (n=701). Data including obstructive apnea-hypopnea index (OAHI), nocturnal oxygen desaturations, sleep efficiency and arousal index were collected. Demographic and clinical data collected included age, race, sex, SCD genotype, body mass index, medications for SCD, length of time on treatment, prior airway surgeries and number of annual hospitalizations for asthma, vaso-occlusive crisis, or acute chest syndrome.

Results: Hydroxyurea therapy was associated with higher NREM SpO2 (β = 1.43, p = 0.004) and REM SpO2 (β = 1.27, p = 0.01) compared to no therapy group in multivariable models. Despite this, children on hydroxyurea spent more time overall with SpO2 < 90% during sleep (3.07% vs. 1.69%, p = 0.01). Baseline SpO2 was significantly lower in the hydroxyurea group (96.21% vs. 96.79%, p = 0.006). AHI and other metrics, including sleep efficiency and arousal index, did not differ significantly between therapy groups. In longitudinal analyses, baseline SpO2 was persistently lower in the hydroxyurea group (p < 0.001), with greater percentage of sleep time spent with SaO2 < 90% (p = 0.03). There were no significant associations between hydroxyurea response groups and annual hospitalizations.

Conclusion: Patients on SCD disease-modifying therapies demonstrate higher oxygen saturation during REM and NREM sleep but persistent abnormalities including obstructive apneas, nocturnal oxygen desaturations, and decreased sleep efficiency. Underlying factors for persistent sleep abnormalities in children with SCD remain to be determined.

EFFECT OF SEMAGLUTIDE ON APNEA HYPOPNEA INDEX IN FEMALE ADOLESCENTS WITH POLYCYSTIC OVARY SYNDROME AND OBESITY

Karolina Bohdan[1], Cristina Giles[2], Allison Shapiro[2], Yesenia Garcia-Reyes[2], Jaclyn Lo[2], Nazeen Morelli[2], Meredith Ware[3], Melanie Cree[2], Stacey Simon[2]

[1] Children's Hospital Colorado, [2] University of Colorado Anschutz Medical Campus, [3] David Geffen School of Medicine at UCLA

Introduction: Polycystic ovary syndrome (PCOS) affects approximately 11% of female adolescents globally and is associated with obesity, obstructive sleep apnea (OSA), and long-term negative health consequences. Weight loss medications are emerging as a treatment for obesity and have been found to improve or resolve OSA in adults but this has not been evaluated in adolescents with PCOS. The aim of the current study was to examine change in apnea-hypopnea index (AHI) following semaglutide (SEMA) intervention compared to an intensive dietary control (DIET) in adolescents with PCOS and obesity.

Methods: Biological female adolescents ages 12-18 years with a diagnosis of PCOS and obesity, sedentary lifestyle (< 2h of moderate exercise per week), and BMI ≥90th percentile were randomized to 16 weeks of either 3/7 mg dosing of semaglutide or weekly counseling with a dietician. Assessments at baseline and post-treatment measured anthropometrics, insulin sensitivity (oral minimal model insulin sensitivity index; OMM Si), and AHI (WatchPAT). Student's t-test was applied to compare the change in AHI between intervention groups (SEMA v. DIET). Pearson correlations examined relationships between change in AHI, % weight loss, and OMM Si separately in each intervention group.

Results: A total of 55 participants were analyzed (SEMA N=38; DIET N=17). The mean age was 15.2±1.68 years, 6±10.90% Black, and 26±47.30% Hispanic. AHI was elevated at baseline across the sample (M=18.5±11.4). AHI decreased by -2.2±13.1 in the SEMA group and increased by 4.4±13.1 in the DIET group; however, this was not a statistically significant difference (p=>0.05). Change in AHI was not significantly correlated with percent weight loss or insulin sensitivity in either the SEMA or DIET groups (all p-value's >0.05).

Conclusion: In this sample of adolescents with PCOS and obesity, change in AHI was not statistically significant following weight loss intervention, however, those who had 4 months of SEMA showed a decrease in AHI while those in the dietary control condition increased AHI. Further research is needed in larger samples over longer study periods to examine the impact of weight loss medications on AHI in adolescents with PCOS and obesity.

SLEEP AND BREATHING: POSTSURGICAL OUTCOME IN CHILDREN WITH ACHONDROPLASIA

Joanna Lee[1], Katharina Graw-Panzer[2]

[1] NewYork-Presbyterian - Weill Cornell Medicine, [2] Weill Cornell Medicine

Introduction: Achondroplasia is the most common bone dysplasia in humans, occurring in 1/20,000 live births. Most patients with achondroplasia have concomitant sleep apnea and foramen magnum stenosis. This study examines the characteristics of sleep-disordered breathing in children with achondroplasia and determines how adenotonsillectomy and foramen magnum decompression surgery affect clinical outcome.
Methods: This is a retrospective chart review of patients seen at New-York-Presbyterian Hospital/Weill Cornell Medical Center between January 2013 and October 2024 who had polysomnography performed. Demographic information, comorbidities, polysomnography data, and surgical outcomes were collected. The severity of obstructive sleep apnea (OSA) was defined based on obstructive apnea-hypopnea index (OAHI): 1-4.9 mild, 5-9.9 moderate, 10 and above severe. Results are presented as Median (Q1, Q3). Analysis of pre- and post-variables was performed using the Wilcoxon test.
Results: 22 individual patients underwent polysomnography. 55% were female. 19% White/Caucasian, 19% Latino/Hispanic, 14% Black/African American, 14% Asian American. 91% had foramen magnum stenosis, and 55% had symptoms of sleep disordered breathing. Median number of polysomnography performed per patient was 2 (1, 5). 33% had undergone decompression surgery prior to the sleep study. Age at first study was 14 months (4.8, 41.3). The study showed no OSA in 18%, mild OSA in 27%, moderate OSA in 14% and severe OSA in 41% of patients. OAHI was 5.4 (1.6, 15.2) and central apnea index 0.7 (0.4, 1.5). 8 patients had polysomnography done pre and post adenotonsillectomy. All had foramen magnum stenosis and 4 had prior decompression surgery. Adenoidectomy and/or tonsillectomy was done at the discretion of the surgeon. All 8 patients had severe OSA before surgery and 6 had severe and 2 moderate OSA after surgery (OAHI pre 47.0 (20.1, 77.4), post 14.2 (7.55, 77.35), p-value 0.8). Decompression status was not significant. Postoperatively all patients required positive airway pressure (PAP) for sleep, 1 tracheostomy and 4 revision surgery.
Conclusion: Children with achondroplasia present with a very high rate of obstructive sleep apnea. Despite adenotonsillectomy and decompression surgery there is residual moderate-severe OSA requiring PAP as well as further surgeries. We are hopeful that new therapies for achondroplasia will change that outcome.

TIME TO THERAPY INITIATION FOR SEVERE OBSTRUCTIVE SLEEP APNEA IN CHILDREN

Swati Jayaram[1], Lauren Gironda[1], James Ruda[2], Sarah Cohen[1], Maninder Kalra[1]
[1] Division of Pulmonary and Sleep Medicine, Nationwide Children's Hospital, [2] Division of Otolaryngology, Nationwide Children's Hospital

Introduction: Obstructive Sleep Apnea (OSA) is associated with neuro-cognitive, cardiovascular, and metabolic morbidity in children, with those with severe OSA being at a higher risk. Timely initiation of appropriate therapy is key to reducing morbidity from severe OSA. This Quality Improvement project's goal was to perform a baseline evaluation of the time to initial therapy initiation in children with severe OSA at our institution as a first step to address barriers to timely intervention.
Methods: A chart review was completed for all patients diagnosed with severe OSA at Nationwide Children's Hospital sleep laboratory from January-September 2023. Severe OSA was defined as an AHI of ≥ 10 or greater, and urgent intervention was defined as therapy initiation within 48 hours.
Results: 216 patients met inclusion criteria with 51 children age < 1 yr., 13 children age ≥1 to < 2 yrs., and 152 children age ≥2yrs. Urgent intervention was taken in 75% (n=38) of children age < 1 yr., 38% (n=5) of children age ≥1 to < 2 yrs., and 13% (n=20) of children age ≥2 yrs. Intervention was completed within 14 days in 84% (n=43) of children age < 1 yr., 46% (n=6) of children age ≥1 to < 2 yrs., and 24% (n=37) of children age ≥2 yrs. Oxygen supplementation was the initial intervention in 86.5% (n=44) of children age < 1 yr., 38.4% (n=5) of children age ≥1 to < 2 yrs., and 6.5% (n=10) of children age ≥2 yrs. Positive airway pressure therapy was the initial intervention in 0.2% (n=1) of children age < 1 yr., 23% (n=3) of children age ≥1to< 2 yrs., and 51.3% (n=78) of children age ≥2 yrs. Surgical intervention in patients without prior adenotonsillectomy was completed in 21.5% (n=11) of children age < 1yr., 53.8% (n=7) of children age ≥1 to < 2 yrs., and 67.5% (n=73) of children age ≥2 yrs.
Conclusion: A multidisciplinary collaborative approach is important in timely initiation of management in children with severe OSA. The time to intervention and type of intervention selected differed across age groups. Barriers to timely intervention will be addressed in future projects using quality improvement methodology.

TIMING OF NON-INVASIVE POSITIVE PRESSURE VENTILATION INITIATION IN CHILDREN WITH SLEEP DISORDERED BREATHING WHO ARE NON-ENGLISH SPEAKERS

Mariana Bedoya[1], Rachel Ruppert[1], Emily Hahn[1], Cyndya Shibao[1]
[1] Vanderbilt University Medical Center

Introduction: Sleep-disordered breathing (SDB) affects 10-17% of children, and obstructive sleep apnea (OSA) occurs in 1-3%. The initiation of treatment in a timely manner is crucial to decrease the adverse outcomes of untreated SDB. Language and cultural differences might exacerbate health inequalities, which may contribute to delays in the diagnosis and management of OSA. This study aims to evaluate the time from the placement of non-invasive positive pressure ventilation (NIPPV) order in the electronic medical record to the initiation of treatment, and to compare if there is a time difference between English vs. Non-English speaker families.
Methods: A retrospective review was conducted on patients seen at the Pediatric Pulmonary and Sleep Clinic at Monroe Carell Jr. Children's Hospital at Vanderbilt, a national referral center for sleep disorders, from 2017 to 2024. We used non-parametric test (Mann Whitney U test) to evaluate for differences in time from order to NIPPV initiation between English and non-English speaker. In addition, a subset analysis was made of time from order to NIPPV initiation between severe and non-severe OSA. Severe OSA was defined using an obstructive apnea hypopnea index of ≥ 10/h.
Results: Complete data was available for 186 children, representing 50% of the total sample. The median time from order to NIPPV set up was 25.5 days (IQR 13 - 61.5) for the entire cohort. No significant difference was observed between English-speaking (24.5 days, IQR 12.8 - 50.3) and non-English-speaking families (28.5 days, IQR 13.8 - 69.0; P = 0.51). Similarly, time from order to NIPPV initiation did not differ significantly between children with severe OSA (23 days, IQR 12.0 - 40.5) and non-severe OSA (26 days, IQR 13.0 - 64.5; P = 0.34).

Conclusion: Our study found that at our institution, there is no significant differences in the time from order to NIPPV initiation based on language proficiency or OSA severity. Future direction is to expedite the initiation of NIPPV by identifying and addressing the challenges from the order placement to the start of NIPPV.

TIME TO FIRST POSITIVE AIRWAY PRESSURE FOLLOW UP VISIT IN CHILDREN WITH OBSTRUCTIVE SLEEP APNEA

Leah Berichon[1], Karen Annis[1], Amy Henderson[1], Alpa Patel[2], Maninder Kalra[2]

[1] Nationwide Children's Hospital, [2] Division of Pulmonary and Sleep Medicine, Nationwide Children's Hospital

Introduction: Positive airway pressure (PAP), a highly efficacious treatment for pediatric OSA, can be limited by adherence challenges. Patient education by respiratory therapists after PAP initiation have been shown to predict compliance with therapy. First few weeks after initiation have been identified as a critical timeframe to promote education and mitigate problems. The aim of this quality improvement project was to improve PAP patient initial follow up.
Methods: All children who were set up on PAP at Nationwide Children's hospital Sleep Center and followed up at Sleep clinic were included. Aim statement: The project will increase the % of new PAP patient seen within 60 days of therapy initiation from a baseline of 50% to a goal of 75% accomplish by Dec 30 th, 2024 and sustain for 1 year. Key Drivers: • Provider PAP clinic availability • Scheduler workflow • RT clinic staffing • Parent/Patient availability • Patient Compliance, therapy buy-in Interventions: • Provider template modification • Add on clinics for PAP patients • Scheduler/ RT meetings • Team chat group • RT schedule standardized at satellites • Follow up calls within 14 days of receiving machine
Results: A total of 132 patients were set up on PAP from Jan-October 2024. The baseline compliance of new PAP patient seen within 60 days of therapy initiation was 50% in Jan -June (N=64). July and August (N=35) compliance increased to 65%. Goal compliance was achieved in > 80% during September and October (N=33).
Conclusion: Our results indicate that process improvement in the pediatric sleep clinic using quality improvement methodology can be utilized to improve PAP patient follow up.

ADHERENCE TO CPAP THERAPY IN CHILDREN: FINDINGS FROM A RESPIRATORY THERAPIST DRIVEN CPAP CLINIC

Audrey Chikalla[1], Ambika Chidambaram[2], Leigherin Hurd[1], Kiran Nandalike[3]

[1] University of California, Davis Medical Center, [2] University of California, Davis, [3] UCD Health

Introduction: There is an increasing number of children needing continuous positive airway pressure (CPAP) therapy for obstructive sleep apnea (OSA) but the adherence to CPAP therapy remains less than 50% in children. Our sleep center implemented a respiratory therapist (RT) driven CPAP clinic that utilized an individualized approach to address specific barriers to CPAP adherence. In addition, we aimed to evaluate the facilitators and barriers to CPAP therapy in children in this clinic.
Methods: The RT driven CPAP clinic was implemented in January 2024, and the children were followed at 4-6 weeks intervals for at least one visit, then at set intervals based on their adherence to therapy. Our database included, number of clinic visits, adherence (>4 hours per night, 70% of the nights), demographics, polysomnographic data and barriers to therapy. The data was analyzed using descriptive statistics.
Results: 58 patients were seen in the clinic. 29/58 (50%) were adherent with CPAP therapy. The median age in both groups (adherent and non-adherent) was the same at 13 years of age (range: adherent 1 to 20 years; non-adherent 1 to 21 years), and median number of RT visits in both groups was 1 (range: adherent 1 to 4 visits, non-adherent 1 to 6 visits). The higher frequency of RT visits (average 1.8 vs. 1.5), male gender (75% vs. 60%), Hispanic race (70% vs. 50%), presence of comorbidities in addition to obesity (64% vs. 40%) was associated with adherence to CPAP therapy. The age and severity of OSA was not associated with improved adherence. Children with morbid obesity (37% vs 6.8%), and Asian and other races (37% vs. 10%) were associated with poor adherence. The commonly reported barriers to therapy were related to the interface and pressure discomfort.
Conclusion: We report 50% CPAP adherence in our RT driven CPAP clinic cohort. The frequent RT guided clinic appointments are not only feasible but also improved adherence in children using CPAP. To further improve adherence, we plan to expand our interfaces available for children in our clinic. In addition, barriers to therapy in morbidly obese children and Asian and other races need to be explored further.

AUTISM IN THE SLEEP CENTER: A LOOK AT PEDIATRIC AUTISTIC PATIENTS ON CPAP

Emily Ethridge[1], Kristi Pruss[1], April Scribner[1], Beverly Spray[1], Supryia Jambhekar[1]

[1] Arkansas Children's Hospital

Introduction: For patients diagnosed with Autism Spectrum Disorder (ASD), tolerating positive airway pressure (PAP) can be challenging. Identifying comorbidities that may contribute to adherence difficulties can help tailor care for these individuals.
Methods: A retrospective chart review was conducted to identify subjects and placed into two research groups: subjects with ASD (sASD) and control subjects without ASD (control). Statistical analysis was performed to compare the adherence outcomes of groups. Furthermore, each group was analyzed for those subjects with attention deficit/hyperactivity disorder (ADHD).
Results: Mean ages for control group was 15.4 (SD=3.4) and 14.5 (SD=4.2) years with and without ADHD, respectively. Mean ages for sASD was 15.8 (SD=2.7) and 14.8 (SD=4.0) years with and without ADHD, respectively. Subjects were predominately male (78.3% and 67.3%; sASD and control, respectively). A two-factor ANCOVA was performed to determine if total adherence and > 4 hours per night adherence differed between sASD and control groups. Each group was further evaluated, looking at those with and without ADHD. Adjustment was made for age at first visit. Since multiple measures were collected on adherence data, values were averaged for analyses. The group (sASD vs. control) by ADHD diagnosis (yes or no) was significant. Adjusted means for total adherence were 74.9% and 63.1% for sASD with and without ADHD and 72.7% and 81.4% for controls with and without

ADHD, respectively. Total adherence differed significantly between sASD and controls without ADHD (p=.009). There was no significant difference in total adherence between sASD with ADHD, sASD without ADHD and controls with ADHD. The same findings existed for adherence > 4 hours per night. Adjusted means were 37.0% and 52.7% for sASD with and without ADHD and 45.6% and 61.7% for controls with and without ADHD, respectively.
Conclusion: In the absence of co-existing ADHD, PAP adherence was statistically worse in patients with ASD as compared to control patients. We can infer that comorbidities play a role in PAP adherence in children. Further statistical analysis on this data to assess other factors contributing to adherence rates such as specific behavioral and sensory issues are being performed and will be available.

ADHERENCE TO A POSITIVE AIRWAY PRESSURE TRIAL IN YOUTH WITH DOWN SYNDROME: A BASELINE DESCRIPTION

Melissa Xanthopoulos[1], Kelly Byars[2], Neepa Gurbani[3], Jareen Meinzen-Derr[3], Christine Heubi[3], Anna Esbensen[3], Yolanda Yu[1], Ignacio Tapia[4]
[1] Children's Hospital of Philadelphia, [2] Cincinnati Children's Hospital Medical Center, [3] Cincinnati Children's Medical Center, [4] University of Miami Miller School of Medicine

Introduction: Down syndrome (DS) is the leading genetic cause of intellectual impairment and is often associated with obstructive sleep apnea (OSA). OSA frequently persists in this population despite adenotonsillectomy. Therefore, positive airway pressure (PAP) is commonly prescribed treatment of OSA in youth with DS, and often managed by medical providers, nurses and respiratory therapists (RT) with limited psychological support available. While children with DS encounter similar PAP implementation challenges as their typically developing peers, their neurodevelopmental differences can create additional barriers that may deter both caregivers and healthcare providers from pursuing PAP.
Methods: This multicenter randomized-controlled trial evaluates whether the addition of psychological support improves PAP treatment outcomes compared to standard care (STD: physician, nurse, RT). Both groups participate in four structured telehealth visits over 6 months, with neurobehavioral and quality of life assessments conducted at baseline, 6, and 12 months. The intervention group receives supplemental behavioral assessment, personalized implementation strategies, and supportive follow-up calls. PAP adherence is the primary outcome to determine the effectiveness of psychological support in treatment success. Other baseline outcome measures include the parent-reported Pediatric Quality of Life Inventory Physical Score (PedsQLPhy), PedsQL Psychosocial Score (PedsQLPsy), and the NIH Toolbox 9 Hole Pegboard Dexterity Test (PDT).
Results: Twenty-six individuals have been randomized (male, N=14; White, N=19; Black, N=4; Asian, N= 2; Other, N=1; Hispanic, N=3). Mean±SD age is 11.8±3.6 years with a BMIz of 1.2±0.9 (BMI percentile=80.8±21.5). Baseline obstructive apnea hypopnea index is 16.1±12.6 events/hour and Epworth Sleepiness scores are 6.3±5.1. Baseline outcome scores were PedsQLPhy (68.6±18.5), PedsQLPsy (65.2±13.2), and PDT (Dominant Hand=48.5±23.2 seconds; Nondominant Hand=53.2±27.8 seconds). All participants successfully completed the Pegboard task. All participants completed titration polysomnogram except one in the STD who was unable to tolerate it.
Conclusion: This ongoing trial will provide important insights into whether behavioral psychology support improves PAP adherence in youth with DS. Baseline data demonstrate moderate-to-severe OSA, normal DS quality of life scores, and impaired fine motor dexterity, though participants successfully completed all study procedures. These findings highlight both the significant clinical burden in this population and the feasibility of conducting complex interventional trials.

OSA ENDOTYPES AND ATOMOXETINE-OXYBUTYNIN TREATMENT RESPONSE IN CHILDREN WITH DOWN SYNDROME

Daniel Combs[1], Jamie Edgin[2], Chiu-Hsieh Hsu[3], Kenneth Bottrill[3], Sicily La Rue[3], Adam Dean[3], Natalie Provencio-Dean[3], Sairam Parthasarathy[3], Atqiya Aishah[4], Scott Sands[5]
[1] Department of Pediatrics, University of Arizona, [2] Virginia Tech, [3] University of Arizona, [4] Harvard Medical School and Brigham and Women's Hospital, [5] Brigham and Women's Hospital and Harvard Medical School

Introduction: Obstructive sleep apnea (OSA) is highly prevalent in children with Down syndrome (DS) and current OSA treatments have limited effectiveness. Positive airway pressure therapy is poorly tolerated and adenotonsillectomy is not curative for most children with DS. In our recent trial, the combination of atomoxetine plus oxybutynin (ato-oxy) reduced OSA severity by 51% in children with DS, with considerable variability in responses to treatment. Here we evaluated the potential utility of OSA endotyping, where physiologic characteristics are extracted from clinical polysomnography, to predict ato-oxy treatment response in children with DS.
Methods: A randomized, double-blind, crossover pilot trial examined the short-term efficacy of ato-oxy in 15 children aged 6 to 17 years with DS and OSA. Participants received 4 weeks of low dose (0.5 mg/kg atomoxetine and 5 mg oxybutynin) as well as 4 weeks of high dose (1.2 mg/kg atomoxetine and 5 mg oxybutynin) in random order. Endotype characteristics including collapsibility (per Vpassive), muscle compensation, loop gain and arousal threshold were extracted from baseline polysomnography. Primary mixed model analysis evaluated the association between baseline collapsibility and ato-oxy response (% reduction in apnea-hypopnea index [AHI]), adjusting for baseline AHI and dose; secondary analyses examined the remaining endotypic characteristics, and further adjustment for BMI percentile.
Results: Twelve participants had available data for analysis. Milder collapsibility was associated with a greater treatment response with a 26% greater reduction in AHI per standard deviation reduction in collapsibility (95% confidence interval: [11, 41] %, p=0.002). Greater muscle compensation was associated with a weaker treatment response (−23% [−44, −3], p=0.028), but the association was partially attenuated with additional adjustment for collapsibility (−12%). Arousal threshold and loop gain were not significant predictors. The association with collapsibility was not attenuated with adjustment for BMI (+34 [19, 48] %).
Conclusion: In our early-phase trial, milder airway collapsibility and weaker muscle compensation were predictors of a greater ato-oxy treatment response in children with DS which may help identify individuals with DS and OSA more likely to benefit from muscle stimulation targeted therapies in future trials.

STANDARDIZING POLICIES AND PROCEDURES FOR HYPOGLOSSAL NERVE IMPLANTATION IN PEDIATRIC TRISOMY 21 PATIENTS: A TERTIARY CARE CENTER'S EXPERIENCE

Binal Kancherla[1], Mary Musso[1], Kevin Kaplan[2], Amee Revana[1], Lacie Petitto[1], Jennifer Kazmerski[1], Auburne Hutchins[1]

[1] Texas Children's Hospital, [2] Baylor College of Medicine

Introduction: Implantation of the hypoglossal nerve stimulator (HGNS) is recognized as an effective treatment for persistent obstructive sleep apnea (OSA) in children with trisomy 21, particularly in cases where positive airway pressure (PAP) therapy is ineffective or not tolerated. Standardized protocols for HGNS implantation and management in pediatric patients have not been well established or published. Standardized protocols can prevent inconsistent outcomes, decrease procedural risks, and increase accessibility to treatment. This gap in systematic protocols has identified the need for well-defined policies and procedures that streamline workflow processes to ensure adequate patient access, enhance perioperative management, and improve long-term follow up care.
Methods: Texas Children's Hospital Sleep Center developed and has successfully implemented a comprehensive care pathway, which was supported by a multidisciplinary team of providers to standardize their HGNS program. In this paper, we summarize our multidisciplinary approach and outline the current sleep clinic and laboratory protocols utilized to evaluate, treat and manage children prior to and after HGNS implantation.
Results: Within a 6-month period, our sleep center successfully treated four children with trisomy 21 using this approach. Standard written protocols were outlined and presented to staff and faculty. Faculty were part of online training and simulation procedures. In addition, ongoing partnership was established with the device manufacturer to train clinical staff and edit protocols.
Conclusion: By standardizing these processes, healthcare systems can consider adopting such protocols to help ensure consistency in practice, improve patient outcomes, and promote evidence-based advancements in pediatric OSA management. Furthermore, a standardized framework can potentially enable multicenter research collaborations while facilitating robust comparisons of outcomes and fostering continuous improvements in care delivery. Furthermore, a standardized framework can potentially enable multicenter research collaborations while facilitating robust comparisons of outcomes and fostering continuous improvements in care delivery.

IMPLEMENTATION OUTCOMES OF A SLEEP CLINICAL DECISION SUPPORT TOOL IN PRIMARY CARE

Eberechukwu Uwah[1], Mondal Antara[1], Roberts Amy[1], James Guevara[1], Ignacio Tapia[2], Gregory Lawton[1], Maura Powell[1], Anthony Luberti[1], Alexander Fiks[1], Ariel Williamson[3]

[1] Children's Hospital of Philadelphia, [2] University of Miami Miller School of Medicine, [3] The Ballmer Institute for Children's Behavioral Health, University of Oregon

Introduction: Childhood sleep disordered breathing (SDB) is highly prevalent and associated with poor neurobehavioral outcomes, underscoring the importance of early identification. However, most outpatient settings, including primary care, lack feasible tools to identify SDB symptoms and support referrals for further evaluation. This pilot study evaluated the initial adoption, reach, acceptability, and initial effectiveness of an electronic health record (EHR)-based primary care clinical decision support (CDS) tool for the management of abnormal SDB screening results.
Methods: The CDS was iteratively developed and deployed in all well child visits at 4 primary care sites from 06/2022-06/2023. Those with reported habitual snoring (≥3 nights/week) received 2-3 age-based questions about labored breathing/gasping, mouth breathing, and bed-wetting, drawn from validated SDB measures. A best practice alert (BPA) appeared when ≥1 of the additional questions were endorsed, with a prompt to refer to specialty care (sleep or otolaryngology) for further assessment, in line with pediatric guidelines. Retrospective electronic health record data were drawn to examine outcomes during the implementation year. Chi-squared tests examined BPA activation and referrals. Primary care clinicians rated CDS acceptability using the System Usability Scale.
Results: A total of 49,125 unique children (6 months-18 years, 51% boys, 51% African American/Black, 5% Asian, 5% Hispanic/Latine, 31% White) were screened for SDB in >90% of well visits, reflecting high adoption. Thirteen percent (n=6257) endorsed habitual snoring. Of the habitually snoring children, the BPA fired for 60% (n=3748) who had ≥1 additional SDB symptom endorsed (i.e., reach). BPA activation was significantly associated with specialty care referrals (p = <.001), with 41% (1524/3748) of snoring children with ≥1 additional symptom referred to specialty care. Of 19 clinician respondents, 68% agreed/strongly agreed to feeling satisfied with the CDS, while 84% agreed/strongly agreed that it was easy to use and helped initiate discussions with families.
Conclusion: Findings indicate high reach and adoption of CDS for SDB in primary care, with evidence of good acceptability and preliminary effectiveness in supporting specialty care referrals for symptomatic children. Further research is warranted to evaluate the long-term impact of the CDS on patient outcomes and healthcare efficiency.

IMPACT OF PATIENT ACTIVATION ON PEDIATRIC OSA DETECTION AND MANAGEMENT IN PRIMARY CARE

Ian Jones[1], Randall Grout[2], Jennifer Hillstrom[3], Ronald Chervin[4], Eneida Mendonca[5], Stephen Downs[6], Sarah Honaker[1]

[1] Indiana University School of Medicine, [2] Eskenazi Health; Indiana University School of Medicine, [3] Eskenazi Health, [4] Sleep Disorders Center and Department of Neurology, University of Michigan, [5] Cincinnati Children's Hospital Medical Center and University of Cincinnati College of Medicine, [6] Wake Forest University School of Medicine

Introduction: Pediatric OSA is often undetected, partly due to gaps in parental awareness of OSA. Automatic OSA screening traditionally involves primary care provider (PCP) alerts but does not inform parents of their child's OSA risk. Health activation messaging can activate parents to raise concerns with medical providers; however, this approach has not been examined in pediatric

OSA. The study aimed to examine: 1) parental response to a pediatric OSA health activation message and 2) the impact of that response on OSA evaluation and action at a subsequent PCP visit.
Methods: In eight primary care clinics parents responded to OSA screening items in the patient portal. For children who screened positive, their parents viewed a health activation message that: 1) communicated the child's positive screen, 2) provided education, and 3) encouraged discussion at the scheduled PCP visit. PCPs also received an EHR alert about OSA risk. Data were extracted from EHR reports and PCP encounters. Activation was assessed by parental response to an item asking if they plan to discuss OSA with their child's PCP. OSA evaluation was assessed via documentation of OSA symptoms in the provider note.
Results: Of parents who viewed the message (n=148; children 2-13 years; M=7.4 years; SD = 2.8; 58.1% male), 45.9% indicated their plan to speak to their child's provider at a subsequent visit about OSA (high activation), 17.6% did not plan to do so (low activation), and 36.5% were unsure. Children whose parents had high (vs. low) activation tended to have more OSA symptoms (M=2.9, SD=1.4 vs. M=1.5, SD=0.7; F(1,93)=23.9, p<.01). Children of patients with high activation (vs. low) were also more likely to receive an OSA evaluation (75.0% vs. 54.0%; X2=3.9, p<.05) and follow up action (e.g., polysomnography or ENT referral; 61.8% vs. 23.0%; X2=11.3; p<.01).
Conclusion: Children of parents who are activated about their child's OSA risk are more likely receive OSA evaluation and action. Health communication messaging is likely to be a promising strategy to improve primary care pediatric OSA detection, but further research is needed to optimize parent activation.

PRACTICE TRENDS IN PEDIATRIC HOME SLEEP TEST UTILIZATION

Ayelet Snow[1], Matthew Balog[1], Innessa Donskoy[1], Africa Washington[2], Darius Loghmanee[1]
[1] Advocate Children's Hospital, [2] Advocate Healthcare

Introduction: The current AASM position on home sleep apnea testing (HSAT) states it is "not recommended for the diagnosis of obstructive sleep apnea in children". Potential underestimation of severity and unreliable data collection are cited as possible issues. However, as awareness of pediatric OSA increases, there has been an uptick in the development and research of HSAT use in children. A recent systematic review identified 62 studies, 66.7% of which demonstrated high diagnostic reliability for OSA when using Type III HSAT in children. Our aim is to describe the utilization of this technology within our institution.
Methods: A retrospective search of our electronic medical record (EMR) was conducted for patients who were ordered an HSAT between 1/1/2022 and 11/30/2024. The query yielded 194 pediatric HSAT orders of which 82 were completed (43%).
Results: Of the 82 completed pediatric HSATs, patient ages ranged from 2.7 to 21 years (average 13.8). Patients spent an average of 28 days from order date to HSAT completion, compared to 68 days for an in lab study. Average recording time was 9.8 hours. Two studies (2%) had < 3 hours of recording. Two nights of recording were obtained for 17% (14) of patients, with no statistically significant differences between nights in AHI, SpO2 nadir and hours recorded. No OSA was found in 29% of patients (23), mild in 35% (29), moderate in 13% (12) and severe in 22% (18).
Conclusion: Utilization of pediatric home sleep testing in our institution demonstrated feasibility across a range of ages, with valuable clinical data derived from most studies. Moderate and severe sleep apnea were noted in nearly half of the HSATs, offering an expedited, less invasive path to treatment. The significant number of uncompleted orders highlights demand and barriers to completion. While further studies are needed to continue evaluating HSAT reliability in children, our findings demonstrate that home sleep testing can be a strong diagnostic tool in the work up of significant pediatric OSA.

A PILOT STUDY OF THE SLEEPIMAGE HOME SLEEP APNEA TEST COMPARED TO POLYSOMNOGRAPHY IN CHILDREN 2 TO 6 YEARS OF AGE

Ann Murray[1], Christine Matarese[2], robin lloyd[2], Channing Sorensen[1], Timothy Morgenthaler[3], Allison LeMahieu[2], Dennis Reckward[2], Robyn Tullis[2], Mark Bellinger[2], Ginny Brown[2], Daniel Herold[2], Julie Baughn[2]
[1] Mayo Clinic Rochester, [2] Mayo Clinic, [3] Mayo Clinic, Rochester, Minnesota

Introduction: The SleepImage is an HSAT device (sHSAT) that uses photoplethysmography and oxygen saturation data to generate an apnea hypopnea index (AHI). This sHSAT has been FDA cleared as a software-as-a-medical-device for use in children 2 years and older for diagnosing obstructive sleep apnea (OSA). To our knowledge this sHSAT has not been tested on children concurrent with the gold standard polysomnography (PSG).
Methods: This study evaluated 50 children 2-6 years of age with tonsillar hypertrophy and OSA symptoms with sHSAT during simultaneous in-lab PSG. Aims were to determine the technical feasibility of using sHSAT in this population and to compare sHSAT results to PSG. The primary endpoint was AHI by sHSAT compared to AHI by PSG and presence of OSA. Sensitivity analysis was performed for presence or absence of OSA diagnosis based on sHSAT versus PSG. Bland-Altman and concordance correlation calculations were used for comparisons.
Results: 50 patients, median age 4 (IQR 3-5), met criteria; 39 completed PSG and HSAT. The sensitivity with sHSAT for OSA prevalence based on proprietary categorization was 94.1%, specificity 22.7%, LR+ 1.22, and LR- 0.26, with PSG OSA prevalence of 43.6%. There was a 9% sHSAT total failure rate, and the device frequently fell off, resulting in TST difference of -226.9 ±182.8 min between sHSAT and PSG. PSG was trimmed to include only segments where HSAT was confirmed to be on before comparisons. Concordance correlation coefficient between sAHI and AHI-PSG was 0.52. The Bland-Altman analysis comparing sAHI and PSG AHI revealed a mean difference of 0.73 (95% confidence limits: -3.47 to 4.93). Considering only obstructive events, the Bland-Altman the sAHI vs the AHI-PSG shows a mean difference of 1.52 (95%CI -5.40 to 8.44).
Conclusion: This pilot study demonstrated challenges with feasibility in using the sHSAT in this age group given likelihood of technical difficulties leading to absent or truncated data. When compared with PSG, sHSAT demonstrated a high false-positive rate for diagnosis of OSA, particularly concerning if guiding surgical management. This topic is of considerable importance to the practice of pediatric sleep medicine; further investigation of technological advances in this area is imperative.

COUNTING SHEEP AT HOME: ADVANCING PEDIATRIC SLEEP APNEA TESTING

Brandon Jones[1], Ravali Inja[1], Mahalakshmi Somayaji[2], Darko Stefanovski[3], Christopher Cielo[1]

[1] Children's Hospital of Philadelphia, [2] The Children's Hospital of Philadelphia, [3] University of Pennsylvania School of Veterinary Medicine

Introduction: In-laboratory polysomnography (PSG) is currently the standard clinical test for evaluating obstructive sleep apnea (OSA) in children, but barriers including cost, accessibility, and discomfort highlight the critical need for alternative testing modalities such as home sleep apnea testing (HSAT) in pediatrics. Level II HSAT with electroencephalogram (EEG) may be more accurate for the diagnosis of OSA in children but requires a technologist to set up the equipment compared with Level III HSAT without EEG. We aimed to compare the accuracy of Level II HSAT versus Level III HSAT for the diagnosis of pediatric OSA.
Methods: Children aged 2 through 17-years-old completed Level II HSAT as part of a larger study comparing HSAT with PSG. Level II HSAT was scored using AASM pediatric scoring rules. EEG was removed from the montage and HSAT studies were re-scored as Level III studies by investigators blinded to the Level II scoring. An obstructive apnea hypopnea index (OAHI) of 2 events/hour was the threshold used for a diagnosis of OSA. Level II and Level III HSAT OAHI were compared using sign rank test, Spearman's rank correlation, and Lin's test of concordance.
Results: Fifteen participants, including 10 (67%) females were included. Median (range) age was 6.0 (Range: 2.9, 17.1) years. Level III HSAT OAHI was 1.0 (0.2, 9.2), and Level II HSAT OAHI, was 1.8 (Range: 0.3, 23), p = 0.15. By Level III HSAT, obstructive hypopnea index was 0.3 (0, 1.6), and Level II HSAT was 1.2 (0.1, 13), p= 0.002. Six (0.4) participants had a diagnosis of OSA by Level II HSAT and 2 (0.13) by Level III HSAT (p=0.09). There was a moderate correlation between Level II HSAT and Level III HSAT (Spearman r=0.61, p=0.02) but poor concordance (concordance correlation coefficient=0.5).
Conclusion: In this pediatric pilot study, there was a moderate correlation between Level II and Level III HSAT OAHI, but poor concordance. Removal of HSAT EEG resulted in significantly less obstructive hypopneas and underestimation of OSA. These findings suggest a potential difference between the two testing methods for detecting pediatric OSA, but future studies comparing HSAT to PSG with larger cohorts are needed.

SLEEP DISORDERED BREATHING IN TERM INFANTS: PHENOTYPE AND DIAGNOSTIC DATA

Liz Lezama[1], Aarti Shakkottai[2]

[1] University of Texas Southwestern, [2] University of Texas Southwestern

Introduction: Sleep-disordered breathing (SDB) is common in neonates and infants. Unfortunately, most of the data in this population is focused on high-risk infants. Little data exists on whether term, otherwise healthy, infants should follow the same diagnostic and treatment standards that are currently in place for high-risk infants.
Methods: A retrospective review of medical records and PSG data in term infants 0-12 months of age presenting symptoms suggestive of SDB, who underwent diagnostic Polysomnography (PSG) between 2017 to 2023.
Results: Fifteen subjects were enrolled. The majority (80%) were male and 40% were of non-White race. Snoring was the most common symptom at presentation, followed by stridor, noisy breathing, and BRUE (brief resolved unexplained events), respectively. The average age sleep study conducted was 7.4 months. The diagnosis of moderate-severe obstructive sleep apnea (OSA) defined as an obstructive apnea-hypopnea index (oAHI) ≥ 5/hour, was present in 73% of subjects. The mean oAHI was 17.9/hr. Central sleep apnea was identified in 6 subjects with a mean central apnea index (CAI) of 3.3/hr. The mean total sleep time was 396 minutes, and the arousal index was 15.1 events/hr. Sleep efficiency was 78.5% across the cohort. Ten infants were diagnosed with moderate-severe OSA and underwent airway evaluation; four were diagnosed with laryngomalacia, followed by other abnormalities such as piriform aperture stenosis, adenoidal hypertrophy, and type I cleft. Three had a normal evaluation. Six subjects were diagnosed with reflux. The therapeutic interventions in this cohort varied from observation, oxygen, and high-flow nasal cannula support to surgical management (adenotonsillectomy and supraglottoplasty). Out of the group of ten subjects, (70%), had a follow-up PSG, which showed resolution of SDB by 2-3 years of age in the majority of the cohort; two infants demonstrated improvement of severe OSA by 1 year of age following interventions, and only one showed persistence of severe OSA after adenoidectomy.
Conclusion: Moderate to severe OSA was the most prevalent disorder in this cohort. This study highlights the heterogeneity in interventions and outcomes among infants diagnosed with SDB. These findings also suggest the need for further research to improve diagnostic accuracy and treatment guidelines for term infants with SDB.

RESPIRATORY CYCLE-RELATED EEG CHANGES (RCREC) OBSERVED DURING SLEEP OF NEONATES WITH MYELOMENINGOCELE

Joseph Burns[1], Ronald Chervin[2], Stephanie Rau[3], Fauziya Hassan[4], Thornton Mason[5], John Barks[6], Renee Shellhaas[7]

[1] Michigan Tech Research Institute, Michigan Technological University, [2] Sleep Disorders Center and Department of Neurology, University of Michigan, [3] Division of Pediatric Neurology, Department of Pediatrics, University of Michigan, [4] Sleep Disorders Center, Division of Pulmonary Medicine, Department of Pediatrics, University of Michigan, [5] Division of Pediatric Neurology, Department of Pediatrics, Children's Hospital of Philadelphia and University of Pennsylvania, [6] Division of Neonatology, Department of Pediatrics, University of Michigan, [7] Department of Neurology, Washington University in St. Louis

Introduction: Respiratory Cycle-Related EEG Changes (RCREC) measured during the sleep of children and adults may represent subtle cortical microarousals exacerbated by labored breathing in obstructive sleep apnea. However, the existence of RCREC has not been investigated previously in newborns.
Methods: Nine North American Fetal Therapy Network centers collaborated in a prospective polysomnographic study (at ≥32

weeks postmenstrual age) of sleep among 171 neonates (gestational age at birth 30-41 weeks) with myelomeningocele in neonatal intensive care units. The RCREC for NREM and REM sleep were computed (AJRCCM 2005;171:652-8) for the entire night in 5 frequency ranges -- delta 2-4 Hz, theta 4-8 Hz, alpha 8-12 Hz, sigma 12-15 Hz, and beta 15-18 Hz) -- using C3-M2 EEG and the nasal-oral thermocouple signal. The RCREC were compared to gestational age at birth, and the apnea-hypopnea index (AHI).
Results: Statistically-significant RCREC (ANOVA, p< 0.01) appeared in at least some frequency ranges in most neonates during NREM sleep (delta n=170, theta 164, alpha 159, sigma 160, beta 164), and during REM sleep (delta 170, theta 163, alpha 147, sigma 161, beta 163). In NREM sleep, the RCREC varied inversely with gestational age (delta: Spearman rho=-0.16, p=0.03; theta: rho=-0.34, p=< 0.0001; alpha: rho=-0.45, p=< 0.0001; sigma: rho=-0.23, p=0.003; beta: rho=-0.21, p=0.007). Theta and alpha RCREC increased with AHI (rho=0.18, p=0.02, and rho=0.25, p=0.001, respectively). In REM sleep, RCREC also varied inversely with gestational age (delta: rho=-0.24, p=0.001; theta: rho=-0.20, p=0.009; alpha: rho=-0.28, p=0.0002; sigma: rho=-0.22, p=0.004; beta: rho=-0.18, p=0.02). Only alpha RCREC varied with AHI during active sleep (rho=0.18, p=0.02).
Conclusion: These data demonstrate RCREC in neonates for the first time. As in older individuals, only limited associations appear with AHI. Moreover, the synchronization between EEG power and the respiratory cycle increases, on average, with lower gestational age at birth. Although these data are specific to infants with myelomeningocele, we have also found RCREC in preterm newborns without MMC (unpublished observations). Previous findings in children and adults that RCREC may predict daytime sleepiness, as well or better than standard polysomnographic measures (Sleep 2006;29:495-503), suggest that infant RCREC merits additional study.

DISCORDANCE BETWEEN SYMPTOM SEVERITY AND POLYSOMNOGRAPHIC FINDINGS IN CHILDREN WITH CEREBRAL PALSY

David Zopf[1], Hannah Turbeville[2], Louise O'Brien[2]
[1] University of Wisconsin - Madison, [2] University of Michigan

Introduction: Children with cerebral palsy or other complex neurologic disorders frequently demonstrate symptoms of severe upper airway obstruction yet not all are diagnosed with severe obstructive sleep apnea (OSA). The goal of this study was to determine whether there was discordance between symptom severity and polysomnographic findings in children with cerebral palsy who had mild to moderate OSA.
Methods: A retrospective review was undertaken of baseline polysomnograms performed in children with cerebral palsy between 2008-2023 who had clinical concern for severe airway obstruction. Children were included in the analysis if the AHI was less than 10. Median and inter-quartile range (IQR) were reported for non-normally distributed data, and mean and standard deviation (SD) were reported for normally distributed data.
Results: A total of 47 children aged 2-19 years were included in the analysis. Over half (55%) had a seizure disorder. Median AHI was 2.3 (IQR: 2.9), median oxygen nadir was 89% (IQR: 6) and median time < 90% oxygenation was 0% (IQR: 3.4). Children had frequent hospital admissions for respiratory complications with a mean of 80 days (SD 89) spent in hospital, the majority of which (86%) were in the intensive care unit and often intubated. The mean duration of intubation was 37 days (SD 42). To correct upper airway obstruction children often underwent multiple surgical procedures, with a mean of 2.5 surgeries per child. Overall, 17% of children required a tracheostomy and four children (8.5% of the sample) died.
Conclusion: In children with clinical evidence of severe upper airway obstruction, polysomnographic results did not reflect the clinical concern. We strongly recommend multidisciplinary evaluation of children with cerebral palsy and astute clinical judgement with recognition of the need for continued care or observation if there is discordance between symptoms of airway obstruction, yet a reassuring polysomnogram.

POLYSOMNOGRAPHIC CHARACTERISTICS IN CHILDREN WITH DUCHENNE MUSCULAR DYSTROPHY (DMD) COMPARED TO NORMAL CHILDREN

Janki Naidugari[1], Arpita Lakhotia[1], Theresa Kluthe[1], Karim El-Kersh[1], Amanda Rogers[1], Egambaram Senthilvel[2]
[1] University of Louisville, [2] University of Louisville Department of Pediatrics, Division of Sleep Medicine

Introduction: Children with Duchenne Muscular Dystrophy (DMD) are prone to develop sleep disordered breathing due to various risk factors. The aim of this study is to assess the polysomnographic characteristics in children with DMD compared to age, gender, and AHI controlled matched children without DMD.
Methods: This was a single-center retrospective study involving children with confirmed DMD who underwent overnight polysomnography (PSG). OSA severity was categorized by obstructive apnea-hypopnea index (OAHI) as normal (< 1 event/hr), mild (1–4.9 events/h), moderate (5–9.9 events/h), or severe (≥ 10 events/h).
Results: The DMD group included 12 children, and the control group included 9 children. The gender, mean age and BMI of the DMD and control groups were 91.7% male, 11.25 years, and 21.13 versus 88.9% male, 12.11 years and 23.71 respectively. In the DMD group, functional statuses were: 8.3% late ambulatory, 66.7% early non-ambulatory, and 25% late non-ambulatory. Severe OSA was identified in 50% of the DMD group, and in 57.1% of the control group. There were no differences between the median total sleep time, sleep stages and arousal indices. Similarly, there were no differences in the median OAHI, central apnea index, mean oxygen saturation and carbon dioxide level between the groups. However, the mean heart rates were significantly higher in DMD group [86.29 (16.72) vs 68.59 (10.65) p= 0.012]. 58.3%, and 8.3% of DMD children were treated with prednisolone, deflazacort, respectively, and 25% were not receiving steroids. DMD children receiving steroids had a lower mean CO2 in REM sleep than those who were not [43 (39.00-43.00 vs 47(46.50-47.50) p=0.048]. Eleven DMD children received ACE inhibitor preventative therapy for delaying the progression of cardiomyopathy. 3 children received PAP therapy.
Conclusion: Half of the children with DMD had severe OSA. There were no significant differences between most of the PSG parameters between the groups except higher heart rate was noted in DMD. REM carbon dioxide level was lower in DMD children who were receiving steroids.

POLYSOMNOGRAPHIC CHARACTERISTICS IN CHILDREN WITH SPINAL MUSCULAR ATROPHY COMPARED TO NORMAL CHILDREN

Janki Naidugari[1], Arpita Lakhotia[1], Theresa Kluthe[1], Karim El-Kersh[1], Amanda Rogers[1], Egambaram Senthilvel[2]

[1] University of Louisville, [2] University of Louisville Department of Pediatrics, Division of Sleep Medicine

Introduction: Children with Spinal Muscular Atrophy (SMA) are prone to develop sleep disordered breathing due to various risk factors. The aim of this study is to assess the polysomnographic characteristics in children with SMA compared to age, gender, and AHI controlled matched children without SMA.
Methods: This was a single-center retrospective study involving children with confirmed SMA who underwent overnight polysomnography (PSG). OSA severity was categorized by obstructive apnea-hypopnea index (OAHI) as normal (< 1 event/hr), mild (1–4.9 events/h), moderate (5–9.9 events/h), or severe (≥ 10 events/h).
Results: The SMA group included 15 children who had available PSG (out of total 29 children with SMA), and the control group included 12 matched children. The gender, mean age and median BMI of the SMA and control groups were 66.7% female, 2 years, and 16.9 versus 66.7% female, 4 years and 16.7 respectively. In the SMA group, copy numbers 2, 3 and 4 were 46.7%, 26.7%, and 20% respectively. Functional statuses were: 5 non-sitters, 1 sitter, 4 standards, and 5 walkers. OSA was identified in 60% of SMA group and in 88% of the control group. There was no difference in median total sleep time, mean sleep efficiency, REM sleep, and median arousal index between the groups. However, the SMA group spent less time in stage 3 sleep [100.38 (38.69) vs 131.13 (37.08) p = 0.047], non-REM [270.67 (83.89) vs 343.95 (50.16) p= 0.013] and left position [0.00 [0.00 vs 88.20 p = 0.003]. There was no significant difference in apnea hypopnea index, obstructive apnea-hypopnea index (OAHI), central apnea index (CAI), and oxygen saturations; however, the mean Non-REM CO2 was lower [39.40 (2.38) vs 42.58 (2.39) p = 0.011] and the mean heart rate was higher [104.98 (16.06) vs 86.15 (20.53) p = 0.013] in the SMA group. SMA subjects were being treated with Nusinersen, Onasemnogene, and Risdiplam 60%, 26.7%, and 26.7% respectively during baseline PSG. 3 SMA children were initiated on PAP therapy.
Conclusion: More than half of the SMA children had OSA. Children with SMA spent less time in Non-REM and left side position, and had higher heart rates compared to the matched children.

EXAMINING 200LB (91KG) WEIGHT AS INDICATION FOR INITIATION OF SPLIT NIGHT POLYSOMNOGRAPHY IN PEDIATRIC PATIENTS

Leena Stemler[1], Brent Haberman[2]

[1] St. Louis University Hospital/Cardinal Glennon Children's Hospital, [2] Cardinal Glennon Children's Hospital

Introduction: Obstructive Sleep Apnea (OSA) is an evolving area of study in pediatrics. OSA affects nearly half a million children in the United States and polysomnography is recommended to differentiate primary snoring (PS) from OSA. Cardinal Glennon Children's Hospital in St. Louis is equipped to complete both diagnostic and split night studies. Protocols are in place to guide technicians in their management of patients. Continuous positive airway pressure (CPAP) can be initiated in studies ordered as a "split night study" as opposed to a diagnostic study. One of the parameters in place is the use of 200lb weight as a marker to initiate CPAP if an apnea hypopnea index of 15/hr is noted during the study. The advantages of completing a split study are that patients do not have to undergo the duress of a sleep study twice, CPAP can be initiated in a timely manner, and healthcare costs can be mitigated by performing one study instead of two. The weight cut off of 200lbs was chosen based on provider experience, and we have not examined the effectiveness of this parameter. This study aims to evaluate the sensitivity and specificity of this weight parameter and adjust our limit based on our results.
Methods: We will analyze data for a two month period to determine if eligible patients require CPAP during their split study. We will also evaluate all of the sleep studies done at this time. We will then examine how many patients not meeting the 200lb parameter end up needing a CPAP titration study. Then, based on the sensitivity and specificity data from our 200lb parameter, we can adjust our protocol as needed.
Results: Data will be collected starting December 2024 and will continue until Feb 1 2025. Results pending on this data collection.
Conclusion: This study is important for establishing a data driven protocol to effectively capture pediatric patients who would benefit from CPAP for OSA. If we can accurately tailor our protocol, we can help our patients receive beneficial CPAP treatment in a more timely and cost-efficient manner.

COMPARISON OF MRI-BASED DYNAMIC 4D AIRWAY MEASUREMENTS AND DISE RESULTS IN PEDIATRIC PATIENTS WITH PERSISTENT OSA

Caitlin Fletcher[1], Maeve Slife[1], Keith McConnell[1], Robert Fleck[1], Carol Li[1], Raouf Amin[1], Qiwei Xiao[1], Alister Bates[1]

[1] Cincinnati Childrens Hospital

Introduction: Obstructive sleep apnea (OSA) is persistent in approximately 40% of pediatric patients following adenotonsillectomy (AT), often leading to secondary surgical interventions. Magnetic resonance imaging (MRI) and drug induced sleep endoscopy (DISE) are crucial for secondary surgical planning, although it is unclear whether these diagnostic modalities agree regarding location and severity of airway obstruction. Comparing measurements from dynamic airway models reconstructed from MRI with DISE results provides insight into how these modalities may contrast and complement one another in identifying surgical targets for persistent OSA.
Methods: DISE and MRI of the upper airway (under ketamine/dexmedetomidine-induced sedation) were performed on 33 pediatric subjects (aged 3-18 yr, mean=9.56) with persistent OSA after AT. Dynamic airway models were created by segmenting static MR images and registering cine-MR images throughout a breath cycle. Spatiotemporal minimal measurements of dynamics, or cross-sectional area (CSA) ratios, size (minimum CSA, normalized by cricoid CSA), and shape (ratio of diameters) were calculated from the airway model every 1mm and 1ms. DISE

findings were scored based on obstruction pattern and severity. Airway measurements were compared (unpaired t-test, 95% CI) between DISE severity scores within each region.
Results: Subjects with adenoid hypertrophy on DISE exhibit eccentric airway shape on airway reconstruction of the nasopharynx (P=0.013), but neither airway CSA nor dynamics are different from subjects without adenoid hypertrophy. A trend of eccentric airway shape in the nasopharynx (P=0.052) is also found in subjects with velum collapse, with no differences in CSA or dynamics of the airway. The CSA of the airway in the oropharynx is smaller in subjects with complete tongue base collapse (P=0.04); however, there are no differences in shape or dynamics.
Conclusion: DISE scores and airway shape on airway models agree at the adenoids and velum. Collapse visualized on DISE is associated with decreased size on airway models at the tongue base. Airway dynamics are similar between DISE scores at the velum and tongue base. The partial agreement between DISE scores and airway model measurements indicates each technique may be sensitive to different patterns of airway obstruction. Future studies should investigate the association between the results of multimodal airway evaluation and surgical outcomes.

WAKING UP PEDIATRICIANS TO OBSTRUCTIVE SLEEP APNEA SCREENING

Michael Ragnone[1], Hannah Adams[1], Innessa Donskoy[2], Matthew Balog[2], Darius Loghmanee[2], Ayelet Snow[2]
[1] Advocate Children's Hospital Park Ridge, [2] Advocate Children's Hospital

Introduction: Childhood obstructive sleep apnea (OSA) affects approximately 1.2% to 5.7% of children with many experiencing delays in diagnosis and treatment. This is multifactorial, including providers' lack of utilization of validated OSA screening tools, such as the Pediatric Sleep Questionnaire (PSQ). Residency offers an ideal opportunity to introduce such tools, as learners can integrate them into their practice early on.
Methods: This mixed-methods quality improvement project used a resident targeted educational program to increase OSA awareness, review screening guidelines, and discuss next steps for children with positive PSQ results. Following the lecture, an anonymous survey assessed attendees' prior knowledge of the PSQ, confidence in ordering sleep studies, anticipated use of the PSQ, and perceived barriers. To address identified barriers, PSQ screening forms were placed in each clinic room to increase accessibility for providers. An electronic medical record (EMR) query was used to gauge our interventions' efficacy in increasing PSQ usage.
Results: Through an anonymous post lecture survey, 87.5% of attendees responded that they screen for routine snoring during their well-child checks at most or every visit. However, 100% of residents had never used the PSQ screening before. At 62.5%, most respondents anticipated using the PSQ when indicated at most or every visit. Most encouragingly, 100% of respondents reported feeling "more confident" regarding indications for ordering polysomnography or pediatric sleep medicine referral. The initial two weeks post-lecture saw no increase in PSQ usage among residents, but the data collection will be ongoing until June 2025.
Conclusion: This study aimed to increase PSQ utilization in one pediatric outpatient clinic through a resident-led lecture on OSA screening and improved accessibility to PSQ forms in the clinic. While initial PSQ utilization was low, residents expressed increased confidence in diagnosing OSA and planned to implement the tool moving forward. The most frequent barriers identified were time and accessibility to forms, prompting a secondary intervention to improve form access. By increasing the PSQ utilization, we hypothesize that we will identify more children with undiagnosed OSA and get them to indicated care sooner, as well as better characterize key factors predictive of OSA in this clinic's population.

PRACTICE PATTERNS IN PEDIATRIC PSG UTILIZATION PRE-AND-POST OPERATIVELY

Matthew Balog[1], Innessa Donskoy[1], Ayelet Snow[1], Darius Loghmanee[1]
[1] Advocate Children's Hospital

Introduction: Tonsillectomy is a common procedure in the United States with 289,000 pediatric ambulatory procedures completed annually. Since 2002, multiple professional organizations published guidelines recommending the use of Polysomnography (PSG) in young children prior to adenotonsillectomy. In cases of moderate to severe obstructive sleep apnea syndrome (OSAS) or in patients with high-risk comorbidities, a post-operative PSG is recommended also. Despite these guidelines, adherence remains low with 22% of American Society of Pediatric Otolaryngology (ASPO) members stating they order PSGs "always" or "most of the time" for children under 3 years of age. Previous clinical studies showed overall pre-surgical PSG compliance at 30% with rates climbing to 51-57% for children with high-risk comorbid conditions.
Methods: In this retrospective chart review, an electronic medical record (EMR) query for patients under 2 years old who underwent an adenoidectomy, tonsillectomy, or adenotonsillectomy from 1/1/2020 to 10/31/2024 was performed. The query included if a PSG was completed and basic PSG metrics. The query yielded a convenience sample of 424 children.
Results: Of the 424 children, 137 had pre-operative OSA diagnosis with 76% (103) obtaining a PSG within a year prior to surgical intervention and 61% (63) showing moderate or severe sleep apnea. Adherence to the recommendations varied yearly, ranging from 65-91%. ENT Practice variation was seen with compliance ranging from 27-100%. Post operative PSG completion for patients with at least moderate OSAS (AHI or REM AHI > 10/hr.) was 24% (15) with rates varying yearly from 0-40%. ENT Practice variation was seen with compliance ranging from 0-60%.
Conclusion: The pre-operative PSG completion rate compared to previous studies is encouraging, however, the low post-operative PSG rate highlights the need for closer partnerships with parents and physicians. As there is no expert consensus on the AHI defining severe OSAS, sleep clinicians should partner closely with their ENT colleagues in establishing practice patterns centered around expedient, quality care and patient safety. Dedicated continuous quality assurance and improvement programs measuring adherence to practice guidelines are needed. EMR tools for physicians, and educational electronic messaging for parents could aid in increasing post-operative PSG rates.

SLEEP HEALTH PHENOTYPES IN EARLY CHILDHOOD: ASSOCIATIONS WITH CAREGIVER SLEEP-RELATED FACTORS

Monica Ordway[1], Baram Kang[2], Michael Garza[2], Natalie Barnett[3], Meredith Wallace[4]

[1] Yale School Of Nursing, [2] Yale University School of Nursing, [3] Nanit Lab, [4] University of Pittsburgh

Introduction: Although sleep health is recognized as multidimensional, most studies focus on individual dimensions, overlooking the diversity in sleep patterns. Developing comprehensive sleep health phenotypes that reflect early childhood variability could enable personalized sleep goals and targeted interventions. Such phenotypes should incorporate subjective and objective sleep dimensions, account for developmental changes, and consider the role of caregivers in shaping sleep habits. This study aimed to identify distinct sleep phenotypes in early childhood and explore their associations with caregiver sleep-related factors.

Methods: We conducted a cross-sectional observational study of primary caregivers of toddlers aged 12–30 months recruited from a database of families using baby video monitors to track their children's sleep. Sleep phenotypes were identified using k-means clustering based on parental self-reported sleep data (BISQ-R) and objective sleep data via autovideosomnography (M=11.22; SD=2.82). Caregiver knowledge, attitudes, self-efficacy, and beliefs about sleep were assessed with a 19-item survey, and their associations with sleep phenotypes were analyzed. Descriptive analyses, including ANOVA, were performed using RStudio version 4.2.1.

Results: Among 1,036 participants (77.9% mothers; 78% non-Hispanic White; 78.3% aged 30–39 years), three distinct sleep phenotypes were identified: Group 1 (16%): late bedtime, short sleep duration, irregular bedtimes, and high parental perception; Group 2 (39%): recommended bedtime, acceptable sleep duration, somewhat consistent bedtime, and suboptimal parental perception; and Group 3 (46%): early bedtime, long sleep duration, consistent bedtime, and high parental perception. Parental knowledge, attitudes, self-efficacy, and beliefs differed significantly among groups, with Group 3 scoring highest across all domains. Post-hoc analyses revealed that Group 3 parents had significantly higher sleep knowledge compared to Group 1 ($p=0.001$) and Group 2 ($p=0.003$). Parental attitudes were significantly better in Group 3 than Group 1 ($p=0.02$). Self-efficacy was lowest in Group 1 compared to Group 2 ($p=0.04$) and Group 3 ($p< 0.001$). Parental beliefs differed significantly across all groups ($p's=< 0.03$) with Group 1 scoring lowest.

Conclusion: This study identified three distinct toddler sleep patterns and highlighted significant links between caregiver cognitive and behavioral factors and early childhood sleep phenotypes. These findings may guide tailored interventions to improve early sleep health and mitigate potential long-term physical and socioemotional consequences.

UNDERSTANDING CONTRIBUTORS TO EARLY CHILDHOOD SLEEP INTERVENTION RESPONSE: A MIXED METHODS STUDY

Brizhay Davis[1], Katherine Wu[1], Olivia Cicalese[1], Chimereodo Okoroji[2], Amanda Ayala[1], Kristina Boling-Smith[1], Bethany Harvey[1], Rachel Honore[1], Amy Kratchman[3], L'Vonne McMillan[1], Alexander Fiks[1], Thomas Power[1], Jodi Mindell[4], Ariel Williamson[5]

[1] Children's Hospital of Philadelphia, [2] Cincinnati Children's Hospital Medical Center and Department of Pediatrics, University of Cincinnati College of Medicine, [3] Novartis Pharmaceutical Company, [4] Saint Joseph's University, [5] The Ballmer Institute for Children's Behavioral Health, University of Oregon

Introduction: This mixed-methods study sought to identify contributors to caregiver-reported child sleep improvements after receiving Sleep Well!, a behavioral sleep intervention for 1-5-year-olds, by examining (1) quantitative data from intervention sessions and (2) qualitative caregiver perceptions at post-intervention.

Methods: Forty-six caregiver-child dyads (caregivers: 96% mothers, 64% non-Latine Black, 40%≦high school education; children: 40% girls, 67% non-Latine Black) randomized to Sleep Well! completed a 3-session telehealth intervention. Interventionists completed fidelity forms to indicate session content implemented (intervention components, suggested strategies, handouts, homework) and rated family engagement using a Likert scale item. Forty-two caregivers also completed post-intervention ratings of child sleep problems (Brief Child Sleep Questionnaire item, primary trial outcome) and semi-structured qualitative interviews, coded using thematic analysis. Child sleep improvements were dichotomized into "resolved sleep problem" versus "small to severe problem." Quantitative analyses (chi-square and t-tests) assessed relationships between session content, interventionist-rated engagement, and sleep problem resolution, while qualitative themes were stratified by sleep problem resolution status.

Results: A total of 64% (n=27) of dyads reported post-intervention sleep problem resolution. Intervention components, suggested strategies, handouts, and homework were not associated with sleep problem resolution. There was a moderate ($d=0.69$) difference in reporting of a resolved sleep problem based on interventionist-rated engagement, with higher engagement ratings for caregivers reporting a resolved sleep problem, although this did not reach statistical significance, $p=.10$. Furthermore, qualitative themes of strong intervention-related acceptability, cultural humility, and positive feedback did not differ according to whether the caregiver quantitatively reported a resolved child sleep problem. However, caregivers reporting a resolved child sleep problem qualitatively reported feeling well-equipped with tools from the intervention to manage child sleep, whereas those with an unresolved child sleep problem qualitatively expressed less confidence managing child sleep, citing their child's behavior as a challenge to sleep improvements.

Conclusion: Although caregivers reporting an unresolved child sleep problem after Sleep Well! participation qualitatively expressed positive intervention feedback, they also described less confidence in sleep strategies and more challenging child behaviors. Additional research is needed to develop more personalized strategies to address caregiver-reported challenging child behaviors, confidence in intervention strategies, and intervention engagement.

THE POWER DOWN: A NEW SENSORY-BASED BEDTIME INTERVENTION FOR CHILDREN WITH ADHD

Amy Hartman[1], Heather Joseph[2], Jessie Northrup[1], Tracey Murray[1], Isabel Brovender[1], Victoria Wong[1], Adriane Soehner[1]
[1] University of Pittsburgh, [2] University of Pittsburgh

Introduction: It is well known that children with attention deficit hyperactivity disorder (ADHD) have an elevated risk for poor sleep health. Sensory over-responsivity is also common for children with ADHD potentially impacting the ability for children to transition to sleep. Current interventions do not incorporate sensory-specific theories to decrease hyperarousal level at bedtime to support sleep health. This pilot study trials a novel sensory-based intervention targeting bedtime cognitive and physiological hyperarousal.
Methods: Children (6-13 yrs) with ADHD and their caregivers are being recruited to participant in a 3-week pilot intervention trial (total goal n=30). Biophysiological measures of arousal (e.g. electrodermal activity, physical activity) and sleep (actigraphy) are captured using the Empatica EmbracePlus and daily sleep and emotion diaries are completed. Caregivers complete a manualized gentle pressure massage and mindfulness protocol called the "Power Down". Intervention feasibility and acceptability are measured through qualitative interviews and questionnaires. Preliminary efficacy is measured through change in sleep and bedtime arousal measures at the end of the intervention trial (2 weeks long) compared to a 1-week baseline.
Results: Recruitment is on-going. Currently, one participant has completed the three-week study (8 years old, male) and one is half-way through the study (11 years old, male). Both participants and their caregivers identified transitioning to sleep as the primary difficulty related to sleep health. Both participant's caregivers reported that the Power Down intervention was acceptable, appropriate, and feasible after initial training (all agree to completely agree, 5-pt Likert scale). Data collection from the wearable device was feasible, with participants wearing the device for 22/25 days and 13/14 days of data collection. The Power Down was completed 12/13 and 7/9 days by the caregiver at the time of preliminary analysis. Preliminary efficacy will be examined upon completion of each participant's participation and will be updated at the time of the conference.
Conclusion: The Power Down has successfully been implemented with our first participants. As recruitment continues, interim data analysis will be conducted to examine continued acceptability, feasibility, and preliminary efficacy of the intervention.

FEASIBILITY AND ACCEPTABILITY OF SHEETS: A NEW DIGITAL INTERVENTION FOR ENHANCING SLEEP REGULARITY IN ADOLESCENTS

Jessica Lunsford-Avery[1], Ryan Shaw[1], Matthew Engelhard[1], Naomi Davis[1], Maggie Sweitzer[1], Shubha Parekh[1], Naomi Duke[1]
[1] Duke University School of Medicine

Introduction: Adolescence is associated with irregular sleep patterns, which in turn increases risk of onset and maintenance of internalizing symptoms (e.g., anxiety) and externalizing behaviors (e.g., risk-taking). Behavioral sleep interventions targeting sleep regularity that are optimized for real-world practice settings and widespread dissemination are needed to support psychiatric wellness during this critical development period. The objective of the current study was to evaluate the feasibility and acceptability of Sustainable Habits for Encouraging Even Teen Sleep (SHEETS), a novel six-week digital intervention designed to target sleep regularity as a mechanism to support psychiatric health in adolescents.
Methods: Adolescents aged 12-14 (target N=50) were recruited from primary care clinics and community advertisements. Participants were randomized to receive 6 weeks of either the SHEETS intervention app (targeting sleep regularity) or an active control intervention app (targeting general health behaviors). Both apps included similar graphics, activities (e.g., videos, quizzes), and gaming/incentive structures. Both groups received a Garmin activity tracker, which communicated real-time feedback about either sleep regularity (SHEETS) or physical activity (control) via the app. Feasibility and acceptability metrics included retention rate, engagement with app content (number of activities completed/assigned), and participant report of intervention satisfaction.
Results: Of 54 adolescents randomized (45% female, 44% minoritized race/ethnicity), 50 completed their assigned digital intervention (retention rate, 93%), meeting the target enrollment goal. In both interventions, there were 25 completers of 27 assigned. On average, participants completed 80% (median: 91%) of the app activities for SHEETS and 85% (median: 94%) of the active control. Engagement did not differ between interventions ($t(49)=.77$, $p=.45$). The majority of participants rated the SHEETS intervention app as easy to use (88%), visually appealing (76%), and reported satisfaction with the Garmin device (88%); results were similar for the active control.
Conclusion: SHEETS is a new digital intervention that aims to support psychiatric health in adolescents by enhancing sleep regularity. Both SHEETS and the active control app were associated with high engagement and satisfaction, suggesting digital sleep interventions are feasible and acceptable for use with adolescents. Future analyses will assess the effectiveness of SHEETS compared to active control on improving sleep regularity and psychiatric health in adolescents.

SOCIAL DETERMINANTS OF HEALTH PREDICTING ADHERENCE TO IN-HOME SLEEP EXTENSION IN ADOLESCENTS WITH HABITUALLY INSUFFICIENT SLEEP

Caitlyn Maye[1], Emily Cooper[2], Angel Bernard[3], Karolina Bohdan[3], Stephen Hawkins[2], Stacey Simon[2]

[1] Children's Hospital of Colorado, [2] University of Colorado Anschutz Medical Campus, [3] Children's Hospital Colorado

Introduction: Adolescents are at risk for insufficient sleep and late bedtimes due to biological, environmental, and social determinants of health (SDoH) factors. Insufficient sleep is associated with negative outcomes, including risk for obesity and mental health problems. Behavioral interventions may improve sleep health in adolescents, but factors that contribute to adherence are unknown. This study examined SDoH and other individual factors hypothesized to impact adherence to an in-home behavioral sleep extension manipulation in adolescents with habitually insufficient sleep.
Methods: Fifty-four adolescents (M=16.0±1.3y) with ≤7h sleep on school days completed a randomized crossover study of one week each of typical sleep (TS; usual school schedule) and sleep extension (EXT; ≥1h additional time in bed) in counterbalanced order. Sleep duration and timing were assessed with wrist-worn actigraphy. Participants completed baseline questionnaires of mood (PROMIS Depression & Anxiety) and sleep quality (Adolescent Sleep-Wake Scale, ASWS). SDoH data included age, BMI percentile, race/ethnicity, and the Child Opportunity Index (COI),a measure of social vulnerability. Linear mixed models were fit to predict sleep duration and bedtime based on the above factors, adjusting for condition, randomization, and period.
Results: During EXT compared to TS, participants increased sleep duration on average by 1.2h (TS 5.7±0.8h, EXT 6.9±0.8h) and advanced bedtime by 1.3h (TS 00:24±1.1h; EXT 23:06±1.1h). Lower COI, indicating living in lower opportunity neighborhoods, was associated with later bedtime (0.11h per 10-unit increase in COI; p=0.042), independent of sleep condition. Race/ethnicity was significantly associated with bedtime and sleep duration, such that sleep duration was lower by an average of 0.58 h for non-Hispanic non-White participants (p=0.013), independent of sleep condition. Poorer baseline sleep quality was associated with greater improvement in sleep duration during EXT (0.55h increase per 1-unit increase in sleep quality; p=0.045). No significant associations were found for age, mood, or BMI.
Conclusion: Among adolescents with habitually insufficient sleep, SDoH risk factors were associated with poorer sleep. Further research is needed to understand specific barriers to sleep health in adolescents living in lower opportunity neighborhoods and from historically minoritized backgrounds, and to tailor sleep interventions to address these unique needs.

AUTISM SPECTRUM MEALTIME BEHAVIOR: LINKS TO TRYPTOPHAN INDEX AND SLEEP PATTERNS IN CHILDREN AGED 3–6 YEARS

Naoki Sakane[1], Junichiro Somei[1], Yaeko Kawaguchi[2], Seiko Sakane[1]
[1] Kyoto Medical Center, [2] Kyoto

Introduction: Autism spectrum disorder (ASD) is a neurodevelopmental condition characterized by two main domains: (1) social communication and interaction, and (2) restricted, repetitive patterns of behavior, interests, or activities. Parents and caregivers of children with ASD have reported problematic mealtime behaviors; however, it is unclear which of these behaviors impact sleep. Additionally, a higher intake of tryptophan at breakfast may promote serotonin synthesis in children. This study aimed to investigate the association between mealtime behaviors and sleep behaviors in children aged 3-6 years.
Methods: A total of 283 children aged 3-6 years were included in the study. Mealtime behaviors were assessed using the Autism Spectrum Disorder Mealtime Behavior Questionnaire (ASD-MBQ), focusing on selective eating, clumsiness/manners, interest and concentration on eating, oral motor function, and overeating. Data on wake-up time, bedtime, total sleep duration, and midpoint of sleep were collected. The Tryptophan index (Trp-index) at breakfast was calculated as the amount of tryptophan per meal, based on the tryptophan content per 100 g of food and a standard portion size per meal.
Results: Compared to the non-selective eating group (n=121), the selective eating group (n=162) exhibited later wake-up times (6:44 ± 0:28 vs. 6:52 ± 0:32; P = 0.043), later bedtimes (21:15 ± 0:37 vs. 21:33 ± 0:33; P < 0.001), later midpoints of sleep (2:00 ± 0:27 vs. 2:13 ± 0:31; P< 0.001), shorter total sleep duration (9.5 ± 0.6 vs. 9.3 ± 0.7 hours; P = 0.021), and a lower Trp-Index (285 ± 167 vs. 234 ± 149; P = 0.007). However, there were no significant differences between the groups in age, sex, or breakfast frequency per week. Additionally, three other mealtime behaviors—interest and concentration on eating, oral motor function, and overeating—did not appear to influence sleep behavior.
Conclusion: We identified mealtime behaviors associated with sleep patterns and tryptophan intake at breakfast. This information can help healthcare professionals educate families about problematic mealtime and sleep behaviors in preschool children.

SLEEP PROBLEMS AND AUTISTIC BEHAVIORS IN CHILDREN WITH DOWN SYNDROME OR AUTISM SPECTRUM DISORDER

Shayleigh Page[1], Bruno Saconi[1], Amy Sawyer[2]
[1] Perelman School of Medicine at the University of Pennsylvania, [2] University of Pennsylvania School of Nursing

Introduction: Over two-thirds of children with Down Syndrome (DS) have obstructive sleep apnea and behavioral sleep problems are also common. About 20% of children with DS have co-morbid autism spectrum disorder (ASD). Autistic behaviors may contribute to behavioral sleep problems in DS, but this is understudied. We (1) compared sleep problems by diagnostic group (DS or ASD), and (2) described the association between autistic behaviors and sleep problems across the full sample.
Methods: This is a secondary analysis of data collected for a convergent mixed methods study on family management of mealtime and bedtime. Caregivers of children (4-10y) with DS or ASD were recruited from an urban children's hospital. Caregivers completed the Children's Sleep Habits Questionnaire (CSHQ) to assess sleep and the Social Responsiveness Scale-2 (SRS-2) to evaluate autistic behaviors. CSHQ scores were compared between groups using Mann Whitney U tests. Separate multiple linear regression models were fitted to assess the influence of SRS-2 domains on CSHQ scores, adjusting for DS diagnosis, age, and gender.
Results: Of N=85 participants, 29 had a child with DS and 56 ASD. Overall, 88.5% of the DS group and 84.3% of the ASD group had sleep problems (CSHQ score ≥ 41). There were no significant differences in total CSHQ scores between groups (p > 0.05). In the DS only group, 48.3% had elevated SRS-2 scores. In adjusted analysis, greater restricted and repetitive behaviors (adjusted mean

difference [95% CI] = 0.685 [0.178, 1.191], p =.009) and younger age (adjusted mean difference [95% CI] = -1.224 [-2.304, -0.143], p =.027) were associated with higher CSHQ scores, indicating greater parental concern about sleep problems.
Conclusion: Autistic behaviors were common in the DS group, even without an ASD diagnosis. Restrictive and repetitive behaviors, in particular, predicted the severity of sleep problems across the full sample. Future work should examine associations between autistic behaviors and sleep characteristics in a larger cohort of children with DS.

DO CHILDREN LIVING WITH A CHRONIC DISEASE HAVE MORE DISTURBED SLEEP THAN THEIR HEALTHY PEERS?

Cecilie Paulsrud[1], Steffen Thorsen[1], Pernille Helms[1], Mia Sofie Weis[1], Ajenthen Ranjan[1], Poul Jennum[2], Nanette Mol Debes[3], Jannet Svensson[1]
[1] Steno Diabetes Center Copenhagen/Department of Pediatrics, Herlev and Gentofte Hospital, [2] Danish Center for Sleep Medicine/ Rigshospitalet-Glostrup, [3] Department of Pediatrics, Herlev and Gentofte Hospital

Introduction: Living with a chronic disease (LCD) may impact sleep in children. We aimed to compare sleep in children LCD and healthy controls.
Methods: Design: Prospective study. Children and adolescents aged 6–17 years old answered the Sleep Screening Questionnaire Children and Adolescents (SSQ–CA) twice. They wore actigraphy (AG) for seven nights and at-home polysomnography (PSG) for one night. Statistics: Unpaired two-sampled t-tests.
Results: We included 65 LCD and 63 healthy age-matched children. Compared to the healthy controls the 6–12-year-olds LCD had shorter total sleep time (TST): AG:16.1 min, [95% CI -0.3; 32.6], SSQ–CA: 19.9 min [-0.7–40.5], later chronotype and chronotype score: AG: 00:25, [-00:07; 00:57] and significantly longer objectively measured sleep latency. Except for a higher sleep and feeling safe subscale score, no major differences in either SSQ-CA or AG measures were seen between the adolescent groups (13–17–year–olds). An inverse correlation between TST and glycated hemoglobin (HbA1c) (AG: r=-0.49, SSQ: r=-0.4) was shown in children with type 1 diabetes, and an inverse correlation between TST and monthly headache attacks (AG: r=-0.79) in children with tension-type headache.
Conclusion: Children LCD present more sleep disturbances than healthy controls, especially in the 6–12-year-olds. Sleep evaluation should be considered as part of the clinical evaluation.

SLEEP HEALTH IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL DISEASE

Seema Rani[1], Abigail Strang[2], Nicole Divirgilio[2], Aimee Hildenbrand[2], Kimberly Canter[2], Amanda Lewis[2], Robin Miller[2], Aaron Chidekel[2]
[1] Nemours Children's Health, [2] NCH, DE

Introduction: Youth with sickle cell disease (SCD) are at increased risk for respiratory and non-respiratory sleep impairment. Poor sleep is associated with vaso-occlusive crisis (VOC) and poor health-related quality of life (HRQL). We examined relationships between indicators of sleep health and healthcare utilization (HCU) for VOC and explored subjective and objective measures of sleep utilizing sleep diary and actigraphy in youth with SCD compared to healthy controls.
Methods: Cross-sectional 2-year study of youth ages 8-17 years with SCD (any genotype) and matched, healthy controls. Participants completed validated sleep questionnaires and Pediatric Quality of Life Inventory (PedsQL). Both populations completed 2-week sleep diary and actigraphy. Data was collected on HCU for VOC. Area deprivation index (ADI) for neighborhood rankings were calculated.
Results: 50 youth with SCD (60% female, Mean age=12.7 years, 66% HbSS) and 37 controls (57% female, Mean age=13.1 years) participated. Groups did not differ in anthropometrics. No statistically significant differences in the following in SCD and non-SCD groups: PROMIS SD or SRI scores, Child or Adolescent Sleep Hygiene Scores, and Epworth Sleepiness Scale. 38% of youth with SCD had scores indicating increased daytime sleepiness and screened higher risk for sleep disordered breathing (SDB) on PSQ. 32% of the youth with SCD had positive PSQ. SCD was associated with worse HRQL. 51% of youth with SCD had HCU for VOC. No significant association identified between HCU for VOC and sleep. ADI was significantly increased in children with SCD for both state, and national deciles. ADI did not correlate with measures of sleep health. No difference in actigraphy and sleep diaries between the cohorts. Correlative statistics between actigraphy and sleep diary, demonstrated moderate correlation between sleep duration and sleep time but poor correlation between sleep latency and sleep efficiency.
Conclusion: Youth with SCD in their baseline state of health reported comparable sleep to controls but had worse HRQL and higher ADI. Youth with SCD had significantly increased risk for SDB compared to controls. Indices of sleep health were not associated with HCU for VOC among youth with SCD. Sleep diary and actigraphy measures of sleep were similar in both populations

SLEEP AMONG ADOLESCENTS EXPERIENCING SUBTHRESHOLD PAIN

Melanie Stearns[1], Christina McCrae[1], Kevin McGovney[2], Ashley Curtis[1], Amy Costa[1], Mary Beth Miller[2], Uma Nair[1]
[1] University of South Florida, [2] University of Missouri

Introduction: Increased pain is associated with worse sleep among adults, but scant studies have examined this connection in adolescents. Specifically, no studies have examined sleep in adolescents experiencing subthreshold pain or how sleep differs among adolescents experiencing different pain levels. This study fills that gap.
Methods: Adolescents (N=400, Mage=15.23, 50%-female) experiencing pain in the past 3 months reported their average sleep onset latency (SOL) and total sleep time (TST) over the past month and average pain intensity over the past week (1-100

scale) as part of an online data collection. They also completed the Insomnia Severity Index (ISI). Pain responses were divided into four categories: no pain (0-29), subthreshold pain (30-49), moderate pain (50-69), and severe pain (70-100). SPSS One-way ANOVAs evaluated the effect of pain group on sleep (SOL, TST, ISI). Follow-up t-tests clarified significant group differences.
Results: A one-way ANOVA revealed a significant difference in SOL among the groups (F(3, 196)=3.68, p=.013). The subthreshold pain group reported higher SOL (M=75.29+\-52.59) than the no pain group (M=48.22+\-51.21, p=.007), the moderate pain group (M=50.33+\-41.22, p=.006), and the severe pain group (M=52.17+\-42.14, p=.044). A one-way ANOVA revealed a significant difference in ISI among the groups (F(3, 196)=4.78, p=.003). The no pain group reported lower ISI (M=10.27+\-6.24) than the subthreshold pain group (M=13.41+\-6.07, p=.009), the moderate pain group (M=13.45+\-6.19, p=.016), and the severe pain group (M=14.77+\-6.05, p=.002). There were no other significant differences among the groups for SOL or ISI. There was no significant difference in TST between the two groups (F(3, 196)=2.10, p=.101).
Conclusion: These results suggest that adolescents experiencing pain are at risk for sleep problems, particularly those who reported subthreshold pain levels. Thus, adolescents with pain and poor sleep may benefit from behavioral sleep interventions, even if they are only experiencing subthreshold pain. We encourage longitudinal and experimental research methodologies to further explore sleep characteristics among adolescents experiencing subthreshold pain.

PREVALENCE OF SLEEP CONCERNS AND SLEEP HYPNOTIC USE IN CHILDREN WITH RARE NEUROGENETIC CONDITIONS

Jennifer MacLean[1], Lauren Mattas[1], Rebecca Levy[2]
[1] Pediatric Neurology, Lucile Packard Children's Hospital Stanford, [2] Division of Child Neurology, Dept of Neurology and Neurological Sciences, Stanford Medicine

Introduction: Sleep disturbances are common in the pediatric population and contribute to significant stress on both the child and their care providers. Sleep has been linked to early brain development and learning, and poor sleep has been shown to contribute to behavioral problems and attention concerns. While some sleep disturbances are known to be associated with specific genetic conditions, their overall prevalence in children with rare neurogenetic conditions remains to be quantified.
Methods: Retrospective chart review was performed of all new patient consultations at a pediatric neurogenomics clinic in a sixth month period. Charts were queried for sleep concern based on prevalence of the following criteria: previous or current evaluation for sleep disordered breathing, spontaneous patient or caregiver complaint of sleep disturbance, or prescription for sleep hypnotic medication.
Results: Of the fifty nine pediatric patients seen for new consultations 33.9% were identified as having sleep concerns. Most prevalent concern was insomnia, though sleep apnea, excessive daytime sleepiness, and parasomnias were also identified. Some caregivers and patients identified multiple concerns. Of the seventeen patients with insomnia concerns identified, seven were already prescribed medication for sleep hypnotic benefit. It was noted in all of these patients insomnia was identified as a persistent concern. Sleep hypnotics utilized included clonidine, trazodone, guanfacine, and clobazam (utilized concurrently for insomnia and seizures in a single patient.) Melatonin and cannabidiol were frequently self-reported by caregivers who obtained them as over the counter supplements, but were not included in these analyses.
Conclusion: Children with rare genetic conditions, including those without a specific sleep disorder associated, should be screened for sleep disturbances and treated as appropriate. Polysomnography should be utilized if there are symptoms of sleep disordered breathing, particularly in conditions associated with hypotonia or airway malformation. In cases of insomnia consideration should be given for behavioral sleep interventions and, if clinically indicated, pharmacotherapy in conjunction with these interventions. These findings have led to our clinic adding screening for sleep disturbance as a standard assessment at all appointments to optimize care. Further research is needed in regards to pharmacotherapy in these conditions, particularly medications that may have cross-utilization for other symptoms, limiting polypharmacy.

DAILY ASSOCIATIONS BETWEEN SLEEP AND OPPOSITIONAL BEHAVIORS IN CHILDREN WITH OPPOSITIONAL DEFIANT DISORDER

Melanie Stearns[1], Kevin McGovney[2], Jason Craggs[1], Deborah Bell[2], David Gozal[3], Christina McCrae[1]
[1] University of South Florida, [2] University of Missouri, [3] Marshall University

Introduction: There is a strong relationship between increased oppositional behavioral problems and worse sleep among children with Oppositional Defiant Disorder (ODD). Indeed, approximately 50% of the children diagnosed with ODD also have sleep problems. However, no studies examined the daily relationship between oppositional behaviors and sleep in a sample of school-aged children with ODD and insomnia. This study fills that gap.
Methods: Parents of children with ODD and insomnia (N=8, Mage=9.62, 75% male) completed 14 days of daily sleep and behavior diaries for their children. Sleep variables included sleep onset latency-SOL, wake after sleep onset-WASO, and total sleep time-TST. Behavior variables included whether a parent-child argument occurred and whether the child yelled that day. Multilevel models (Rv4.2.2) examined daily associations between child sleep and behavior, controlling for child age and gender.
Results: Daily child argumentative behavior was associated with increased child WASO later that night (B=5.00, SE=2.38, p=.039). Daily child yelling had a trending association with increased child WASO later that night (B=5.17, SE=2.90, p=.079). Daily argumentative behavior was not associated with daily child SOL (p=.335) or TST (p =.570). Daily child yelling was not associated with daily child SOL (p=.695) or TST (p=.544).
Conclusion: Analyses suggest a relationship between daily child behavior and disrupted sleep (WASO). Given that parents in this study reported on their child's sleep, future studies should utilize objective sleep measures as well as longitudinal/multi-method

studies to determine causality. Future studies should examine whether poor sleep the previous night impacts child behavior the following night. In addition, the current study's results suggest that the efficacy of child sleep interventions might benefit from also targeting child behavior if the child has a history of oppositional behaviors.

DIFFERENCES IN INTERNALIZING SYMPTOMS ACROSS LATENT TRAJECTORY CLASSES OF CHILD SLEEP ANXIETY

Goun Jo[1], Seung Yun Baek[2], Hyunsik Kim[2], Sanha Lee[3], Yun Mi Shin[3], Aly Suh[1]

[1] Sungshin Women's University, [2] Sogang University, [3] Ajou University School of Medicine

Introduction: Previous studies suggest that emotional distress in children from family relationships is associated with declines in both objective sleep indicators and subjective sleep quality. Even after accounting for factors such as school-related anxiety and anxiety sensitivity, there is a close connection between sleep difficulties and internalizing symptoms in children. This study explores longitudinal trajectories of sleep anxiety and examines internalizing symptoms across different sleep anxiety trajectories.
Methods: This study conducted secondary analysis based on a large-scale prospective cohort study in South Korea. Data was collected annually from 2015 (Time1) to 2021 (Time7), with survey responses from children's primary caregivers. At Time1, the average age of the children (n = 381) was 3.3 ± 0.9 years (50.3% girls). Children's sleep anxiety was assessed using a subscale of the Children's Sleep Habits Questionnaire (CSHQ), and internalizing symptoms were measured using the total internalizing score from the Child Behavior Checklist (CBCL). Time1 internalizing scores captured early broad tendencies. Latent class growth analysis (LCGA) was conducted to identify sleep anxiety trajectories from Time1 to 7. Welch's ANOVA examined differences in Time1 internalizing scores among different trajectory groups.
Results: LCGA identified a 4-class quadratic model as the optimal solution. Class1 exhibited high sleep anxiety throughout all time points, while Class2 showed low sleep anxiety with a continuous downward trend. Class3 displayed low sleep anxiety at Time1, which increased over time, while Class4 showed high sleep anxiety that decreased significantly. Welch's ANOVA revealed significant differences in internalizing scores across latent classes ($p < .05$). Post hoc tests showed that Class4 had significantly higher internalizing scores than Class1 and 2 but no difference with Class3. Participants in Class4 exhibited the most severe internalizing problems (e.g., anxiety, depression, somatization).
Conclusion: These findings indicate that children's longitudinal sleep anxiety trajectories are closely linked to early, broad internalizing symptoms. Specifically, our results suggest that early internalizing symptoms may predict later sleep anxiety trajectories, with children exhibiting higher internalizing scores at earlier time points displaying more severe sleep anxiety patterns over time.
Support (if any): This research was supported by a grant of the R&D project, funded by the National Center for Mental Health (grant number: MHER22B03).

ASSOCIATION OF BEDTIME RESISTANCE AND SLEEP OUTCOMES IN TODDLERS

Jodi Mindell[1], Mikayla Carson[2], Erin Leichman[2], M. Catherine Mack[3], Katie Rotella[3]

[1] Saint Joseph's University, [2] Saint Joseph's University, [3] Kenvue Brands

Introduction: Bedtime resistance is commonly reported. However, little is known about the nature of bedtime resistance throughout toddlerhood and its association with sleep. Thus, the aims of this study are to 1) examine the prevalence of bedtime resistance in toddlers, and 2) determine associations between bedtime resistance, sleep parameters, and maternal perceptions of toddler sleep.
Methods: 318 mothers of toddlers (12-36 mos; M =23.1 mos) completed the Brief Infant Sleep Questionnaire–Revised (BISQ-R) and questions about bedtime resistance.
Results: Overall, 61.3% (n=195) indicated that their toddler exhibited resistance, fighting, and/or stalling at bedtime (bedtime resisters; BR), on an average 4.42 nights/week. BRs had later bedtimes (8:41pm vs 8:15pm), took longer to fall asleep (41.44 vs. 21.02mins), had more frequent (1.32 vs. 0.85) and longer night awakenings (31.23 vs. 17.32mins), and reduced longest stretch of sleep (7.53 vs. 8.76hrs) than those who did not resist bedtime, $p<.001$. BRs also had shorter total nighttime sleep (9.38 vs. 10.10 hrs) and total sleep per 24h (11.45 vs. 12.20hrs), $p<.001$. However, there were no differences in waketime, $p > .05$. In addition, BRs were less likely to have a consistent bedtime routine (5+ nights/week) (88.6% vs. 77.4%; $p=.012$). Mothers of BRs were more likely to perceive their toddler's sleep to be a problem (54.4% vs. 19.5%; $p<.001$) and bedtime to be difficult (48.7% vs. 3.3%; $p=.009$). Further, they were less likely to report that their child slept well during the night (59.5% vs. 84.6%; $p<.001$) and were less confident in managing their toddler's evening sleep (70.8% vs. 96.7%; $p<.001$). Similarly, bedtime resistance was associated with a higher likelihood of nap problems (35.0% vs. 10.8%; $p<.001$).
Conclusion: Approximately two-thirds of mothers report their toddlers exhibit bedtime resistance, which is associated with later bedtimes, decreased implementation of a consistent bedtime routine, prolonged sleep onset, worse sleep consolidation, and a higher likelihood of perceived sleep and nap problems. Interestingly, not all mothers who reported bedtime resistance perceived their toddler's sleep to be problematic. Thus, assessment and management of behavioral issues at bedtime is important and may result in improved sleep health.

SEX AND SCREEN TIME MODERATES THE RELATIONSHIP BETWEEN CAFFEINE INTAKE AND SLEEP DURATION AMONGST US ADOLESCENTS

Chris Cho[1], Ann Swartz[1], Paul Peppard[2]

[1] University of Wisconsin-Milwaukee, [2] University of Wisconsin-Madison

Introduction: Approximately 72% of high school students do not get enough sleep (8-10 hours) on school nights. Insufficient

sleep is associated with obesity, diabetes, injuries, poor mental health, and problems with attention and behavior among adolescents. The reasons for sleep loss differs by sex. Screen time and daily caffeine intake has been found to be associated with sleep disturbance and daytime sleepiness. The American Academy of Pediatrics recommends that adolescents aged 12 – 17 should limit their caffeine intake to less than 100mg per day. However, the relationship between caffeine and sleep duration may be moderated by sex and excessive computer screen time.
Methods: Data on 640 adolescents (ages 16–17 years, 53% female) from the National Health and Nutrition Examination Survey conducted between 2015–2018. Screen time was determined by self-reported computer use during leisure time (≥2 (excessive) vs. < 2 hours/day). Excessive caffeine intake was assessed using 2-day dietary recall and categorized as number of days (0, 1, or 2 days) with >100mg. Self-reported sleep duration ranged 3 to 14 hours per school night. Linear regression for complex survey data was used to analyze the data. The fully conditional specification method was used to handle missing data.
Results: While excessive caffeine was positively associated with sleep duration, the strength of the relationship varied by sex (p=0.018) and excessive computer use (p=0.020), respectively. Specifically, females who consumed excessive caffeine for 1 or 2 days reported 0.57 hours (SE=0.24), and 0.59 hours (SE=0.25) longer average sleep duration, respectively. Furthermore, among adolescents with excessive computer/screen time, those who consumed excessive caffeine for 1 day and 2 days reported 0.51 (SE=0.19) and 0.86 hours (SE=0.25) longer sleep duration, respectively. No difference in the caffeine-sleep duration association was found amongst males and those reporting < 2 hours of screen time. The longer sleep duration was due mainly to later wake-up time as bedtime were similar.
Conclusion: Sex and excessive screen time moderates the association between excessive caffeine intake and sleep duration. Longer self-reported sleep duration may not indicate restful sleep as caffeine has been shown to disrupt sleep and affect circadian rhythm.

LONGITUDINAL LINKAGES AMONG NEIGHBORHOOD QUALITY, SLEEP QUALITY, AND ADOLESCENT DEPRESSIVE SYMPTOMS

Estelle Berger[1], Jennifer Pfeifer[1], Ariel Williamson[2]
[1] Department of Psychology, University of Oregon, [2] The Ballmer Institute for Children's Behavioral Health, University of Oregon

Introduction: During adolescence, girls become disproportionately vulnerable to depression, while also undergoing marked changes in sleep. Although sleep and mood are robustly linked, environmental factors like neighborhood quality can impact both sleep and mood. This study examined linkages among neighborhood quality, sleep quality, and depressive symptoms longitudinally in a cohort of adolescent girls.
Methods: This study leverages data from the Transitions in Adolescent Girls (TAG) study, a prospective longitudinal examination of biological and psychosocial changes in adolescence. Wave 1 included N=174 adolescents, aged 10.0-13.0 years at enrollment (4.7% African American/Black, 10.3% Hispanic/Latine, 4.2% Native American or Native Alaskan, 65.7% White, 4.7% Asian, 0.5% Native Hawaiian or Pacific Islander, 6.6% Multiracial, 2.3% Other; 10.1% non-cisgender-identifying, 46.8% sexual minority identifying). Neighborhood quality was measured using the Child Opportunity Index 3.0 (COI), with scores (range= 1-100) reported by Census tract and normed at the state level, with higher scores reflecting better neighborhood quality. Wave 1 scores ranged from 5-91 (M=43.36; SD=26.77). At each wave, depressive symptoms were assessed using the Center for Epidemiological Studies Depression Scale for Children. Sleep was assessed using the Pittsburgh Sleep Quality Index, which has been validated in adolescent samples and reflects global sleep quality. We used linear regression to examine whether wave 1 neighborhood quality and wave 3 sleep quality were associated with depressive symptoms at wave 4, controlling for depressive symptoms at wave 3.
Results: Girls living in higher quality neighborhoods (i.e., higher wave 1 COI scores) subsequently experienced less severe depressive symptoms compared to those living in neighborhoods of poorer quality (b =.002, p =.055). When looking at the interaction between neighborhood quality and wave 3 sleep quality, those with the poorest quality sleep experienced significantly elevated depressive symptoms in wave 4, regardless of neighborhood quality. Further, those living in neighborhoods with the lowest COI scores experienced significantly greater depressive symptoms, regardless of sleep quality.
Conclusion: Initial findings suggest that neighborhood and sleep quality are independently and longitudinally associated with greater adolescent depressive symptoms. Future work will examine the impacts of neighborhood and sleep quality on the emergence and worsening of depressive symptoms over multiple study waves.

ACCEPTABILITY OF INFANT BEHAVIORAL SLEEP INTERVENTION BY BLACK MOTHERS OF INFANTS

Safia Ahmed[1], Alicia Chung[2], Jazmyne Whitlow[3], Rebecca McAdams[4], Lara McKenzie[4], Jodi Mindell[5], Sarah Honaker[1]
[1] Indiana University School of Medicine, [2] NYU Grossman School of Medicine, [3] Healthy Minds & Kayenta Therapy, [4] The Abigail Wexner Research Institute, Nationwide Children's Hospital, [5] Saint Joseph's Univeersity

Introduction: Infant Behavioral Sleep Intervention (BSI) is highly effective with demonstrated benefits to infant and family sleep and functioning. However, a survey study suggested lower acceptability of extinction-based approaches by Black mothers of infants. Factors contributing to lower acceptability have not yet been identified. One objective of the Sleep Guidance in Black Families with Infant Children (SLUMBER) study was to examine acceptability of infant BSI in Black families and identify factors impacting acceptability.
Methods: Black mothers (n=20; 60% with a college degree) with an infant birth-9 months (M=4.2 months; 70% male) recruited through social media participated in semi-structured virtual interviews. Interview transcripts were analyzed with NVivo software using a grounded theory thematic descriptive approach.
Results: Acceptability of extinction-based infant BSI varied, with 45% (n=9) of mothers highly supportive, 25% (n=5) with moderate/mixed support, and 30% (n=6) not supportive. Most

mothers (n=11, 55%) perceived infant BSI as well-aligned with their cultural and/or personal values. Of those mothers who were not supportive, 33% (n=2) were fundamentally against BSI, whereas 67% (n=4) felt it was acceptable but not a good fit for them personally. The most common facilitator was perceived benefit of infants learning to self-soothe, which almost all (n=18; 90%) noted as a desired goal, followed by benefits to infant and/or parental sleep (n=5; 25%). Common identified barriers included fear that the baby would feel abandoned (n=16; 80%), difficulty tolerating their infant crying (n=13; 65%), and the possibility that crying could indicate a problem (n=8; 40%). For those mothers reporting mixed acceptability, facilitating factors for engaging in infant BSI included: potential benefits to the infant's current and future sleep; older infant age; assurance that the infant was not hungry; and option to check and provide comfort during the process.
Conclusion: Infant BSI is broadly acceptable to most Black mothers of infants, although concerns for negative impacts on the infant and parental tolerance of crying were identified as potential barriers. Study findings have implications for developing culturally appropriate infant BSI interventions for Black families.

ADAPTING A COMMUNITY-ENGAGED SLEEP INTERVENTION FOR SCHOOL-AGE CHILDREN WITH AUTISM SPECTRUM DISORDER

Megan Wenzell[1], Max Wiznitzer[2], Ronald Hickman[1], Carolyn Ievers-Landis[3], James Spilsbury[2], Andrew Schlegelmilch[4], Stephanie Griggs[1]
[1] Case Western Reserve University Frances Payne Bolton School of Nursing, [2] Case Western Reserve University School of Medicine, [3] University Hospitals Cleveland Medical Center, Case Western Reserve University School of Medicine, [4] Private Practice for Children, Adults and Families Specializing in working with Neurodiverse Individuals

Introduction: Up to 78% of children with autism spectrum disorder (ASD) have sleep disturbance. In ASD, shorter sleep duration < 7 hours and lower sleep efficiency < 85% are associated with disruptive behavior, anxiety and increased parental stress. The purpose of this study is to collect qualitative data for the eventual adaptation of a modification of the Youth version of the Transdiagnostic Sleep and Circadian Intervention (TranS-C) to improve sleep health dimensions (B-SATED: behaviors, satisfaction, alertness, timing, efficiency, duration) in children with ASD.
Methods: A qualitative descriptive approach was used to collect data with a purposive sample of parents of children with ASD age 6-12 years with moderate or greater sleep disturbance. Children with a moderate to severe sleep apnea diagnosis were excluded. Parents completed a 1-hour, think-aloud Zoom interview. A semi-structured guide was used to collect information on the intervention format and delivery as well as sleep barriers and facilitators. Interviews were audio-recorded, transcribed verbatim, and analyzed using deductive content analysis and inductive identification of emergent themes via Dedoose version 9.0.17.
Results: Twelve parents (91.7% Female; mean age= 42.4 + 7.01 years) of children with ASD (58.3% Female, mean age= 9.5 + 2.06) completed the interviews. All parents expressed interest in the intervention and preferred Zoom for all sessions. Three parents (25%) stated their child would participate, five (41.7%) expressed willingness to try, and four (33.3%) said their child would not participate, citing reasons such as limited communication and hyperactivity. Parents provided recommendations to increase child engagement in sessions (e.g., preferred characters, artistic components). Parents identified facilitators of good sleep (consistent routine, physical activity, turning screens off before bed) and barriers of good sleep (co-sleeping, loud noises, sickness, multiple sleep locations, and anxiety).
Conclusion: Our preliminary results suggest that the TranS-C-Youth-Autism intervention is appropriate for parents of children with ASD. Our team is among the first to include experts from diverse multidisciplinary backgrounds and parents of children with ASD in the intervention adaptation process. We strongly believe that the modified intervention will be useful to parents of children with ASD due to our innovative community-engaged approach.

SLEEP REGULARITY TO ADVANCE ADOLESCENT HEALTH EQUITY: CONTEXTUAL PATHWAYS AND COMMUNITY VOICES

Naomi Duke[1], Carolina Sierra[2], Matthew Gibson[3], Allison Falls[4], Jessica Lunsford-Avery[1]
[1] Duke University School of Medicine, [2] Northwestern, [3] Duke, [4] Mass General Brigham

Introduction: Sleep is integral to health, and we know disparities exist with regard to sleep health. Sleep irregularity, etiologically distinct from sleep duration, is more common among adolescents with minoritized race and ethnic identities, and is associated with poor cardiometabolic and psychiatric health. The objective of this qualitative study was to identify facilitators and barriers to sleep regularity and targets to enhance adolescent sleep interventions, taking account of youth lived experiences.
Methods: This study, a university-community partnership, consisted of 10 semi-structured focus group interviews (FGIs) (N=60), sampling three key groups: (1) adolescents self-identifying as African American, Black, and/or Hispanic, ages 12-14, (2) their caregivers, and (3) community stakeholders, including educators, youth advocates, and clergy. FGI question development was guided by a socioecological framework with community member consultation. FGIs were conducted in English and Spanish, and occurred onsite at a youth-serving organization (n=4) or via Zoom in collaboration with local schools (n=6). Thematic analysis was used to identify key themes across contextual levels pertinent for sleep regularity.
Results: Dominant themes representing challenges to establishing and prioritizing regular sleep routines included increasing academic requirements translating into late nights or all-nighters, the seeming impossibility of balancing academics and extracurricular and work-related activities, and the ubiquitous presence of nighttime technology use. Factors situated at the intersection of household and school also emerged as significant barriers to sleep regularity, including mismatches between school start and end times and caregiver work schedules, which resulted in youth

spending extended hours in before- and after-school care arrangements. Relevant targets for structural interventions centered on mitigating adversity experiences, including violence exposure and the impact of educational and social policies yielding feelings and incidents of marginalization, hopelessness, anxiety, rumination and hypervigilance. Such interventions should also advocate for systems that increase access to mental health supports as facilitators of youth self-value, safety, emotional regulation and sleep.
Conclusion: Youth, caregivers, and community advocates identified key themes representing multiple mechanisms by which context influences sleep regularity. Interventions integrating supports across socioecological levels are critical to the development of culturally-relevant and community-engaged advances for adolescent sleep regularity.

EFFECTS OF AN INTEGRATED SLEEP AND CIRCADIAN INTERVENTION ON REWARD SENSITIVITY AND IMPULSIVITY METRICS IN ADOLESCENTS WITH DELAYED SLEEP TIMING

Delainey Wescott[1], Daniel Buysse[2], Duncan Clark[1], Greg Siegle[1], Meredith Wallace[1], Nina Oryshkewych[1], Allysa Quick[1], Riya Mirchandaney[1], Brant Hasler[1]
[1] University of Pittsburgh, [2] University of Pittsburgh School of Medicine

Introduction: Developmental delays in sleep coupled with early school start times lead to insufficient and misaligned sleep during adolescence. Short sleep and circadian misalignment can negatively impact reward sensitivity and impulsivity processes implicated in substance use behaviors. We tested whether an integrated sleep/circadian intervention advanced and extended sleep and modified reward sensitivity and impulsivity. We also determined if advanced sleep/circadian timing were associated with changes in reward and/or impulsivity.
Methods: Following an 8-day baseline period, 74 high school juniors and seniors (ages 16-19, 64% female sex at birth) were randomized to a 2-week sleep/circadian manipulation (n=38) or a sleep monitoring control (n=36). The manipulation included stable wake times, increased morning light (Re-Timers), decreased evening light (blue-blocking glasses), and advanced weeknight bedtimes. Circadian phase was measured using salivary dim light melatonin onset (4 pg/ml). Actigraphy-assessed sleep was measured continuously. Reward and impulsivity metrics were captured using self-report (Behavioral Activation Scale [BAS]; UPPS-P Impulsivity Scale) and behavioral tasks (Balloon Analogue Risk Task [BART], Cued Go/No-Go Task [CGNG]). Substance use was assessed using a Timeline Followback Interview. Multilevel models compared sleep, circadian, and reward-related changes between conditions across time, and tested associations between sleep/circadian and reward-related changes controlling for sex at birth.
Results: At baseline, 18% of participants reported cannabis and 35% in alcohol use during the past 3-months. The sleep/circadian manipulation advanced circadian phase by ~48-minutes (B=-0.58; p< 0.001), extended weeknight sleep by ~43-minutes (B=0.81; p=0.004), and prevented an increase in behavioral reward activation (BART: B=-0.40; p=0.048) compared to the control condition. Increased weeknight sleep was associated with decreased lack of perseverance (UPPS-P: B=-0.16; p=0.037) and increased reward responsiveness (BAS: B=0.26; p=0.027).
Conclusion: A 2-week integrated sleep/circadian intervention advanced and extended sleep for adolescents with delayed sleep timing who may be at risk for engaging in substance use behaviors. Despite relatively low rates of substance use in the current sample, our findings support the hypothesis that changes in sleep behaviors relate to changes in reward sensitivity and impulsivity. Longer-term interventions may be necessary to test if sleep and circadian changes can be maintained and whether changes in reward sensitivity and impulsivity reduce future substance use.

REVISED CUTOFF SCORE FOR THE CHILDREN'S SLEEP HABITS QUESTIONNAIRE IN TODDLERS AND PRESCHOOL CHILDREN WITH EPILEPSY

Yi-Shan Sung[1], Shao-Yu Tsai[2]
[1] National Taiwan University, [2] School of Nursing, College of Medicine, National Taiwan University

Introduction: Sleep disturbances are a significant concern for children with epilepsy, affecting over 70% of this sample. The Children's Sleep Habits Questionnaire (CSHQ) is widely used to screen for sleep problems in children. However, its standard cutoff score of 41 is designed for general Western pediatric samples aged 4–10 years. It may not fully capture the unique sleep challenges faced by toddlers and preschool-age children with epilepsy in Taiwan. Previous research has emphasized revising the CSHQ for younger children and specific cultural contexts. For example, co-sleeping is common among young children and Asian samples and may not necessarily indicate sleep disturbances. This study aimed to identify a revised CSHQ cutoff score for toddlers and preschool-age children with epilepsy, incorporating objective actigraphy measurements to improve the accuracy of detecting sleep disturbances in this sample.
Methods: This study included 141 toddlers and preschool-age children with epilepsy (mean age: 3.79 ± 1.29 years). Sleep assessments were conducted using the CSHQ and actigraphy. Actigraphy-defined sleep disturbances were determined using established objective criteria: wake after sleep onset (WASO) > 50 minutes, sleep efficiency < 85%, and sleep latency > 45 minutes. Receiver operating characteristic (ROC) curve analysis was performed to determine the optimal CSHQ cutoff score. Chi-square tests were used to assess the association between actigraphy-defined sleep disturbances and CSHQ cutoff scores.
Results: ROC curve analysis revealed an optimal CSHQ cutoff score of 48.5, which maximized both sensitivity (85%) and specificity (82%) for detecting significant sleep disturbances in this sample. The CSHQ standard cutoff score of 41 showed no significant association with actigraphy-defined sleep disturbances ($\chi 2$ =0.98, p=0.32). However, the revised cutoff score of 48.5 demonstrated a significant association with actigraphy-defined sleep disturbances ($\chi 2$ =5.24, p=0.02).
Conclusion: The findings of this study suggest that adjusting the CSHQ cutoff to 48.5 improves its accuracy in detecting sleep disturbances in toddlers and preschool-age children with epilepsy. This revised cutoff score enhances the alignment between the CSHQ and objective actigraphy measures, offering a more reliable screening tool for sleep problems in this sample.

CLAIMS-BASED PEDIATRIC INSOMNIA DIAGNOSIS, MANAGEMENT, AND INSURANCE-RELATED DISPARITIES

Si Hao Tang[1], Jungwon Min[2], Xuemei Zhang[2], Eberechukwu Uwah[2], Heather Griffis[2], Christopher Cielo[2], Alexander Fiks[2], Ignacio Tapia[3], Jodi Mindell[4], Ariel Williamson[5]

[1] Drexel University College of Medicine, [2] Children's Hospital of Philadelphia, [3] University of Miami Miller School of Medicine, [4] Saint Joseph's University, [5] The Ballmer Institute for Children's Behavioral Health, University of Oregon

Introduction: Insomnia impacts 10-30% of children and adolescents. While cognitive-behavioral therapy is the evidence-based treatment for insomnia, there are few providers and low rates of outpatient diagnosis, which may limit access. Research suggests that children in lower-income homes and neighborhoods experience greater insomnia symptoms compared to those in higher-income settings, but few studies have examined disparities in care. Additionally, although there are no FDA-approved pediatric insomnia medications in the US, little is known about outpatient prescribing beyond clinician surveys. This study used claims data to characterize pediatric insomnia incidence and management, including disparities in care.

Methods: We used 2017 IBM® MarketScan® insurance claims (n=12,394,902) to identify 0-17-year-olds with (a) a new insomnia diagnosis (i.e., no diagnosis in the prior year,) and (b) 1-year post-diagnosis and prescription data, to examine follow-up care. Multivariate logistic regression with covariates (age, sex, and prior/concurrent chronic medical, neurodevelopmental, or behavioral health disorders) examined disparities in insomnia management by commercial versus Medicaid coverage.

Results: The overall incidence of new insomnia diagnosis was 0.47% (n=58,269). Of those with 1-year post-diagnosis and prescription data (n=35,506, 53.4% boys), most (52.6%) were adolescents and 66.3% were Medicaid-insured. While 37.9% of these youth had a behavioral health visit and 20.3% had a psychological assessment during the 1-year post-diagnosis, 14.8% received no treatment, and 5.7% received pharmacologic care only, without any office visits, including primary care or other specialties. Alpha agonists (30.0%) and antidepressants (14.5%) were most prescribed. Compared to those with commercial insurance, Medicaid-insured children had lower odds of behavioral health visits (Odds ratio [OR]=0.66, p<.001) and higher odds of receiving pharmacologic care (OR=1.69, p<.001) in the year post-diagnosis, even when covarying for co-occurring medical, neurodevelopmental, and behavioral health conditions. Medicaid-insured children were only slightly less likely than commercially insured children to have had a psychological assessment (OR=0.93, p<.01).

Conclusion: The incidence of insomnia was exceptionally low (< 1%) compared to epidemiologic research. Findings also suggest insurance-related disparities, with limited behavioral health follow-up in Medicaid-insured versus commercially insured youth, yet increased likelihood of receiving pharmacological management. Findings highlight the need to standardize evidence-based and equitable pediatric insomnia diagnosis and management.

SCORING ACTIGRAPHY WITH AND WITHOUT SLEEP DIARIES: A COMPARISON OF HIERARCHICAL PROCEDURES AMONG CHILDREN WITH SLEEP PROBLEMS

Carter Baker[1], Megan Rech[1], Fatima Qureshi[1], Anthony Cifre[1], Alyssa Vieira[1], Annika Myers[1], Jinu Kim[1], Yuexin Zhang[1], Candice Alfano[1]

[1] University of Houston

Introduction: Actigraphy is a widely used approach for measuring sleep, but there is a lack of consensus regarding determination of the rest interval (i.e., "time in bed"). Methods often employ a hierarchy of inputs from multiple data sources. Examples include a procedure developed by Patel and colleagues (2015), event marker > sleep diary > light > activity ("original approach"), and a modified procedure (Kubala et al., 2019), event marker > light > sleep diary > activity ("modified approach"). Yet, sleep diaries are burdensome to complete and vulnerable to inaccuracies (e.g., due to recall bias), particularly when completed by parents/caregivers. Here, we compared these hierarchical procedures, with and without the inclusion of sleep diaries, to assess rest interval length among youth with elevated rates of sleep problems.

Methods: N=25 children adopted from foster care (68% female), ages 7 to 14 years (M=9.68, SD=2.63), recruited as part of a larger study. All scored in the clinical range on a parent-report measure of sleep problems. Here, 7 nights of actigraphy (Actiwatch Spectrum, Philips Respironics) and sleep diary data per participant were analyzed.

Results: A two-way repeated measures ANOVA was used to determine the effect of scoring method on rest interval length across 7 nights. The mean rest interval length (hours) across all participants and nights for each scoring approach was as follows: original approach with sleep diary, M=9.77±1.51; original approach without sleep diary, M=9.72±1.46; modified approach with sleep diary, M=9.78±1.48; and modified approach without sleep diary, M=9.72±1.46. There was no statistically significant interaction between scoring method and night, F(4.957, 118.974) = 0.339, p=.887; therefore, main effects were examined. Surprisingly, there was no statistically significant difference in rest interval length between scoring methods, F(1.090, 26.159) = 2.799, p =.104. Rest interval length also did not significantly differ between nights, F(3.607, 86.561) = 1.395, p=.245.

Conclusion: We found that the inclusion versus exclusion of sleep diary data did not result in significant differences in rest interval length for either scoring approach. The extent to which use of parent-reported sleep diaries improves actigraphy-based assessment of sleep among populations of children with high rates of sleep problems warrants further study.

ASSESSING THE EFFECT OF THE COVID-19 PANDEMIC ON SLEEP PATTERNS IN CHILDREN USING POLYSOMNOGRAPHY

Eloy Espinoza[1]

[1] St Luke's University Healthcare Center

Introduction: The COVID-19 pandemic, lockdown, quarantines, virtual classrooms, and work-from-home policies during this pandemic have had a significant impact on the sleep patterns of children and caregivers. Multiple international studies have revealed the pandemic has caused increased sleep latency, sleep disruption, increased use of sleep aides, and worsening of previously diagnosed sleep disorders. To our knowledge, no studies have objectively recorded the impact of a global pandemic on children via review of the polysomnogram (PSG) to date. This study aimed to quantify the impact of a global pandemic on sleep patterns within the pediatric population via polysomnographic review.
Methods: A retrospective case-control study enrolled 6-12-year-old children, excluding those with mild-severe obstructive sleep apnea. Conducted at a single academic center.
Results: Ninety-nine children underwent PSG during the pre-pandemic period in 2019, and 85 children underwent PSG during the COVID-19 pandemic. The PSG studies analyzed sleep parameters such as sleep efficiency, sleep latency, total sleep time, REM latency, total REM time, REM AHI, and arousal index. Data analysis was done with SPSS version 26. Estimates were adjusted ANCOVA. There was a statistically significant reduction in Sleep Efficiency ($P < 0.0001$), an increase in Sleep Latency ($P < 0.029$), and a reduction in % REM Sleep and total REM time ($P < 0.001$).
Conclusion: The data showed a statistically significant decline in pediatric sleep efficiency and sleep quality associated with the pandemic, specifically increased sleep latency and decreased total REM sleep. This data validates the published reports, with subjective data gathered through surveys and online questionnaires. This could significantly impact the maintenance of sleep health in children during periods of stress such as the COVID-19 pandemic.

PREVALENCE OF RESTLESS LEG SYNDROME IN CHILDREN WITH CYSTIC FIBROSIS

Swati Jayaram[1], Michelle Gillespie[1], Katelyn Krivchenia[1], Mariah Eisner[1], Amanda Jacobson-Kelly[2], Karen McCoy[1], Maninder Kalra[1]

[1] Division of Pulmonary and Sleep Medicine, Nationwide Children's Hospital, [2] Division of Hematology/Oncology, Nationwide Children's Hospital

Introduction: Restless leg syndrome (RLS) is a sleep disorder affecting 2-4% of school-aged children and adolescents with iron deficiency being implicated in its pathogenesis. Patients with cystic fibrosis (CF) are at risk for iron deficiency and prior studies show up to 11% of adults with CF have RLS. There is a paucity of research addressing RLS in children with CF. The objective of this study is to investigate the prevalence of RLS in children with CF and to examine the relationship between the severity of RLS symptoms and iron status.
Methods: This was a single-center, prospective, observational study recruiting children and adolescents with CF aged 10-18 years seen in outpatient clinic from December 2023 to December 2024. Patient and Parent screening questionnaires for RLS using International Restless Legs Syndrome Study Group (IRLS) pediatric criteria were administered to consented families. The RLS severity scale was completed in patients with positive screening questionnaires. A chart review was performed to collect clinical information on subjects' nutritional, respiratory, and iron status (using red cell distribution width (RDW) as a surrogate for this).
Results: Seventy-six patients consented to participate in the study. Of these, 46 were female, with a mean age of 14.2 + 2.5 years and a mean body mass index of 21 + 3.4 kg/m2. Five patients tested positive for definite RLS, resulting in a prevalence rate of 6.6% in CF patients. According to the IRLS severity scale, one case was classified as mild, three as moderate and one as severe. RDW ranged from 11.6% to 17.8% and RLS prevalence was 10.5% in the highest RDW quartile and 5.2% in the lowest RDW quartile.
Conclusion: This is the first report of RLS prevalence in children with CF using IRLS pediatric criteria. This study highlights the need for further research examining the relationship between iron levels, as measured by ferritin, and the severity of RLS in this population. Such studies are crucial to establishing a reliable understanding of how iron status may influence the development and severity of RLS in children with CF and could inform more targeted interventions or treatments.

A GOOD NIGHT'S SLEEP? THE ASSOCIATION BETWEEN NEURODEVELOPMENTAL DISORDERS AND RESTLESS SLEEP DISORDER

Diana Kagan[1], David Wensley[2], Marie Wright[2], James Lee[2], Lena Xiao[2]

[1] The University of British Columbia, [2] BC Children's Hospital

Introduction: Sleep disorders are prevalent in children and are associated with behavioral and neurocognitive impacts when left untreated. A recently identified sleep-related movement disorder, restless sleep disorder (RSD), is characterized by frequent body movements during sleep resulting in daytime impairment. RSD is diagnosed based on clinical symptoms as well as objective evidence of restless sleep on an overnight polysomnogram and improves with iron supplementation. Despite the frequent comorbidity of sleep disruption among children with neurodevelopmental disorders, there is a paucity of data assessing the association between RSD and neurodevelopmental disorders. Thus, we sought to evaluate the association between RSD and neurodevelopmental disorders in children.
Methods: This is an interim analysis of a retrospective study of children aged 6-18 years old who completed a baseline diagnostic polysomnogram at British Columbia Children's Hospital between December 2023 – May 2024. Polysomnogram data was evaluated for large muscle movements according to the International Restless Legs Syndrome Study Group standards. Neurodevelopmental disorders were classified according to the DSM-5.
Results: There were 150 children (median age = 11 years, females = 57/154 (38.0%) and 57/150 (38.0%) had a neurodevelopmental disorder. In total, there were 23/150 (15.3%) children with RSD, 48/150 (32.0%) with moderate or severe obstructive sleep apnea, and 2/150 (1.3%) with restless legs syndrome. Of the children with neurodevelopmental disorders, 5/57 (8.8%) had RSD whereas 18/93 (19.4%) children without a neurodevelopmental disorder were found to have RSD ($p = 0.081$). Children with a neurodevelopmental disorder were more likely to receive iron supplementation (18% of

children with neurodevelopmental disorders vs 3.9% of children without neurodevelopmental disorders; p=0.012), which may confound the results.
Conclusion: In this interim analysis, we did not find an association between neurodevelopmental disorders and RSD. However, children with neurodevelopmental disorders were more likely to receive iron supplementation, which may confound our results. Data collection is ongoing to better elucidate this relationship. Ultimately, the results of this study will examine the association between neurodevelopmental disorders and RSD to inform the need for the routine assessment of RSD in children with neurodevelopmental disorders.
Support (if any): We thank the BC Children's Hospital Research Institute for providing funding.

SCORING LARGE MUSCLE MOVEMENTS IN PEDIATRIC SLEEP STUDIES: AN EDUCATIONAL MODULE FOR SLEEP TECHNOLOGISTS

Shauna Michelle Vandoren[1], David Ingram[1]
[1] Children's Mercy Kansas City

Introduction: Restless Sleep Disorder (RSD) has recently been recognized as a distinct sleep disorder, with Large Muscle Movement (LMM) scoring being a crucial component of its diagnostic criteria. This project aimed to develop and implement an online educational module to enhance the knowledge and skills of sleep technologists to accurately score LMMs.
Methods: We constructed an online learning module that included training on the identification and scoring of LMMs in pediatric sleep studies. The module consisted of a 10-question pre-assessment, the educational content (which explained the background of RSD diagnosis, the role of LMMs in diagnostic criteria, and current scoring rules), a repeat of the 10 questions for post-assessment, and a feedback section regarding the module and LMM scoring in general.
Results: Preliminary results indicate a significant improvement in the accuracy and consistency of LMM scoring among sleep technologists who completed the module. The average post-module assessment scores showed a marked increase compared to pre-module scores, with total scores on the 10-question learning assessment increasing from 63.3+/-20.6% pre-module to 90.0+/- 8.9% post-module (p=0.017). Eighty percent of technologists agreed or strongly agreed with the statement that "As a result of taking this course I am confident I can recognize the clinical characteristics, symptoms, and diagnostic criteria of RSD." Similarly, 60% agreed or strongly agreed with the state that "As a result of taking this course, I am confident I can accurately apply scoring guidelines for LMM events in sleep studies." Feedback from technologists regarding the module itself, as well as questions and suggestions regarding LMM scoring in general, provided valuable information for potential future revisions of scoring rules.
Conclusion: An online educational module significantly improved the knowledge and ability of sleep technologists to score LMMs accurately, thereby aiding in the diagnosis of RSD. This initiative highlights the importance of continuous education and training in maintaining high standards of care in pediatric sleep studies.

PARENTAL SLEEP KNOWLEDGE AND TODDLER SLEEP: ASSOCIATIONS WITH CULTURAL VALUES AND ACCULTURATION AMONG MEXICAN AMERICAN FAMILIES

Melissa Fineman[1], Maria Flores[2], Ileana Barron[3], Suzanna Martinez[4], Ariel Williamson[5], Darcy Thompson[2], Lisa Meltzer[6]
[1] University of Colorado School of Medicine, [2] University of Colorado, [3] Office of Research, Denver Health and Hospital Authority, [4] UCSF School of Medicine, [5] The Ballmer Institute for Children's Behavioral Health, University of Oregon, [6] National Jewish Health

Introduction: Cultural values and acculturation strongly influence parenting behavior, yet few studies have considered how they may influence toddler sleep. This study characterized parental sleep knowledge, values, acculturation, and bedtime among toddlers from Mexican American families.
Methods: 158 parents (156 mothers; 19-45 years; mean education 12.3±3.0 years) of Mexican American toddlers (62% boys; 12-16 months) completed surveys in Spanish (54.4%) or English. Toddlers wore an actigraph for 7 days/nights to estimate average bedtime. Participants were asked about Mexican American cultural values of respect (V-Resp, 8 items, range 1-5, higher score indicating stronger endorsement), acculturation to non-Hispanic U.S. culture (6 items, range 1-4, ≥2.5=high acculturation), and sleep knowledge (10 True/False items; range 1-10).
Results: Parents averaged 7.5 + 1.7 correct on the sleep knowledge measure, with the most common incorrect responses for the items "children who do not get enough sleep are more likely to be overweight" (SK-OV, 50.7% incorrect) and "children only need a bedtime routine if they have trouble falling asleep" (SK-BR, 41.8% incorrect). More parents that incorrectly answered SK-OV (vs. correct) had high acculturation scores (72.7% vs. 27.3%, X2=4.0, p=.046). More parents that incorrectly answered SK-BR (vs. correct) had low acculturation scores (57.6% vs. 42.4%, X2=24.3, p=<.001). Parents that incorrectly answered SK-BR and SK-OV had higher V-Resp scores (SK-BR: $\bar{x}$=4.0 vs. 3.7, F=10.2, p=.002; SK-OV: $\bar{x}$=4.0 vs. 3.7, F=11.3, p=.001). Toddlers of parents that incorrectly answered SK-BR and SK-OV had significantly later bedtimes (22 min, p=.033; and 24 min, p=.021 respectively). In a stepwise regression controlling for parental age and education, V-Resp was significantly associated with later toddler bedtime (R2=.211, β=.364, p=.002).
Conclusion: High acculturation and Mexican American cultural values of respect were associated with parent sleep knowledge and toddler bedtime in Mexican American families. The measure used to assess cultural values focuses on intergenerational behaviors and the influence of elder wisdom, suggesting perhaps parental knowledge and toddler sleep routines are based on what has been learned from family vs. health professionals. Understanding cultural values and acculturative differences is crucial for personalizing sleep education and addressing common misconceptions about toddler sleep health for Mexican American families in both clinical and community settings.

PARENTING PRACTICES REGARDING SCREEN USE AT BEDTIME AND ITS RELATIONSHIP WITH TODDLER SLEEP IN MEXICAN AMERICAN FAMILIES

Darcy Thompson[1], Lauren Clark[2], Natasha Cabrera[3], Sarah Schmiege[4], Lisa Meltzer[5]

[1] University of Colorado, [2] University of California Los Angeles, [3] University of Maryland, [4] University of Colorado Anschutz Medical Campus, [5] National Jewish Health

Introduction: Screen use around bedtime starts for many children in early childhood despite recommendations to restrict such use. Evidence is currently lacking on the relationship of parenting practices regarding sleep and screens with objectively measured toddler sleep. Such findings could inform the design of culturally-relevant interventions promoting healthy screen use and sleep in toddlers. The objective of this study was to evaluate whether maternal parenting practices regarding sleep and screens are associated with toddler sleep in Mexican American families.
Methods: Mexican American families with toddlers were recruited from a safety-net health system. Mothers completed orally administered surveys that included items on parenting practices regarding screen use and sleep: (1) the frequency of having their toddler use a screen device to help their child fall asleep and (2) the frequency of allowing their toddler to use a screen device before bedtime. Responses to each item were dichotomized (never/ever). Toddler average bedtime, sleep-onset time, and duration were measured with 7 days/nights of actigraphy. Data were analyzed using t-tests to evaluate the relationship between each parenting practice and sleep outcomes.
Results: 384 mother-toddler dyads participated. Mothers were on average 31.4 years old (SD=6.0), 85% were partnered, and mean education level was 11.6 years (SD=2.5). Toddlers were on average 21.2 months old (SD=3.1) and about half were boys (49%). Mothers who reported ever using screens to help their toddler fall asleep, versus those who reported never, had toddlers with significantly later average bedtime (24 minutes, p<.01), later average sleep-onset time (24 minutes, p<.01), and shorter average sleep duration (18 minutes, p< 0.03). There were no differences in toddler sleep (average bedtime, sleep onset-time, and sleep duration) in those with mothers who reported ever versus never allowing toddler screen use before bed.
Conclusion: Parental use of screens to help a toddler fall asleep is associated with toddler sleep, including later bedtimes and shorter sleep durations, whereas the general practice of allowing screen use before bed was not associated with toddler sleep. Parental use of screens as a behavioral tool to help their toddler fall asleep may create a sleep onset association that negatively impacts child sleep.

MEDICAL CLOWNS IMPROVE SLEEP AND SHORTEN HOSPITALIZATION DURATION IN HOSPITALIZED CHILDREN

Giora Pillar[1], Maya Shimshi Barash[2]

[1] Carmel Hospital and Technion Faculty of Medicine, [2] Carmel Hospital and Technion IIT

Introduction: Intervention by medical clowns has been shown to reduce stress and anxiety, which in turn may affect sleep. It is well established that sleep is important for recovery from injury and illnesses. Thus, we sought to examine the ability of medical clowns to positively impact children's sleep and health during hospitalization.
Methods: The study is an observational matching (case-control) interventional study which took place at the department of pediatrics in Carmel Medical Center. Forty-two hospitalized children ages 2-17 were included in two equal groups of intervention or control. Children in the control group were recruited based on matching of the chief complaint, medical diagnosis and age of the children in the intervention group in a 1:1 matching. Sleep was objectively evaluated for two consecutive nights using actigraphy, and subjectively utilizing sleep questionnaires. Hospitalization duration and demographics were also monitored. The study group had an encounter with a medical clown (15-30min) before bedtime on either the first or the second hospitalization night, while the control group was not exposed to a medical clowns at all.
Results: Study (clown) and control groups (n=21 in each) were comparable in age and clinical characteristics. The study group had a significantly delayed wake-up time compared to the control group (06:59±46min vs. 07:26±42min, p< 0.05) (mean difference of 27min). Sleep period time was significantly longer in the study versus the control group (570±76 vs. 500±66.1min, p< 0.05), a total mean increase of 70 minutes. Sleep efficiency was significantly higher in the study group (92.3±4.6% vs. 87.9±8.7%, p< 0.05). Within the clown group, when comparing nights with and without a medical clown, total sleep time was on average 54 minutes longer on the night of the intervention (518±74min vs. 464±59min, p< 0.01), and the wake after sleep onset (WASO) significantly shorter (42±25min vs. 66±58, p< 0.05), mean difference of 24min). Regarding general medical outcomes, hospital stay was significantly shorter in the clown group vs. control (104±42h vs. 128±42h, p< 0.05).
Conclusion: An encounter with a medical clown before bedtime in hospitalized children improves sleep and shortens hospital stay.

A PRELIMINARY EVALUATION OF THE EFFECTS OF HIGHLY EFFECTIVE MODULATOR THERAPY ON SLEEP IN PRESCHOOL CHILDREN WITH CYSTIC FIBROSIS

Lauren Greenawald[1], Aaron chidekel[2], Kimberly Canter[2], Kimberly Renner[1], Kerry Smallacombe[1]

[1] Nemours Childrens Hospital Delaware, [2] NCH, DE

Introduction: Sleep is critical to health and development in pediatrics. More than one quarter of healthy children experience sleep disturbances, and chronic illnesses such as Cystic Fibrosis (CF) can exacerbate sleep difficulties. Pediatric CF has been associated with snoring, impaired sleep quality, and daytime sleepiness. Polysomnogram findings include shorter sleep times, frequent arousals and reduced REM. CF Transmembrane Regulator (CFTR) modulator medications have revolutionized CF care; however, as these therapies and potential adverse effects are fully evaluated, it is critical to assess sleep health. We hypothesized that pediatric CF patients on Elexacaftor/Tezacaftor/Ivacaftor (ETI) therapy will have stable or improved sleep.

Methods: This IRB approved, prospective study was conducted at Nemours Children's Hospital, Delaware. Ten ETI-eligible patients aged 2-5 years were enrolled and parents/guardians completed surveys at three office visits. Parents/guardians completed the Brief Infant Sleep Questionnaire (BISQ-R) and a 25-item investigator-designed questionnaire reviewing medical symptoms during sleep. Exclusion criteria included English as a second language.
Results: The 10 patients (5 male) had an average age of 4.2 years. To date, 0/10 children reported baseline nocturnal respiratory symptoms and 0/10 parents/guardians felt a CF diagnosis affected sleep. During a pulmonary exacerbation, 3/10 patients reported nighttime awakenings and a negative impact on sleep quality compared to 2/9 at visit 2. BISQ-R results showed 10/10 children had a consistent bedtime routine at least 5 nights a week. Patients slept an avg 7.5 hours at visit 1 with 6/10 patients having at least one nighttime awakening. At visit 2, patients slept an avg 9.5 hours and no change in nocturnal awakenings. One patient reported longer sleep latency and a later bedtime at visit 2. Two parents reported bedtime was more challenging at visit 2 compared to visit 1. Official BISQ-R scoring is pending at this time but will be available for conference.
Conclusion: Sleep evaluation in this cohort of preschoolers with CF and ETI initiation shows a healthy baseline and improvement in sleep measures. Limitations include a small sample size and additional confounders may be natural changes in sleep due to patient age. Data suggests evaluation of sleep may be helpful for preschoolers on ETI therapy.

POLYSOMNOGRAPHIC DATA IN CHILDREN WITH CYSTIC FIBROSIS ON HIGHLY EFFECTIVE MODULATOR THERAPY

Aarti Shakkottai[1]
[1] University of Texas Southwestern Medical Center

Introduction: Sleep disorders are highly prevalent among people with chronic disease. Cystic fibrosis (CF) is a chronic, life-limiting, multisystem genetic disease that is the most common single-gene disorder among Caucasians worldwide. Highly effective modulator therapies (HEMTs), by targeting the defective protein in CF, have led to dramatic improvements in sinopulmonary disease, nutritional status, quality of life, and life-expectancy. However, the impact of HEMTs on sleep is still unknown.
Methods: A single-center retrospective analysis of polysomnographic data from 2012-2023 in children with CF on HEMTs.
Results: Polysomnographic (PSG) data were available in 34 children with CF. Mean age of the participants was 10.7±4.8 years. Fifty-three percent were female. Five participants (15%) were of non-White race and 9 participants (26%) identified as Hispanic. Lung function was normal, on average, and the mean body mass index percentile (BMI) was 65.7±28.9%tile. Average duration of HEMT use was 2.1±1.4 years. Sleep complaints were common: snoring in 67%, daytime sleepiness in 38%, insomnia in 41%, and restless sleep in 69%. Participants also had several comorbidities: attention-deficit hyperactivity disorder (ADHD) in 26%, anxiety/depression in 18%, enuresis in 26%, diabetes in 12%, dependence on nighttime feeds in 12%, and iron deficiency (ferritin< 30ng/mL) in 63%. Obstructive sleep apnea (OSA), defined as an obstructive apnea-hypopnea index (oAHI)≥1/hour, was present in 71% of participants and 18% had moderate-severe OSA (oAHI≥5/hour). Duration of HEMT use was linked to presence of moderate OSA (p=0.02) but not insomnia (p=0.2) or restless sleep (p=0.1). OSA was associated with snoring (p=0.005) but not any other sleep complaint or comorbid condition. Presence of ADHD was associated with more insomnia symptoms (p=0.02) and dependence on nighttime feeds was associated with restless sleep (p=0.02). Twenty-four percent of participants had tonsillar hypertrophy and 29% had enlarged adenoids, but, neither were associated with increased risk for OSA (p=0.3).
Conclusion: Sleep complaints are common among children with CF even in the post-HEMT era. Frequency of OSA continues to be high among children on HEMTs despite improvements in sinopulmonary disease. Children with CF, including those on HEMTs, should be routinely screened for the presence of sleep disorders.

PREVALENCE & TREATMENT OF SLEEP PROBLEMS IN PEDIATRIC BRAIN CANCER

Kayla LaRosa[1], *Keerthi Narasimhan*[2], *Valerie Crabtree*[3], *Emily Singer*[2], *Mustafa Barbour*[4], *Lauren Hayes*[1]
[1] University of Louisville/Norton Children's Medical Group, [2] University of Louisville, [3] St. Jude Children's Research Hospital, [4] Norton Children's Cancer Institute

Introduction: Survivors of pediatric brain tumor may experience excessive daytime sleepiness (EDS), as well as other sleep problems due to tumor location and its treatment. Despite this, there are little to no findings on the prevalence and treatment of sleep problems, including EDS. The aim of this study is to document the prevalence of and treatment for sleep problems within this population.
Methods: Retrospective chart review was conducted for individuals diagnosed with pediatric brain tumors with documented sleep issues at one hospital system within the last 15 years. Fatigue was included as it was used interchangeably with daytime sleepiness in the medical record.
Results: Sixty-six charts were available for review. Of those, 28 had a benign tumor, and therefore, chart review was not completed. Of the remaining 38, concerns with fatigue or sleep were present in 74% (n = 28). Sleep concerns included Insomnia (21%), Hypersomnia due to a Medical Condition (3.5%), and Obstructive Sleep Apnea (3.5%). The vast majority, however, fell into the "Other" category (68%), including descriptions of sleep problems (e.g., daytime sleepiness, trouble falling or staying asleep) with no formal sleep disorder diagnosis. Sleep Medicine was consulted for 17% of cases, with the average time from cancer diagnosis to first mention of sleep problems being 5 years, 5 months. The average length of time from cancer diagnosis to assessment by Sleep Medicine was 10.5 years. For those with sleep issues on cancer treatment, 46% did not receive targeted sleep recommendations. When recommendations were provided, 18% included medication for sleep issues and 7% Physical therapy/exercise. Psychology was consulted for 61% of cases; however, sleep concerns were never listed as the reason for the referral.
Conclusion: Sleep concerns were common (74%) in pediatric brain tumor. However, there was a 5-year gap between

identification of problems and referral to Sleep Medicine. Most youth did not receive recommendations to improve their sleep while they were receiving cancer treatment. Further, while Psychology was a part of the care team for most cases (61%) they were not referred to in order to address sleep concerns.
Support (if any): This study is supported by the Kentucky Pediatric Cancer Research Trust Fund.

CHILDREN AND ADOLESCENTS WITH GUT-BRAIN DISORDERS HAVE WORSE SLEEP APNEA INDICES, SLEEP AROUSALS, AND PERIODIC LIMB MOVEMENTS THAN HEALTHY CHILDREN

Neha Santucci[1], Bailey Fessler[1], Rashmi Sahay[1], Kelly Byars[1], Jennifer Hardy[1], Erick Madis[2], Christopher King[1], Thomas Dye[1]
[1] Cincinnati Children's Hospital Medical Center, [2] University of Cincinnati College of Medicine

Introduction: Children with disorders of gut-brain interaction (DGBI) often report poor sleep. However, the presence of sleep disorders and polysomnography (PSG) characteristics have not been previously described. Thus, we aimed to compare PSG changes in children with DGBI compared to healthy controls and describe sleep disorders seen in DGBI patients.
Methods: In a retrospective review, patients aged 7-19 years who met Rome IV criteria for DGBI without organic GI or systemic conditions were studied. Demographic data, GI and sleep symptoms, and diagnoses were collected, with PSG metrics obtained within one year of the GI clinic visit. PSG metrics were compared to a control group of healthy children aged 4-18 years from a sleep research repository. The analyzed metrics included total sleep time, sleep efficiency after onset, sleep stages (REM, NREM1, NREM2, NREM3, REM cycles, and latency), sleep apnea-hypopnea index (AHI), obstructive-apnea-hypopnea index (OAHI), arousal index and arousal episodes, and periodic limb movement index (PLMS-I). Linear regression analyses were conducted to examine differences between groups, adjusting for age, race, and BMI.
Results: In a study of 102 children with DGBI, 66% were females, 88% Caucasian, 30% having irritable bowel syndrome, 29% functional abdominal pain, 21% functional dyspepsia, 13% functional constipation, and 5% cyclic vomiting. The mean age was 13.9 years ± 3.3, and mean BMI was 26.4 ± 7.6. In contrast, 203 controls had a mean age of 10.7 years ± 2.6, a mean BMI of 22 ± 6.7, with 57% females and 64% Caucasian. DGBI patients had lower sleep efficiency ($p=0.002$), NREM3 ($p< 0.0001$), REM sleep ($p=0.05$), shorter REM latency ($p=0.002$), and REM cycles ($p=0.002$). They had higher apnea (OAHI $p< 0.0001$), arousal index, arousal episodes, and periodic limb movements. Significant differences remained after controlling for age, BMI, and race ($p<=0.05$). Common sleep complaints included snoring, sleep onset issues, and excessive daytime sleepiness, with diagnoses of obstructive sleep apnea, primary snoring, and insomnia.
Conclusion: Children with DGBI often have obstructive sleep apnea, primary snoring, insomnia, with less slow wave sleep and more apnea, arousal episodes, and limb movements. A thorough investigation and treatment of sleep disorders may improve outcomes for pediatric DGBI.

IMPACT OF NOCTURNAL HYPOXEMIA IN SICKLE CELL DISEASE ON SLEEP ARCHITECTURE

Seema Rani[1], Lauren Pyfer[2], Jobayer Hossain[3], Abigail Strang[3], Robin Miller[3], Nicole Divirgilio[3], Aaron Chidekel[3]
[1] Nemours Children's Health, [2] NYU, [3] NCH, DE

Introduction: Youth with Sickle Cell Disease (SCD) are at increased risk for sleep related issues both respiratory and non-respiratory. N3 and REM sleep are essential for overall functioning, academic performance, learning and hormonal and immune regulation. Reduction in N3 sleep could play a role in preexisting inflammation and have an additional effect on pain in this population. We evaluated sleep architecture in children with SCD, in those with nocturnal hypoxemia (NH) compared to those without NH.
Methods: IRB-approved exploratory retrospective chart review on 75 children with SCD (ages 2–20 years; mean age 10 ± 4.7 years), referred for an overnight polysomnogram (PSG). Data collected included demographics, hematologic parameters, medication history, and PSG parameters.
Results: Our cohort was equally male (37) and female (38) and 97% being Black/African American. Mean BMI z-score was 0.773. Participants were grouped by NH status (NH: n=7; non-NH: n=68) and by obstructive sleep apnea (OSA) diagnosis (OSA: n=43; non-OSA: n=32). NH was defined as presence of oxygen saturation below 90% for more than 5% of the total sleep duration. Diagnosis of OSA was based on interpretation of sleep certified physician. NH was significantly associated with SS genotype (85.7%, $p=0.005$) and increased markers of hemolysis including lower hemoglobin, higher reticulocyte count and higher bilirubin level. Oxygen saturation nadir was significantly lower in NH group (mean 80.3, SD 6.7) compared to the non-NH group (M 88.7, SD 7.5) No statistically significant difference in N1, N2 or REM sleep, however there was significant reduction of N3 sleep among NH group (21.3%, SD=8.3) compared to the non-NH group (32.8%, SD=16; $p=0.009$). OSA was not associated with an increased prevalence of NH or changes in sleep architecture. There was significantly increased periodic limb movements in the non-NH group compared to the NH group.
Conclusion: In youth with SCD, NH was associated with SS genotype and increased markers of hemolysis and anemia. Among children with SCD, we found reduced N3 sleep in those with NH compared to those without NH. These findings highlight the importance of screening for NH and the need for interventions to optimize sleep to improve health outcomes for children with SCD.

CHARACTERIZING THE COMPLEXITY OF REM SLEEP ACROSS PEDIATRIC DEVELOPMENT: A NOVEL METRIC APPROACH

Toshihiro Imamura[1], Cheng-Bang Chen[2], Ignacio Tapia[3], Diane Lim[4]
[1] University of Pennsylvania, [2] University of Miami, [3] University of Miami Miller School of Medicine, [4] Miami VA Medical Center

Introduction: Rapid eye movement (REM) sleep plays a critical role in neurodevelopment, yet current measures lack the sensitivity to capture age-specific REM dynamics that reflect evolving neural architecture. Chaos analytics involves analyzing complex, nonlinear, and dynamic systems where traditional methods may fail to capture the underlying patterns. Recurrence Analyses is one primary method of visualizing and quantifying this alternating complex pattern of "chaos" and "order" that recur. We established Multilevel Heterogeneous Recurrence Analysis (MHRA) to increase specificity and quantification of complex EEG patterns. MHRA offers a flexible framework for uncovering dynamic brain characteristics across multiple scales. With recurrence-based approach using chaos-driven metrics, we described age-specific REM sleep micro- and macrostructural features in pediatric populations.
Methods: REM sleep data from children and adolescents aged 6–18 years were analyzed using MHRA. For microstructural analysis, electroencephalogram (EEG) signals were extracted from REM epochs, normalized, and analyzed to quantify dynamic properties within each epoch. For macrostructural analysis, sleep stages (Wake, N1, N2, N3, REM) were segmented into 30-second epochs, producing symbolic sequences to represent stage transitions throughout the night. MHRA was applied to visualize dynamic recurrence patterns using Heterogeneous Recurrence Plots and Fractal Maps. Machine learning techniques were integrated to identify age-specific features across the micro- and macrostructural levels.
Results: Principal Component Analysis was performed to identify and explore age-related variations in REM EEG micro- and macrostructural features across pediatric age groups. The analysis revealed that the extracted REM micro- and macrostructural dynamics exhibited clear and distinct age-related patterns among children and adolescents aged 6 to 18 years. These findings demonstrate that the proposed methods successfully captured age-specific neurodevelopmental signatures, reflecting the evolving characteristics of REM sleep across developmental stages.
Conclusion: Our findings suggest that both micro- and macrostructures of REM sleep contain distinct developmental signatures across different age groups. This methodology offers promise as a diagnostic tool for detecting atypical neurodevelopment early in life, potentially enabling earlier therapeutic interventions and improved outcomes for children with developmental concerns.

VALIDATING MOTRPAC SLEEP HIGH DENSITY EEG DATA COLLECTION IN CHILDREN AND ADOLESCENTS

Caitlin Carroll[1], Ivy Chen[2], Henry Lin[2], Sheldon Watanabe[2], Dylan Barry[2], Destiny Berisha[2], Abhishek Dave[2], Bryce Mander[2], Shlomit Radom-Aizik[2], Ariel Neikrug[2], Ruth Benca[3]
[1] Wake Forest University School of Medicine, [2] University of California, Irvine, [3] Wake Forest University

Introduction: Adolescence is marked by profound changes in sleep-wake physiology, driven by recognized neurodevelopmental shifts impacting macro- and micro-architecture of the electroencephalogram (EEG) during sleep. Ensuring reliable and high-quality data is critical for studying these developmental processes, particularly in multicenter settings. In this ancillary study to the Molecular Transducers of Physical Activity Consortium (MoTrPAC), we aimed to assess the reliability and data quality of sleep EEG by evaluating consistency and concordance in data collected across two sites, using identical platforms.
Methods: 113 participants (Mage=14.5±2.5 years, 55% Female) completed the Pediatric MoTrPAC study and underwent standard overnight polysomnography (PSG) with high-density EEG (hdEEG; 128 channels) at two sleep laboratory sites: UCI Sleep Laboratory (n=66) or the Research Center for Exercise Medicine and Sleep (RCEMS/PERC; n=47). Both sites used the same equipment and protocols (Natus Neurology equipment, Waveguard original EEG cap, and Natus SleepWorks software). All recordings were scored by a boarded sleep medicine physician, using 30-second epochs. EEG data underwent preprocessing, artifact rejection, and segmentation into concatenated NREM epochs. Spectral power was calculated for frequency bands using a multitaper approach. Threshold-free cluster enhancement (TFCE) was used for multiple comparisons correction across topography.
Results: Total sleep time and time spent in each sleep stage did not differ between sites. Similarly, we observed no site-based differences in absolute or relative spectral power across all frequency bands. Consistent with prior work, age-related decreases in absolute power were observed at both sites for slow wave activity, slow oscillations, delta, theta, sigma, and beta frequency bands (all $p < 0.05$, TFCE corrected). Conversely, relative power in higher frequency bands including sigma, beta, and gamma increased with age (all $p < 0.05$, TFCE corrected). These patterns were observed at both sites with no significant differences between sites.
Conclusion: This study demonstrates the reliability of PSG with hdEEG data collected at two sites using identical platforms. The findings align with previous studies showing age-related changes in spectral power, reflecting neurodevelopmental processes. These results validate the use of PSG with hdEEG for multicenter studies and support combining data across sites for future analyses advancing our understanding of sleep neurophysiology in adolescence.

BRAIN LACTATE CONCENTRATIONS AFTER ADOLESCENT CONCUSSION ARE ASSOCIATED WITH SLEEP EFFICIENCY

Catherine Donahue[1], Katherine Smulligan[2], Mathew Wingerson[1], Joshua Kniss[1], Stacey Simon[3], Katherine Breedlove[4], Alexander Lin[4], Julie Wilson[1], David Howell[1]
[1] Children's Hospital Colorado, [2] Boston Children's Hospital, [3] University of Colorado Anschutz Medical Campus, [4] Brigham and Women's Hospital

Introduction: Lactate, a metabolic byproduct of neuronal activity, is cleared during sleep and considered a surrogate marker of glymphatic system activity. Following a concussion, brain lactate levels may rise because of increased demand for energy to restore cellular homeostasis. Clearance of lactate is increased during sleep, and as such is considered a surrogate marker of glymphatic system activity. Sleep may be disrupted following concussion, and poor sleep after concussion is associated with greater symptomatology and longer recovery, potentially due to altered glymphatic clearance. Whether post-concussion sleep

efficiency is related to lactate concentrations is unknown. The purpose of our study was to evaluate the association between sleep efficiency and brain lactate in adolescents with concussion.
Methods: Using magnetic resonance spectroscopy (MRSpect) we assessed brain lactate concentration in the anterior cingulate gyrus (ACG) and posterior cingulate gyrus (PCG) in adolescents within 21 days of concussion. Scans were performed at 3T (Skyra, Siemens, Erlangen, Germany) using PRESS localization: TR=2000, TE=30ms, voxel size=20x20x20mm3, number of averages=128. Sleep efficiency was self-reported using the Pittsburgh Sleep Quality Index (PSQI) from date of injury through date of assessment and calculated as the average time asleep divided by the average time in bed (%). Separate linear regression models were constructed to determine the independent associations between sleep efficiency and lactate concentrations in the ACG and PCG, while controlling for biological sex.
Results: 27 adolescents with a concussion (15.8±1.27 years; 51% female; 11.8±4.19 days since injury) were included in analysis. After concussion, mean sleep efficiency was 88.2±12.8%, and mean lactate concentrations in the ACG and PCG were 0.74±0.24 mmol and 0.81±0.31mmol, respectively. After controlling for biological sex, worse (lower) sleep efficiency was associated with significantly higher lactate concentrations in the ACG (β= -20.71 p=0.05, 95%CI:-41.7-0.33), but no association was observed in the PCG (β=-3.17, p=0.71, 95%CI:-21.0-14.68).
Conclusion: Our results suggest that higher lactate concentrations may be associated with worse sleep efficiency, and may reflect poor glymphatic system function. Higher lactate levels may be part of an adaptive response to the brain's increased energy demands following concussion.

Introduction: Sleep disturbances affect up to 80% of children with autism spectrum disorder (ASD). Previous studies have used either subjective surveys and/or objective data (actigraphy) to characterize sleep disturbances. In this study, we aim to elucidate the congruence between subjective and objective measures of sleep in ASD.
Methods: Children aged 6-11 years were enrolled in an ongoing study to assess sleep and neurobehavior. Sleep was assessed objectively using actigraphy and subjectively using a 2-week sleep diary and the Children's Sleep Habits Questionnaire (CHSQ). The primary outcomes of interest were total sleep time (TST) and number of awakenings (NOA).
Results: Data from 24 typically developed children (TD) (age:8±1.7 years) and 16 with ASD (8.7±1.6 years) were included. Actigraphy was well tolerated, with no difference in days collected (ASD:11.7±2.4 days; TD:11.1±3.0, p=0.492). Actigraphy revealed that children with ASD had reduced TST (478 vs 503 minutes, p=0.027) but no significant difference in NOA. CSHQ showed no significant difference in NOA but did show differences among groups in reported TST (ASD:551 vs TD:598 minutes, p=0.044) and total CSHQ scores (ASD:49 vs TD:39, p< 0.001), with higher scores indicating greater sleep disturbances in children with ASD. Subjective reporting from sleep diary showed no differences between groups in TST or average NOA. In children with ASD, actigraphy measured TST correlated weakly with CSHQ data (r=0.496, p=0.051) and did not correlate with sleep diary (r=0.334, p=0.206) data. For NOA, actigraphy showed no correlation with either sleep diary (r=–0.063, p=0.816) or CSHQ (r=–0.368, p=0.178) data. Interestingly, in TD participants, there was a strong correlation between actigraphy TST and TST reported on sleep diary data (r=0.524, p=0.010).
Conclusion: Objective measures like actigraphy effectively differentiated TST patterns between children with ASD and TD, aligning with differences observed in total CSHQ scores. However, among children with ASD, we found limited agreement between CSHQ, sleep diaries and actigraphy in estimating TST and NOA. These findings highlight the importance of incorporating both subjective and objective measures for a comprehensive assessment of sleep in autism.

TRAJECTORY OF SLEEP PATTERNS ACROSS ADOLESCENCE IN AUTISTIC AND NEUROTYPICAL YOUTH

Beth Malow[1], Rachael Muscatello[1], Trey McGonigle[1], Simon Vandekar[1], Blythe Corbett[1]
[1] Vanderbilt University Medical Center

Introduction: Changes in sleep-wake patterns during adolescence often manifest as later bedtimes, which is attributable to biological and hormonal maturation signaling pubertal onset along with behavioral factors (e.g., high homework loads, evening texting, less stringent enforcement of bedtimes by parents). Sleep patterns can impact waking cognitive function, such as daytime sleepiness. While sleep-wake patterns in typically developing (TD) adolescents have been well characterized, there are sparse data on these patterns in autistic adolescents.
Methods: Sleep data were collected annually at four time points as part of a 4-year longitudinal study on pubertal development and stress. Changes in self-reported weekday bedtime across pubertal status (Tanner stages 1-5) was compared between participants who are typically developing and those with autism, using mixed effects models adjusted for sex, melatonin use, and diagnosis by puberty interaction. A repeated measures longitudinal proportional odds model was used to model reported daytime sleepiness using the same independent variables. Puberty was fit nonlinearly in both models using splines with 3 degrees of freedom (df).
Results: The total sample consisted of 244 participants, 140 with autism and 104 who were TD. There was evidence for a difference between autistic and TD participants in the change in weekday bedtime across pubertal stages (diagnosis by puberty interaction, x2=24.27, df=3, p< 0.001). At time 1 (ages 10-13 years), bedtime was comparable in the autism and TD participants. As Tanner stage progressed, the TD participants had later bedtimes compared to those with autism. Moreover, there was a

significant diagnosis by puberty in daytime sleepiness (x2=18.11, df=2, p< 0.001) characterized by TD adolescents endorsing greater daytime sleepiness at later pubertal stages than autistic adolescents.
Conclusion: Autistic and TD adolescents exhibit differences in weekday bedtime and daytime sleepiness with pubertal development. These differences may be related to hormonal differences or behavioral factors in these populations and warrant further study.

SLEEP DISRUPTION, IMMUNE BALANCE AND ASTHMA STATUS IN URBAN CHILDREN WITH ASTHMA

Daphne Koinis-Mitchell[1], Gailen Marshall[2], Sheryl Kopel[3], Shira Dunsinger[4], Caroline Gredvig-Ardito[5], Mary Carskadon[5]
[1] Alpert Medical School of Brown University, [2] University of Mississippi Medical Center, [3] Brown University Health, [4] Brown University, [5] EP Bradley Hospital

Introduction: Children with asthma living in urban settings are at risk for disrupted sleep due to nocturnal asthma symptoms, environmental triggers, and/or urban stressors. Altered immune function is central to sleep disruption and diminished asthma control and may reflect short- or long-term changes in children's asthma status. This study examines changes in immune balance and asthma resulting from a lab-based, experimental sleep disruption protocol in a sample of urban children with asthma.
Methods: Data are derived from a study examining the effects of experimentally disrupted sleep on immune balance and lung function in urban children with persistent asthma. Twenty-four children (8-10 years-old; 50% Black, 46% Latino, 4% "other") completed a baseline night of uninterrupted sleep, followed by a disruption night, during which they were awoken for 2 minutes between 20-minute intervals of uninterrupted sleep. Children followed their typical sleep schedule (≥9.5 hours' time in bed) for 6 days with a monitored lead-in before the protocol. Morning immune biomarker assessments followed baseline and disruption nights.
Results: The arousal protocol resulted in disrupted sleep, as indicated by changes in the sleep fragmentation index from baseline (M=3.9, SD= 1.8) to disruption (M=5.1, SD= 1.6; t=-7.07, p<.001). Results from immune balance data (Th1/Th2 cytokine ratios) indicate selective alterations in the immune response following sleep disruption including a significant within-person decrease between baseline and disruption in the IFNG/IL5 ratio, t=2.19, p=.04, which could support increased eosinophil levels resulting from sleep fragmentation. There was a significant within-person increase in the IFNG/ILI3 ratio from baseline to disruption, t=-2.64, p=.02, suggesting no acute effects on airway mucus production. There was no change in the IFNG/IL-4 ratio suggesting no major effect of IgE levels reflecting changes in acute obstruction, t=-1.21, p=.26.
Conclusion: Urban children with persistent asthma are vulnerable to sleep disruption, which may adversely impact daily functioning and worsen nocturnal asthma, potentially producing greater sleep disruption and creating a clinically negative feedback spiral. Results indicate that even a single night of disrupted sleep may trigger an eosinophilic inflammatory response that could lead to negative changes in asthma control.

SLEEP PATTERNS AND ADIPOSITY IN CHILDREN WITH OVERWEIGHT AND OBESITY

Shao-Yu Tsai[1], Yi-Ching Tung[2], Chuen-Min Huang[3], Shu-Yu Kuo[4], Chien-Chang Lee[5]
[1] School of Nursing, College of Medicine, National Taiwan University, [2] National Taiwan University Children's Hospital, [3] National Yunlin University of Science and Technology, [4] Taipei Medical University, [5] National Taiwan University Hospital

Introduction: Overweight and obesity affect approximately 340 million children and adolescents aged 5-19 years worldwide. If left untreated, these conditions often persist into adulthood, increasing the likelihood of long-term health complications. Although sleep plays a critical role in weight regulation, much of the existing research has focused primarily on the relationship between short sleep duration and childhood obesity, leaving other dimensions of sleep less explored. This study examines how four aspects of sleep—timing, quality, quantity, and variability—are related to adiposity outcomes in school-age children with overweight and obesity.
Methods: A total of 246 children aged 6 to 9 years with overweight or obesity were recruited from 10 public elementary schools in Taipei, Taiwan. Each child's sleep was measured using wrist-worn actigraphy over seven consecutive days. Body mass index (BMI), BMI-for-age z-scores, and body fat percentage were calculated based on weight, height, and skinfold thickness following standard protocols. Relationships between sleep variables and adiposity measures were examined using bivariate and multiple linear regression analyses.
Results: Bivariate analysis revealed that later sleep onset was associated with higher body fat percentage (p =.01), shorter sleep duration was linked with increased BMI and body fat percentage (p <.05), and greater variability in sleep duration was correlated with elevated BMI, BMI-for-age z-scores, and body fat percentage (all p <.05). In the multiple linear regression analysis, variability in sleep duration emerged as the only significant predictor of body fat percentage (b = 2.36; 95% CI: 0.28–4.43; p =.02).
Conclusion: These findings suggest that improving sleep consistency may be a key strategy in weight management interventions for children with overweight or obesity. Future randomized controlled trials are warranted to assess whether maintaining regular sleep patterns can positively impact adiposity in this population.

DAYTIME NAPPING AND NIGHTTIME SLEEP IN CHILDREN WITH EPILEPSY: A SECONDARY ANALYSIS

Feng-Hsiang Cheng[1], Shao-Yu Tsai[1]
[1] School of Nursing, College of Medicine, National Taiwan University

Introduction: Children with epilepsy have a higher prevalence of sleep disturbances compared to their healthy peers. Although younger children naturally engage in more frequent daytime napping than older children due to developmental sleep needs, napping has also been shown to influence nighttime sleep. However, research on the relationship between napping and nighttime sleep in children with epilepsy remains limited.
Methods: This secondary analysis utilized data from a previous study on sleep in children with epilepsy conducted in Taiwan between 2015 and 2018. The sample included 141 children with epilepsy, aged from 1.5 to 6 years. Caregivers provided demographic information, epilepsy diaries and sleep diaries. Children wore actigraphy monitors for 7 days. Children were categorized based on their napping patterns into regular nappers (n=115) who napped ≥ 6 days and irregular nappers (n=26) who napped < 6 days over the monitoring period. The regular nappers were further classified as early nappers (n=73) whose naps ended before 5 p.m. and late nappers (n=42) whose naps extended beyond 5 p.m.
Results: The mean number of naps per day was 1.02 ± 0.45. Younger children exhibited more frequent napping (3.59 vs. 4.65 years, $p < 0.001$) and later nap timing (3.27 vs. 3.78 years, $p < 0.05$). Regular nappers had longer total daily sleep durations than irregular nappers (561 vs. 531 minutes, $p < 0.05$), with no significant differences in nighttime sleep between the groups. Early nappers experienced fewer total daily seizures (0.13 vs. 0.69 times, $p < 0.05$) and daytime seizures (0.05 vs. 0.48 times, $p < 0.05$) compared to late nappers, while nighttime sleep duration remained similar between the groups.
Conclusion: Regular napping is associated with longer total sleep duration in young children with epilepsy without affecting nighttime sleep, while early nap is associated with fewer daily and daytime seizures. These findings suggest that incorporating regular and early napping into daily routines may improve sleep and potentially reduce seizure frequency. Further research is needed to confirm these findings and explore the long-term effects of regular napping in this population.

SLEEP AND DEPRESSION IN ADOLESCENTS WITH PERSISTENT POST CONCUSSIVE SYMPTOMS

Gabrielle Deutsch[1], Paola Malerba[1], Sean Rose[1], Kelly McNally[1], Neil Kulkarni[1]
[1] Nationwide Children's Hospital

Introduction: 30% of concussed patients show persistent post concussive symptoms (PPCS), which can lead to social/academic deficits. To better understand the role of sleep in PPCS in adolescents, we acquired daytime sleep EEG (nap) in adolescents with PPCS and age-matched controls, paired to a neurocognitive battery and self-reported measures of sleep, anxiety, and depression.
Methods: Adolescents (13–18 years old) were recruited into a healthy control group (n=23, 12 females) or an injury group (n=37, 27 females). Injury group included those presenting with PPCS (30 days to 1-year post-injury), with average 122 days between injury and testing. Participants completed the Pittsburgh Sleep Quality Index (PSQI), the Revised Children's Anxiety and Depression Scale (RCADS), and the Weschler Intelligence Scale for Children/Weschler Adult Intelligence Scale processing speed index (PSI). They underwent a 1.5-hour nap with 24-channel electroencephalogram acquisition. Sleep technicians scored sleep architecture according to American Academy of Sleep Medicine guidelines. We compared sleep architecture, PSQI, RCADS depression/anxiety, and PSI scores between groups using independent sample t-tests. We explored interactions between PSQI and RCADS-depression, and between PSQI and PSI, with Pearson's correlations. We compared PSQI in participants with increased depression scores (RCADS-depression ≥ 65) versus all other participants, using independent samples t-tests.
Results: Time spent in each sleep stage was similar between groups. Injury group had significantly worse scores in PSQI ($p< 0.01$), RCADS-depression ($p=.023$), and PSI ($p=0.011$). No significant differences were found in RCADS-anxiety ($p=0.053$). PSQI positively correlated with RCADS-depression scores considering all participants combined ($r =.738$, $p=<.01$), only controls ($r =.721$, $p<.01$) and only injury group ($r =.716$, $p<.01$). PSI and PSQI showed positive correlation trending significance ($r=-.260$, $p=.143$).
Conclusion: We found deficits in sleep quality, depression symptomatology, and executive functioning in adolescents with PPCS compared to controls, with no differences in anxiety or nap architecture. Correlation between subjective sleep quality and depression scores warrants further study. Future analyses will explore potential differences in sleep oscillations on the recorded EEG between adolescents with PPCS and controls.

SLEEP DISTURBANCE ON INPATIENT POLYSOMNOGRAPHY IN PEDIATRIC PATIENTS WITH ACUTE STAGE OF ANTI–N-METHYL-D-ASPARTATE (NMDA) RECEPTOR ENCEPHALITIS

Jennifer MacLean[1], Anjalee Galion[2], Janetta Arellano[2]
[1] Pediatric Neurology, Children's Hospital Orange County, [2] Pediatric Neurology, Children's Hospital of Orange County

Introduction: Anti-N-methyl-D-aspartate (NMDA) receptor encephalitis is an antibody mediated autoimmune encephalitis with significant neurologic and psychiatric symptoms. Sleep disturbance is often present during the acute phase of the initial presentation and persist over one year after disease onset. There is limited literature detailing polysomnographic findings in patients with this condition in the acute or recovery phases, with no reports on pediatric patients.
Methods: Retrospective chart and polysomnographic data review was performed on three pediatric patients who presented to our center with acute encephalopathy. All patients were diagnosed during hospitalization with laboratory confirmed anti-NMDA receptor encephalitis and underwent polysomnography during this initial presentation.
Results: Patient 1, a 16-month-old female, was noted on polysomnography to have significantly decreased sleep efficiency (34%) with prolonged sleep latency and wake after sleep onset. She was also noted to have sleep apnea with an apnea hypopnea index (AHI) of 4/hour, with REM association. Patient 2, an 18-month-old female, was appreciated to have decreased REM latency with normal sleep latency and sleep efficiency (95%.)

Patient 3, a five-year-old male, was also noted to have decreased REM latency with normal sleep latency. His sleep efficiency was decreased at 66.5%, though diagnostic assessment was limited to 58 minutes, as patient was appreciated to have severe sleep apnea with an obstructive apnea hypopnea index (OAHI) of 53.1/hour, and central apnea index (CAI) of 7.3/hour leading to subsequent conversion to bilevel titration by protocol.
Conclusion: Sleep disturbance in children with anti-NMDA receptor encephalitis is multifactorial, and currently not part of the core diagnostic criteria. All three patients demonstrated differing concerns on objective polysomnographic data. As seen in our patients, obstructive and central sleep apnea may be present and should be appropriately treated to minimize cardiopulmonary stress and maximize sleep benefits including during the acute presentation. Abnormalities in sleep architecture were also noted in all patients. Further studies are indicated to determine if sleep disturbances may be a prognosticating factor associated with severity of disease or relapse risk.

OBJECTIVE SLEEP, INTERNALIZING SYMPTOMS, AND EMOTION REGULATION IN ADOLESCENTS: FINDINGS FROM THE ABCD STUDY

Sarah Izabel[1], Orsolya Kiss[2], Adam Krause[3], Ethan T. Hunt[4], Alexandra Potter[5], Micah Johnson[6], Sarahjane L. Dube[5], Nicholas Allgaier[5], Hugh Garavan[5], Andrea Goldstein-Piekarski[3]
[1] Stanford School of Medicine, [2] SRI International, [3] Stanford University, [4] UTHealth Houston School of Public Health in Austin, [5] University of Vermont, [6] Department of Family Medicine at University of California Los Angeles

Introduction: Poor sleep health and emotional dysregulation are key health determinants linked to public health issues, yet their impact on adolescent mental health is underexplored. Additionally, studies assessing sleep health in adolescents rely mostly on self-reports, lacking objective data. Using data from the Adolescent Brain Cognitive Development (ABCD) study, we investigated associations between objectively measured sleep duration, night-to-night variability, and time of sleep onset with self-reported internalizing symptoms and emotional dysregulation.
Methods: Objective sleep data (Fitbit Charge 2) from the year 4 follow-up (release 5.0 of the ABCD data) was available for 1,370 adolescents (Mean age±SD: [14.09 ± 0.69 years], 51.84% female). Participants were classified as short vs. non-short sleepers (SS vs NS) based on the sample mean of ≤7.05 hours of sleep per night. Night-to-night variability in sleep duration was assessed using the standard deviation of weekday sleep duration, and the weekly average time of sleep onset was calculated. Reappraisal and suppression (ERQ-CA), reflecting different emotion regulation strategies, and internalizing symptoms (BPM-Y) were self-reported. Linear regression analyses examined associations between sleep, internalizing symptoms, and emotion regulation, including interactions with sex at year 4 follow-up. Covariates were current age, sex, race and ethnicity, and parental education.
Results: Our analysis revealed that participants who were short sleepers exhibited significantly higher mean internalizing symptoms compared to non-short sleepers (b=0.046, p=0.040). Participants experiencing greater night-to-night variability also showed higher mean internalizing symptoms (b=0.009, p=0.001). Interestingly, this effect was particularly pronounced among girls (variability by sex interaction: b=0.006, p=0.014). Moreover, we found that participants experiencing greater night-to-night variability in their sleep had higher mean suppression scores (b= 0.006, p= 0.003). Additionally, we found that those with later sleep onset times had higher mean internalizing symptoms (b=0.0001, p=0.048).
Conclusion: The relationship between sleep and mental health is not universal in adolescents and instead depends on factors such as the type of sleep disturbance, emotional dysregulation measurement, and sex. While internalizing symptoms were linked to multiple objective measures of sleep dysfunction, the relationship between emotion regulation was specific to night-to-night variability, emphasizing the need for tailored interventions that consider these nuanced dynamics.

INFANT SLEEP AND PARENTING PRACTICES IN FIRST-GENERATION LATINX IMMIGRANTS

Itzel Sotamba[1], Amy Janis[2], AJ Schwictenberg[2], Kameron Moding[2], Kayla Empson[3], Sarah Honaker[4]
[1] Indiana University Indianapolis, [2] Purdue University, [3] Indiana University Bloomington, [4] Indiana University School of Medicine

Introduction: Previous studies have examined infant sleep in US Latinx populations, which include individuals who have come to the US recently, as well as those who have lived in the US for several generations. Parenting practices of first-generation immigrants may be more culturally influenced by their country of birth. This study aims to describe infant sleep patterns and parenting practices in first-generation US mothers born in Mexico and Central American countries.
Methods: Mothers of healthy infants (4-6 months) completed online questionnaires including the Brief Infant Sleep Questionnaire – Revised (BISQ-R), a demographic form, and a 24-hour recall diary for seven days/nights. Each were part of a larger study, Sleep and Health in the Home (SHH) Study, on infant sleep and culture in Black and Latinx families. Assessment measures were completed in Spanish.
Results: Fourteen participating mothers (21-39 years) were born in Mexico (35.7%) or one of six Central American countries (64.2%), living in a medium-sized US city. Most infants (78.6%) slept in a crib or co-sleeper attached to the parental bed, with only one mother reporting bedsharing. The most common sleep onset method was being held or rocked by an adult (57.1%), followed by in the room with an adult but without being held (35.7%), or in a room independently (5.3%). Average child bedtime ranged from 7:50pm to 12:22am (M=8:53PM). Typical nighttime sleep ranged from 8.3 to 13.8 hours, M(SD) = 10.8 (1.47) hours, with an average of 1.6 night wakings and 22.6 minutes (SD=21.7) awake during the night. Mothers did not perceive their child as having a sleep problem, with only one mother (7.1%) endorsing a "very small" problem. Maternal confidence was high, with 85.7% of mothers feeling "very sure" and 14.3% feeling "somewhat sure" they can manage their infant's sleep.
Conclusion: This is one of the first studies to examine infant sleep in first-generation US Latinx families. Mothers endorsed few problems and high confidence managing their infant's sleep.

Notably, the average bedtime was later than recommended and few mothers put their infant to sleep independently, suggesting potential sleep health intervention targets.

NAPS AMONG MEXICAN AMERICAN TODDLERS: PARENTAL BELIEFS AND TODDLER NAP DURATION, SLEEP LOCATION, AND SLEEP DURATION

Elena Marraudino[1], Melissa Fineman[2], Lucy Dorado Arredondo[3], Ariel Williamson[4], Suzanna Martinez[5], Darcy Thompson[6], Lisa Meltzer[7]

[1] University of Colorado Anschutz Medical Campus, [2] University of Colorado School of Medicine, [3] Denver Health, [4] The Ballmer Institute for Children's Behavioral Health, University of Oregon, [5] UCSF School of Medicine, [6] University of Colorado, [7] National Jewish Health

Introduction: Naps are important for early childhood development, yet few studies have considered parental beliefs about naps. This study characterizes parental beliefs about naps, and how nap beliefs relate to toddler nap duration, toddler bedsharing, and toddler sleep duration among Mexican American families.
Methods: 172 parents (170 mothers; 19-45 years; mean education 12.3 + 3.0 years; 87% room sharing, 41% bedsharing) of Mexican American toddlers (62% boys; 12-16 months) completed a 12-item nap belief measure in Spanish (55%) or English. Toddlers wore an actigraph for 7 days/nights to measure average nap, nighttime, and 24-hour sleep duration.
Results: Frequencies report on those who agreed/strongly agreed (vs. disagreed/strongly disagreed). Parents believed naps were important (100%), good for their child (99%), and an important part of the child's (99%) and parent's day (95%). Most parents believed naps affect the child's (77%) and parent's mood (52%), with almost half of parents wishing their child napped longer (47%) or fell asleep faster for naps (49%). Of the 73% of parents not wanting to change something about their child's nap, 53% wanted their child to nap longer and/or fall asleep faster. More parents with long napping toddlers (average nap >1 hour vs. < 1 hour) agreed the child's nap affected the parent's mood (57% vs. 38%, X2=4.5, p=.04), while more parents with short napping toddlers wished the child napped longer (60% vs. 38%, X2=6.3, p=.01). More parents of bedsharing toddlers (vs. sleeping in their own bed/crib) reported they wished their child napped longer (57% vs. 41%, X2=4.1, p=.04). Among parents who agreed naps affected the child's mood, toddler nighttime sleep duration was 20 minutes longer (t=2.35, p=.01) and toddler 24-hour sleep duration was 27 minutes longer (t=2.67, p=.005).
Conclusion: Findings from this ongoing study suggest that parents of Mexican American toddlers believe naps are important and affect both child and parent mood. The desire for longer naps in bedsharing parents may be related to the toddler needing parental presence to fall asleep. Longer nighttime and 24-hour sleep duration among toddlers whose parents believe naps impact the child's mood may suggest parents place an increased importance on sleep.

MOTHERS' AND FATHERS' BELIEFS ABOUT BEDTIME SCREEN USE AND TODDLERS' SLEEP IN MEXICAN AMERICAN FAMILIES

Anthony Munoz-Gauna[1], Melissa Fineman[2], Anne Spacone[2], Ariel Williamson[3], Suzanna Martinez[4], Lisa Meltzer[5], Darcy Thompson[6]

[1] University of Colorado Anschutz Medical Campus, [2] University of Colorado School of Medicine, [3] The Ballmer Institute for Children's Behavioral Health, University of Oregon, [4] UCSF School of Medicine, [5] National Jewish Health, [6] University of Colorado

Introduction: Parental beliefs about sleep are associated with sleep-related parenting behaviors and child sleep. However, few studies have considered parental beliefs about bedtime screen use and their relationship with children's sleep, especially in early childhood. Further, most studies focus on mothers, despite the important role that fathers play in early child development. This study examined mothers' and fathers' beliefs about screen use at bedtime and toddler sleep in Mexican American families.
Methods: 42 mother-father dyads (mothers 21-43 years, education mean=13.0 years, sd=2.9; fathers 21-45 years; education mean=12.0 years, sd=2.8) of Mexican American toddlers (64.3% boys; 12-16 months) completed a measure regarding beliefs about bedtime screen use in Spanish (40.5%) or English. Toddlers wore an actigraph for 7 days/nights. T-tests compared bedtime and sleep duration between parents who agreed vs. disagreed with each belief. Due to the small sample size, meaningful effect sizes (Cohen's d) vs. p-values are reported.
Results: 12% of mothers and 19% of fathers agreed that using a screen device at bedtime helps toddlers relax, with toddlers whose mothers agreed (vs. disagreed) having later bedtimes (31 minutes, d=.46) and shorter sleep duration (24 minutes, d=.52). Among fathers who agreed (vs. disagreed), toddlers had later bedtimes (50 minutes, d=.77) and shorter sleep duration (18 minutes, d=.36). Approximately 43% of mothers and 41% of fathers agreed that watching a screen device at bedtime helps toddlers remain quiet. Among mothers who agreed (vs. disagreed), toddlers slept 19 minutes less (d=.38). Finally, 10% of mothers and 21% of fathers agreed that using a screen device at bedtime helps toddlers fall asleep, with toddlers whose fathers agreed (vs. disagreed) having shorter sleep duration (16 minutes, d=.32).
Conclusion: More fathers than mothers were positive about screen use at bedtime. Positive parental beliefs in both mothers and fathers were associated with clinically meaningful sleep differences, including later toddler bedtimes and shorter toddler sleep duration. It is important to identify both mother and father sleep-related screen beliefs when addressing toddler sleep in clinical and community settings. Data collection is ongoing in a large, longitudinal study of Mexican American families.

PARENTS VS. CHILDCARE WORKERS: NAPPING BELIEFS ACROSS AGES 1 TO 5

Rachel Pétrin[1], Marie-Hélène Pennestri[2], Geneviève Forest[1]

[1] Université du Québec en Outaouais, [2] McGill University

Introduction: Sleep beliefs are critical drivers of children's sleep practices; however, research has predominantly focused on nocturnal sleep. Little is known about beliefs surrounding napping, especially during the preschool years when children gradually transition from regular napping to its cessation. Since most preschoolers attend childcare, understanding how parents' and childcare workers' napping beliefs align or diverge can provide valuable insights into how these perspectives may influence children's sleep health. This study examined the differences in napping beliefs between parents and childcare workers, focusing on how they vary according to children's age.
Methods: An anonymous online survey was conducted in Quebec from June to December 2024. Participants included 925 parents of children aged 1-5 years and 1,069 childcare workers caring for preschoolers. Both groups completed an adapted version of the Nap Beliefs Scale, which assessed positive (favorable) and negative (unfavorable) beliefs about napping across four age brackets (1-2, 2-3, 3-4, 4-5 years). A MANOVA was performed to compare napping beliefs between parents and childcare workers across the four age categories, followed by univariate ANOVAs to examine group-specific differences in napping beliefs by age and belief type.
Results: Results showed a significant multivariate effect of Group on Napping belief scores (Pillai's Trace = 0.14, $F(8, 1985) = 41.05$, $p < .001$). Childcare workers had significantly more positive beliefs compared to parents for children aged 3-4 ($F(1, 1992) = 44.97$, $p < .001$) and 4-5 years ($F(1, 1992) = 112.59$, $p < .001$). In parallel, parents reported significantly higher negative beliefs than childcare workers for children aged 2-3 ($F(1, 1992) = 53.98$, $p < .001$), 3-4 ($F(1, 1992) = 176.25$, $p < .001$), and 4-5 years ($F(1, 1992) = 201.43$, $p < .001$).
Conclusion: Findings suggest that parents and childcare workers hold distinct beliefs about napping, particularly for older preschoolers. While childcare workers tend to view napping as beneficial across all ages, parents may perceive napping for older children more negatively than younger children. This highlights the importance of fostering dialogue and evidence-based education to bridge the gap between these viewpoints and promote sleep practices that support children's development needs.

LONGITUDINAL ASSOCIATION BETWEEN CO-SLEEPING AND SLEEP ANXIETY IN A 6-YEAR CHILD COHORT STUDY

Sooyeon Suh[1], Sungkyoung Shin[1], Sanha Lee[2], Yun Mi Shin[2]
[1] Sungshin Women's University, [2] Ajou University School of Medicine

Introduction: The impact of co-sleeping on children and parents has been insufficiently explored in longitudinal research. Although previous studies have reported associations between co-sleeping and sleep problems, this study examines these relationships over a 6-year period using longitudinal data, especially in a country with high co-sleeping rates.
Methods: This study is based on a larger prospective child cohort study in South Korea. We used data from 2016 (Time 1) to 2021 (Time 6), and data was connected annually. The mean age of the children (n = 298) at baseline was 3.37 ± 0.87 years (50.00% girls). Sleep problems and sleeping arrangements were assessed using the Children's Sleep Habits Questionnaire (CSHQ). Children who were reported sleeping in the same bed with other family members more than twice a week were categorized as co-sleeping. An autoregressive cross-lagged model (ACLM) was used to examine the relationship between children's sleeping arrangements and sleep problems. Before conducting the ACLM, multiple imputations were performed to address missing data. Participants with missing data on co-sleeping variables or with more than 25% missing data were excluded.
Results: At Time 1, 94.97% of the children reported co-sleeping, with more than 70% of the sample co-sleeping at each time point. Sleep anxiety and co-sleeping showed a significant longitudinal relationship. Goodness-of-fit indices for the final model were adequate (CFI=0.940, TLI=0.934, RMSEA=0.080, and SRMR=0.086). All autoregressive paths between co-sleeping (ORs=1.29-4.71) and sleep anxiety (βs=0.61-0.79) were significant. From Time 2 to 4, high levels of sleep anxiety at the previous time point significantly increased the likelihood of co-sleeping at the subsequent time point (ORs=1.20-1.22). From Time 3 to 6, co-sleeping at the previous time point significantly predicted greater sleep anxiety at the next time point (βs=0.14-0.20).
Conclusion: Our findings indicate that co-sleeping was longitudinally associated with sleep anxiety. Specifically, while sleep anxiety may lead to co-sleeping during early childhood, the influence of co-sleeping on sleep anxiety appears to become more pronounced as children grow older.

UNCOVERING ETHNIC/RACIAL DISPARITIES IN PEDIATRIC SLEEP QUALITY: INSIGHTS FROM THE SAN DIEGO SLEEP SURVEY

Megan Warner[1], Florence Wu[2], Sarah Inkelis[3], Jeremy Landeo Gutierrez[4], Rakesh Bhattacharjee[5]
[1] Radys Children's Hospital/UCSD, [2] University of California, San Diego, [3] University of California, San Francisco, [4] University of California San Diego, [5] Division of Pulmonary Medicine, Department of Pediatrics, University of California San Diego/Rady Children's Hospital

Introduction: Pediatric sleep questionnaires are essential tools for screening sleep disorders, especially where access to pediatric sleep specialists and laboratories is limited and often where underserved and minoritized populations receive care. Moreover, there is limited knowledge on the prevalence of sleep symptoms among representative race/ethnic pediatric groups in the U.S. To address this, we developed the San Diego Sleep Survey (SDSS) with the goal to assess a wide range of sleep symptoms within a clinical setting. This study aimed to identify potential differences in reported sleep symptoms between patient-reported ethnicities and racial groups.
Methods: Caregivers of patients referred to the Rady Children's Hospital Sleep Center in San Diego, California, completed the SDSS via the Epic® Electronic Medical Record (EMR) system. The SDSS is a 51-item questionnaire utilizing a 4-point Likert scale (Never, Sometimes, Usually, Do Not Know) to provide detailed insights into sleep difficulties. Five domain scores are used to evaluate pediatric sleep issues: insomnia, sleep-disordered breathing (SDB), parasomnias, sleep hygiene, and daytime symptoms (DS), with lower scores indicating better sleep health.

The survey is available in both English and Spanish, and demographics were extracted from the EMR.
Results: 1,362 patients completed the SDSS and PSQ from 2011 to 2021. The mean age was 8.174.62 years, and 554 (40.7%) were female. The cohort included 647 (47.5%) Hispanic, 558 (41.0%) Non-Hispanic White (NHW) patients, 85 (6.2%) Non-Hispanic Asian (NHA), and 72 (5.3%) Non-Hispanic Black (NHB). SDB scores were significantly lower among NHW children compared to Hispanic and NHB children ($p < 0.01$). In contrast, DS scores were significantly higher for NHW patients compared to Hispanic and NHB children. No differences in insomnia scores were observed across ethnic groups. Finally, sleep hygiene scores were significantly lower ($p < 0.05$) among NHW children compared to other groups.
Conclusion: The application of the SDSS in a large pediatric sleep clinic population revealed significant differences in reported sleep symptoms across children of various race/ethnicities. Although the sample included a smaller number of NHB children, the findings highlight substantial variations in symptom reporting by race/ethnicity, underscoring the impact of healthcare disparities on pediatric sleep health outcomes.

APPLICATION OF THE SAN DIEGO SLEEP SURVEY (SDSS) TO ASSESS POST-SURGICAL RESPONSE IN CHILDREN WITH SLEEP DISORDERS

Florence Wu[1], Megan Warner[2], Sarah Inkelis[3], Christina Finch[4], Rakesh Bhattacharjee[4]

[1] University of California, San Diego, [2] Radys Children's Hospital/UCSD, [3] University of California, San Francisco, [4] University of California San Diego

Introduction: Sleep questionnaires are commonly used to gather detailed information about sleep patterns and disturbances, aiding in the identification of sleep disorders. In children, these questionnaires serve as valuable screening tools, particularly in settings where access to pediatric sleep specialists and polysomnography is scarce. Since pediatric sleep-disordered breathing (SDB) is often managed surgically, we evaluated the utility of a pediatric sleep questionnaire in assessing surgical outcomes by comparing responses before and after surgery.
Methods: Caregivers of patients referred to Rady Children's Hospital, San Diego, California, completed the San Diego Sleep Survey (SDSS) through the Epic® Electronic Medical Record (EMR) system. The SDSS, a 51-item scale, utilized a 4-item Likert-type scale (Never, Sometimes, Usually, Do Not Know) to provide graded insights into sleep difficulties. Five domain scores were employed to assess pediatric sleep problems: insomnia, SDB, sleep disorder (e.g., parasomnia), sleep hygiene, and daytime symptoms (DS). Only patients who completed the survey before and after airway surgery (tonsillectomy, adenoidectomy, adenotonsillectomy, or lingual tonsillectomy) were included.
Results: 76 patients were identified from 6/2017-11/2021, with a mean±SD age of 7.34± 4.39 years, 42 females. Most were Hispanic (n=42) or non-Hispanic White (n=21). Surgeries included adenotonsillectomy (n=57), tonsillectomy (n=4), adenoidectomy (n=11), and lingual tonsillectomy (n=4). Comparison of pre- and post-surgical scores across the five domains of the SDSS revealed significant improvements in four domains: SDB score (pre: 21.42±6.58, post: 16.39±5.04; $p< 0.001$), insomnia score (pre: 14.72±3.74, post: 13.79±3.55; $p=0.003$), sleep disorder score (pre: 6.50±1.60, post: 5.76±1.92; $p< 0.001$), and DS score (pre: 25.04±7.62, post: 22.13±7.34; $p< 0.001$). No significant change was observed in the sleep hygiene score (pre: 9.18±2.31, post: 9.28±2.28; $p=0.663$). Comparison of survey responses between Hispanic and non-Hispanic children showed no significant differences across any of the domains.
Conclusion: The SDSS results demonstrate significant improvements in four out of five sleep domains following airway surgery for SDB in children, including the domain assessing behavioral sleep disturbances (Insomnia). These findings suggest that airway surgery in children not only alleviates symptoms directly related to SDB but also leads to broader improvements in overall sleep quality.

SLEEP DISPARITIES IN CANADIAN CHILDREN UNDER 18 YEARS: A SCOPING REVIEW

Mya Dockrill[1], Brendan Flores[2], Youssouf Aidara[2], Penny Corkum[1], Guido Simonelli[2]

[1] Dalhousie University, [2] Université de Montréal

Introduction: Insufficient sleep is prevalent in children and has many adverse health outcomes. Children facing health inequities (e.g., from a low socioeconomic background, or a racial/ethnic minority) have more sleep difficulties and are less likely to receive treatment. There is a lack of research investigating pediatric sleep and health inequities, particularly in Canada. Thus, the objective was to summarize the extant literature in this area.
Methods: A list of health inequities was developed following the Canadian Institute of Health Research EDI dimensions and in consultation with the Canadian Sleep Research Consortium. Four key electronic databases (PubMed, EMBASE, PsycInfo, CINAHL) were searched. Studies were included if they were 1) in English or French, 2) original studies (e.g., empirical data collected), 3) conducted in Canada, 4) with children under 18 years, 5) population-based studies, and 6) reported on sleep outcomes and health inequities.
Results: Three reviewers screened 15,448 abstracts and titles resulting in 357 articles full-text articles. After screening, 25 studies were included in this review, focusing on sleep in the context of low socioeconomic status (18 studies), gender/sex (17 studies), family composition/caretaking (9 studies), housing/neighbourhood characteristics (8 studies), race/ethnicity (8 studies), immigrants/refugees (3 studies), and language (1 study). No studies were found in the following categories: religious affiliation, cultural diversity, and sexual/gender minorities. Of note, no distinction was made between sex and gender in the literature. Much of the research has been done with Caucasian, adolescents and school-aged children, in Quebec or Ontario. Generally, it appears that sleep health and disordered sleep are negatively affected by low socioeconomic status, poor housing/neighbourhood conditions, and in non-Caucasian children. The findings are varied in terms of sex differences with most studies suggesting no differences (76%) and some suggesting differences between boys and girls with 67% of the literature suggesting that boys sleep better. There is no clear link between sleep disturbances and family composition and caretaking.
Conclusion: This is the first review to investigate the impact of health inequities on sleep in Canadian children. Identifying and

understanding this link will inform the modification and development of sleep interventions to better meet the needs of these diverse individuals.

PARENTING STRESS PARTIALLY MEDIATES THE RELATIONSHIP BETWEEN CHILD AND PARENTAL SLEEP QUALITY

Jeremie Potvin[1], Annie Bérubé[1], Geneviève Forest[1]
[1] Université du Québec en Outaouais

Introduction: Sleep is crucial for parents of young children, especially given its influence on parental sensitivity. Yet, parents' sleep has been shown to be influenced by child sleep disturbances, which remain common during toddlerhood and the preschool years. Furthermore, child sleep disturbances have been linked to parenting stress, which is in turn associated with parental sleep. Therefore, this study aimed to investigate the potential mediating effect of parenting stress on the association between child sleep disturbances and parental sleep quality.
Methods: Participants included 68 parents (91.2% mothers, age M = 34.07, SD = 5.37) of children aged between 29 and 72 months. Child sleep quality, parental sleep quality and parenting stress were measured using the Children's Sleep Habits Questionnaire, the Pittsburgh Sleep Quality Index and the short form of the Parenting Stress Index respectively. For all measures, higher scores represent more difficulties in the corresponding component (i.e., worse sleep and more stress). A multiple regression analysis was conducted to assess the mediating effect of parenting stress on the relationship between child and parent sleep quality, while controlling for parent age, education and ethnicity.
Results: The model with all predictors was significant F(5, 62)=7.76, p <.001 and explained 38.50% of the variance in parental sleep quality. Results suggest a significant indirect pathway from child sleep quality to parenting stress to parental sleep quality (b =.05, 95% CI [.005,.103]).
Conclusion: These results suggests that the relationship between child and parent sleep quality are partially explained by its effect on parenting stress. While child sleep quality remains the strongest predictor of parental sleep quality, parenting stress can partly explain how child sleep disturbances contribute to parental sleep quality by accentuating its influence. Therefore, parenting stress should be considered when adressing parent and child sleep.

Chan School of Public Health, [4] Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Harvard Medical School, [5] Division of Neurology and Sleep Medicine, Boston Children's Hospital, Harvard Medical School, [6] Department of Social and Behavioral Sciences, Harvard T.H. Chan School of Public Health, [7] Division of Allergy and Immunology, Boston Children's Hospital, Harvard Medical School, [8] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Emerging data implies air pollution contributes to pediatric sleep disparities. While most research has focused on particulate matter, the sleep health effect of nitrogen dioxide (NO2), another critical component of air pollution, has not been extensively studied. This study investigated the association between indoor NO2 exposure and adverse sleep outcomes in a pediatric sample.
Methods: Participants were children from predominantly low-income communities in Boston, Massachusetts. Indoor NO2 levels were measured by the Environmental Multipollutant Monitoring Assembly devices in participants' living areas for 7 days. The all-day 95th percentiles of indoor NO2 levels were averaged over the monitoring period. Elevated indoor NO2 was defined as ≥ 80th percentile of the average 95th percentile daily indoor NO2 measurements (≥69.48 ppb). Primary outcomes were short sleep duration and sleep-disordered breathing (SDB). Short sleep duration was defined as an averaged 7-day sleep duration < 8 hours measured by ActiGraph GT3X+. SDB was defined as ≥5 events/hour with >3% desaturation assessed by WatchPAT 200U or Nonin WristOx 3150 oximeter for one night. We assessed the associations through logistic regression primarily adjusted for age, sex, race and ethnicity, household income, neighborhood Child Opportunity Index, and seasonality. We further adjusted for physical activity, asthma, body mass index percentile, gas cooking stoves, outdoor NO2 levels, and indoor PM2.5 levels separately as sensitivity analyses.
Results: Our analytical sample included 242 subjects (43% female, 40% Hispanic, 26% Black, 21% White, and 9% Other) with a mean age of 9.5. The median of the average daily 95th percentile indoor NO2 was 41.1 ppb. Children with elevated indoor NO2 exposure had 2.87 times higher odds (95% CI: 1.26, 6.50) of short sleep duration than those with lower NO2 exposure. The association remained when additionally adjusted for other potential confounders. A positive but insignificant association between high indoor NO2 exposure and SDB was found (OR=1.38, 95%CI: 0.64, 2.95).
Conclusion: Children with elevated indoor NO2 exposure, which exceeded EPA's annual safety guideline (53 ppb), had greater odds of short sleep duration, even after adjustment for individual and neighborhood confounders. Interventions targeting indoor air quality may provide novel approaches for reducing pediatric sleep disparities.

IMPACT OF SLEEP APNEA, SHORT SLEEP, AND INSOMNIA SYMPTOMS ON BLOOD PRESSURE MATURATIONAL TRAJECTORIES

Julio Fernandez-Mendoza[1], Natasha Morales-Ghinaglia[2], Raegan Atha[1], Anthony Rahawi[1], Susan Calhoun[1], Alexandros Vgontzas[3], Duanping Liao[1], Edward Bixler[1], Jason Liao[1]

[1] Penn State College of Medicine, [2] Geisinger Commonwealth School of Medicine, [3] Sleep Research and Treatment Center, Penn State College of Medicine

Introduction: Sleep apnea, insomnia symptoms, and short sleep have all been associated with higher blood pressure (BP) levels in youth. However, it remains unknown whether these highly-prevalent sleep disorders have a long-term impact on the abnormal maturational trajectories of BP levels from childhood through early adulthood.
Methods: A total of 698 participants from the Penn State Child Cohort, a randomly-selected population-based sample (52% female, 24% racial/ethnic minority), underwent in-lab BP measurements and polysomnography studies in childhood (5-12y), adolescence (12-19y), and young adulthood (20-30y) with a median follow-up time of 16y. Growth mixture models were used to classify the 698 individual trajectories of systolic (SBP) and diastolic (DBP) into three latent classes, respectively. Within each latent class, the longitudinal associations of sleep apnea, insomnia symptoms, and short sleep with SBP and DBP levels were tested, adjusting for sex, age, race/ethnicity, and body mass index.
Results: SBP showed three age-related latent classes: one quadratic (3% of subjects) and one linear (24.5% of subjects) with higher SBP levels (104.2 mmHg for class 1 and 106.2 mmHg for class 2), and one linear (72.5% of subjects) with lower SBP levels (96.6 mmHg) in childhood. Sleep apnea (P=0.03) and insomnia symptoms (P=0.04) were associated with higher SBP levels in the first latent class, while sleep apnea (P=0.04) and short sleep (P=0.007) were associated with higher SBP levels in the third latent class which had lower SBP levels in childhood. DBP showed three age-related latent classes: two quadratic (84% and 5.7% of subjects) and one linear (10.8% of subjects) with higher DBP levels (65.5 mmHg) in childhood. While insomnia symptoms did not significantly impact DBP latent classes, short sleep was associated with higher DBP levels in the first (P=0.01) and third (P=0.04) quadratic classes, and sleep apnea (P=0.03) in the third quadratic class (P=0.02).
Conclusion: Sleep apnea, insomnia symptoms, and short sleep not only increase BP levels acutely, but also impact the developmental trajectories of BP levels across the lifespan. Future studies should examine the synergistic effect of these three sleep disorders to identify phenotypes with the greatest impact on developmental BP trajectories.

SLEEP HEALTH, FATIGUE, AND PAIN OUTCOMES AFTER GENDER AFFIRMING SURGERY IN TRANSGENDER AND GENDER DIVERSE ADOLESCENTS AND YOUNG ADULTS

Jor Grapentine[1], Jessica Olsen[1], Jessica Dietch[1], Anna Wilson[2], Sarah Feldstein Ewing[3]
[1] Oregon State University, [2] Oregon Health & Science University, [3] University of Connecticut School of Medicine

Introduction: Trans/gender-diverse adolescents and young adults (AYAs) are at elevated risk for poor sleep health, driven by mental health challenges and minority stressors. Gender-affirming surgery (GAS) is an effective intervention that is associated with improved mental health and well-being. This secondary analysis examines the relationships between fatigue, sleep quality, sleep disturbances, and pain outcomes in trans/gender-diverse AYAs who underwent GAS.
Methods: Two longitudinal studies enrolled AYAs who underwent GAS and received an opioid prescription within 72 hours for postsurgical pain. Study 1 included 31 adolescents (14-18 years), and Study 2 included 36 young adults (18-25 years). Participants completed PROMIS measures of pain interference, pain intensity, and anxiety and the Adolescent Sleep-Wake Scale (Study 1) or PROMIS Sleep Disturbance (Study 2). Linear regressions examined sleep and fatigue variables as predictors of pain intensity and interference, unadjusted and adjusted for anxiety.
Results: The majority of participants were trans men/masculine/male (Study 1: 59.2%, Study 2: 56.8%) who underwent mastectomy/top surgery (Study 1: 60%, Study 2: 67%). In study 1, participants reported elevated past-week fatigue (M= 60.60 [9.22]) and average sleep quality (M=34.19 [8.65]). Fatigue was associated with pain interference in the unadjusted model (β=39, SE=.13, p=.007) but not after adjusting for anxiety (p =.061). In Study 2, participants reported elevated fatigue (M=61.52 [9.74]) and average sleep disturbance (M=56.57 [6.39]). Fatigue was associated with pain interference (β=0.23, SE= 0.07, p=.003) and remained significant after adjusting for anxiety (p=.004). Pain intensity was not associated with fatigue or sleep health in either study.
Conclusion: Fatigue was associated with pain interference in trans/gender-diverse young adults but not in adolescents, potentially reflecting differences in pain processing or coping mechanisms across age groups. Sleep disturbance and quality were not associated with pain outcomes. Other sleep dimensions (e.g., efficiency, timing) may demonstrate a stronger relationship, which should be studied using objective and subjective sleep measures.

IMPACT OF PEDIATRIC SLEEP PROBLEMS ON PARENTAL SLEEP QUALITY IN AMERICAN MILITARY FAMILIES

Benjamin Long[1]
[1] Wilford Hall Medical Center

Introduction: There is a high incidence of poor sleep quality in active-duty servicemembers. Deployment exposure is a commonly explored causal factor for poor sleep. However, more recent research highlights the importance of non-deployment factors, with one study reporting the "birth of child/adoption" as commonly contributing to poor sleep. This is consistent with previous research reporting parenthood as a significant factor in poor sleep quality, especially in parents of children with sleep problems. However, no previous research has considered the impact of pediatric sleep problems on parental sleep quality in American military families.

Methods: A chart review was completed for children (age 0-12) referred to a military sleep center. Chart review (N=34) included documentation of parental global Pittsburgh Sleep Quality Index (PSQI) scores, reported frequency of parental sleep disturbance attributed to the child's sleep problem, and active-duty status of the parent.

Results: Both active-duty and dependent-spouse parents reported poor sleep quality (M: 7.94 and 11.41 respectively), but dependent spouses had significantly worse global PSQI scores (p< 0.01). Both active-duty and dependent-spouse parents reported that their child's sleep problem disturbed their sleep, on average, 1-2 nights/week (M: 2.12 and 2.82 respectively). However, dependent spouses were significantly more likely to report 3+ nights/week (p< 0.01). To date, mean follow-up global PSQI scores for all parents showed significant improvement (p< 0.01), with a decrease by 6.3 points (M: baseline PSQI 11.75 and follow-up PSQI 5.5). Additionally, frequency of parental sleep disturbance attributed to the child's sleep problem significantly decreased to less than once a week (p=0.02).
Conclusion: The presence of pediatric sleep problems contributes to poor sleep quality for both active-duty and dependent-spouse parents. However, pediatric sleep problems may disproportionately affect dependent spouses. Additionally, parental sleep quality significantly improved upon treatment of the child's sleep problem. This suggests that targeting pediatric sleep disturbances may be an important component of addressing active-duty servicemember sleep quality. Limitations included small follow-up sample size (n=8) and inability to determine further demographic information of parents. Because sleep is an important component of military readiness, military leadership should consider further research into the impact of pediatric sleep disturbances on servicemember sleep quality.

TIGERCHAT: SLEEP HABITS IN SECOND AND THIRD GRADE STUDENTS IN A RURAL ELEMENTARY SCHOOL

Christine Feeley[1], Erin Thornton[1]
[1] Auburn University College of Nursing

Introduction: There is increasing awareness of the importance of sleep for health and wellness in children, and the impact sleep habits make. However, many children and families are not reporting healthy sleep habits or adequate sleep. The purpose of this project is to describe sleep habits in 8-10 year olds attending an elementary school in a rural area.
Methods: TigerCHAT is a school-based health education program for children K-6th grades. It focuses on 45-minute sessions addressing various health topics, including sleep. Data are collected after IRB approval. In fall of 2024, nursing students led small groups of students in a sleep educational module during their gym period. Before education began, 56 2nd and 3rd grade students filled out the Sleep Habits Questionnaire.
Results: To describe sleep patterns in this population, we analyzed frequencies, percentages, and correlations. The majority of students reported consistently following a bedtime routine (39.3%, n=22), always watching TV before bed (33.9%, n=19) or almost always (19.6%, n=11), and going to bed at the same time every night (always: 17.9%, n=10; almost always: 17.9%, n=10). Notably, a majority of 2nd and 3rd graders reported using a cell phone before bed (62.5%, n=35). There were significant correlations between phone use and TV watching before bed (p<.001, r=.603), and between gaming before bed and maintaining a consistent bedtime (p<.001, r=.484).
Conclusion: More education may be necessary in young children regarding the use of technology before bed. More information is needed for families and children on when screens should be turned off for the night. While the majority of children reported adhering to a bedtime routine, many of those routines incorporated screens.

A PRELIMINARY ANALYSIS OF THE ASSOCIATION BETWEEN SLEEP QUALITY AND BEHAVIOR FOLLOWING A CHILD SLEEP INTERVENTION

Rachel Pétrin[1], Évelyne Touchette[2], Annie Bérubé[1], Marie-Hélène Pennestri[3], Geneviève Forest[1]
[1] Université du Québec en Outaouais, [2] Université du Québec à Trois-Rivières, [3] McGill University

Introduction: It is well-established that sleep is essential for children's physical, cognitive, and socioemotional development. Insufficient or poor-quality sleep has consistently been linked to behavioral difficulties in children. Interventions targeting parental sleep beliefs and practices may play a key role in improving both child sleep and related behavioral outcomes. This study aimed to examine whether improvements in children's sleep quality following a short sleep intervention predict changes in behavioral outcomes.
Methods: A total of 74 parent-child dyads with children aged 3 to 5 participated in a two-hour group intervention on children's sleep (2–4 families). While parents received the intervention, children engaged in sleep-related educational activities in another room. A short follow-up group session occurred two weeks later, attended only by the parents. Measures for this study were collected before the intervention (T1) and about two months later (T2). Parents completed various questionnaires, including the Children's Sleep Habits Questionnaire (CSHQ) and the Strengths and Difficulties Questionnaire (SDQ). A hierarchical linear regression was conducted to determine whether changes in sleep quality (CSHQ scores) predicted children's behavioral outcomes (SDQ scores) at T2. T1 behavioral difficulties and sleep quality were entered in the first block, while T2 sleep quality was added in the second block. The dependent variable was T2 behavioral difficulties.
Results: The first model was significant (F(2, 71) = 47.799, p <.001) and accounted for 57.4% of the variance. T1 behavioral difficulties predicted T2 behavioral difficulties (B =.682, p <.001), but T1 sleep quality was not a significant predictor (B =.133, p =.29). Adding T2 sleep quality explained an additional 3.1% of the variance (B =.355, p =.02). This change in R2 was significant (F(3, 70) = 35.644, p <.001), with the final model explaining 60.5% of the variance in T2 behavioral difficulties.
Conclusion: This study highlights the significant role of improving sleep quality in reducing behavioral difficulties in preschool-aged children. A short intervention targeting parental sleep beliefs and practices can effectively promote healthier sleep patterns and positive behavioral outcomes in young children.

FACTORS ASSOCIATED WITH THE USE OF SELF-HELP STRATEGIES FOR SLEEP IN CHILDREN AND ADOLESCENTS WITH EPILEPSY

Pei-Yu Wu[1], Shao-Yu Tsai[1]
[1] School of Nursing, College of Medicine, National Taiwan University

Introduction: Sleep problems are common in children and adolescents with epilepsy. Our previous analyses have shown that this population used a variety of self-help strategies to improve sleep. However, factors associated with the use of these self-help strategies have not been investigated. Exploring these factors is crucial for identifying the groups of children and adolescents most in need of intervention. This cross-sectional observational study aims to examine factors associated with the use of self-help strategies for sleep in children and adolescents with epilepsy.
Methods: A convenience sample of 251 children and adolescents with epilepsy aged 1-18 years and their parents or caregivers were recruited from a university-affiliated hospital in Northern Taiwan. Participants completed a socio-demographic form and 1-week diaries documenting their self-help strategies for sleep. Multivariate regression analyses were conducted to explore factors associated with the use of self-help strategies for sleep in children and adolescents with epilepsy.
Results: The mean age of children and adolescents with epilepsy was 6.1 ± 4.47 years, and 56.2% were male. A total of 177 (70.5%) parents reported using self-help strategies to help their children's sleep. The most commonly used self-help strategies were accompanying the child (46.6%) and relaxation techniques (25.1%). Multivariate analyses revealed that younger age (β = -.071, p <.01), having an employed mother (β = 0.371, p <.01), being an only child (β = 0.312, p <.01), and a higher frequency of seizures over the past 3 months (β =.284, p <.01) were significantly associated with greater strategy use.
Conclusion: This study shows that various demographic and clinical factors are associated with the use of self-help strategies for improving sleep in children and adolescents with epilepsy. Future studies should explore how these factors influence the choice and effectiveness of self-help strategies for sleep in this population.

RETROSPECTIVE EXAMINATION OF SLEEP TIMING AND OUTCOMES IN RECUPERATIVE ENVIRONMENTS (RESTORE)

Daniel Tan[1], Shaina Schwartz[1], Sheila Maurer[1]
[1] Cone Health

Introduction: Sleep is essential for the physical, cognitive, and emotional development of children and adolescents. In hospital settings, achieving restorative sleep is often disrupted by environmental factors, medication timing, and complex clinical presentations. This study investigates the impact of sleep medication timing and type on achieving sufficient sleep and examines its relationship with length of stay (LOS) in pediatric patients.
Methods: A retrospective analysis was conducted on 5,871 pediatric patients aged 3 to 17 years who received sleep aids during emergency department visits or inpatient stays at Cone Health between January 19, 2013, and August 11, 2024. Sufficient sleep was assessed based on American Academy of Sleep Medicine (AASM) guidelines for age-appropriate sleep durations. Statistical analyses, including independent t-tests and linear regression, were performed to evaluate the relationships among age, gender, medication timing, medication type, restorative sleep outcomes, and LOS.
Results: The study population had a mean age of 10.7 years, with teenagers (13–17 years) achieving the highest rate of sufficient sleep (92.4%), followed by children aged 6–12 years (70.0%) and 3–5 years (39.9%). Antihistamines, primarily diphenhydramine, were the most commonly prescribed sleep aids (83.8%), followed by benzodiazepines (10.1%). Patients achieving sufficient sleep had a significantly longer mean LOS (4.4 days) compared to those who did not (1.3 days, p < 0.001). Patients prescribed benzodiazepines or Z drugs experienced the longest LOS (14.2 days) compared to those receiving other medications (2.5 days, p < 0.001). Younger children were less likely to achieve restorative sleep, suggesting greater vulnerability to hospital environmental disruptions and suboptimal medication effects.
Conclusion: Restorative sleep is critical for pediatric recovery but remains difficult to achieve in hospital settings, especially for younger patients. Although sufficient sleep was associated with longer LOS, this likely reflects greater clinical complexity rather than the impact of sleep itself. Environmental adjustments, optimized medication timing, and evidence-based protocols—such as the use of melatonin for circadian rhythm regulation—are needed to promote high-quality sleep. Future research should stratify patients by condition type and medication indications to better understand the interplay between sleep and clinical outcomes. Incorporating sleep as a fundamental aspect of pediatric care can improve recovery and overall well-being.

RELATIVE EFFICACY OF SLEEP ALONE OR TOGETHER WITH TARGETED EATING AND ACTIVITY BEHAVIORS FOR PEDIATRIC WEIGHT REGULATION: A RANDOMIZED CLINICAL TRIAL

Chantelle Hart[1], Brian Egleston[2], Hollie Raynor[3], Andrea Kelly[4], Megan Heere[5], Sharon Herring[5], Jennifer Fisher[1]
[1] Temple University, [2] Fox Chase Cancer Center, [3] University of Tennessee Knoxville, [4] Children's Hospital of Philadelphia, [5] Temple University School of Medicine

Introduction: Sleep plays an important role in pediatric weight regulation. However, the few pediatric clinical trials that have been conducted have focused on large experimental changes in sleep with little attention to the clinical utility of enhancing sleep as a stand-alone or adjunct treatment for pediatric weight control. Thus, the present study assessed the relative efficacy of a behavioral intervention to enhance sleep alone versus together with targeted eating and activity behaviors on change in body mass index z-scores (BMIz).
Methods: Youth aged 6-11 years (y) who were reported to sleep 9.5 hours/night or less were enrolled between February 2018 and July 2022 and randomly assigned to: optimize sleep (OS; behavioral intervention to enhance nocturnal sleep) or optimize sleep plus (OSP; behavioral intervention to enhance sleep plus reduce sugar sweetened beverages, sweet and salty snack foods, television viewing, and increase physical activity). Interventions were delivered to parent-child dyads in-person/virtually and by phone across eight sessions. Assessments were completed at baseline, 6- (end of treatment/primary outcome) and 12-months. Parents reported demographic information; child height and weight were measured to calculate BMI and BMIz. Intent to treat analyses using regressions and multiple imputation (e.g., Covid pandemic increased missingness) controlled for the respective baseline

value of the outcome; those focused on BMI also controlled for child age and biological sex.
Results: Seventy-eight children (M[SD] age = 8.72y[1.40]; 47% female; 82% African American/Black; 13% Hispanic/Latino; 47% with overweight/obesity; M[SD] sleep period = 514[36] min) were randomized. No between-group differences on key demographics or BMIz/BMI were present at baseline. Children randomized to OSP had greater reductions in BMIz at 6 months (OS: 0.14[0.49] vs. OSP: -0.24[0.63], p = 0.035). Findings for BMI at 6 months were consistent but did not reach statistical significance (p = 0.059). By 12 months, BMI and BMIz did not differ by intervention.
Conclusion: Children randomized to enhance sleep duration together with specific eating and activity behaviors demonstrated clinically meaningful differences in BMIz at 6 months. Findings need to be considered in light of the Covid-19 pandemic and should be replicated in future studies.

ACCOUNTING FOR EARLY SCHOOL START TIMES: COMMUTE TIMES AND MODE OF TRANSPORTATION FOR U.S. TEENS

Gretchen Morris[1], Sara Jaffie[1], Ben Chico[1], Terra Ziporyn[2], Amy Wolfson[1]
[1] Loyola University Maryland, [2] Start School Later

Introduction: Long school commutes in combination with early school start times force adolescents to wake up at times that are misaligned with their biological clocks resulting in social jet lag, insufficient and poor-quality sleep with numerous negative consequences for health, safety, and school performance (Crowley et al., 2018; Pereira et al., 2014). Likewise, school districts tend to focus on transportation (e.g., use of school buses) as a barrier to setting developmentally appropriate school start times. However, few studies have examined and the relative role that buses play relative to other modes of school transportation (e.g., walking, driving, etc.) in school commutes on a national scale.
Methods: Data from the 2022 National Household Travel Survey (NHTS) was examined to identify school transportation trends. The sample consisted of 553 adolescents ages 11-18 years (51% ages 14-18), 44% female, 83% white, and 70% residing in urban/suburban area across different regions of the U.S (e.g., Northeast, Midwest, etc.). Commute times, start/end times, trip distance, and mode of transportation to school were examined.
Results: The most common mode of transportation was via car (car = 53.5%; school bus = 33.1%; public transportation = 2%; walk/bike = 11.8.%). Over half the sample (58.1%) left for school before 7:30am (M = 7:29 am, range = 5:40 – 10:50 am), and overall average commute times were just under 20 minutes (M = 19.2, SD = 23.5). However, youth who reported using public transportation had the longest commute times (M = 36.25, SD = 13.77).
Conclusion: These findings underscore the importance of considering how early adolescents need to leave home for school when establishing healthy school hours. Although school districts base school start times on yellow bus schedules, only about a third of the adolescents reported relying on school bus transportation. Furthermore, with many adolescents traveling by car to school early in the morning by car school districts are putting families and young drivers at risk for fall asleep at the wheel motor vehicle accidents.

SCHOOL START TIMES AND TRANSPORTATION POLICY: REVIEW OF STATE CODES REGARDING STUDENT TRANSPORTATION

Sara Jaffie[1], Ben Chico[1], Amy Wolfson[1], Gretchen Morris[1], Terra Ziporyn[2]
[1] Loyola University Maryland, [2] Start School Later

Introduction: Developmental changes and psychosocial pressures create a shift in sleep and wake times in adolescents, leading to social jetlag and widespread insufficient sleep for middle and high school students. Researchers, clinicians, educators, and parents/caregivers often advocate for later school start times (SSTs) to accommodate these changes. However, transportation is frequently cited as a barrier to delaying school hours to times recommended by sleep and health organizations (8:30 am or later). While federal law requires public schools to provide transportation for children who are unhoused or with individualized education plans, state regulations vary. This study focused on understanding US state regulations regarding school transportation policies to better inform researchers, clinicians, and policymakers.
Methods: Using legislative codes, a team of researchers examined all 50 US states' policies and regulations regarding mandated transportation, minimum distances students must live from their school, ride duration limits, pickup times, and state/local funding.
Results: Only 34 states mandate schools to provide any level of transportation to students (e.g., districts required to provide transportation when "reasonable and desirable"; only for non-city districts; or via vans in addition to school buses). Only 10 states limit trip duration for districts (range = 30 - 90 min). Over two-thirds (70%) of states include minimum distances students must live from school to qualify for provided transportation (range =.75 - 5 miles). Only 30 states have regulations mentioning at least partial state funding for school transportation.
Conclusion: Although school districts focus on school bus transportation as one of the major barriers to setting school hours that give middle and high school students opportunities for adequate and appropriately timed sleep, surprisingly few facilitate healthy hours by regulating ride duration, transportation type, and how early in the morning youth are allowed to travel to school. States following California and Florida's lead in facilitating healthy sleep for adolescents should consider travel start times, as well as commute times and distance, in future policies.

THE EFFECT OF EXTENDING TOTAL BEDTIME ON COGNITIVE PERFORMANCE AND DAYTIME SLEEPINESS IN HIGH SCHOOL STUDENTS

Jack Zarrouf[1], Sarah Yaekoub[1], Mark Zarrouf[2]
[1] T. L. Hanna, [2] Glenview School for Engineering

Introduction: Scientists and public are very interested and worried about the negative effects of sleep deprivation on human life and cognition. Many studies showed evidence of negative outcomes on cognitive and physical health. The goal for this study is to evaluate the effect of sleep extension on cognitive tests and sleepiness in high school students over one month.

Methods: This study investigated students' cognitive performance using ZZTest; sleep activity tracker using Colm smart ring findings and daytime sleepiness with the effect of daily sleep extension. 30 healthy teenage students were asked to participate in a 4 week study: They maintained their habitual sleep-wake schedule for a one-week baseline period followed by a one-week sleep extension period, followed by a 2 week maintenance schedule. Testing was done at 0, 1 and 2 weeks. Activity tracker and sleepiness scales were done at 0, 1, 2, 3 and 4 weeks. Parental consents were obtained prior to participation in the study.
Results: 30 participants started the study. Only 15 participants had available data at the end of the 4 weeks. Mean bedtime (SD) / wake up (SD) time for the four weeks were as follows 22:40 (0.83) / 6:40 (0.89), second week 19:10 (8.2)/ 2nd 7:00 for the 3rd week 21:50 (2.78)/ 7:20 (1.12). Total subjective bedtime improved significantly between the 1st and the second week 56.97 (7.69) Vs. 60.28 (6.46) P=0.01. ESS scales improved between the first and the second week 6.20 (3.50) vs 4.44 (2.58). The ZZtest cognitive test significantly improved 4.88(3.19)vs 6.40 (1.08). Most participants maintained the extended sleep time during the 3 and 4th week, although this did not translate into significant improvement of ESS or ZZtest when comparing the 2nd week results with the 3rd and 4th week results.
Conclusion: Extending sleep time in teenage high school students improved cognitive tests and sleepiness. Most students maintained the extended sleep time over the remaining 2 weeks maintenance period when asked to keep the activity tracker and monitor their sleep.

EFFECTS OF TRANS-C INTERVENTION ON DIET AND PHYSICAL ACTIVITY IN ADOLESCENTS

Giulia Da Silva[1], Sara Stewart[1], Kate Hunter[1], Alicia Goff[1], Kara Duraccio[1]
[1] Brigham Young University

Introduction: Dietary intake and physical activity are two primary factors influencing the prevalence of chronic diseases such as obesity, diabetes, and cardiovascular disorders. However, achieving and maintaining improvements in these behaviors is challenging, particularly for adolescents. Preliminary research suggests that improving sleep may naturally increase healthy eating and activity behaviors. This study evaluated whether a sleep intervention (the Transdiagnostic Intervention for Sleep and Circadian Dysfunction; TranS-C) could indirectly positively influence dietary intake and physical activity outcomes in adolescents.
Methods: 31 adolescents (ages 14-18, all as self-identified night-owls) completed a six-week TranS-C sleep intervention. For one week before and after the intervention, participants wore a waist accelerometer (Actigraph GT3x+) for one week and completed two randomized dietary recalls (The Automated Self-Administered 24-Hour [ASA24] Dietary Assessment Tool) and completed a measure of food reward (The Power of Food Scale [PFS]). We conducted a series of paired sample t-tests to compare average caloric intake and macronutrient intake (grams of carbohydrates, fats, sugars, and proteins), average sedentary, light, and average moderate-to-vigorous physical activity, and the PFS total score from pre- to post-intervention.
Results: We observed a trend towards decreased sedentary activity following the intervention (p=.053; d =.426), with no changes in light activity (p=.779) or MVPA (p=.831). We did not observe changes in the PFS total score (p=.985) nor their caloric intake (p=.320) or macronutrient intake with the total protein (p=.283, d=.22), and carbohydrates (p=.975 d=.006) consumed. We did notice a trend towards decreasing fat levels (p=.05 d=.413) after the intervention.
Conclusion: Adolescents who undergo an intervention aimed to improve their sleep demonstrated slightly less sedentary activity following the intervention, even without directly intervening in improving physical health. However, no other changes in physical activity or dietary outcomes were noted. While we are uncertain whether dietary and physical activity behaviors would continue to improve following prolonged periods of improved sleep, these preliminary data suggest that sleep interventions alone may not be sufficient for improving adolescent dietary and physical activity behaviors.

PARENTAL EMOTIONAL REGULATION AND WELL-BEING FOLLOWING AN ADOLESCENT SLEEP INTERVENTION

Katherine Russell[1], Sarah Brewer[1], Solei Paget[1], Kara Duraccio[1], Daniel Kay[1]
[1] Brigham Young University

Introduction: Preliminary research suggests adolescents receiving the Transdiagnostic Intervention for Sleep and Circadian Dysfunction (TranS-C) show improved mental health following treatment; however, few studies investigate how sleep interventions for youth impact parents. This secondary analysis aimed to investigate parent outcomes resulting from their child's participation in a TranS-C intervention; we hypothesized that parent's anxiety, stress, and depression would decrease, emotional regulation abilities, parenting self-efficacy and overall subjective happiness would increase, and sleep quality would improve as a result of their child participating in the sleep intervention.
Methods: 31 adolescent participants (ages 14-18) with night-owl tendencies participated in a 6-week TranS-C intervention; 22 parents completed the following questionnaires before and immediately following the intervention: the short-form versions of the Depression Anxiety and Stress Scale (DASS-21) and Difficulties in Emotion Regulation Scale (DERS-18), Me as a Parent scale (MaaP), Pittsburgh Sleep Quality Index (PSQI), and the Subjective Happiness Scale (SHS). Paired sample t-tests were used to evaluate parent outcomes following the intervention.
Results: A significant decrease in the DERS-18 (reflecting greater emotional regulation abilities; p=0.028) was observed post-intervention, driven by change in the awareness of emotional response subscale (p=0.036). No significant changes observed following the intervention on DASS-21 (p=0.095), MaaP (p=0.231), PSQI (p=0.855), or SHS (p=0.866).
Conclusion: Adolescent Trans-C intervention improved parents' emotional regulation abilities, particularly awareness of their emotional responses. Other measures indicate parental depression and anxiety, parenting efficacy, sleep quality, and happiness were not affected as a result of their child's sleep intervention. Improved adolescent sleep patterns may reduce the emotional labor parents need to manage their child's sleep, allowing parents to use regulation skills in other areas.

MIXED-METHODS RESULTS OF INTERVIEWS WITH BLACK CAREGIVERS OF YOUNG CHILDREN DURING CHILD BEDTIME ROUTINES

Alicia Chung[1], Willa Johnson[1], Laurie Brotman[1], Keng-Yen Huang[1], Girardin Jean-Louis[2]

[1] NYU Grossman School of Medicine, [2] University of Miami Miller School of Medicine

Introduction: Black children experience a disproportionate rate of sleep health disparities compared to other racial groups. Tailored interventions for Black families require information about context and fit of evidence-based interventions. We aimed to elucidate Black caregiver experiences during their child's bedtime routine.
Methods: Black caregivers of young children were interviewed in-person and virtually. Qualitative interviews focused on contextual factors in the home, household structure, environment and beliefs and values about parenting practices related to their child's sleep. Three adapted validated measures were completed on child routines, routine consistency, child temperament and parenting practices during bedtime. Statistical analysis included descriptive statistics and correlations with composite variable on child sleep, based on eligibility criteria of behavioral sleep problems. Participant interviews were analyzed using an implementation science rapid qualitative analysis approach.
Results: Thirty caregivers (1 grandma, 25 moms, 4 dads) participated. About 50% of whom identified as African-American, 14% Jamaican, 10% Haitian, and the remainder mixed multi-ethnic groups. Parents' age ranged from 31-55 and were 41 years old on average. Children's ages ranged from 3-8 years old and were 5 years old on average. Participants answered 56% of knowledge questions about child sleep accurately. About 82% of parents reported their child went to bed before 9pm, 55% reported dependent sleep (e.g. sharing a bed/room with a caregiver or sibling), 86% reported sleep onset (< 15 minutes), and 93% reported consistent waketime (>5 nights). Qualitative interviews provided clarifying insight on survey responses. For instance, some parents reported sleep dependency due to lack of space or personal choice. Sleep dependency may be a parental choice to comfort child during sleep due to changes in household structure (e.g. divorce) or personal values not to want to leave the child alone (e.g. night wakings/terrors). Bedtime resistance (p=0.003) and permissive parenting (p=0.004) was significantly correlated with later bedtimes. Daily living routines (p=0.019) and more bedtime routines (p< 0.001) were significantly correlated with adaptive behaviors and greater independent sleep respectively.
Conclusion: Qualitative data may be needed to fully understand parent experiences during their child's bedtime. A variety of tailored evidence-based strategies may be needed to optimize child sleep among Black families.

ACTIGRAPHY-BASED ASSESSMENT OF SLEEP HEALTH IN PEDIATRIC CRANIOPHARYNGIOMA PATIENTS

Dana Kamara[1], Alice Bai[2], Kayce Hopper[3], Kathryn Russell[2], Belinda Mandrell[2], Merrill Wise[4], Thomas Merchant[2], Valerie Crabtree[2]

[1] University of Colorado/Children's Hospital of Colorado, [2] St. Jude Children's Research Hospital, [3] University of Mississippi, [4] Mid-South Pulmonary and Sleep Specialists, PC

Introduction: Treatment of craniopharyngioma, a rare brain tumor, may compromise sleep-regulating structures such as the suprachiasmatic nuclei and lateral hypothalamus. Patients commonly experience excessive sleep fragmentation, daytime sleepiness, and central disorders of hypersomnolence (CDH). This study objectively characterizes sleep health among pediatric craniopharyngioma patients by comparing nighttime actigraphy metrics to National Sleep Foundation age-based consensus guidelines for sleep duration (2014) and quality (2017).
Methods: Study participants were pediatric craniopharyngioma patients enrolled in an institutional phase II proton therapy trial. Participants wore actigraphy for at least 3 nights and parents completed sleep diary data. Variables included total time in bed, total sleep time (TST), sleep efficiency (SE), sleep onset latency (SOL), and wake after sleep onset (WASO). CDH were diagnosed by standard AASM guidelines. Differences between ages, pubertal status, CDH status, hypothalamic tumor involvement, and BMI z-score were examined.
Results: Data from 65 patients ages 1-19 years (mean = 8.95±4.55) were included, 67.7% white, 50.8% female. Mean overnight TST was inappropriately short among toddlers (7.11 hours) and preschoolers (7.96 hours). School-age children (7.86 hours) and teenagers (7.28 hours) also slept less than the minimum recommended duration for their age. SE was within appropriate ranges for all age groups except preschoolers (84.02%) regardless of sleep disorder status and school age children with narcolepsy (83.62%). SOL was longer than appropriate among preschoolers (39.45 minutes) and school-aged children (31.69 minutes) overall, and among school-aged (37.73 minutes) and teenage (31.46 minutes) patients with narcolepsy. Mean WASO durations were longer than recommended for all age groups in our sample (range 50.05-91.10 minutes).
Conclusion: Pediatric craniopharyngioma patients in our sample did not achieve recommended TST, SOL, or WASO durations in certain age groups. Preschoolers overall and school-age children with narcolepsy did not achieve recommended values by any metric assessed. Future studies including assessment of daytime sleep are warranted to further characterizing sleep health in pediatric craniopharyngioma.

COMPARISON AND VALIDATION OF OPEN SOURCE ACTIGRAPHY VERSUS POLYSOMNOGRAM IN A CLINICAL PEDIATRIC POPULATION

Nina Kuei[1], Sally Ibrahim[2], Kyle Harris[3], Christine Marlow[4], James Spilsbury[5]

[1] University Hospitals, [2] University Hospitals Cleveland Medical Center and Case Western Reserve University, [3] University of Cincinnati College of Medicine, [4] Case Western Reserve University, [5] Case Western Reserve University School of Medicine

Introduction: Obtaining sleep metrics assists clinicians in accurately diagnosing and treating sleep disorders. Actigraphy is commonly utilized to obtain sleep metrics by estimating sleep/wake through accelerometer-detected body movement. A limited number of studies compared these devices to gold-standard polysomnography (PSG) in pediatric populations, yet efforts to assess validity has gained interest in light of recent clinical device support discontinuation.
Methods: This study examines a clinical sample of children ages 6-16 undergoing a PSG who also underwent simultaneous GENEActiv wrist-worn accelerometer devices recording either at 85.7Hz or 100Hz. Open-source R package GGIR was used to derive sleep/wake classifications for actigraphy data. R Studio was used to synchronize accelerometer and PSG epochs (30 seconds) and calculate performance metrics (sensitivity, specificity, and accuracy). Paired T-tests assessed differences in performance metrics by use of a sleep log (SL) vs. no SL. Similarly, subgroup analyses assessed differences in metrics by sleep disorders (severe/moderate OSA, restless legs/periodic limb movements/other movement disorders), sex, age (≥13years vs. < 13 years).
Results: There were 56 children (mean age=10.5 years, 50% female). At 85.7Hz(n=27), actigraphy with SL had greater sensitivity ((90.9%+5.3% vs. 78.7 + 25.1%, p=0.009, greater accuracy 88.9%+4.5% vs. 79.4%+19.7%, p=0.013, but non-significant decreased specificity (72.8%+18.2% vs. 77.2%+24.7%, p=0.165) compared to actigraphy without SL. Similarly, at 100Hz (n=29), actigraphy with SL had greater sensitivity (86.8%+7.9% vs. 75.2%+25.1%, p=0.012) and accuracy (83.3%+9.0% vs 75.8%+20.0%, p=0.034) with decreased specificity (70.9%+27.4% vs. 77.8%+28.6%, p=0.004) compared to actigraphy without SL. Results remained largely consistent in sensitivity analyses when different disorder groups were removed from the analysis. Additional analyses revealed greater sensitivity among teens vs. younger children at 85.7Hz (93.2%+4.5% vs. 89.3%+5.3%, p =0.048) and 100Hz (92.3%+4.9% vs. 85.0%+8.0%, p=0.01), and lower specificity at 85Hz (61.6%+ 20.8% vs. 80.6%+11.5%, p=0.016). No sex differences were observed in test metrics.
Conclusion: At both 85.7Hz and 100Hz, SL use with actigraphy increased accuracy and sensitivity metrics, with a slight trade-off in specificity compared to no SL use. Results lend confidence to using actigraphy with a sleep log as a general estimate of sleep/wake patterns in pediatric populations.

EVALUATING A NEW SLEEP TESTING DEVICE FOR PEDIATRIC PATIENTS: A COMPARATIVE ANALYSIS OF TYPE 2 HST VS IN-LAB PSG

Benjamin Fox[1], Murad Shihab[1], Asher Tal[2], Abed Nassir[3], Dahlia Kushinsky[4], Ofer Barnea[3]
[1] Shamir Medical Center, [2] Favculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, [3] Tel Aviv university, [4] Dormotech Medical Ltd.

Introduction: High-quality sleep is critical for children's and adolescents' development and health. Despite the high prevalence of sleep disorders in this population, few polysomnography devices have tested specifically for pediatric use. We evaluated the Dormotech device, a novel sleep monitoring system designed for both clinical and home-based sleep studies, against gold standard polysomnographic equipment.
Methods: Twenty-six children (mean age = 11.0 years, 50% female, mean body mass index 26.0 kg/m2) underwent simultaneous sleep studies with the novel device and gold-standard polysomnography in a sleep clinic. Data were manually scored following recommended guidelines. The primary outcome was apnea-hypopnea index (AHI) and its corresponding severity classification level (i.e. normal, mild, moderate, severe). Secondary endpoints included other standard polysomnography (PSG) parameters.
Results: The mean AHI measured by the novel device was 5.6 ± 15.3 events/h (mean ± standard deviation) while it was 5.2 ± 13.8 events/h from the gold standard PSG (p = 0.95, t-test). AHI severity classification showed excellent inter-test agreement (Cohen's kappa = 0.87). Secondary endpoints demonstrated high correlation between devices, with no statistically significant differences in simultaneously recorded sleep measurements. No adverse safety events were reported.
Conclusion: The novel device provides sleep study data comparable to conventional polysomnography in pediatric patients, offering clinically identical test interpretation in nearly all cases. Its design enables flexible usage in both clinical and home settings in this population, improving accessibility of sleep disorder diagnostics. These results, combined with previous adult studies, suggest the device's substantial equivalence to established, gold-standard PSG systems in usability, efficacy, and safety for a wide population of patients.

COMPARISON OF OBJECTIVE AND SUBJECTIVE MEASURES IN ASSESSING SLEEP PATTERNS OF PREMATURE INFANTS

Laura Ramos Socarras[1], Valérie Lebel[1], Geneviève Forest[1]
[1] Université du Québec en Outaouais

Introduction: Premature infants exhibit unique sleep patterns, making the assessment of their sleep particularly challenging. Actigraphy and the Brief Infant Sleep Questionnaire (BISQ) are commonly used tools to evaluate infant sleep, yet comparisons between these methods remain limited in this population. The objective of this study is to determine whether significant differences exist between sleep data obtained through actigraphy and BISQ reports in premature newborns.
Methods: This study included 34 premature newborns (≤32 weeks of gestation) who wore actigraphy devices for three consecutive weekdays, one month after discharge from the neonatal unit. Actigraphy variables were measured for a nighttime period from 7:00 PM to 7:00 AM, using the average of the three nights. Parents also completed multiple questionnaires, including the BISQ and sleep diaries to corroborate actigraphy data. Exploratory paired t-tests were conducted to examine differences in sleep duration, number of nocturnal awakenings, and wake after sleep onset (WASO) between actigraphy data and BISQ parental reports.
Results: Results showed significant differences for all variables. BISQ-reported sleep duration was significantly longer than actigraphy-measured sleep duration (excluding WASO), overestimating by 59.35 minutes ($t(33) = 2.71$, $p = .01$). When comparing BISQ sleep duration to actigraphy-measured total sleep time (including WASO), BISQ underestimated sleep duration by 122.06 minutes ($t(33) = -6.48$, $p < .001$). BISQ-reported number of awakenings was significantly lower compared to actigraphy, with a mean difference of 1.26 awakenings ($t(33) = -3.85$, $p < .001$). Similarly,

BISQ-reported WASO was, on average, 71.40 minutes shorter than actigraphy-measured WASO ($t(33) = -4.28$, $p < .001$).
Conclusion: These discrepancies between BISQ parental reports and actigraphy measures could reflect the subjective nature of parental reports, which provide a generalized overview of sleep, compared to the objective data that measure sleep on few specific nights. Our results suggest that the BISQ and actigraphy may not capture the same aspects of infant sleep, emphasizing the importance of selecting the appropriate tool based on the research or clinical objective. This is particularly relevant for premature infants, whose sleep tends to be more fragmented, making precise measurements essential for understanding their unique sleep patterns.

RELATIONSHIP BETWEEN PACIFIER USE AND INFANT SLEEP METRICS OBTAINED WITH AUTO-VIDEOSOMONOGRAPHY

Maristella Lucchini[1], Daniela Macia[1], Liat Tikotzky[2], Sarah Berger[3], Natalie Barnett[1]
[1] Nanit Lab, [2] Ben-Gurion University of the Negev, [3] College of Staten Island, City University of New York

Introduction: Pacifiers are routinely utilized among infants worldwide, yet their potential influence on infant sleep remains underexplored. Existing research offers conflicting insights, with one large-scale study finding no differences in sleep outcomes between pacifier users (PU) and non-users (nPU); however, this study relied on parent-reported sleep metrics, which are subject to bias. Other studies have utilized objective polysomnography measures, but these have been limited by small sample sizes and only one night of data per child in an unfamiliar environment, restricting their generalizability. To address these gaps, this study leverages a large sample and objective sleep metrics obtained through autovideosomnography, providing a novel and robust approach to understanding the relationship between pacifier use and infant sleep.
Methods: Among Nanit users, we recruited 243 families of infants 4-7 months. We obtained the following sleep metrics for each infant via autovideosmonography (5-14 nights): nighttime sleep duration (NSD), nighttime awakenings (NA), parental visits (PV). Additionally, we obtained parental reports on NDS and NA with the BISQ-R. We ran linear regressions with sleep metrics as outcomes, use of pacifier based on parental report as predictor and infant's age as covariate.
Results: Forty-one percent of infants were PU. Compared to nPU, PU had more PV (β=1.4±0.3,p< 0.001). PU were also more likely to sleep in a bassinet, rather than in a crib, compared to nPU (PU 20% vs nPU 6%). However, no differences were found between the groups in NSD and NA both for objective and parent-report metrics. Moreover, there was no difference in age, proportion of infants who fell asleep on their own or being held/rocked, or with an adult in the room without being held/rocked.
Conclusion: This is the first study to analyze the relationship between pacifier use at night and objective infant sleep metrics. While results from parental reports show no differences, as described by previous literature, objective sleep metrics show more parental interventions for infants using pacifiers, despite having the same nighttime sleep duration and awakenings, and mostly similar sleep ecology and parental involvement at bedtime.

EVALUATION OF AGE-APPROPRIATE SLEEP METRICS IN PEDIATRIC PATIENTS UNDERGOING OVERNIGHT POLYSOMNOGRAPHY AT GEISINGER

Soumendro Goswami[1], John Karstens[1], Hema Murali[1], Sreelatha Naik[1]
[1] Geisinger

Introduction: The American Academy of Sleep Medicine (AASM) recommends age-specific total sleep time (TST) and REM sleep percentages for optimal pediatric health. This study evaluates whether pediatric patients undergoing overnight polysomnography (PSG) at our Geisinger Sleep Lab achieve these recommended sleep metrics. Identifying deviations from guideline-based sleep parameters can inform targeted interventions to improve pediatric sleep outcomes.
Methods: The Geisinger Sleep Medicine database was queried for children ages 1-17 at the Geisinger South Wilkes-Barre lab between December 2023 and November 2024. TST, REM sleep percentage, and sleep onset time were extracted. Data were compared to the AASM consensus guidelines for recommended sleep durations and REM percentages for pediatric patients.
Results: The average TST ranged from 397 minutes (6.6 hours) at age 1 to 436 minutes (7.3 hours) at age 4, falling below AASM recommendations of 11-14 hours for children aged 1-2 years and 10-13 hours for ages 3-5 years. For ages 5-17, average TST varied from 431.7 minutes (7.2 hours) at age 5 to 412.7 minutes (6.9 hours) at age 9, consistently below the recommended 9-12 hours for ages 6-12 and 8-10 hours for teenagers. Average REM percentages ranged from 4.9% to 16.6%, lower than the expected 20-25%. Younger children achieved approximately 30-40 minutes more TST than older children. Sleep onset times ranged from 9:23 PM to 10:50 PM, later than recommended for these age groups.
Conclusion: Our findings suggest that most pediatric patients in our sleep lab do not achieve age-appropriate sleep metrics as defined by AASM guidelines, potentially underdiagnosing sleep-disordered breathing severity. Reduced TST and REM percentages likely reflect delayed sleep onset and circadian misalignment, exacerbated by inconsistent PSG start times. Contributing factors include late bedtimes, increased screen exposure, and inconsistent parental enforcement of sleep hygiene among older children. Stricter parental regulation of younger children's routines and stronger homeostatic drive may explain their relatively longer TST. Addressing environmental and scheduling factors could optimize sleep in this population and improve testing quality. Future studies should evaluate whether educating patients and parents and increasing sleep opportunities in the laboratory can enhance the characterization of sleep-disordered breathing.

ROUTINE SCREENING FOR EXCESSIVE DAYTIME SLEEPINESS IN PEDIATRIC BRAIN TUMOR

Kayla LaRosa[1], Keerthi Narasimhan[2], Valerie Crabtree[3], Emily Singer[2], Mustafa Barbour[4], Lauren Hayes[1]
[1] University of Louisville/Norton Children's Medical Group, [2] University of Louisville, [3] St. Jude Children's Research Hospital, [4] Norton Children's Cancer Institute

Introduction: Youth with brain tumor may experience excessive daytime sleepiness (EDS) associated with central disorders of hypersomnolence (CDH).1 EDS impairs daily functioning, negatively affects mood and quality of life, and further exacerbates cognitive and academic difficulties associated with brain tumor.2 The aim of this study is to summarize findings from universal screening of these issues in pediatric brain tumor.
Methods: Youth receiving treatment or surveillance for pediatric brain tumor presenting to inpatient or outpatient settings were screened for symptoms of EDS using the Modified Epworth Sleepiness Scale (M-ESS) and the Pediatric Hypersomnolence Survey (PHS). A cut off score of 6 was utilized on the M-ESS.3 The PHS has not yet been used in pediatric cancer, therefore, it was trialed to determine level of agreement with other screening methods. The standard cut off score of 24 or 8 on the sleepiness subscale score was used. Elevated ratings were discussed with the primary oncologist, and a referral was made to Sleep Medicine if deemed necessary.
Results: Eighteen youth with brain tumor completed screening for sleep problems (61% Low Grade Astrocytoma, 83.3% White). A total of 38.9% (n=7) scored above the cut off on the M-ESS, indicating concern for EDS. On the PHS, a total of 16.6% (n = 3) scored above the cut off for Total score and the Sleepiness subscale, indicating concern for narcolepsy or hypersomnia. Three (16.6%) participants were referred to Sleep Medicine for further evaluation and three others (16.6%) were already established with Sleep Medicine at the time of screening.
Conclusion: EDS and CDH may be common in pediatric brain tumor.1,2 Screening measures led to increased referral to Sleep Medicine. Despite this, due to discrepancy between measures, further research is needed to determine the best screening methods to accurately determine the presence of EDS in pediatric brain tumor.

CHILDREN'S BEDTIME STORY BOOKS: POSITIVE AND NEGATIVE PRESENTATIONS OF SLEEP

Sumin Im[1], Augustine Gallespen[1], Autumn Reynolds[1], Michelle Garrison[1]
[1] Purdue University

Introduction: The way sleep and bedtime are portrayed in children's books may influence the perceptions of sleep for both young children and their guardians, leading to potential mirroring of the behaviors and attitudes depicted in the stories. The goal of this mixed-method study was to examine the trends of depictions of sleep and bedtime in picture books for children.
Methods: Our team selected picture books about sleep intended for young children from local libraries using search terms "sleep" and "bedtime". Each book was coded using a structured abstract form by at least two team members for sleep portrayal, quantifying the pages of both positive and negative depictions and character attitudes. Disagreements were resolved by team consensus. Books were then examined for four thematic codes: bedtime routine, child character refusing to sleep, nurturing approach during bedtime, and positivity/relaxation to help transition to sleep. Nine books were selected based on their general attitude toward sleep and categorized into three attitudes: child has no difficulty sleeping and book emphasizes benefits of sleep, nurturing approach to child's sleep difficulties, and authoritative approach to child's sleep difficulties. The nine books were then analyzed qualitatively identifying common themes.
Results: A total of 50 picture books were examined across the four thematic codes. The majority of books (54%) offered characters exhibiting a nurturing approach to the bedtime process, exhibited through verbal and active affirmations. During the bedtime process, 58% of books contained a bedtime routine with 30% having relaxing activities to help the transition to sleep during the routine, such as reading books or cleaning up. However, 36% of books contained a child character who refused to go to bed/sleep, often containing imagery of frowning and crying while insisting "I am not sleepy!"
Conclusion: The data pool represents books with themes of sleep and bedtime commonly read to young children, but may not be a large enough sample for broad generalizations. Many books lack positive portrayals or evidence-based strategies, often missing a positive guardian attitude and showing poor bedtime behavior. Careful attention to sleep presentation may be important for positive effects on parent and child behaviors and attitudes.

A NARRATIVE REVIEW OF ARTIFICIAL INTELLIGENCE/MACHINE LEARNING METHODS IN PEDIATRIC SLEEP

Natalie Mitchell[1], Ariana Calloway[1], Syed-Amad Hussain[2], Elizabeth Lyman[1], Devante Barnes[1], Mattina Davenport[1]
[1] Nationwide Children's Hospital, [2] The Ohio State University

Introduction: Artificial Intelligence/Machine Learning (AI/ML) methods have risen in capability and application since 2012. In pediatric sleep health, these approaches have the potential to improve the surveillance and detection of pediatric sleep problems and disorders, automated scoring of polysomnography data, computational phenotyping, and clinical predictive algorithms. Sleep-related AI/ML innovations are endless and becoming increasingly prevalent in adult-focused sleep medicine and research. However, this review outlines the current AI/ML methods that have been deployed among pediatric sleep populations.
Methods: A review of the literature was conducted using PubMed, Embase, Web of Science, and Scopus to obtain articles related to AI/ML and pediatric sleep search terms. The criterion for article inclusion and full text review included: English language, published after the year 2012, and topically related to the application of an AI/ML method in pediatric sleep.
Results: This search yielded 3585 articles, which was narrowed to 1968 for screening after removing duplicates in Covidence. After applying screening criteria, 60 articles met the criteria for full-text review. AI/ML applications at the intersection of pediatric sleep include the following: predictive algorithms (e.g., obstructive sleep apnea detection, infant sleep, children with neurodevelopmental disabilities and comorbid sleep problems, adolescents with comorbid mental health conditions), automated sleep stage and duration scoring for pediatric polysomnography and actigraphy, and computational phenotyping in children with autism spectrum disorder. However, there is still need for leveraging studies leveraging feasible natural language processing approaches, healthcare-based detection tools, translational AI/ML methods that can be deployed as community-based solutions, and population-level surveillance of pediatric sleep.

Conclusion: This narrative review provides an overview of the existing AI/ML methodology that has been deployed in pediatric sleep, offers suggestions for future applications across age groups and settings, and an equity-based framework for designing future research that will further the intersecting fields of pediatric sleep and AI/ML. Despite the current progress that has been made in deploying AI/ML, design and implementation gaps remain among historically underserved sleep care populations. Future studies that center equity and population-level pediatric sleep health are crucial for innovative insights to be garnered.

UTILITY OF VIDEO EEG DURING OVERNIGHT POLYSOMNOGRAPHY: A SINGLE CENTER EXPERIENCE

Harish Rao[1], Anuja Bandyopadhyay[2], Hasnaa Jalou[2]
[1] Riley Hospital for Children, Indiana School of Medicine, [2] Riley Hospital for Children

Introduction: Overnight attended polysomnography (PSG) is the recommended diagnostic test to diagnose sleep disordered breathing in children. But PSG is also often utilized to ascertain nocturnal events such as atypical parasomnias or seizures with additional video EEG (VEEG). In this VEEG PSG montage, eight EEG electrodes are added to standard PSG montage to capture and correlate EEG activity with motor events during sleep. The additional EEG data is interpreted by an epileptologist.
Methods: In this single center retrospective study, we reviewed clinical, PSG and VEEG data from seventy-one consecutive VEEG PSGs over the past 2 years.
Results: Age ranged from 1 to 16 years: median age being 6 years. VEEG PSG were ordered by different specialties (Sleep Medicine 35, Neurology 9, Developmental Medicine 5, Primary care 17, Genetics 3, Pulmonology 2). Indication for VEEG with PSG was mostly to ascertain nocturnal events such as parasomnia, movement disorders and rule out seizures. In our cohort, twenty-five children had moderate – severe OSA & three had periodic limb movement disorder. Only one out of fifty participants had an episode of confusional arousal during the VEEG PSG; no nocturnal events were observed in other studies. EEG abnormality noted in 17/50 VEEG PSGs. Seven children had diffuse slowing (diffuse encephalopathy). Bursts of sharp or spike waves with abnormal EEG activity noted in eleven patients.
Conclusion: VEEG PSG is a useful tool to ascertain events during sleep and helps differentiate between parasomnias, nocturnal seizures, and other motor activity. In our study, the VEEG PSG yield was low as only one patient had a parasomnia episode during the study. Seventeen patients demonstrated abnormal EEG during VEEG PSG, but this cohort already had underlying neurological disorders such as epilepsy or other developmental disorders. These patients had previously shown EEG abnormality on their routine EEGs. Though VEEG PSG could be an extremely valuable tool to distinguish and diagnose nocturnal events, it should be used sparingly in patients with high positive predictive value. VEEG PSG set up is labor intensive and reimbursements are routinely not submitted as there is no specific billing code for the additional montage

ASSOCIATIONS BETWEEN SLEEP HEALTH AND CHRONIC CONDITIONS: A CROSS-SECTIONAL STUDY OF NHANES 2017–2020

Allan Porcacchia[1], Julia Vallim[2], Vânia D'Almeida[2], Monica Andersen[3], Sergio Tufik[3]

[1] Universidade Federal de São Paulo, [2] UNIFESP - Universidade Federal de São Paulo, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Influenced by a range of lifestyle choices, environmental exposures, technological advancements, and health-related conditions, sleep impairment has become a significant public health concern. Sleep is increasingly acknowledged as a core component of overall health. Prevalent among adult populations, sleep disturbances not only impose substantial economic burden, but also increase the risk of chronic diseases. This study aims to investigate the impact of dimensions of sleep health on the probability of having 5 key public health outcomes.
Methods: This study utilized data from 2 editions of the National Health and Nutrition Examination Surveys (NHANES) conducted in the United States between 2017 and March 2020, yielding a final sample size ranging from 7,361 to 7,373 participants. Sleep health was assessed considering 5 main domains: symptoms indicative of sleep breathing disorders, other sleep disorders symptoms, frequency of daytime sleepiness, weekly sleep regularity (social jetlag), and chronotype (determined by mid-sleep on free days adjusted for sleep debt on workdays - MSFsc). The primary outcomes evaluated were the likelihood of having cardiovascular, respiratory and thyroid diseases, stroke, and cancer. Binary logistic regression models were employed in the analysis of the data.
Results: The participants had a mean age of 49.9 years, with 51.2% identifying as women and a mean body mass index of 30.0kg/m². Respiratory disease was reported by 20.5% of participants, thyroid disease by 11.4%, cancer by 9.9%, cardiovascular disease by 8.5%, and stroke by 4.6%. Concerning sleep-related variables, 27.5% of participants reported difficulty sleeping, 47.4% experienced snoring, 12.3% had episodes of breathing cessation during sleep, and 25% presented symptoms of daytime sleepiness. The mean social jetlag was approximately 3 hours, with MSFsc occurring around 3:00 AM. Sleep difficulties were associated with a higher risk of all outcomes except stroke. Excessive daytime sleepiness was significantly related to increased risk of stroke, cardiovascular, respiratory, and thyroid diseases. A later chronotype was associated with a higher risk of thyroid, cardiovascular, and respiratory diseases.
Conclusion: Impaired sleep health, specifically marked by insomnia and sleep apnea symptoms, and later chronotype, was associated with increased risk of stroke, cardiovascular, respiratory, and thyroid diseases.

INCREASED RISK OF CARDIOMETABOLIC DISORDERS, INCLUDING HYPERTENSION, HYPERLIPIDEMIA, AND DIABETES, IN PATIENTS WITH NARCOLEPSY

Christopher Kaufmann[1], Munaza Riaz[1], Haesuk Park[1], Wei-Hsuan Lo-Ciganic[2], Debbie Wilson[1], Emerson Wickwire[3], Atul Malhotra[4], Rakesh Bhattacharjee[4]

[1] University of Florida, [2] University of Pittsburgh, [3] University of Maryland Baltimore, [4] University of California, San Diego

Introduction: Emerging evidence suggests narcolepsy is associated with cardiovascular disease (CVD) and major adverse cardiovascular events (MACE). However, its association with cardiometabolic disorders, which contribute to elevated CVD risks, remains poorly understood. In this study, we examined whether narcolepsy is associated with increased risk of cardiometabolic disorders (including hypertension, hyperlipidemia, and diabetes) as well as CVD and MACE.
Methods: This retrospective cohort study used data from the 2005-2021 MarketScan® Commercial and Medicare Supplemental databases. We identified persons with narcolepsy (PWN) defined as having ≥2 outpatient claims for either NT1 or NT2 narcolepsy subtypes based on ICD-9 and -10 codes. We employed propensity score (PS) matching (1 to up to 3 ratio) to identify a comparison group without narcolepsy and hypersomnolence. The index date was the date of the first narcolepsy diagnosis for the narcolepsy group and the corresponding encounter date for the matched comparison group (non-narcolepsy group). We excluded individuals with CVD, MACE, hypertension, hyperlipidemia, diabetes, and metabolic fatty liver disease during the year prior to the index date (baseline period). PS-matching balanced demographics, comorbidities and use of medications in the baseline period. We employed time-dependent Cox regression proportional hazards models to determine the association between narcolepsy and time to the incidence of outcomes of interest. We controlled for narcolepsy medication use at baseline (i.e., wake-promoting agents, stimulants, and oxybate) and time-varying post-index stimulant use.
Results: The final cohort included 22,293 PWN and 63,709 without narcolepsy/hypersomnolence. The mean age of the cohort was 35.5 (± 14.0) years, and 63.7% were female. Compared to those without narcolepsy, PWN had a significantly higher risk of developing CVD (adjusted hazard ratio [aHR]=1.97, 95% confidence interval [CI]=1.65-2.36) and MACE (aHR=2.18, 95% CI=1.68-2.83). PWN also had an increased risk for hypertension (aHR=1.44, 95% CI=1.34-1.54), hyperlipidemia (aHR=1.48, 95% CI=1.39-1.57), and diabetes (aHR=1.61, 95% CI=1.40-1.83) compared to those without narcolepsy.
Conclusion: Using a large representative US claims dataset, narcolepsy was associated with an increased risk of hypertension, hyperlipidemia, and diabetes, further providing compelling evidence that enhances our understanding of how narcolepsy is linked to CVD and MACE.

AGE- AND SEX-SPECIFIC RELATIONSHIP OF SLEEP APNEA-SPECIFIC HEART RATE RESPONSE AND ATRIAL FIBRILLATION INCIDENCE

Catherine Heinzinger[1], Matheus Lima Diniz Araujo[1], Delaney Ryan[2], James Bena[2], Nicolas Thompson[2], Alex Milinovich[3], Nancy Foldvary-Schaefer[1], David Van Wagoner[4], Mina Chung[5], Reena Mehra[6]

[1] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [2] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [3] Quantitative Health Sciences, Lerner Research, Cleveland Clinic, [4] Lerner Research

Institute, Cleveland Clinic, Cleveland, OH, [5] Heart, Vascular, and Thoracic Institute, Cleveland Clinic, Cleveland, OH, [6] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, Seattle, WA

Introduction: Autonomic dysfunction (AD) is implicated in sleep apnea and atrial fibrillation (AF), however age- and sex-specific interactions are unclear. We hypothesize age- and sex-specific differences in sleep apnea-specific heart rate response (ΔHR), an AD biomarker, on AF susceptibility.
Methods: Cleveland Clinic patients (age≥18) who underwent polysomnography 1/2/2000-12/30/2017 were retrospectively examined. Cox proportional hazards models were constructed for time from sleep study to AF by diagnosis code. ΔHR (respiratory event-related electrocardiogram-based heart rate difference; signal processing via Python®) was adjusted for demographics, body mass index (BMI), tobacco use, cardiopulmonary disease, anti-arrhythmic medications, positive airway pressure, and minimum heart rate during events. Statistical analyses were conducted using R and SAS.
Results: The sample included n=23,419 patients (age 51[41-61] years, 51% male, 74% White, BMI 34[29-40] kg/m2, apnea hypopnea index 18.3[7.5-42.6]) over7±3-years. High vs. mid-range ΔHR was associated with 22% increased AF incidence (HR=1.22, 95%CI=1.09-1.35); low vs. mid-range was not. An interaction of ΔHR by sex (p=0.031) for low vs. mid-range ΔHR showed AF incidence was lower in males than females (HR=0.77, 95%CI=0.61-0.97). In sex-stratified models, high vs. mid-range ΔHR in females showed the highest AF incidence (HR=1.27, 95%CI=1.06-1.52), followed by low vs. mid-range in females (HR=1.22, 95%CI=1.03-1.45), high vs. mid-range in males (HR=1.18, 95%CI=1.03-1.35), and low vs. mid-range in males though non-significant (HR=0.93, 95%CI=0.79-1.09). An interaction of ΔHR by age (p< 0.001) showed older patients (age>51) had 51% increased AF incidence relative to younger patients for high vs. mid-range ΔHR (HR=1.51, 95%CI=1.18-1.94); among younger patients, low vs. mid-range ΔHR had 42% increased AF incidence (HR=1.42, 95%CI=1.08-1.86). A ΔHR by race interaction was non-significant (p=0.905).
Conclusion: A polysomnography-derived sleep apnea-specific AD biomarker was associated with AF with important age- and sex-specific interactions. There was a U-shaped trend in females and older patients, a positive linear trend in males, and a negative linear trend in younger patients. Younger females with low ΔHR had highest AF incidence. Findings suggest sleep apnea-specific AD plays a role in AF development, highlighting the need for tailored management of sleep apnea-related AF risk based on age and sex.

A MULTI-OMICS STUDY OF THE ASSOCIATION BETWEEN INSOMNIA WITH OBJECTIVE SHORT SLEEP DURATION PHENOTYPE AND HIGH BLOOD PRESSURE

Yanyuan Dai[1], Yun Li[1], Alexandros Vgontzas[2]
[1] Shantou University Mental Health Center, [2] Sleep Research and Treatment Center, Penn State College of Medicine

Introduction: Insomnia with objective short sleep duration is associated with increased hypertension risk. We aimed to explore the mechanism underlying the association between objective short sleep duration and hypertension in patients with chronic insomnia disorder (CID) by multi-omics.
Methods: CID was defined according to International Classification of Sleep Disorders-3, and objective short sleep was based on the median value of total sleep time of the overall subjects during an overnight polysomnography. We used the mean values of measured nighttime and morning systolic (SBP) and diastolic blood pressure (DBP) for analysis. Serum metabolomics and fecal 16S rDNA amplicon sequencing were used to explore characteristic metabolites and analyze gut microbiota distribution, respectively.
Results: One hundred three patients with CID and 70 normal sleepers were included. We found 53 objective short sleep duration insomnia phenotype (ISSD)-related serum metabolites. Among the 53 ISSD-related serum metabolites, indoxyl sulfate was positively correlated with BP after adjusting for confounding factors (SBP: β=0.250, p=0.028; DBP: β=0.256, p=0.030) in ISSD. In addition, the level of serum indoxyl sulfate was significantly correlated with the genera Prevotella 9 (r=0.378, p=0.027), CAG-56 (r=-0.359, p=0.037), Ruminiclostridium 9 (r=-0.340, p=0.049) and Ruminococcus 2 (r=-0.356, p=0.039) in ISSD.
Conclusion: Our study suggests that the ISSD phenotype is associated with significant changes in serum metabolic profile, including high levels of indoxyl sulfate. The latter molecule correlates both with BP and gut microbiota in patients with the ISSD phenotype, suggesting that indoxyl sulfate may be the molecular path resulting in increased hypertension risk in this phenotype.

CHARACTERIZING ARRHYTHMIA BURDEN IN OBSTRUCTIVE AND CENTRAL SLEEP APNEA WITH A MULTI-DIAGNOSTIC MONITOR

Cathy Goldstein[1], Surina Sharma[2], Nancy Collop[3], Brennan Torstrick[4], Zak Loring[5], David Frankel[6], Ilene Rosen[6]
[1] University of Michigan, [2] Emory University, [3] Emory University School of Medicine, [4] Huxley Medical, Inc., [5] Duke University, [6] University of Pennsylvania

Introduction: Obstructive (OSA) and central sleep apnea (CSA) are associated with higher prevalence of atrial fibrillation and other arrhythmias. Arrhythmia detection is possible with in-lab polysomnography (PSG) but not with home sleep apnea tests (HSAT) that typically lack the electrocardiogram (ECG). SANSA (Huxley Medical, Inc.) is a chest-worn monitor with HSAT and Holter ECG capabilities to simultaneously detect OSA, CSA, and arrhythmias at home. This study used this monitor to characterize nocturnal arrhythmias in patients with OSA and CSA.
Methods: Data was analyzed from 151 subjects with suspected sleep disordered breathing who wore the chest monitor for a single night. The apnea-hypopnea index (AHI) and central AHI (cAHI) were calculated with the monitor's automated algorithm using a 3% oxygen desaturation threshold. A cardiac technician reviewed ECG recordings to identify presence of clinically significant arrhythmias including multi-focal or high burden premature ventricular complexes (PVCs), atrial or ventricular bi/tri/quadrigeminy, ventricular tachycardia, atrial fibrillation, second- or third-degree atrioventricular block, and sinus pauses.
Results: At least one clinically significant arrhythmia was observed in 32% (48/151) of all subjects, 26% (9/35) of those with AHI< 5, 34% (39/116) of those with AHI≥5, and 79% (11/14) of those with

cAHI≥5. Significant arrhythmias of supraventricular origin were observed in 9% of subjects with AHI≥5 and 36% with cAHI≥5 but were not observed in subjects with AHI< 5. Atrial fibrillation was observed in three subjects overall, all with AHI≥5 and one with cAHI≥5. Ventricular arrhythmias were observed in most subjects with significant arrhythmias. Medical histories demonstrated that only 21% of all detected arrhythmias had been previously diagnosed.

Conclusion: Patients with OSA and CSA experienced more nocturnal cardiac arrhythmias than those without. This work motivates additional investigation in larger populations to understand how simultaneous detection of sleep-disordered breathing and arrhythmias in the home environment could impact diagnosis, risk stratification, and outcomes.

SLEEP APNEA-SPECIFIC HYPOXIC BURDEN AS A PREDICTOR OF INCIDENT HEART FAILURE COMPARED TO TRADITIONAL MEASURES

Abdallah Almegdadi[1], Matheus Lima Diniz Araujo[1], Delaney Ryan[2], James Bena[2], Nicolas Thompson[2], Alex Milinovich[3], Reena Mehra[4], Nancy Foldvary-Schaefer[1], Michael Faulx[5], Catherine Heinzinger[1]

[1] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [2] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [3] Quantitative Health Sciences, Lerner Research, Cleveland Clinic, [4] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, Seattle, WA, [5] Heart, Vascular, and Thoracic Institute, Cleveland Clinic, Cleveland, OH

Introduction: Apnea hypopnea index (AHI) is the prevailing measure of obstructive sleep apnea (OSA) presence and severity. Despite numerous consequences, AHI calculation measures only frequency of respiratory events. Measures which characterize OSA mechanistically may have better prognostic ability. Sleep apnea-specific hypoxic burden (SAHB) has been associated with incident heart failure (HF) in men. We hypothesized that SAHB predicts incident HF and offers superior predictive performance than traditional measures in this larger cohort of men and women.

Methods: We retrospectively examined Cleveland Clinic patients (age≥18) who underwent polysomnography 2006-2017, excluding those with HF before or at the time of polysomnogram. Cox proportional hazards models of multiple-imputed datasets were constructed for incident HF by SAHB, AHI, and T90 in separate models adjusted for age, sex, race, body mass index, tobacco use, central sleep apnea, cardiovascular comorbidities, and positive airway pressure (time-varying). An interaction term was created between SAHB and sex. Non-nested partial likelihood ratio tests compared models.

Results: The sample included N=26,161 patients: age 51.1±14.1 years, 52% male, 75% White, 17% developed HF during follow-up (6.95 [5.12-8.93] years). A 1-SD increase in SAHB was associated with 5% higher HF incidence (HR=1.05, 95%CI=1.01-1.09); 1-SD increase in AHI was associated with 11% higher HF incidence (HR=1.11, 95%CI=1.07-1.16); 1-SD increase in T90 was associated with 19% higher HF incidence (HR=1.19, 95%CI=1.15-1.22). HF incidence in males with increasing SAHB was lower than in females (interaction p< 0.001). Both the AHI and T90 models fit better than the SAHB model (p=0.006, p< 0.001, respectively). Adding SAHB into the AHI or T90 models did not improve model fit (p=0.86, p=0.34, respectively).

Conclusion: In this clinical cohort of men and women, while SAHB, AHI, and T90 were independently associated with incident HF, SAHB did not enhance predictive value. Traditional measures demonstrated superior model fit compared to SAHB in predicting HF incidence, and inclusion of SAHB did not improve model performance. Next steps include adding left ventricular ejection fraction data to assess differences across HF subtypes. More research is needed to enrich the knowledge that guides development of these novel diagnostic options.

ENDOTHELIAL-DEPENDENT VASODILATION IS ASSOCIATED WITH SLEEP APNEA-SPECIFIC BLOOD PRESSURE VARIATIONS IN PATIENTS WITH SEVERE OSA

Ning Ding[1], Mei Su[1], Jing Xu[2], Jiani Shen[2], Guihong Wei[2], Qiyun Ma[2], Xilong Zhang[1]

[1] The First Affiliated Hospital with Nanjing Medical University, [2] The Affiliated Huai'an No.[1] People's Hospital of Nanjing Medical University

Introduction: The exact mechanisms behind obstructive sleep apnea (OSA) event-triggered acute blood pressure (BP) variations are unclear. We aimed to assess the association between vascular function and event-triggered BP variation.

Methods: Brachial artery flow-mediated dilation (FMD) and nitroglycerine-induced vasodilation (NID) were measured to assess endothelial and smooth muscle function, respectively. Event-triggered BP variation parameters, including BP surges, nocturnal BP fluctuations (NBPFs), NBPF/apnea-hypopnea index (AHI), and BP peaks and valleys were collected. Comparisons between subgroups, stepwise multiple regression, and ordinal logistic regression analysis were used to explore factors associated with event-triggered BP variation.

Results: A total of 177 patients with severe OSA and without comorbidities were studied. In patients with normal endothelial function (FMD ≥ 10), NBPFs, NBPF/AHI, and BP surges were significantly associated with FMD (all $P < 0.05$). The relationships between nocturnal BP variations and vasodilation function were not significant in patients with impaired endothelial function (FMD < 10). However, sympathetic activity markers were independently associated with BP variations in both subgroups (all $P < 0.05$). In ordinal logistic regression analysis, severe nocturnal BP variation in the normal endothelial function group was associated with increased sympathetic activity and higher FMD and drowsiness. In the impaired endothelial function group, only elevated sympathetic tone was associated with an increased risk of high BP variation.

Conclusion: This study has discovered that sympathetic activity is independently associated with OSA event-triggered BP variations regardless of vasodilation function. In patients with normal endothelial function, a high sleep apnea-specific BP variation may be partly associated with endothelial-dependent dilation.

DEVELOPING A NOVEL MARKER OF SLEEP FRAGMENTATION FOR CARDIOMETABOLIC AND MORTALITY RISK PREDICTION

Jiong Chen[1], Clémence Cavaillès[2], Haoqi Sun[3], Haoran zhao[1], Yaqing Gao[4], Donglin xie[5], Xuesong Chen[6], Weijun huang[7], Hongliang Yi[7], Shenda Hong[5], Song Gao[1], Yue Leng[2]

[1] Institute of Medical Technology, Peking University Health Science Center, [2] Department of Psychiatry and Behavioral Sciences, University of California, San Francisco, [3] Beth Israel Deaconess Medical Center, [4] Nuffield Department of Population Health, University of Oxford, [5] National Institute of Health Data Science, Peking University, [6] Five Seasons Medical LLC, [7] Department of Otorhinolaryngology Head and Neck Surgery, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine

Introduction: Sleep fragmentation, linked to increased risks of metabolic and cardiovascular diseases, is often measured using traditional metrics like WASO, SE, and ArI, which rely on arbitrary thresholds. While entropy-based methods (e.g., CE, WSE) offer deeper insights, they require complex EEG data and are unsuitable for long-term wearable monitoring. This study introduces Sleep Temporal Entropy (STE), an entropy-based biomarker, to quantify sleep fragmentation and explore its associations with cardiometabolic disorders and mortality, aiming to improve health risk prediction.

Methods: We analyzed data from two cohorts: the Shanghai Sleep Health Study Cohort (SSHSC, clinic-based) and the Sleep Heart Health Study (SHHS, community-based). Sleep fragmentation was quantified using traditional metrics (WASO, ArI) and entropy-based metrics, including the newly introduced STE, which measures both overall and stage-specific fragmentation using Shannon entropy. Machine learning models and Cox proportional hazards regression were used to predict cardiometabolic disorders and mortality outcomes, with SHAP values applied for post-hoc explanation.

Results: In the SSHSC, STE demonstrated superior predictive power for cardiometabolic disorders compared to traditional metrics. Using XGBoost as the primary model, SHAP analysis identified REM-stage STE as a key contributor, particularly for diabetes, with a SHAP importance score of 0.17. In the SHHS, XGBoost also achieved the highest ROC AUC for predicting all-cause mortality (0.836) and CVD mortality (0.838), with SHAP analysis identifying significant contributions from overall STE and stage-specific metrics, including REM and NREM STE. Survival analyses identified STE exhibited U-shaped associations with all-cause and CVD mortality. Participants in the lowest quintile (Q1) of REM STE had a 97% higher risk of all-cause mortality (hazard ratio [HR] = 1.97, 95% CI: 1.63–2.38) compared to the reference group (Q3), while the highest quintile (Q5) was associated with a 35% higher risk (HR = 1.35, 95% CI: 1.06–1.73). Similar patterns were observed for CVD mortality, where Q1 REM STE was associated with a threefold increase in risk (HR = 3.33, 95% CI: 2.19–5.06).

Conclusion: STE offers a refined method for assessing sleep fragmentation, with a U-shaped relationship to health outcomes, suggesting its potential as a valuable biomarker for predicting cardiometabolic risks and mortality.

CIRCADIAN RHYTHMICITY ACROSS THE 24-H BEHAVIORAL CYCLE IS ASSOCIATED WITH LOWER OUT-OF-OFFICE BLOOD PRESSURE OUTCOMES

Erica Wood[1], Emma Guyonnet[1], Sarahy Martinez[1], Marina Garcia Santos[1], Ariana Lopez[1], Marwah Abdalla[1], Ari Shechter[1], Nour Makarem[2]

[1] Columbia University Irving Medical Center, [2] Mailman School of Public Health, Columbia University Irving Medical Center

Introduction: Rest-activity rhythms (RARs) reflecting sleep-wake cycles, rest-activity patterns, and circadian influences are a measure of circadian rhythmicity in naturalistic settings. Robust RARs are associated with lower office blood pressure (BP) and hypertension risk, but there is limited data on their association with out-of-office BP. This study examined associations of RARs with home BP monitoring (HBPM) and 24-h ambulatory BP monitoring (ABPM) outcomes.

Methods: A community-based sample of 201 middle-aged to older adults was recruited across New York City (mean age(SD): 55±11y, 70% female, 26% Black, 22% Hispanic). Participants completed seven consecutive days of wrist actigraphy concurrent with HBPM and ABPM. Wrist actigraphy was used to estimate non-parametric RAR variables. Morning and evening BP were measured daily using HBPM for 7 days and used to estimate daily averages; mean 24-h, sleep, and wake BP were derived from 24-h ABPM. Linear regression models, adjusted for age, sex, education, and BP medications, examined associations of RARs with BP outcomes.

Results: Greater relative amplitude, indicating more robust RARs (greater circadian rhythmicity), was associated with lower 24-h SBP and DBP, wake SBP, sleep SBP and DBP, and lower mean home SBP and DBP (β ranges:-14mmHg to -37mmHg, $p< 0.01$). Higher most active 10-h period counts, reflecting greater waketime activity, were associated with lower levels of all ABPM and HBPM measurements, while higher least active 5-hour period timing, reflecting later sleep timing, was related to higher sleep SBP and DBP from ABPM ($p< 0.05$ for all). Greater interdaily stability, reflecting more day-to-day sleep-wake and rest-activity pattern regularity, was associated with lower 24-h and sleep SBP and DBP from ABPM and with lower evening SBP from HBPM (β ranges:-12mmHg to -27mmHg, $p< 0.05$). Greater intradaily variability, reflecting higher rhythm fragmentation and sleep inefficiency, was associated with higher levels of all ABPM and HBPM outcomes (β ranges: 6mmHg to 11mmHg, $p< 0.05$).

Conclusion: Greater circadian rhythmicity across the 24-h behavioral cycle is associated with lower out-of-office BP. The timing, regularity, and magnitude of RARs in the 24-h day and across days may represent an important target for optimizing BP, but findings warrant confirmation in larger longitudinal studies.

THE ROLE OF NOVEL POLYSOMNOGRAPHIC PARAMETERS IN PREDICTING BLOOD PRESSURE

Sikawat Thanaviratananich[1], Hao Cheng[2], Krishna Sundar[3]

[1] Cleveland Clinic Foundation, [2] Miami VA Medical Center, [3] UC Davis Medical Center

Introduction: Hypertension is linked to obstructive sleep apnea (OSA) through mechanisms such as heightened

sympathetic activation, sleep arousals, and intermittent hypoxia. Polysomnographic parameters, including the apnea-hypopnea index (AHI), periodic limb movement index, slow-wave sleep, and hypoxic burden, are associated with elevated blood pressure. This study aims to explore the association between novel polysomnographic parameters—oxygen desaturation rate (ODR), oxygen resaturation rate (ORR), and hypoxic burden (HL100)—and blood pressure.
Methods: This cross-sectional study included patients who underwent diagnostic polysomnography. Conventional and novel polysomnographic parameters were analyzed for their correlation with systolic (SBP) and diastolic blood pressure (DBP), measured within one year prior to polysomnography. Forward stepwise linear regression was used to identify predictors of SBP and DBP.
Results: A total of 1,505 patients with a mean age of 44 years were included. Hypertension prevalence was higher in patients with OSA (OSA+) compared to those without (OSA-): 61.4% vs. 42.6% ($p < 0.001$). SBP and DBP were also higher in OSA+ than in OSA- (129.5 vs. 122.7 mmHg, $p < 0.001$; 78.3 vs. 75.7 mmHg, $p < 0.001$). All polysomnographic parameters, except ODR, were significantly correlated with SBP and DBP. Stepwise regression identified AHI, ODI, and ORR as independent predictors of both SBP and DBP, with coefficients of 0.094 ($p = 0.014$), 0.118 ($p = 0.001$), and 821.2 ($p = 0.007$) for SBP, and 0.065 ($p = 0.010$), 0.074 ($p = 0.002$), and 577.6 ($p = 0.004$) for DBP, respectively. Baseline SpO_2 was an independent predictor of DBP only, with a coefficient of -35.4 ($p = 0.016$).
Conclusion: Our study identified novel parameters, including HL100 and ORR, as being associated with SBP and DBP. ORR, in particular, was an independent predictor of both SBP and DBP, alongside AHI and ODI. Higher ORR may increase reactive oxygen species, potentially contributing to elevated blood pressure. ORR is a novel parameter worth exploring further in the context of hypertension.

OBSTRUCTIVE SLEEP APNEA IS ASSOCIATED WITH A HIGHER INCIDENCE OF VENOUS THROMBOEMBOLISM AFTER TOTAL HIP ARTHROPLASTY

Cosmo Fowler[1], Abdulhakim Tlimat[2], Donald Bliwise[1], Nancy Collop[1], Stephen Pastores[3], Dennis Auckley[4]
[1] Emory University School of Medicine, [2] University of Alabama at Birmingham, [3] Memorial Sloan Kettering Cancer Center, [4] Case Western Reserve University - MetroHealth

Introduction: Obstructive sleep apnea (OSA) is a prevalent condition that is strongly associated with cardiovascular comorbidities and has been shown to predict poor outcomes in the post-surgical population. Assessing the independent effect of OSA can be challenging in a retrospective model without a large number of patients. We queried a very large, national dataset and utilized propensity matching to examine the independent association of OSA with venous thromboembolism (VTE) following total hip arthroplasty (THA).
Methods: We queried the TriNetX Research Network, an international electronic health record and claims-derived database of >140 million patients, primarily from the United States. We assessed patients who underwent Current Procedural Terminology-coded THA surgery between 7/1/2014 and 7/1/2024 for those with a preceding OSA diagnosis (and ≥2 ICD-10-CM code appearances overall). We then examined the 28-day post-surgical incidence of VTE and secondarily its constituents, pulmonary embolism (PE) and deep vein thrombosis (DVT), as well as cerebrovascular accident (CVA) and myocardial infarction (MI), in addition to collecting 19 demographic and comorbidity variables (as well as 7 body mass index sub-stratifications) with which in-platform propensity-matched analyses were conducted to assess the individual weight of OSA on the outcome variables.
Results: Of 191,094 patients who underwent THA (all in the US), 19,501 had a preceding OSA diagnosis, while 157,738 had no OSA diagnosis at any time point. Prior to propensity matching, the OSA cohort carried a significantly higher risk of all outcomes assessed (VTE RR 1.9, CI 1.8 – 2.1; PE RR 2.4, CI 2.0 – 2.8; DVT RR 1.7, CI 1.5 – 2.0; CVA RR 2.0, CI 1.7 – 2.4, and MI RR 2.0, CI 1.6 – 2.4, all $p< 0.001$) in the 28 days post-THA surgery. Following propensity matching, VTE remained significantly associated with OSA (RR 1.2, CI 1.1 – 1.4, $p = 0.007$), as did the secondary outcome of PE (RR 1.4, CI 1.1 – 1.7, $p=0.004$), while other secondary outcomes did not.
Conclusion: These findings further support the independent association of OSA with post-hip arthroplasty VTE, with increased rates persisting even after extensive propensity matching for associated comorbidities. Further investigation examining potential effect modification by treatment status is necessary.

SEX DIFFERENCES IN PRESENTING SYMPTOMS AND VASCULAR FUNCTION IN MODERATE-TO-SEVERE OSA

Mandana Mahmoudi[1], Nusrat Mim[1], Destiny Collazo[2], Elizabeth Sanchez[2], Yu Chang[1], Ari Klapholz[2], Rudolfo Miranda[2], Pearl Marks[2], R. Nisha Aurora[2]
[1] NYU Langone Grossman School of Medicine, [2] NYU Grossman School of Medicine

Introduction: There are known sex differences in the clinical presentation of OSA. Women often present with atypical symptoms such as fatigue and insomnia, while men frequently report sleepiness. The existing evidence suggests that the presence of sleepiness in persons with OSA is associated with worse cardiometabolic outcomes. However, it is unclear if atypical symptoms may also be associated with adverse cardiovascular outcomes. Most of the available literature has focused on the association between health outcomes and sleepiness as determined by the Epworth-Sleepiness-Scale (ESS). The objective of the current analyses was to determine if atypical OSA symptoms such as fatigue, insomnia, and sleep quality are associated with vascular dysfunction, a marker of cardiovascular health, in persons with OSA, and if the association varies by sex.
Methods: Adults ages 55-75 years with newly diagnosed moderate or severe OSA (apnea hypopnea index (AHI)≥15 events/hr) on home-sleep-testing, and a hemoglobinA1c< 6.5% were enrolled. Exclusion criteria included the use hypoglycemic agents or medications for weight loss. Outcomes included the reactive hyperemic index (RHI) from Endopat®, a metric of vascular dysfunction, along with the following surveys: the ESS, Fatigue Severity Scale (FSS), Insomnia Severity Index (ISI), and the Pittsburgh Sleep Quality Index (PSQI). The median and interquartile range (IQR) were utilized to calculate a Mann-Whitney-U-test to compare each outcome for men and women.
Results: A total of 31 participants were included for the analysis - 19 women and 12 men. The median AHI for the whole group was 30.6 events/hr (IQR=24.0–44.7 events/hr), 26.6 events/

hr (IQR=24.3–40.9 events/hr) for women, and 39.1 events/hr (IQR=23.5-54.8 events/hr) for men (p=0.46 for gender differences). Clinical but no statistically significant differences were seen for ESS-scores between men and women: ESS=8.0 versus 11.0 (p=0.98). Compared to men, there was a trend towards increased fatigue in women, FSS=32.5 versus 43 (p=0.07). Women reported worse sleep quality, PSQI=7.6 versus 10.5 (p=< 0.01). No difference was noticed in insomnia-scores between men and women, ISI=12.5 versus 15 (p=0.14). Women were found to have lower RHI scores compared to men: 1.52 versus 1.68 (p=0.02).
Conclusion: Compared to men, women with moderate-to-severe OSA had worse fatigue, sleep quality, and vascular function.

IMPACT OF OBSTRUCTIVE SLEEP APNEA ON YOUNG-ONSET STROKE HOSPITALIZATIONS AND MODIFIABLE CARDIOVASCULAR RISK FACTORS: A NATIONWIDE ANALYSIS'

Maneeth Mylavarapu[1], Mipasha Patel[2], Mehak Preet Marwah[3], Ritika Parekh[4], Ishita Gupta[5], Hajra Khursheed Mehdi[6], Sai Prasanna Lekkala[7], Rupak Desai[8]

[1] Walker Baptist Medical Center, [2] Government Medical College, [3] Guru Gobind Singh Medical College and Hospital, [4] K.J Somaiya Medical College and Research Centre, [5] Dr Baba Saheb Ambedkar Medical College and Hospital, [6] The Polyclinic Ballard, [7] UCHealth Parkview Medical Center, [8] Independent Outcomes Researcher

Introduction: Obstructive Sleep Apnea (OSA) is known to have adverse cardiovascular effects in young patients. The study's objective was to evaluate how cardiovascular disease (CVD) risk factors predict young-onset stroke (YOS) in cohorts with and without OSA.
Methods: Using the National Inpatient Sample dataset (2016-2020) and relevant ICD-10 codes, we identified hospitalized patients with YOS (ages 18-44). We studied CVD risk factors (hypertension, diabetes, hyperlipidemia, smoking, obesity, peripheral vascular disease, and prior stroke) as predictors of YOS using multivariable logistic regression analysis in non-OSA and OSA cohorts. A p-value ≤ 0.05 was considered statistically significant.
Results: Of 262,850 young hospitalized adults with stroke, 14190 (5.4%) patients had OSA. Patients with OSA were more likely to be male (67.2% vs. 51%) and had higher rates of hypertension (33% vs. 17.2%), diabetes (13.7% vs. 7.3%), hyperlipidemia (47.7% vs. 24.5%), obesity (66.3% vs. 19.5%), prior myocardial infarction (5.1% vs. 2.6%), prior transient ischemic attack (12.1% vs. 8.9%), and smoking (19.7% vs. 16%). Unadjusted analysis revealed that OSA was associated with a lower risk of all-cause mortality (4.3% vs. 7.8%). The multivariable logistic regression analysis indicated that in patients with OSA, complicated hypertension (OR=2.94, 95% CI 2.39-3.61), hyperlipidemia (OR=2.38, 95% CI 2.05-2.76), and peripheral vascular disease (OR=3.28, 95% CI 2.47-4.35) significantly increased the risk of stroke. Interestingly, smoking (OR=0.73, 95% CI 0.61-0.87) and obesity (OR=0.73, 95% CI 0.63-0.85) were associated with a reduced risk of stroke in the OSA cohort (all p< 0.001)
Conclusion: Hypertension, hyperlipidemia, and peripheral vascular disease predict YOS in the OSA cohort. Despite having more comorbidities, the OSA cohort is associated with lower all-cause mortality. Future research should investigate the long-term outcomes of OSA on stroke recovery and develop tailored interventions to enhance healthcare for this population.

BURDEN OF OBSTRUCTIVE SLEEP APNEA IN HOSPITALIZED YOUNG ADULTS WITH OBESITY: ACUTE CORONARY SYNDROME AND IN-HOSPITAL OUTCOMES (NIS 2016–2020 STUDY)'

Ishita Gupta[1], Hajra Khursheed Mehdi[2], Ritika Parekh[3], Maneeth Mylavarapu[4], Sai Prasanna Lekkala[5], Mipasha Patel[6], Mehak Preet Marwah[7], Rupak Desai[8]

[1] Dr Baba Saheb Ambedkar Medical College and Hospital, [2] The Polyclinic Ballard, [3] K.J Somaiya Medical College and Research Centre, [4] Walker Baptist Medical Center, [5] UCHealth Parkview Medical Center, [6] Government Medical College, [7] Guru Gobind Singh Medical College and Hospital, [8] Independent Outcomes Researcher

Introduction: Obstructive sleep apnea (OSA) significantly impacts cardiovascular and metabolic disorders, especially in obese individuals. Prior studies mainly focused on older adults, leaving a gap in understanding acute coronary syndrome (ACS) risk in younger obese adults with OSA.
Methods: Using the National Inpatient Sample (2016–2020) and ICD-10 codes, hospitalizations in young obese patients were identified. Baseline demographics, comorbidities, and outcomes were compared between OSA+ and OSA- cohorts. Odds of ACS-related hospitalizations and in-hospital mortality were analyzed using multivariable regression.
Results: Among 70,950 ACS-related admissions in young obese adults, 12,145 (17.12%) had OSA. The OSA+ cohort had a median age of 40 and more males. They had higher rates of complicated hypertension (37.8% vs. 27.1%), diabetes (28.6% vs. 23.9%), hyperlipidemia (59. 2% vs. 55.7%), and prior myocardial infarction (13.8% vs. 11.2%). Regarding clinical outcomes, the OSA+ cohort has higher patients on CPAP (6.5% vs 1.6%) and respiratory failure (18.3% vs 12.4%). Unadjusted regression showed OSA increased ACS risk (OR = 1.81, 95% CI 1.73–1.89, p < 0.001). After adjusting for demographics, hospital characteristics, and comorbidities, OSA was linked to reduced ACS risk (OR = 0.72, 95% CI 0.68–0.76, p < 0.001). Adjusted models showed no significant effect on in-hospital mortality (OR = 1.20, 95% CI 0.90–1.59, p = 0.214).
Conclusion: OSA in young, obese adults is linked to higher comorbidity rates and ACS-related hospitalizations. Early detection and management are crucial to reducing ACS risk and improving outcomes.

NOCTURNAL HYPOXEMIA DUE TO SDB IS ASSOCIATED WITH POOR PULMONARY HEMODYNAMICS IN PATIENTS WITH CHRONIC THROMBOEMBOLIC PULMONARY DISEASE

Teng Han[1], Xiaolei Zhang[1]

[1] China-Japan Friendship Hospital

Introduction: Although a general association between nocturnal hypoxemia or sleep-disordered breathing (SDB) and pulmonary arterial hypertension (PAH) has been established, little is known about the unique pathophysiologic contributions of SDB and nocturnal hypoxemia to chronic thromboembolic pulmonary disease (CTEPD). We therefore chose to examine the associations of SDB and nocturnal hypoxemia with hemodynamic indices obtained via right heart catheterization (RHC) in hospitalized patients with CTEPD. We hypothesized that the severity of CTEPD would be associated with SDB and nocturnal hypoxemia severity.
Methods: Patients with CTEPD with or without PH who had undergone polysomnography (PSG) between July 2022 and March 2024 were enrolled. A nocturnal mean oxygen saturation by pulse oximetry (MeanSpO2) < 90% was defined as nocturnal hypoxemia, and a saturation less than 90% (T90) for more than 20% of the total sleep time indicated severe nocturnal hypoxemia. The relationships between right heart catheterization measurements and T90 or MeanSpO2 were calculated using multiple linear regression and logistic regression analyses.
Results: The prevalence of severe nocturnal hypoxemia in the entire cohort was 42.86%, and SDB (AHI≥15/h) affected 55.84% of patients and predominantly manifested as hypopnea. Nocturnal hypoxemia remained significantly associated with mPAP (T90: β=0.296, P=0.019; MeanSpO2: β=-0.333, P=0.009) and PVR (T90: β=0.294, P=0.021; MeanSpO2: β=-0.310, P=0.015) after adjusting for age, sex, BMI, AHI and diurnal PaO2. Receiver operating characteristic (ROC) curves for the detection of a mPAP≥25 mmHg, PVR>3 WU and WHO FC III-IV indicated that nocturnal hypoxemia parameters had moderate predictive value. (T90: AUCmPAP=0.698, AUCPVR=0.733, AUCWHO-FC=0.729; MeanSpO2: AUCmPAP=0.691, AUCPVR=0.731, AUCWHO-FC=0.707;)
Conclusion: SDB is highly prevalent in patients with CTEPH and CTEPD without PH predominantly manifested as hypopnea rather than apnea, and overweight was not a commonly reported characteristic. Independent of the severity of OSA, nocturnal hypoxemia is significantly correlated with hemodynamics in patients with CTEPD, and promoting sleep oximetry among patients with CTEPD is worthwhile.

IMPACT OF OBSTRUCTIVE SLEEP APNEA AND PULMONARY HYPERTENSION ON HOSPITAL RE-ADMISSION AND OVERALL SURVIVAL IN RURAL APPALACHIA POPULATION

Kassandra Olgers[1], Mortoza Farahnaz Anwar[2], Asif Rahman[3], Manoj Nepal[2], Scott Knollinger[4], Edward Rojas[5], Himanshu Deshwal[2], Robert Stansbury[6], Sijin Wen[7], Sunil Sharma[5]
[1] West Virginia University Hospital, [2] WVU, [3] WVU Research Corporation, [4] WVU Medicine, [5] West Virginia University, [6] West Virginia University School of Medicine, [7] WVU School of Public Health

Introduction: Obstructive sleep apnea (OSA) is a highly prevalent comorbid condition and is present in 12-13% of patients with pulmonary hypertension (PH). However direct causality for pulmonary hypertension and its impact on long-term outcome in PH patients is not clearly established. This study aims to understand the prognostic impact of OHS and PH on hospital re-admission and survival in rural Appalachia.
Methods: We conducted a retrospective study including hospitalized patients undergoing evaluation for OSA from Nov 2019 to January 2024. The sample size was divided into two cohorts depending on presence of absence of OSA and each cohort was subclassified based on presence of absence of PH based on echocardiography. Baseline characteristics were summarized as mean (± standard deviation) for continuous variables and frequency/percentages for categorical variables. Hospital re-admission rates and survival were assessed using Kaplan-Meier (KM) survival curves and Cox proportional hazard ratios.
Results: We included a total of 573 patients (228 patients without OSA and 345 patients with OSA). In the OSA cohort, 195 patients had echocardiographic evidence of PH. In the non-OSA cohort, 103 patients had evidence of PH. Patients with PH in no OSA cohort had the highest risk of mortality (HR=1.95, 95%CI=1.19-3.20, p=0.008), whereas patients with OSA and PH did not significantly alter survival (HR=1.11, p=0.67). On KM curves, OSA and PH cohort had better survival (HR=0.58, p=0.01). Interestingly, body mass index (BMI) was associated with lower odds of hospital re-admission in rural Appalachia (HR-0.98,CI=0.98-0.99, p=0.002), adjusted for age, gender and BMI.
Conclusion: Our study identifies a paradox of better survival in patients with OSA and echocardiographic evidence of PH compared to patients with PH and no OSA in rural Appalachia. Furthermore, BMI had an inverse association with hospital re-admission rate. The reason for these findings remain unclear, however, we hypothesize, that an inpatient sleep medicine service, closer follow-up on discharge and monitoring of patients with OSA and PH may play a role and need to be studied in future studies.

CARDIAC ARREST AND MORTALITY IN OSA PATIENT WITH MORBID OBESITY

Saud Alawad[1], Nawaf Alsaeed[1], Ahmad Jarrar[1], bandar Alyami[1], Sunil Sharma[2]
[1] West Virginia University Hospital, [2] West Virginia University

Introduction: Obstructive sleep apnea (OSA) is a highly prevalent and fatal disorder characterized by intermittent upper airway obstruction during sleep. Obesity, on the other hand higher BMI (body mass index). Individuals with morbid obesity (BMI ≥40) often have aggravated cardiovascular outcomes, including a higher probability of cardiac arrest and death. Nevertheless, comparative long-standing data on cardiovascular arrest and mortality in OSA patients with mild to moderate obesity (BMI 30 to 39.9) vs. morbid obesity are limited. The purpose of this study is to assess the 5-year risk of cardiac arrest and all-cause mortality in OSA patients stratified by BMI: 30-39.9 (obesity) vs. ≥40 (morbid obesity).
Methods: A retrospective cohort study was conducted utilizing the TriNetX Global Health Research Network, evaluating de identified EHRs (electronic health records) from various healthcare organizations from January of 2000 to December of 2019 from United State Collaborative network. Eligible participants/patients were aged >18 years with confirmed sleep disorder (OSA) diagnosis. Patients with other sleep ailments were not included to isolate the OSA group. Two cohorts were defined.

patients with a BMI of 30–39.9 and those with a BMI ≥40. Propensity score matching was utilized to balance demographic and comorbidity variations. Patients were followed for five years to analyze cardiac arrest and all-cause mortality.
Results: During the five-year follow-up, the incidence of cardiac arrest was higher in the morbid obesity group (BMI ≥40) (n=143,169) compared to the group with the OSA and BMI of 30-39.9 (n=263,758), with a risk ratio of 1.554 (95% CI: 1.37-1.761). Similarly, all-cause mortality was increased in the OSA group with a BMI ≥40, with a RR of 1.614 (95% CI: 1.55-1.681).
Conclusion: OSA patients with morbid obesity (BMI ≥40) face a significantly increased risk of cardiac arrest and all-cause mortality compared to OSA patients with a BMI of 30-39.9. These findings highlight the critical need for targeted interventions and enhanced monitoring of cardiovascular risks in this high-risk population. Further prospective research is required to validate these findings and guide clinical practice.

RELATIONSHIP BETWEEN POSITIONAL OBSTRUCTIVE SLEEP APNEA AND EXCESSIVE DAYTIMESLEEPINESS IN PATIENTS WITH ATRIAL FIBRILLATION

Xiaoyue Liu[1], Patrick Stafford[2], Kenneth Bilchick[2], Sula Mazimba[3], Jeongok Logan[2], Yeilim Cho[4], Younghoon Kwon[5]
[1] New York University, [2] University of Virginia, [3] Advent Health, [4] University of Washington, School of Medicine, Department of Psychiatry and Behavioral Sciences, [5] University of Washington

Introduction: Obstructive sleep apnea (OSA) is highly prevalent in patients with atrial fibrillation (AF). Prior studies have suggested that OSA-related excessive daytime sleepiness symptom (EDS) is less pronounced in patients with AF. Positional obstructive sleep apnea (POSA) is common, affecting nearly half of the patients with OSA, including patients with AF. However, symptomatic manifestation of OSA by POSA status is unknown. We investigated whether POSA affected the likelihood of EDS differently in patients with AF compared to those without AF.
Methods: We reviewed and included patients with and without (1:1 match) a history of AF who underwent clinically indicated in-lab sleep study at a single academic sleep center. Patients with OSA (apnea-hypopnea index [AHI] ≥ 5 events/hour), who achieved at least 30 minutes in both supine and non-supine positions were included. POSA was defined as OSA patients with a supine/non-supine AHI ratio ≥ 2. EDS was determined using an Epworth Sleepiness Scale score of 11 or higher. We performed multiple logistic regression separately for AF and non-AF groups to examine the relationship between POSA and EDS. Analyses were adjusted for age, sex, body mass index, AHI, total sleep time, and cardiovascular risk factors including hypertension and type 2 diabetes.
Results: Among 223 adult patients (mean age 62 ±14 years, 55% male, 51% with a history of AF [n = 114]) included, 55% were identified to have POSA. EDS was present in 43% of the entire group and 42% and 45% in the AF and non-AF subgroups, respectively. In patients with AF, POSA was associated with a lower likelihood of EDS (adjusted odds ratio [aOR]: 0.29; 95% confidence interval [CI]: 0.10-0.81). In contrast, no significant association was observed (aOR: 0.78; 95%CI: 0.31-2.00) in patients without AF.
Conclusion: We identified different symptomatic manifestation of POSA by AF status. OSA patients with AF and POSA were less likely to have EDS than OSA patients with AF and no POSA. Given that EDS is an important determinant of clinical decision making in OSA treatment and potentially a critical cardiovascular risk marker, consideration of POSA status may be useful in AF patients with a comorbid OSA.

ASSOCIATION OF HIGH-RISK OSA WITH INCIDENT ATRIAL FIBRILLATION: THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS

Jing Xu[1], Younghoon Kwon[2], Neda Esmaeili[1], Oguz Akbilgic[3], Jennifer Lobo[4], Kenneth Bilchick[4], Pamela Lutsey[5], Lin Yee Chen[5], Elsayed Z Soliman[3], Susan Heckbert[2], Scott Sands[1], Susan Redline[6], Ali Azarbarzin[1]
[1] Brigham and Women's Hospital and Harvard Medical School, [2] University of Washington, [3] Wake Forest University School of Medicine, [4] University of Virginia, [5] University of Minnesota, [6] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Obstructive sleep apnea (OSA) is associated with atrial fibrillation (AF), a significant cause of morbidity and mortality. However, this association varies by population characteristics and definitions of OSA and AF. This study examined whether "High-Risk" OSA, characterized by elevated OSA-related hypoxic burden (HB) or heart rate response (ΔHR), is linked to increased AF incidence.
Methods: The analysis used data from the Multi-Ethnic Study of Atherosclerosis (MESA), including polysomnography (2010-2013), and ascertainment of AF through 2018 (median follow-up time of 6.8 years). OSA-related HB was quantified as the cumulative area under the desaturation curve and ΔHR was defined as the increase in heart rate upon event termination. High-Risk OSA was defined by the presence of an apnea-hypopnea index (AHI) ≥15 events/h) with either a high ΔHR (highest tertile) or a high HB (highest tertile); Low-Risk OSA was defined as an ≥ 15 events/h and neither an elevated HB or ΔHR; and non-OSA was defined as an AHI< 15 events/h. AF was ascertained from hospitalization and outpatient diagnosis codes. Individuals with a history of AF or cardiovascular disease at the baseline were excluded. Cox regression models estimated the hazard ratios of incident AF for High- and Low-Risk OSA (vs. non-OSA), adjusting for age, sex, race, body-mass-index, diabetes, and hypertension.
Results: A total of 1,689 participants (54.6% female) were included, with a median [interquartile range] age of 66.0 [60.0-74.0] years, HB of 35.4 [18.0-69.5] %min/h, and ΔHR of 7.7 [5.9-9.9] bpm. During follow-up, AF was identified in 14.6% of the High-Risk OSA group (N = 680), 9.5% of the Low-Risk OSA group (N = 294), and 8.5% of the No-OSA group (N = 715). Compared to the non-OSA group, an increased hazard ratio (HR) for incident AF was found in High-Risk OSA (HR: 1.63 [95% CI: 1.16-2.30], P = 0.005) but not in Low-Risk OSA (HR: 1.05 [0.66-1.66], P = 0.8). Associations were weaker in subgroups defined by high HB (HR=1.21) or high ΔHR (HR=1.47).
Conclusion: OSA-related heart rate surge or severe hypoxemia may be useful for predicting which patients with OSA are at increased risk for incident AF.

UNRAVELING GUT MICROBIOTA LINK IN OBSTRUCTIVE SLEEP APNEA WITH CHRONIC THROMBOEMBOLIC PULMONARY HYPERTENSION

Linfan Su[1], Lingwu Wu[1], Xiaolei Zhang[1]
[1] China-Japan Friendship Hospital

Introduction: Patients with chronic thromboembolic pulmonary hypertension (CTEPH) show a relatively high prevalence of obstructive sleep apnea (OSA). The association between OSA and CTEPH is of critical importance, as their coexistence significantly endangers health. The gut microbiota is known to play a central and decisive role in the progression of cardiopulmonary diseases. However, the specific alterations and underlying mechanisms in the context of OSA and CTEPH comorbidity remain largely obscure and urgently require in-depth exploration.
Methods: Participants were recruited from China-Japan Friendship Hospital and divided into three groups: healthy controls (Controls, n = 12), OSA (n = 12), and CTEPH + OSA (n = 12). Fecal samples were collected from participants to extract bacterial DNA for 16S rRNA sequencing. Meanwhile, clinical indices such as right heart catheterization parameters, blood gas analysis, inflammatory factors, and coagulation indices were collected.
Results: Compared to the Controls, the CTEPH + OSA group displayed a marked deterioration in mean pulmonary arterial pressure, significant aberrations in AHI, and a pronounced activation of inflammatory and coagulation cascades. Notably, the gut microbiota diversity was significantly diminished, accompanied by a distinct alteration in the Firmicutes/Bacteroidetes ratio. There was a notable depletion of specific beneficial bacteria and a concurrent increase in harmful taxa. Spearman correlation analysis demonstrated that the reduced abundance of Faecalibacterium was significantly negatively correlated with IH-related indicators like AHI and T90, and was positively correlated with the mean SpO2. ($P < 0.05$). Compared to the isolated OSA group, the CTEPH + OSA cohort exhibited unique and characteristic shifts in microbiota structure and functional prediction pathways. The abundance of Faecalibacterium, in particular, demonstrated a highly significant and close correlation with the severity of CTEPH, underpinning its potential as a crucial biomarker.
Conclusion: Gut microbiota dysregulation occurs in CTEPH patients with OSA, and IH may be involved. This affects the gut barrier and inflammatory response, providing new targets and ideas for improving the prognosis of CTEPH patients with OSA. Future larger sample studies and mechanism explorations are warranted.

THE ROLE OF TREM1 IN MEDIATING ATHEROSCLEROSIS INDUCED BY OSA: INSIGHTS INTO MECHANISMS AND THERAPEUTIC IMPLICATIONS

Xiaoling Gao[1]
[1] The Second Affiliated Hospital of Shanxi Medical University

Introduction: To investigate the role of TREM-1 in atherosclerosis (AS) development triggered by obstructive sleep apnea syndrome (OSAS) and understand the underlying mechanisms.
Methods: Mendelian randomization (MR) analysis was conducted using genome-wide association study (GWAS) summary data to assess the causal relationship between OSAS and AS (Finngen R10). Single-cell RNA sequencing (scRNA-seq) analysis was performed to examine the impact of OSAS on cellular transcriptional status in lung tissue (GSE145435) and peripheral blood (GSE214865) at the single-cell resolution. Additionally, single-cell transcriptional landscapes of aortic AS (GSE155512) were constructed to explore the involvement of macrophages in AS pathology. A chronic intermittent hypoxia (CIH) mouse model was established to evaluate atherosclerosis of aorta formation, polarization of macrophage, and expression level of TREM-1. In vitro experiments utilizing lentiviral RNA were conducted to silence TREM-1 and assess its effect on macrophage polarization.
Results: MR analysis demonstrated a significant association between OSAS and the progression of coronary AS ($P< 0.001$), as well as atherosclerosis in other arterial territories ($P=0.003$). ScRNA-seq analysis revealed that OSAS-induced hypoxia did not significantly alter the cellular composition of lung tissue ($P>0.05$), whilst OSAS patients exhibited enhanced immune activity of CD14+ monocytes in peripheral blood. Macrophage subpopulations in AS tissues of non-OSAS patients showed elevated immune crosstalk with smooth muscle cells, with relatively low TREM-1 expression. In contrast, CIH mice exhibited significantly increased AS plaque area, accompanied by upregulated TREM-1 expression ($P< 0.05$). Infiltrating macrophages in AS under CIH displayed a predominance of the M1 subpopulation. In vitro experiments using macrophages exposed to CIH showed elevated levels of IL-6, TNF-α, and TREM-1, as well as decreased IL-10 and VEGF ($P< 0.05$). Silencing TREM-1 significantly reduced TNF-α expression and increased IL-10 and VEGF expression ($P< 0.05$).
Conclusion: OSAS is genetically linked to aortic atherosclerosis. TREM-1 is involved in OSAS-related AS by influencing macrophage polarization towards M1 and may serve as a potential therapeutic target. OSAS can lead to more TREM-1+ monocytes in the blood, contributing to AS development. Targeting TREM-1 could be a promising approach for treating atherosclerosis.

LOW CEREBRAL COMPLIANCE IN SEVERE SLEEP APNEA: IDENTIFYING AN INTRACRANIAL HYPERTENSIVE STATE THROUGH FULL-NIGHT NON-INVASIVE MONITORING

Gilmar Prado[1], Lívia Farias[2], Douglas Soares[2], Ana-Flavia Machado[2], Letícia Lambert[2], Lucas Martins[2], Davi Muniz[2], Fernando Morgadinho[2]
[1] UNIFESP, [2] Universidade Federal de São Paulo

Introduction: Cerebral compliance (CC) reflects the state of components within the cranial cavity: brain tissue, blood vessels, and cerebrospinal fluid. Changes in these components alter intracranial pressure (ICP). The non-invasive evaluation of P1, P2, and P3 via a CC monitoring device correlates strongly with traditional invasive methods. Sleep influences cerebral metabolism, modulating blood flow and likely CC across sleep stages. Investigating CC variation during normal sleep and obstructive sleep apnea syndrome (OSAS) could improve our understanding of both conditions and may provide valuable insights for the diagnosis and treatment of sleep disorders.

Methods: This pilot study included four patients and two healthy volunteers who underwent Type I polysomnography (PSG) with concurrent non-invasive CC monitoring. A sensor device evaluated curve morphology for systole (P1), intracerebral blood flow (P2), and aortic valve closure (P3). CC curves averaged cardiac beats while excluding artifacts, and the P2/P1 ratio was calculated for each minute of PSG. A ratio ≤1.0 was considered normal, 1.0–1.2 indicated risk of intracranial hypertension, and >1.2 suggested intracranial hypertension.
Results: Two participants without sleep complaints showed normal P2/P1 ratios: Wake: 0.82 ± 0.29; N1: 0.87 ± 0.37; N2: 0.85 ± 0.40; N3: 0.93 ± 0.30; REM: 0.75 ± 0.32. In two patients with moderate OSAS (AHI: 20.4 events/hour, REM AHI: 60.2 events/hour), P2/P1 ratios increased: Wake: 1.21 ± 0.18; N1: 1.30 ± 0.15; N2: 1.24 ± 0.18; N3: 1.16 ± 0.11; REM: 1.21 ± 0.21. In two patients with severe OSAS (AHI: 77.5 events/hour, no REM predominance), P2/P1 values were: Wake: 1.09 ± 0.29; N2: 1.05 ± 0.32; REM: 1.09 ± 0.27.
Conclusion: Preliminary findings suggest severe OSAS reduces CC during sleep, and REM-related OSAS similarly lowers CC. Increased cerebral stiffness may act as a protective mechanism, buffering steep blood flow variations caused by thoracic pressure fluctuations and sympathetic activation during apnea events. Further studies are needed to clarify this phenomenon.

THE RESPIRATORY EVENT-RELATED DROP IN PULSE TRANSIT TIME PREDICTS LEFT VENTRICULAR MORPHOLOGY AND FUNCTION IN OBSTRUCTIVE SLEEP APNEA

Ning Ding[1], Mei Su[1], Jing Xu[2], Jiani Shen[2], Guihong Wei[2], Qiyun Ma[2], Xilong Zhang[1]
[1] The First Affiliated Hospital with Nanjing Medical University, [2] The Affiliated Huai'an No.[1] People's Hospital of Nanjing Medical University

Introduction: Pulse transit time (PTT) is widely used to assess vascular compliance and elasticity. This study aimed to determine whether the respiratory event-related PTT response would identify subclinical Left ventricular (LV) remodeling and dysfunction in obstructive sleep apnea (OSA).
Methods: This retrospective study included OSA patients without pre-existing LV damage who underwent polysomnography between January 2014 and May 2017 at the Affiliated Huaian No.1 People's Hospital and The First Affiliated Hospital of Nanjing Medical University. LV measurements were assessed via echocardiography from December 2023 to May 2024. PTT measurements were validated using SOMNOscreen+ polysomnographic monitoring system. PTT drop magnitude refers to the difference between the initial value of the PTT decrease and the nadir triggered by apneas/hypopneas; PTT drop index is the number of drops per hour; PTT drop rate is the rate of decrease in PTT per second during the descending phase, and PTT area is the area above the waveform after respiratory events. Cox proportional hazard models estimated adjusted hazard ratios for incident LV damage, and receiver operating characteristic (ROC) curves assessed the predictive value.
Results: The sample included 517 individuals with a median (interquartile range) age of 53.0 (43.1-62.4) years and an AHI of 50.6 (32.6-65.5) events/hour. During a median follow-up of 8.3 (7.6-9.3) years, 112 patients (21.7%) had left ventricular hypertrophy (LVH), 249 (48.2%) had left ventricular diastolic dysfunction (LVDD), and none had LV systolic dysfunction. Individuals in the fourth quartile of PTT drop rate had a hazard ratio of 2.53 [95% (CI), 1.47-4.35] for LVH and 4.77 [95% CI, 3.15-7.21] for LVDD, respectively, compared to those in the first quartile. The results remained significant after adjusting for AHI and CVD. In contrast, no consistent associations were found with other PTT metrics, including drop magnitude, nadir, index, or area. In ROC curve analysis, PTT drop rate showed higher accuracy in predicting LVDD than compared to traditional polysomnography metrics.
Conclusion: Respiratory event-related PTT drop rate may be useful for predicting which patients with OSA are at increased risk for LV damage.

UNVEILING NOCTURNAL HYPERTENSION: THE ROLE OF PULSE TRANSIT TIME DERIVED BLOOD PRESSURE DURING POLYSOMNOGRAPHY

Athiwat Tripipitsiriwat[1], Sathida Traiwannakij[2], Nitipatana Chierakul[2], Sirisawat Kunanon[2]
[1] Faculty of Medicine, Siriraj Hospital, Mahidol University, [2] Faculty of Medicine Siriraj Hospital, Mahidol University

Introduction: Obstructive sleep apnea (OSA) is associated with increased cardiovascular risk and high blood pressure. Effective blood pressure (BP) control is crucial to mitigating this risk; however, traditional office BP monitoring is unable to capture nocturnal hypertension and masked hypertension. Patients with OSA undergoing polysomnography may have their BP estimated using pulse transit time (PTT). Nevertheless, PTT-derived BP is underutilized. We aimed to compare and validate the diagnostic capability of PTT-derived BP against the standard 24-hour ambulatory BP monitoring (ABPM).
Methods: Adults referred for full-night polysomnography from suspected OSA were consecutively invited to participate. Participants underwent 24-hour ABPM on the following day. PTT-derived and ABPM-derived BP measurements were compared. Nocturnal hypertension was defined by average nighttime BP ≥ 120/70 mmHg assessed by ABPM or PTT. Participants without OSA (apnea-hypopnea index < 5/h), those who underwent positive airway pressure titration, people with conditions contributing to unreliable pulse transit time (e.g. atrial fibrillation), and inadequate ABPM were excluded.
Results: A total of 64 patients were included in the analysis, with a median age of 48 years (interquartile range 37 – 62), and 37.3% were male. Prior to polysomnography, 46.3% had been diagnosed with hypertension. 29.9%,38.8% and 26.9% had mild, moderate, and severe OSA, respectively. PTT-derived nighttime SBP and DBP were significantly higher than ABPM-derived nighttime SBP and DBP in moderate/severe OSA but not in mild OSA. PTT-derived BP demonstrated a sensitivity of 78% and specificity of 41% in identifying nocturnal hypertension detected by ABPM. Among the participants, ABPM identified elevated BP (average daytime BP≥130/80 and/or average nighttime BP≥ 120/70 mmHg) in 13 out of 36 individuals without a prior diagnosis (masked hypertension). PTT-derived nocturnal BP captured masked hypertension with a sensitivity of 76.9% and specificity of 43.5%.
Conclusion: PTT-derived BP during polysomnography was higher than APBM-derived BP in patients with moderate-severe OSA, while yielded a similar result in patients with mild OSA. The

detection of increased BP using PTT shows promise as a potential screening tool for identifying nocturnal and masked hypertension. Moreover, PTT-derived BP may have prognostic value in OSA.

IMPACT OF CPAP ADHERENCE ON CARDIAC FUNCTION IN PATIENTS WITH HFPEF AND OSA: A REAL-WORLD STUDY

Yi-Seul Choo[1], Seonjeong Kim[1], Heewon Bae[1], Darae Kim[1], Eun Yeon Joo[1]

[1] Samsung Medical Center

Introduction: Obstructive Sleep Apnea (OSA) frequently coexists with Heart Failure with preserved Ejection Fraction (HFpEF), potentially exacerbating left ventricular (LV) dysfunction. Continuous Positive Airway Pressure (CPAP) therapy may improve LV diastolic function, but adherence is a common challenge. This study assessed CPAP compliance rates among HFpEF patients with OSA in a real-world setting and evaluated the impact on cardiac function based on adherence levels.
Methods: From 2007 to 2024, 47 patients with OSA (apnea-hypopnea index ≥ 5 events/hour) and HFpEF (LV ejection fraction ≥ 50%) were studied. Baseline polysomnography, sleep questionnaires, and echocardiography were performed. Patients were classified into "good adherence" (≥4 hours/night, n=27) and "poor adherence" (< 4 hours/night, n=20) groups based on national insurance standards for CPAP reimbursement. Cardiac function was reassessed after approximately 17 months.
Results: The study population (mean age 62.09 ± 12.7 years, 81% male) had a mean apnea-hypopnea index of 39.5 events/hour. Demographics and polysomnographic parameters were comparable between groups, except for a higher prevalence of type 2 diabetes mellitus in the poor adherence group (50% vs 18.5%, p=0.049). At follow-up, the good adherence group had a significant reduction in diastolic blood pressure (baseline 85.4 ± 8.1 mmHg to 81.2 ± 9.4 mmHg, p=0.029), with a non-significant trend toward improvement in LV mass index. No significant differences were observed in LV diastolic function parameters such as early diastolic mitral annular (e′) velocity, left atrial volume index, and right ventricular systolic pressure.
Conclusion: CPAP adherence was associated with reduction in diastolic blood pressure, suggesting potential improvement of afterload in HFpEF patients with OSA. Further studies are needed to explore long-term effects on cardiac remodeling.

RETROSPECTIVE ANALYSIS OF THE IMPACT OF MINERALOCORTICOID RECEPTOR ANTAGONISTS ON SLEEP DISORDERED BREATHING IN PATIENTS WITH SYSTOLIC HEART FAILURE

Nawaf Al-saeed[1], Saud Alawad[2], Ahmad Jarrar[2], Sunil Sharma[1]

[1] West Virginia University, [2] West Virginia University Hospital

Introduction: Sleep disordered breathing (SDB) is a common event in heart failure with reduced ejection fraction (HFrEF). It is often seen as a possible contributor of further worsening of heart failure. The implementation of advancing guideline-directed medical therapy (GDMT) is necessary in improving outcomes in patients with HFrEF. Since implementation of Mineralocorticoid receptor antagonists (MRA) to GDMT, it has led to mortality rate reduction in patients with HFrEF. However, the American College of Cardiology mainly recommends it in patients with ejection fraction (EF) of less than 40% based on present trials. This study aims to assess the impact MRA's regarding the development of SDB in this patient population.
Methods: TrinetX, an application which collects de-identified patient data, was used to perform this retrospective cohort study. 2 groups were formed, the first group composed of patients with HFrEF with ejection fraction (EF) of less than 40% on GDMT including MRA's. The second group comprised of similar characteristics except were on GDMT without MRA's. Age was set at 18 years and older, then propensity score matching was performed. The groups were compared assessing the risk, Risk differences (RD), P-values (p), risk ratio (RR), and confidence intervals (CI).
Results: The groups were studied over 3 years from initiation of their respective GDMT course. First, mortality occurrence was assessed with risks of 19.4% vs 20.804%, RD 1.403% p< 0.0001, RR 0.933(CI: 0.902, 0.965). Then the occurrence of central sleep apnea was assessed with risks of 0.582% vs 0.365%, RD 0.216% p 0.0003, RR 1.592 (CI: 1.238, 2.049). Finally, the development of obstructive sleep apnea was assessed with risks of 7.92% vs 6.137%, RD 1.783% p< 0.0001, RR1.291 (CI: 1.208, 1.379).
Conclusion: This study first confirms the already noted mortality benefit of MRA's in patients with HFrEF. However, it also notes an elevated risk of developing SDB in this at-risk patient population. Thus, providers should have reduced thresholds for evaluating SDB in this patient population. Furthermore, subsequent studies are required to elucidate the mechanism of this phenomenon.

IMPACT OF POST-METABOLIC SURGERY WEIGHT LOSS ON RELATIONSHIP OF SLEEP DISORDERED BREATHING AND CARDIOVASCULAR EVENTS

Sajni Patel[1], James Bena[2], Ali Aminian[1], Loutfi Aboussouan[1], Reena Mehra[3], Catherine Heinzinge[4]

[1] Cleveland Clinic, [2] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [3] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, Seattle, WA, [4] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH

Introduction: Obstructive sleep apnea (OSA) and obesity hypoventilation syndrome (OHS) are known risk factors for major adverse cardiovascular events (MACE): coronary artery disease, cerebrovascular events, heart failure, atrial fibrillation, and all-cause mortality, however the impact of sleep disordered breathing (SDB) on MACE post-metabolic surgery remains understudied. We hypothesized that SDB is associated with MACE post-metabolic surgery, more so with less weight loss.
Methods: The dataset included patients who had polysomnograms (6/17/2011-7/3/2018) before metabolic surgery at Cleveland Clinic and body mass index (BMI) measures within 1 year before MACE or last follow-up, excluding patients with baseline MACE. Patients were classified by SDB: OSA+OHS, OSA only, OHS only, neither, with OSA defined as apnea hypopnea index≥15. Time-dependent BMI %change was calculated

pre-surgery to MACE or last follow-up and stratified into quartiles. An unadjusted Cox proportional hazards model generated hazard ratios with 95% confidence intervals for MACE by SDB group. A multivariable model was adjusted for BMI %change, age, sex, race, surgery type, and key comorbidities. An interaction term was created between BMI %change and 2-level SDB group (OSA or OHS vs. neither) due to low outcome rates.
Results: The sample (N=1,285, age 43.6±11.5 years, 16.5% male, 63.7% White, 64.2% Roux-en-Y surgery, and 32.9% sleeve gastrectomy) had median follow-up of 1.95 years (range:< 1-8.2 years). BMI quartiles were: Q1:>33.1%, Q2:>24.1%-33.1%, Q3:>15.6%-24.1%, Q4:≤15.6%. The unadjusted model revealed 2.42 times greater MACE incidence in patients with OSA+OHS (HR=2.42, 95%CI=1.02-5.76, p=0.006) vs. neither, attenuated with adjustment (p=0.43). BMI reduction had greater impact in those without SDB (HR=1.65, 95%CI=1.08-2.54, p=0.022) vs. those with SDB (HR=1.09, 95%CI=0.88-1.34, p=0.44; interaction p=0.048).
Conclusion: In this cohort undergoing metabolic surgery, SDB, particularly the combination of OSA and OHS, was associated with increased MACE incidence, but no longer after adjustment for demographics, comorbidities, and BMI change. More effective BMI reduction post-metabolic surgery had a stronger protective effect against MACE incidence in those without SDB, highlighting the potential moderating role of SDB in post-metabolic surgery cardiovascular risk. Findings underscore the importance of identifying and managing SDB in patients undergoing metabolic surgery to optimize long-term cardiovascular outcomes.

POST-DISCHARGE TELEMEDICINE MOTIVATIONAL ENHANCEMENT IN ACUTE DECOMPENSATED HEART FAILURE AND OBSTRUCTIVE SLEEP APNEA RANDOMIZED CLINICAL TRIAL

Cinthya Pena-Orbea[1], Eileen Hsich[2], Michelle Drerup[2], Rami Khayat[3], James Bena[4], Shannon Morison[4], Delaney Ryan[4], Reena Mehra[5]

[1] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, [2] Cleveland Clinic, [3] University of California Irvine, [4] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [5] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, Seattle, WA

Introduction: Adherence to Positive Airway Pressure (PAP) in patients with Acute Decompensated Heart Failure (ADHF) and Obstructive Sleep Apnea (OSA) is associated with improved outcomes. However, follow-up with long-term PAP adherence poses a substantial challenge. We hypothesized that motivational enhancement (ME) via a telemedicine intensive approach improves PAP adherence post-discharge in hospitalized patients with ADHF and OSA.
Methods: Telemedicine Intensive Motivational Enhancement (TIME) (NCT04752462) is an ongoing randomized clinical trial designed to investigate telemedicine ME effect on post-discharge PAP adherence, rehospitalizations, and patient-reported outcomes (PRO, Epworth Sleepiness Scare [ESS], Frequency of Obstructive Sleep Apnea Symptoms Questionnaire [FOSQ] and Kansas City Cardiomyopathy Questionnaire [KCCQ-12]) compared to standard of care at 3 and 6 months in patients admitted with ADHF and in-hospital OSA diagnosis. We recruited 75 adult patients with ADHF and OSA (AHI≥5) who were randomly assigned to receive TIME (n=39) or regular care (n=36) and followed for 3 months. Since 3-month PAP adherence (minutes), and PROs were non-normally distributed, groups were compared unadjusted using the Wilcoxon rank sum test, and by linear models with a log-transformed outcome. Models were fit unadjusted and with adjustment for age, sex, race, and body mass index(BMI). All PRO models were adjusted for baseline PRO levels.
Results: Participants are predominantly men (60%), 38.7% of Black race, with BMI of 32.7[IQR:29.1,38.9], LVEF 37.0%[IQR:25.0,54.0], AHI:22.7[IQR:15.1,34.9], ESS:6[IQR:3,10], moderate level of daily impairment (FOSQ score of 15.7[IQR:13.0 - 19.0]) and poor health status at baseline (KCCQ-12 score25.5[IQR 13.5,52.1]). In unadjusted analysis at 3 months, nightly adherence was not significantly different in the TIME vs control group (128.5 [IQR7.0 -260.5] vs 61.5 [IQR5.5 -192.0], p=0.56). The quality of life (KCCQ-12 QoL) subscale was significantly higher in the TIME vs control group (75.0 [IQR50.0-87.5]vs37.5[IQR12.5-75.0], p=0.020), with a baseline adjusted mean increase of 92.5%(95%CI:0.9%-268%, p=0.047). In adjusted analysis, this difference persisted. No group differences were observed in the ESS and FOSQ scores.
Conclusion: TIME did not have significant effects on PAP adherence at 3 months. However, there was an improvement in HF-specific quality of life at 3 months

ATRIAL FIBRILLATION BURDEN IN CENTRAL SLEEP APNEA PATIENTS TREATED WITH PHRENIC NERVE STIMULATOR

Jonathan Na[1], Mohamed Gad[2], Supriya Singh[2], Aparajitha Verma[3], Hamid Afshar[2], Irakli Giorgberdize[2], Miguel Valderrabano[1], Paul Schurmann[1]

[1] Houston Methodist Hospital, [2] Baylor College of Medicine, [3] UTHealth Houston Neurosciences

Introduction: Phrenic Nerve stimulation (PNS) has been FDA-approved for the treatment of moderate-severe central sleep apnea (CSA). Whether PNS impacts the burden of persistent atrial fibrillation (AF) in unclear. The objective is to determine the impact of CSA treatment on AF burden
Methods: This study is a multicentric, retrospective chart review of PNS implants conducted between 2018 and 2024. A total of 21 patients with polysomnography (PSG)-confirmed moderate to severe CSA and predominant central apnea hypopnea Index (AHI) underwent PNS implantation with the remedē system (Respicardia Inc, Minnetonka, MN, USA). After 12 weeks of PNS activation, repeat PSG was schedule. Of this cohort, five patients had persistent atrial fibrillation with previously implanted cardiac devices. Quantification of AF burden was obtained from implanted device interrogation after PNS activation.
Results: In 8 patients (6 left phrenic and 2 right phrenic) with pre and post implant PSG testing, AHI was significantly reduced by PNS (51±27 vs 18±15, p =.015, 95% Confidence interval [8.81, 57.29]. In the 5 patients with persistent AF and concomitant cardiac devices, AF burden was significantly reduced by PNS implantation (pre-implant burden 100 %±0) than the AF burden post implant (60% ± 54.7).

Conclusion: Phrenic Nerve stimulation is effective in reducing the AHI in predominant CSA. There may be a potential benefit in decreasing the AF burden in patients with persistent AF that requires further study

RISK OF CARDIOMETABOLIC OUTCOMES IN INDIVIDUALS WITH TYPE 1 AND TYPE 2 NARCOLEPSY

Munaza Riaz[1], Haesuk Park[1], Christopher Kaufmann[1], Wei-Hsuan Lo-Ciganic[2], Debbie Wilson[1], Atul Malhotra[3], Emerson Wickwire[4], Rakesh Bhattacharjee[3]

[1] University of Florida, [2] University of Pittsburgh, [3] University of California, San Diego, [4] University of Maryland Baltimore

Introduction: Narcolepsy, a chronic neurological sleep disorder, has two subtypes: type 1 (NT1), characterized by cerebrospinal fluid (CSF) orexin deficiency, and type 2 (NT2), characterized by normal CSF orexin levels. Both subtypes share symptoms, such as excessive daytime sleepiness (EDS) and fragmented nocturnal sleep, but cataplexy is specific to NT1. Given orexin's role in autonomic regulation, NT1 is linked to cardiometabolic risks. However, data on cardiometabolic outcomes is limited for both subtypes. Therefore, we assessed the risks of diabetes, hypertension, and hyperlipidemia in patients with NT1 and NT2 compared to individuals without narcolepsy.

Methods: We conducted a retrospective cohort study using 2005-2021 MarketScan® Commercial and Medicare Supplemental databases. Patients newly diagnosed with narcolepsy (NT1 or NT2) with >2 outpatient claims were identified using International Classification of Diseases – Clinical Modification diagnosis codes (NT1 or NT2 group). A comparison cohort without narcolepsy and hypersomnia (non-narcolepsy group) was matched using propensity score (PS) matching (1:3 ratio) based on baseline demographics, comorbidities, and medication use. We excluded patients with any diagnosis of cardiovascular disease, hypertension, hyperlipidemia, diabetes, and metabolic-associated fatty liver disease during 1-year baseline period. After PS-matching, we used time-dependent Cox regression to compare risks of diabetes, hypertension, and hyperlipidemia between NT1 and non-narcolepsy groups and NT2 and non-narcolepsy groups. Models accounted for baseline use of wake-promoting agents, oxybate, stimulants, and time-varying stimulant use during follow-up period.

Results: The final cohort included 86,002 patients (18,309 with NT1, 3,760 with NT2, and 63,709 without narcolepsy). The adjusted model shows that NT1 was associated with higher risks for diabetes (adjusted hazard ratio [aHR] 2.21; 95% confidence interval [CI] 1.59-3.07), hypertension (aHR 1.43; 95% CI 1.18-1.73), and hyperlipidemia (aHR 1.74; 95% CI 1.48-2.04), compared to those without narcolepsy. Similarly, NT2 was associated with higher risks of diabetes (aHR 1.44; 95% CI 1.24-1.66), hypertension (aHR 1.39; 95% CI 1.29-1.51), and hyperlipidemia (aHR 1.43; 95% CI 1.33-1.53), compared to those without narcolepsy.

Conclusion: Using large U.S. claims data, patients with NT1 or NT2 showed increased risks for diabetes, hypertension, and hyperlipidemia compared to those without narcolepsy. EDS and sleep fragmentation may drive these risks.

INCREASED CARDIOMETABOLIC RISK IN NARCOLEPSY: EVIDENCE OF EARLY-LIFE ONSET

Rakesh Bhattacharjee[1], Munaza Riaz[2], Haesuk Park[2], Wei-Hsuan Lo-Ciganic[3], Debbie Wilson[2], Emerson Wickwire[4], Atul Malhotra[5], Christopher Kaufmann[2]

[1] University of California San Diego, [2] University of Florida, [3] University of Pittsburgh, [4] University of Maryland Baltimore, [5] University of California, San Diego

Introduction: Emerging evidence links narcolepsy to major adverse cardiovascular events (MACE). While narcolepsy typically manifests early in life, it remains unclear whether cardiovascular disease (CVD) also develops early. We hypothesized that narcolepsy elevates the risk of cardiometabolic conditions from childhood into later life, potentially explaining the heightened MACE risk in persons with narcolepsy (PWN).

Methods: We conducted a retrospective cohort study using MarketScan® Commercial and Medicare Supplemental databases (2005-2021). PWN were identified by ≥2 outpatient claims for narcolepsy using International Classification of Diseases–Clinical Modification diagnosis codes. A control group of persons without narcolepsy/hypersomnolence was created using propensity score matching (1:3 ratio). Index date was the first narcolepsy diagnosis for PWN and corresponding encounter date for matched controls. Individuals with pre-existing CVD, MACE, hypertension, hyperlipidemia, diabetes, or metabolic fatty liver disease during the year prior to the index date (baseline period), to ensure balanced demographics, comorbidities, and baseline medication use between with and without narcolepsy groups. Cox regression models assessed the association between narcolepsy and time to incident hypertension, hyperlipidemia, and diabetes, adjusting for baseline and time-varying narcolepsy medication (i.e., wake-promoting agents, stimulants, and oxybate) use. Analyses were stratified by age groups (≤25[pediatric], 26–44[adults], 45–65[middle-aged], and >65yrs[older adults]).

Results: The cohort included 22,293 PWN and 63,709 without narcolepsy/hypersomnolence. Mean±SD age was 35.5±14.0 years (63.7% female). PWN had a significantly higher risk of hypertension (adjusted hazard ratio[aHR]:1.44, 95% Confidence Interval[CI]:1.34–1.54), hyperlipidemia (aHR:1.48, 95% CI:1.39–1.57), and diabetes (aHR:1.61, 95% CI:1.40–1.83) compared to those without narcolepsy. These outcomes were elevated across all age groups except older adults (>65yrs). Notably, in the pediatric cohort(< 25yrs), PWN showed nearly double the risk of hypertension (aHR:2.01, 95% CI:1.60–2.53), hyperlipidemia (aHR:1.84, 95% CI:1.53–2.23), and diabetes (aHR:2.37, 95% CI:1.66–3.37) compared to those without narcolepsy/hypersomnolence.

Conclusion: Using a large U.S. claims database, narcolepsy was associated with a significantly increased risk of hypertension, hyperlipidemia, and diabetes across all age groups, with strongest associations observed in younger individuals. Early onset of cardiometabolic risk factors indicate prolonged exposure, potentially increasing the likelihood of MACE later in life and possibly shifting their onset to earlier ages.

NON-DIPPING BLOOD PRESSURE IS ASSOCIATED WITH SLEEP TIMING IN HYPERTENSIVE ADULTS WITH INSOMNIA DISORDER

Christi Ulmer[1], Jade Wu[2], James A Blumenthal[3], Emma Herold[3], Patrick J Smith[4], Gary Koch[5], Kristy Johnson[1], Anthony Viera[3], Jack D. Edinger[6], Alan Hinderliter[7], Andrew Sherwood[3]

Introduction: Blood pressure (BP) dipping during nocturnal sleep is characteristic of a normal circadian BP pattern. A blunted BP dipping pattern (< 10% dip in BP), however, is a cardiovascular disease (CVD) risk factor and is associated with sleep disturbance. Although numerous studies have examined the relationship between nocturnal BP dipping and sleep, most research has been conducted in healthy adult samples and employed self-report measures of sleep disturbance. In the SLEEPRIGHT Trial, we examined associations between BP dipping and variability in sleep timing in a sample of adults with untreated hypertension who also met diagnostic criteria for insomnia disorder.
Methods: Study participants met diagnostic criteria for insomnia disorder and had untreated hypertension, with an office systolic blood pressure (SBP) in the range 130-160 mmHg. BP dipping was assessed using 24-hour ambulatory blood pressure monitoring. Insomnia disorder diagnostic criteria (ICSD-3) were assessed using the Insomnia module of the Structured Clinical Interview for Sleep Disorders (SCISD), and sleep midpoint was ascertained from the Consensus Sleep Diary data. Patients with SBP>160 mm Hg, OSA, severe obesity, atrial fibrillation, congestive heart failure, and sleep and cardiovascular medications were excluded.
Results: Study participants (N=139; 43% male; 78% Caucasian) were 48 years of age (SD=8) with diary sleep midpoint of 4:09 am ± 25 minutes, and sleep duration of 6.57 ± 1.07 hours. In linear regression models adjusted for age, sex, race, body mass index, and daytime blood pressure, variability in sleep midpoint ($F=3.57$, $p=.002$) was significantly associated with SBP dipping, with those having more variable sleep timing exhibiting relatively blunted nocturnal BP dipping.
Conclusion: These observations extend previous research to those with hypertension and comorbid insomnia disorder. Interventions known to regularize sleep timing in those with insomnia disorder, such as Cognitive Behavioral Therapy for Insomnia, might also result in reduced CVD risk through normalized nocturnal BP dipping. Longitudinal findings from the ongoing SLEEPRIGTHT trial will shed light on this possibility.

LOWER SLEEP REGULARITY IS ASSOCIATED WITH FASTER TIME TO CLINICAL EVENT IN ADULTS WITH HEART FAILURE

Brooke Shafer[1], Shirin Hiatt[1], Sophia Kogan[1], Quin Denfeld[1], Andrew McHill[2]

[1] Oregon Health & Science University, [2] Oregon Institute of Occupational Health Sciences, Oregon Health & Science University, Portland, Oregon, USA

Introduction: Disturbances to sleep and the circadian timing system may contribute to morbidity and mortality, particularly in chronic conditions. For example, advancing sleep/wake rhythms to induce circadian disruption significantly reduces lifespans in cardiomyopathic animals; however, it is unclear if these findings extend to humans. Adults with heart failure (HF) often report sleep difficulties and day-to-day variations in sleep timing (e.g., sleep regularity), thus reflecting chronic circadian disruption and possibly increasing adverse event risk. Considering sleep regularity has been shown to be a greater predictor for mortality than sleep duration, we quantified the impact of sleep regularity on 6-month clinical event risk among adults with HF after a hospitalization for HF.
Methods: Data was collected from 32 participants (14 female) following a baseline hospitalization for acute decompensated HF. Sleep regularity index (SRI) was calculated from diary-determined sleep onset and offset collected over ~7-days. Participants were then classified into regular (SRI>87%) or irregular (SRI<= 87%) sleep groups at baseline. Differences between sleep groups were assessed using independent t-tests. Clinical event data (all-cause emergency room visit, hospitalization, and death) were collected through 6 months post-hospitalization. Kaplan-Meier time-to-event curves between sleep groups were generated and then compared using the Log-rank test. Hazard ratios (HR) and 95% confidence intervals (95%CI) were estimated by Cox regression model.
Results: There were no baseline differences between sleep groups (n=16 irregular and n=16 regular) in age (mean±SD, irregular vs. regular, respectively; 63.1±12.2y vs. 62.1±18.0y; p=0.85) or sleep duration (581±145min vs. 535±83min; p=0.27), but SRI was significantly lower in the irregular sleep group (79±7% vs. 92±3%; p< 0.01). Kaplan-Meier analysis showed significant delineation in "time to event" curves between sleep groups (p=0.01), with the irregular sleep group having a greater risk of an event (HR=2.7, 95%CI:1.1-6.6; p=0.02) compared to the regular sleep group.
Conclusion: Irregular sleep patterns after a HF hospitalization predicted worse 6-month clinical event risk among adults with HF; thus, sleep and circadian rhythm disruption may be one mechanistic contributor to poor health outcomes. Improving regularity in sleep patterns may be a potential interventional target to mitigate adverse health events in this population.

ACTIGRAPHY-BASED SLEEP IRREGULARITY MEASURES AND CARDIOMETABOLIC IMAGING BIOMARKERS USING PET/MRI: A DESCRIPTIVE ANALYSIS

Kaveh Gaynor-Sodeifi[1], Bolong Xu[2], Heli Patel[2], Philip Robson[2], Zahi Fayad[1], Indu Ayappa[3], Neomi Shah[1], Vaishnavi Kundel[1]

[1] Icahn School of Medicine at Mount Sinai, [2] Ichan School of Medicine at Mount Sinai, [3] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: There is mounting evidence that irregular sleep patterns are associated with impaired cardiometabolic health. However, few studies have explored this link independent of obstructive sleep apnea (OSA), an important confounder in this relationship. Here, we report a descriptive analysis of our study, investigating the link between irregular sleep, vascular inflammation, and abdominal adiposity in a cohort of patients without significant OSA.
Methods: We recruited adults from ambulatory clinics with ≥1 cardiovascular risk factor and without significant OSA

(Respiratory Disturbance Index ≤20). Sleep patterns were monitored for 10-14 days using actigraphy. Hybrid PET/MRI with 18F-fluorodeoxyglucose (FDG) radiotracer was conducted to characterize vascular inflammation of the carotid arteries and ascending aorta, and visceral and subcutaneous adipose tissue (VAT and SAT) volume and metabolic activity. Image analysis was performed using OsiriX. FDG-uptake was measured using standardized uptake values (SUVmean and SUVmax). Patients with standard deviations in sleep-onset timing >60 minutes were classified as irregular sleepers. We report descriptive baseline characteristics, sleep-wake patterns, and imaging metrics.

Results: 39 participants completed actigraphy and PET/MRI thus far. Baseline characteristics are noted in Table 1. Twelve (31%) participants met criteria for irregular sleep. Irregular sleepers had higher subjective symptoms of daytime sleepiness ($p< 0.05$), shorter sleep (TST 5.9 vs 6.9 hours, $p< 0.05$), and more irregular total sleep time (TST standard deviation 80.7 versus 54.5 min, $p< 0.01$). Participants with irregular sleep were also significantly younger in age ($p< 0.01$). There were no significant differences in adiposity measures or vascular inflammation between the two groups. In exploratory analysis, both age ($\beta=0.007$ $p=0.07$) and BMI ($\beta=0.034$, $p< 0.05$) were positively associated with carotid vascular inflammation.

Conclusion: In preliminary analysis, we found that irregular sleepers were younger in age, with a lower TST, and greater complaints of daytime sleepiness. There were no significant differences in vascular inflammation and abdominal adiposity measures between the two groups. Our results are limited by sample size. In this ongoing study, future analyses with a larger cohort and use of novel metrics for sleep regularity will allow us to better characterize its effects as a modifiable risk factor for cardiometabolic biomarkers, independent of OSA.

METABOLIC SYNDROME, SLEEP PATTERNS AND CHRONOTYPE IN A POPULATION OF YOUNG ADULTS: AN EPIDEMIOLOGICAL STUDY

Nádia Pereira[1], Fernanda Naufel[1], Sonia Togeiro[1], Monica Andersen[2], Sergio Tufik[3], Helena Hachul[1]

[1] Universidade Federal de São Paulo, [2] Departamento de Psicobiologia, Universidade Federal de São Paulo, [3] Universidade de Federal de São Paulo

Introduction: Metabolic syndrome (MetS) is a set of interconnected and hereditary changes characterized by increased blood pressure levels, central obesity, insulin resistance, atherogenic dyslipidemia, risk of type 2 diabetes mellitus (DM2) and atherosclerotic and non-atherosclerotic cardiovascular diseases (CVD). In recent decades, changes in both eating habits and sleep patterns have contributed to an increase in MetS, and associated cardiometabolic diseases. Studies have revealed a connection between short sleep duration and metabolic function, with increased cortisol levels, reduced insulin sensitivity, altered appetite regulation, and reduced leptin levels, which can lead to weight gain, DM2 and cardiovascular diseases.

Methods: Data from the EPISONO 2007 study were analyzed. After exclusion criteria, the sample included 223 individuals aged between 20 and 39 years, and excluded those using psychoactive medications, with incomplete data or only having one or two risk factors for MetS. Participants completed questionnaires about sleep and chronotype. They underwent anthropometric assessments, measurement of blood pressure, blood glucose, total cholesterol and fractions, triglycerides, HOMA-IR, insulin, IL-6, C-reactive protein, ghrelin, leptin, aspartate aminotransferase (AST), alanine aminotransferase (ALT) and baseline polysomnography. Two groups were formed: a control group with 180 individuals without risk factors for MetS, and a metabolic syndrome (MetS) group with 43 individuals presenting three or more of the five diagnostic factors for MetS according to the National Cholesterol Education Program - Adult Treatment Panel III.

Results: The prevalence of MetS was lower compared to other Brazilian studies, being 9.2% in women and 8.6% in men. There was a significant correlation between MetS and altered sleep patterns, and a higher apnea-hypopnea index in men with Mets. No connection were found between MetS and chronotype.

Conclusion: MetS was associated with reduced sleep quality in young adults, regardless of gender, but not with chronotype. Additional studies are needed to explore the relationship between MetS and sleep quality in this age group.

LONGITUDINAL CHANGES IN SELF-REPORTED CHRONOTYPE AND RISK OF CHRONIC DISEASES: AN OUTCOME-WIDE STUDY IN UK BIOBANK

Sina Kianersi[1], Kaitlin Potts[1], Heming Wang[2], Tamar Sofer[3], Raymond Noordam[4], Martin K. Rutter[5], Kathryn M Rexrode[1], Susan Redline[6], Tianyi Huang[7]

[1] Brigham and Women's Hospital, [2] Brigham and Women's Hospital, [3] Cardiovascular Institute, Beth Israel Deaconess Medical Center, Harvard Medical School, [4] LUMC, [5] Manchester University, [6] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [7] National Institute on Aging

Introduction: Self-reported chronotype assessed at a single time point has been associated with chronic disease outcomes. Chronotype, while partially shaped by genetic factors, may shift over time in response to environmental and biological changes or ageing. However, the extent to which chronotype changes occur and the impact of such changes on major chronic disease risk remains underexplored.

Methods: Our outcome-wide study included 51,632 UK Biobank participants who reported chronotype at two time points using a validated question from the Morningness-Eveningness Questionnaire; mean age at the second assessment (i.e., study baseline): 64 years. Chronotype changes were categorized into five levels: no change, small or large change towards morningness, and small or large change towards eveningness. Incidence of eight major chronic diseases was identified via validated algorithms integrating medical records, death registers, and self-reports. Cox proportional hazard models estimated hazard ratios (HR) for associations between chronotype change and incident disease risk, applying a Bonferroni correction.

Results: The two chronotype assessments, on average 7.4 years apart, showed relatively high stability (weighted kappa = 0.764), with 19% shifting towards morningness and 15% towards eveningness. The number of incident cases ranged from 138

for all-cause parkinsonism to 1,288 for cardiovascular disease (CVD) over a median follow-up of 5.0 years. Compared to participants with no change, those with a large change towards morningness had a 2.51-fold increased risk of all-cause dementia (95% CI: 1.15, 5.50), after adjusting for baseline chronotype, time intervals between chronotype measurements, sociodemographic factors, shift work, and lifestyle factors. By contrast, risks associated with a change towards eveningness was 3.37 (1.74, 6.51) for all-cause dementia, 2.27 (1.40, 3.68) for COPD and 1.23 (1.04, 1.46) for type 2 diabetes, versus no chronotype change. However, after Bonferroni correction, only the association between large changes and all-cause dementia remained significant (corrected global p-value: 0.0080). No associations were observed for CVD (stroke/myocardial infarction), asthma, or parkinsonism risks.
Conclusion: Large chronotype changes towards morningness or eveningness were associated with incident chronic disease risk, particularly dementia, in aging adults. These changes may reflect alterations in intrinsic circadian mechanisms and/or influences by environmental and behavioral factors.

Targeted Light Exposure for Poor Sleep Following Acute Coronary Syndrome: A Pilot Randomized Trial

Robin Cumella[1], Miguel Mendieta[1], Nakesha Fray[1] ,David Hiti[1],Ian Kronish[1], Ari Shechter[1]
[1] Columbia University Irving Medical Center

Introduction: Sleep disturbance is common following acute coronary syndrome (ACS) and may contribute to worse prognosis. Short sleep duration following ACS is linked to increased risk of hospital readmission, and both short sleep and insomnia are prospectively associated with recurrent cardiovascular (CVD) events in patients. Sleep may therefore represent a modifiable behavioral target to improve prognosis in these patients. We describe the findings of a pilot randomized clinical trial (RCT) testing the feasibility of a circadian rhythm-based intervention to improve post-ACS sleep.
Methods: Fifteen post-ACS patients with insomnia symptoms and/or short sleep duration were randomized (2:1 allocation) to combined chronotherapy (CC) plus sleep hygiene education (SHE) or SHE alone control. CC consisted of a) bright light therapy (BLT) delivered by a wearable light visor for 30 minutes after awakening and b) short-wavelength light avoidance using blue-light blocking (BLB) glasses in the evening from 8:00pm to bedtime. The intervention was administered daily for 4 weeks. Primary outcomes were study completion, adherence to the treatment, and patient-rated intervention feasibility (Feasibility of Intervention Measure), acceptability (Acceptability of Intervention Measure), appropriateness (Intervention Appropriateness Measure) and usability (System Usability Scale). Secondary outcomes were insomnia symptoms (Insomnia Severity Index), sleep quality (Pittsburgh Sleep Quality Index), and self-reported sleep duration.
Results: Two patients in the CC group dropped before initiating study procedures. Completion of study procedures (i.e., completing all assessments at study endpoint) in the remaining patients was high in the CC and SHE control groups (88% and 100%, respectively). Self-reported adherence to CC (i.e., using BLT and BLB on ≥50% of days) was high (88% and 100%, respectively). The proportion of CC patients who perceived the intervention as feasible (71%) and usable (100%) was high, though fewer CC patients rated the intervention as acceptable (57%) and appropriate to improve sleep (29%). Improvements in insomnia symptoms and self-reported sleep quality and duration were seen in response to the CC intervention (71%).
Conclusion: Post-ACS patients with sleep disturbance had high adherence to this sleep-targeted chronotherapeutic intervention, and most viewed it as feasible and usable. This intervention should be tested in a larger RCT to determine efficacy to improve sleep.

SLEEP DURATION IN THE MONTH FOLLOWING ACUTE CORONARY SYNDROME AND RISK FOR MAJOR ADVERSE CARDIOVASCULAR EVENTS AND MORTALITY: A PROSPECTIVE 1-Y STUDY

Ari Shechter[1], Brandon Fernandez Sedano[1], Talea Cornelius[1], Alexandra Sullivan[1], Donald Edmondson[1]
[1] Columbia University Irving Medical Center

Introduction: Sleep disturbance is a risk factor for incident cardiovascular disease (CVD). Yet less is known about the prospective association between disturbed sleep and risk for recurrent cardiac events. We examined whether short sleep duration in the month following hospital evaluation for acute coronary syndrome (ACS) is associated with increased risk for major acute cardiovascular event (MACE) and/or all-cause mortality (ACM) over the following year.
Methods: Patients were enrolled in this prospective observational study after emergency department evaluation for ACS. Habitual sleep duration was assessed at 1 month after hospital discharge with the question: "During the past month, how many hours of actual sleep did you get at night?" A Cox proportional hazards model was used to assess the association between short sleep duration (< 7 hours) during the month following ACS hospital evaluation and MACE/ACM over the 12 months following hospital discharge. Covariates included age, sex, race/ethnicity, cardiac severity (GRACE-Risk score), comorbidities (Charlson Comorbidity Index), and ACS diagnosis status (confirmed ACS vs. rule-out). Because of the small number of participants with long sleep duration (>9 hours) and the potential association of long sleep with adverse outcomes, participants reporting >9 hours of sleep were excluded from analyses.
Results: The sample included 1,239 patients. Mean (SD) age was 60.6 (12.9) years and 49.6% were female. Mean sleep duration was 5.97 (1.64) hours, with 59.6% reporting sleep duration < 7 hours and 40.36% with sleep duration 7-9 hours. During the follow-up period, 5.2% experienced MACE/ACM. Short sleep duration (vs. not short) had a marginally significant association with 12-month MACE/ACM (HR=1.64; 95% CI: 0.94, 2.84) in covariate adjusted analyses. In sensitivity analysis defining short sleep as < 6 hours and comparing to sleep duration of 6-9 hours, the association of short sleep with 12-month MACE/ACM was statistically significant (HR=1.90; 95% CI: 1.15, 3.12).
Conclusion: Short sleep duration following ACS hospital evaluation is prevalent and is associated with increased risk of MACE/ACM within the following 12 months. Findings suggest that short sleep is an important modifiable behavioral factor to consider after ACS, and that targeting short sleep duration in cardiac patients may help reduce secondary cardiovascular risk.

RACIAL AND ETHNIC AND SEX DIFFERENCES IN THE ASSOCIATION OF SLEEP DURATION AND ADVANCED CARDIOVASCULAR-KIDNEY-METABOLIC SYNDROME

Jelaina Shipman-Lacewell[1], Laura Ward[1], Tene Lewis[1], Viola Vaccarino[1], Dayna Johnson[1]

[1] Emory University

Introduction: Cardiovascular-Kidney-Metabolic Syndrome (CKM), a condition characterized by the comorbid occurrence of metabolic conditions, chronic kidney disease, and cardiovascular disease, can significantly increase the risk for early mortality. Sex, racial, and ethnic differences have been found, with men (compared to women) and Black individuals (compared to White individuals) being more likely to have advanced stage CKM (stages 3 and 4), suggesting the need to examine factors that may be contributing to advanced stage CKM. Poor sleep may be a determinant of CKM, given its link to cardiovascular, chronic kidney, and metabolic conditions independently. We examined associations of objective sleep duration and the occurrence of advanced-stage CKM, and whether the associations differed by sex and race and ethnicity.
Methods: We analyzed cross-sectional data from two cycles (2011-2012 & 2013-2014) of the NHANES study. Individuals were classified into five stages (0-4) of CKM. For the current analyses, individuals were further classified as having advanced CKM (stages 3-4) vs no advanced CKM (stages 0-2). Sleep duration was obtained via actigraphy across a nine day period and coded as short (< 7 hours), recommended (> 7 and < 9 hours), and long (> 9 hours) sleep. Sex and race and ethnicity stratified logistic regressions were fit to determine the association of sleep duration and CKM adjusting for sociodemographic factors, smoking, alcohol use, and depressive symptoms.
Results: The sample (n=4510; Mage = 48.9) was 50% female, 22% Latinx, 42% White, 21% Black, and 13% Asian. Approximately 37% had short sleep duration, 13% had long sleep duration, and 17% had advanced CKM. In fully adjusted models, long compared to recommended sleep duration was associated with an increased odds of advanced CKM for men (aOR: 1.84 CI: [1.05, 3.24]) and Latinx individuals (aOR: 4.64 CI:[2.07, 10.40]). Sleep duration was not associated with advanced CKM in women, or White, Black, or Asian individuals.
Conclusion: Long sleep duration was associated with higher odds of advanced stage CKM among men and Latinx individuals. While cross-sectional, findings may suggest that interventions to improve sleep may reduce the burden of CKM among these populations.

INDIVIDUAL AND CUMULATIVE EFFECTS OF SLEEP ON INCIDENT HEART FAILURE: THE REASONS FOR GEOGRAPHIC AND RACIAL DIFFERENCES IN STROKE (REGARDS) STUDY

Brittanny Polanka[1], Abu Abdullah Hanif[1], Emily Levitan[1], Parag Goyal[2], Megan Petrov[3], Mercedes Carnethon[4], Marwah Abdalla[5], Stephen Thomas[1]

[1] University of Alabama at Birmingham, [2] Weill Cornell Medicine, [3] Edson College of Nursing and Health Innovation, Arizona State University, [4] Northwestern University Feinberg School of Medicine, [5] Columbia University Irving Medical Center

Introduction: Sleep disturbances are contributors to elevated cardiovascular disease event risk. However, research on the cumulative effects of multiple disturbances and the specific risk for heart failure (HF) is limited and lacks representation from diverse populations. We examined the individual and cumulative associations of sleep factors on incident HF among a racially and regionally diverse U.S. sample.
Methods: We utilized the REasons for Geographic and Racial Differences in Stroke (REGARDS) study. Self-reported sleep was assessed between 2013-2016 and incident HF was defined as HF hospitalizations or HF-related mortality through 12/31/2020 (based on clinician-adjudication). Cox proportional hazards models estimated hazard ratios (HRs) for individual (sleep duration, sleep efficiency, sleep mid-point, restless sleep, and sleep-disordered breathing [SDB]) and cumulative (count score of suboptimal factors; categories: 0, 1, 2, 3-5; higher scores indicate more disturbance) sleep factors, with progressive adjustment for sociodemographic (age, sex, race, education, income, geographic region), behavioral (smoking, alcohol, physical inactivity), and medical (diabetes, hypertension, obesity, atrial fibrillation, coronary heart disease, chronic kidney disease, stroke) confounders.
Results: Among 10,440 HF-free participants (mean age= 72.0 years, 55.2% female, 33.3% Black), 370 HF events occurred over median follow-up of 5.9 years. Individually, late sleep mid-point (>4:00AM) compared to intermediate (2-4:00AM; HR=1.52, 95%CI: 1.13–2.03), moderate/most-of-time restless sleep (compared to rarely/some-of-time; HR=1.31, 95%CI: 1.02-1.69), and SDB (compared to no SDB; HR=1.54, 95%CI: 1.02-2.34) were associated with incident HF, adjusting for sociodemographics. Late sleep mid-point remained significantly associated with incident HF after adjusting for behavioral (HR=1.40, 95%CI: 1.04-1.87) but not medical (HR=1.25, 95%CI: 0.93-1.68) confounders. No other individual models were significant. Cumulatively, sleep score 3-5 (compared to 0) was associated with incident HF, adjusting for sociodemographic (HR=1.59, 95%CI: 1.13-2.24) and behavioral (HR=1.51, 95%CI: 1.07-2.12) but not medical (HR=1.17, 95%CI: 0.83-1.66) confounders.
Conclusion: Though some sleep disturbances and greater cumulative sleep burden were associated with increased HF risk in sociodemographic-adjusted models, associations were largely explained by behavioral and medical factors. Further research is needed to clarify pathways linking sleep to HF risk and identify which populations may benefit from sleep-related interventions.

MULTIDIMENSIONAL SLEEP HEALTH IS ASSOCIATED WITH LOWER DIURNAL BLOOD PRESSURE PROFILES FROM OUT-OF-OFFICE BLOOD PRESSURE ASSESSMENT

Erica Wood[1], Emma Guyonnet[1], Sarahy Martinez[1], Ariana Lopez[1], Marina Garcia Santos[1], Ari Shechter[1], Marwah Abdalla[1], Nour Makarem[2]

[1] Columbia University Irving Medical Center, [2] Mailman School of Public Health, Columbia University Irving Medical Center

Introduction: Multidimensional sleep health (MDSH) is associated with lower hypertension risk, but evidence regarding its influence on out-of-office blood pressure (BP) is limited. This study evaluated associations of overall and individual MDSH metrics with ambulatory and home BP (ABPM and HBPM) among middle-aged to older adults in a free-living setting.
Methods: Participants were a community-based sample recruited across New York City (n=201, age:40-80y, 70% female, 26% Black, 22% Hispanic) who completed seven consecutive days of wrist actigraphy concurrent with HBPM and 24-h ABPM. An MDSH score was computed such that participants received a score of 1 for having sleep duration≥7h, sleep efficiency≥85%, sleep midpoint< 4AM, day-to-day sleep duration and timing variability< 60 minutes, very good/excellent self-reported sleep satisfaction, and high daytime alertness; otherwise, they received a score of 0. Components were summed to create an MDSH score (range: 0-6) dichotomized as suboptimal (0-4) and optimal (5-6). Average, morning, and evening systolic (SBP) and diastolic BP (DBP) were derived from HBPM. Mean 24-h, sleep, and wake SBP and DBP were derived from ABPM. Multivariable linear regression evaluated associations of MDSH with BP outcomes.
Results: Each 1-unit increase in the MDSH score was significantly associated with lower 24-h, wake, and sleep SBP and DBP from ABPM and lower average, morning, and evening SBP from HBPM. Optimal vs. suboptimal MSDH was associated with lower mean 24-hour (β=-7.1mmHg; p=0.007), wake (β=-5.70mmHg; p=0.032), and sleep SBP (β=-10.3mmHg; p=0.001) and with lower sleep DBP (β=-5.4mmHg; p=0.008). Optimal MDSH was also related to lower mean SBP and DBP (β=-6.0mmHg and -5.2mmHg; p< 0.01) and lower morning DBP (β=-4.2mmHg; p=0.02) and evening SBP and DBP (β=-8.6 and -6.0mmHg; p< 0.01) from HBPM. Among individual sleep metrics, higher sleep efficiency and regularity, sufficient sleep duration, and greater daytime alertness were significantly associated with more favorable ABPM and HBPM outcomes.
Conclusion: Overall MDSH was consistently associated with lower ecologic BP and more favorable diurnal BP profiles, but not all MDSH components were associated with out-of-office BP outcomes. Adopting an MDSH approach may be critical for optimizing diurnal BP profiles in ecologic settings. Population-based longitudinal studies are needed to confirm these findings.

IMPACT OF CONTEXTUAL AND PHYSIOLOGIC FACTORS ON ADOLESCENT MULTIDIMENSIONAL SLEEP HEALTH FOR CARDIOMETABOLIC HEALTH

Casandra Nyhuis[1], Kristina Lenker[1], Susan Calhoun[1], Jason Liao[1], Alexandros Vgontzas[2], Edward Bixler[1], Duanping Liao[1], Meredith Wallace[3], Julio Fernandez-Mendoza[1]
[1] Penn State College of Medicine, [2] Sleep Research and Treatment Center, Penn State College of Medicine, [3] University of Pittsburgh

Introduction: Good sleep health is essential for optimal cardiometabolic health. However, contextual (schooling) and physiologic (sleep apnea) factors can negatively impact adolescent sleep health. The existing RegUlarity, Satisfaction, Alertness, Timing, Efficiency and Duration (RU-SATED) framework used to derive multidimensional sleep health (MSH) scores does not account for the contribution of these factors to sleep health. In the present study, we developed two MSH models to account for these factors and examined their associations with metabolic syndrome (MetS), an index of cardiometabolic health, and compared their performance to an unweighted MSH score.
Methods: We studied 341 adolescents (16.3±2.2 yr; 47% female; 22.9% racial/ethnic minority) from the Penn State Child Cohort who underwent 9-h, in-lab polysomnography (PSG) and 1-week, at-home actigraphy. Of them, 62% (n=212) were evaluated while in-school. Sex-and-age adjusted z-scores of central obesity, blood pressure, insulin resistance, triglycerides, and HDL were used to define MetS. Sleep apnea was measured using PSG via apnea/hypopnea index. We developed a weighted MSH score to account for being evaluated in-school vs. on-break on all sleep dimensions using coefficients from multivariable linear regression models. PSG-measured sleep apnea was added as a dimension to the weighted MSH score. We examined the associations between the unweighted and two weighted scores, independently, and MetS using linear regression models that adjusted for sex, age, race/ethnicity, and household income.
Results: A higher unweighted MSH score was not significantly associated with lower MetS (β=-0.17, p=0.23). Regression analyses supported divergent coefficients for RU-SATED dimensions; for example, b=0.31 for timing in-school vs. b=-0.37 for timing on-break. A higher weighted MSH score was significantly associated with lower MetS (β=-0.34, p< 0.05). After adding sleep apnea, the weighted MSH score showed an even stronger significant association with lower MetS (β=-0.71, p< 0.001).
Conclusion: An MSH score that accounts for both contextual (schooling) and physiologic (sleep apnea) factors is more strongly associated with cardiometabolic health than one informed by the traditional RU-SATED framework. This finding supports current advocacy efforts to adapt school schedules to adolescent development and the screening for physiologic sleep disorders.

SLEEP DIFFICULTIES AND OBJECTIVELY MEASURED CARDIOVASCULAR DISEASE RISK AMONG CANNABIS CONSUMERS: RESULTS FROM THE HERBAL HEART STUDY

Kylee Krivijanski[1], Amrit Baral[2], Bria-Necole Diggs[2], Ranya Marrakchi El Fellah[1], Sadeaqua Scott[3], Carla Gibbs[3], Claudia Martinez[3], Girardin Jean-Louis[2], Denise Vidot[1]
[1] School of Nursing and Health Studies, University of Miami, [2] University of Miami Miller School of Medicine, [3] University of Miami

Introduction: Cannabis and poor sleep have independently been associated with cardiovascular disease (CVD) risk. This study examines the intersection of sleep, CVD, and cannabis among a cohort of 18-to-35-year-olds.
Methods: Data are from the Herbal Heart Study (N=200), a cohort examining cannabis use and objective measures of subclinical CVD. Cannabis was confirmed by urine. CVD risk was defined as >1 of the following: BMI>25 kg/m2, triglycerides >=150mg/dL, waist-to-hip-ratio (>0.9 male; >0.85 female), total cholesterol >=200mg/dL, LDL >=100mg/dL, BP (systolic >=130mmHg/diastolic >=85mmHg), HDL < 40 for male/<=50 female, VLDL >30mg/dL, and/or cholesterol/HDL ratio >4.5. Difficulty in falling or staying asleep was self-reported via the Medical History Questionnaire. A binary variable, "poor sleep," was created to represent >1 sleep difficulties. Chi-squared tests, Fisher's Exact tests, and multivariable logistic regression estimated the association between sleep variables and CVD risk.

Results: Majority (65.0%) of the sample (mean age: 25.2 years, SD=4.8) were female, 54.5% Hispanic/Latino, and 63.0% cannabis consumers (CB+). CVD risk was less frequent among those with difficulty falling asleep (63.6% vs 82.6%, p=0.01), staying asleep (70.7% vs 83.1%, p=0.02), and poor sleep (70.7% vs 83.1%, p< 0.05). Among CB+, those with difficulty falling asleep (64.5% vs. 82.1%, p=0.04) had lower CVD risk; no significant differences were observed among non-consumers. Demographic-adjusted regression found lower odds of CVD risk among participants with difficulty falling asleep (AOR: 0.35, 95% CI: 0.15-0.81), staying asleep (AOR: 0.26, 95% CI: 0.10-0.67), or poor sleep (AOR: 0.41, 95% CI: 0.20-0.91). CB+ with difficulty falling asleep (AOR: 0.30, 95% CI: 0.10-0.90) and staying asleep (AOR: 0.21, 95% CI: 0.10-0.74) had lower odds of CVD risk; there were no differences among non-consumers.
Conclusion: Self-reported difficulty falling/staying asleep is associated with less CVD risk among 18-to-35-year-old CB+, potentially reflecting behavioral or metabolic differences that warrant further investigation.

GENDER, INFLAMMATION, AND COGNITION AFFECT THE SLEEP TRAJECTORIES OF SUBARACHNOID HEMORRHAGE SURVIVORS

Eeeseung Byun[1], Hilaire Thompson[1], Susan McCurry[1], Suyoung Kwon[2], Suah Park[1], Lalipat Phianhasin[1], Calvin Huynh[1], Theo Bammler[1], Kyra Becker[1], Maria Bleil[1], Michael Levitt[1], Chiyoung Lee[3]
[1] University of Washington, [2] George Mason University, [3] University of Arizona

Introduction: Sleep disturbance after subarachnoid hemorrhage (SAH) impacts recovery and rehabilitation. Longitudinal studies examining trajectories of sleep are needed to understand patients' experiences of sleep over time. We aimed to identify subgroups of SAH survivors based on distinct trajectories of sleep during the first 6 months post-SAH and determine whether they vary according to sociodemographic and clinical characteristics, inflammatory biomarkers (Toll-like receptor 4, Tumor Necrosis Factor-Alpha [TNF-α], Interleukin [IL]-1 beta, and IL-6), and symptoms-related characteristics (depression/anxiety, fatigue, sleep quality, and cognition).
Methods: We conducted a 6-month longitudinal study of 40 SAH survivors (average age: 56.9 years, 32.5% male). Multi-trajectory latent class growth analysis was used to identify salient patient groupings based on the trajectories of objective sleep parameters—sleep efficiency (SE), sleep onset latency (SOL), wake after sleep onset (WASO), and total sleep time (TST)—assessed using actigraphy at 2, 3, and 6 months. Sociodemographic, clinical, and symptom-related characteristics (at 2 months) and inflammatory biomarkers (at 2, 3, and 7 days and 2 months) were compared among trajectory groups using bivariate analyses. Statistical significance was set at $p < 0.1$.
Results: Two trajectory groups were identified: Group 1 (n = 24; "high SE/short SOL/short WASO/adequate TST") and Group 2 (n = 16; "low SE/long SOL/long WASO/insufficient TST"). The mean scores of all sleep parameters remained stable across all three time points (2, 3, and 6 months) in both groups, except for SOL, which significantly decreased in Group 2, but remained higher than that of Group 1. Individuals in Group 1 (vs. Group 2) were more likely to be female and had lower plasma levels of TNF-α and IL-6 at days 3 and 7 post-SAH, respectively. Individuals in Group 1 (vs. Group 2) performed better in the following cognitive domains: immediate memory, visuospatial/constructional ability, attention, and delayed memory tasks at 2 months.
Conclusion: Significant differences between the two trajectory groups were observed in gender proportion, TNF-α and IL-6 plasma levels, and cognitive domains. These findings may help healthcare providers identify patients at risk of developing sleep disturbances. Our study suggests inflammation as a plausible mechanism of sleep disturbances.

TEMPORAL TRENDS AND DISPARITIES IN SLEEP DISORDERS AND CARDIOVASCULAR DISEASE-RELATED MORTALITY IN THE UNITED STATES: A RETROSPECTIVE ANALYSIS

Wajeeh Hassan[1], Javeria Javeid[1], Kalpina Kumar[2], Dinesh Kumar[2], Kabeer Nangdev[3], Tabia Shujaat[2], Usama Ahmed[4], Imama Ahmad[5]
[1] Allama Iqbal Medical College, [2] Dow University of Health Sciences, [3] Chandka Medical College, Shaheed Mohtrama Benazir Bhutto Medical University, [4] Shaikh Khalifa Bin Zayed Al-Nahyan Medical and Dental College, [5] Cleveland Clinic Pulmonary critical care medicine

Introduction: Epidemiological evidence suggests that sleep disorders (SD) are frequently comorbid with cardiovascular diseases (CVD) and have a bidirectional correlation. The increasing prevalence of sleep disorders worldwide is associated with an increase in CVD and its resultant mortality. The objective of our study is to evaluate temporal trends and disparities in sleep disorders and CVD-related mortality among adults in the United States from 1999 to 2020.
Methods: We analyzed the Centers for Disease Control and Prevention's Wide-ranging Online Data for Epidemiologic Research (CDC WONDER) for death certificates (1999-2020) of adults ☐45 years, with SD and CVDs. Age-adjusted mortality rates (AAMR) per 100,000 and annual percent change (APC) were calculated through Joinpoint regression. We used ICD-10 codes to identify sleep disorders (G47) and CVD (I00-I99).
Results: Between 1999 and 2020, 174,649 deaths attributed to CVD and SD were reported in the US. The AAMR increased from 1999 to 2006 [APC=13.6* (95% CI: 11.7 to 16.9)], then rose gradually until 2018 [APC=7.04* (95% CI: 5.9 to 7.6)], with a steep rise from 2018 to 2020 [APC=15.5* (95% CI: 10.6 to 18.1)]. Men had higher AAMR than women (9.6 vs 4.3 respectively). African Americans had the highest AAMR (8.1) while Asians had the lowest (1.9). Geographically, the Midwest had the highest AAMR (8.1) while the Northeast (4.8) had the lowest, with small metropolitan areas (7.7) surpassing large metros (5.6). States above the 90th percentile were Oregon, Wyoming, Montana, Minnesota, and South Dakota.
Conclusion: CVD and SD-related mortality spiked over two decades, especially among African Americans, men, and residents of Midwestern and small metropolitan US. Targeted strategies are needed for prevention, early diagnosis, and CVD and SD burden reduction.

RISING MORTALITY DUE TO SLEEP DISORDERS IN DIABETIC ADULTS: A 22-YEAR RETROSPECTIVE ANALYSIS

Javeria Javeid[1], Laiba Ahmed[1], Wajeeh Hassan[1], Kalpina Kumar[2], Maha Amer[1], Pakeeza Tarar[1], Anees Ali[1], Sheharyar Raashid[3], Imama Ahmad[4]

[1] Allama Iqbal Medical College, [2] Dow University of Health Sciences, [3] Marshall University, [4] Cleveland Clinic Pulmonary critical care medicine

Introduction: There is a complex cause-effect relationship between sleep disorders and diabetes mellitus (DM), with an increased risk of DM in adults with sleeping disorders and patients with DM who have poor sleep quality, sleep duration, and obstructive sleep apnea. Despite this, the relation between sleep inequities and diabetes-related mortality among diverse demographic groups remains underexplored. This retrospective cross-sectional study examines the temporal trends and disparities in mortality due to sleep disorders and DM in the adult United States (US) population from 1999 to 2020.
Methods: We used death certificate data from the US CDC WONDER database of adults ≥25 years old with DM and sleep disorders. Age-adjusted mortality rates (AAMRs) per 1,000,000 population, annual percent change (APC), and average annual percent change (AAPC) were calculated through Joinpoint regression and stratified by gender, race, region, and age groups. We used ICD-10 codes for sleep disorders (G47) and DM (E10-E14).
Results: Between 1999 and 2020, a total of 80,842 deaths attributed to sleep disorders were reported among adults with DM with an overall AAMR of 16.67. The AAMR increased from 1999 to 2006 [APC = 17.94*(95% CI: 15.1 to 22.4)], followed by a steady rise until 2018 [APC = 6.02*(95% CI: 4.6 to 6.8)], and a sharp rise thereafter [APC = 17.3*(95% CI: 10.4 to 20.8)]. Men had double the AAMRs than women (23.2 vs 11.5 respectively) with AAPC of 11.35* vs 10.18* respectively. Non-Hispanic (NH) American Indians had the highest AAMRs (24.2) followed by NH Black (21.2), NH Whites (16.9), Hispanics (11.9), and NH Asians (5.5). Among different age groups, individuals aged 75-84 had the highest mortality rate (57.8) followed by the 65-74 years age group (50.1). Geographically, the Midwest had the highest AAMR (20.8), followed by the West (18.8), South (15.7), and Northeast (11.5). AAMRs were higher in rural areas (18.8) than urban areas (15.9).
Conclusion: Over the past two decades, the mortality from sleep disorders and DM among adults in the US has been on the rise, especially among males, who have double the mortality rates as compared to females, NH American Indians, and residents of rural and Midwestern regions.

DETECTING SLEEP APNEA DURING HOLTER MONITORING WITH A MULTI-DIAGNOSTIC DEVICE

Douglas Kirsch[1], Satish Misra[1], Brennan Torstrick[2], Rohit Mehta[1]

[1] Atrium Health, [2] Huxley Medical, Inc.

Introduction: Obstructive sleep apnea (OSA) affects nearly eighty percent of patients with atrial fibrillation (AF), but most remain undiagnosed. The need to efficiently diagnose and manage patients with AF and other arrhythmias is expected to grow as OSA is increasingly recognized as a key modifiable risk factor. Adding home sleep apnea testing capability to Holter ECG monitors that are already used to assess arrhythmias could facilitate OSA detection and treatment. SANSA (Huxley Medical, Inc.) is a multi-diagnostic chest-worn patch capable of recording ten physiological channels—including ECG, oximetry, and respiratory effort—and was previously validated for diagnosis of OSA against gold standard polysomnography. This study used the monitor to characterize the presence of OSA and arrhythmias in an electrophysiology cohort indicated for ambulatory cardiac monitoring.
Methods: Patients wore the monitor for twenty-four hours as part of an ongoing clinical investigation. The apnea-hypopnea index was calculated using the monitor's automated HSAT algorithm using the three percent (AHI-3%) and four percent (AHI-4%) desaturation threshold criteria. OSA prevalence was determined using an AHI cutoff of five events per hour. Expert cardiac technicians reviewed ECG records to identify AF and other common cardiac arrhythmias.
Results: Data from thirty subjects were available at the time of analysis (73% male, age 52±17 years, BMI 31±8 kg/m2, 70% White, 23% Black, 3% Asian, 10% non-Hispanic). Overall OSA prevalence was 67% using AHI-3% (20/30, 13.3±15.6 [mean ± standard deviation]) and 43% using AHI-4% (13/30, 8.0±12.7). Among subjects with a finding of OSA, 50% (10/20) were moderate and 10% (2/20) were severe using AHI-3%, and 31% (4/13) were moderate and 15% (2/13) were severe using AHI-4%. OSA was most common in subjects with AF (AHI-3%: 86% [6/7], AHI-4%: 57% [4/7]), bi/tri/quadrigeminy (AHI-3%: 90% [9/10], AHI-4%: 50% [5/10]), and ventricular tachycardia (AHI-3%: 100% [2/2], AHI-4%: 50% [1/2]). No subjects with a finding of OSA reported a prior OSA diagnosis.
Conclusion: These data highlight the opportunity for a multi-diagnostic monitor to efficiently detect undiagnosed or untreated OSA during routine Holter monitoring. Collaborating with cardiologists and electrophysiologists to offer streamlined referral pathways could expedite OSA detection and treatment.

ESTIMATING INFLUENCE OF THE RUN-IN PERIOD ON STATISTICAL POWER IN A RANDOMIZED CLINICAL TRIAL OF OSA AND CPAP

Carla Obeid[1], James Bena[2], Joan Aylor[3], Catherine Heinzinger[4], Reena Mehra[5]

[1] Central Michigan University School of Medicine, [2] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [3] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, [4] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [5] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, Seattle, WA

Introduction: A run-in period is sometimes used in randomized clinical trials to exclude non-adherent participants, yet its influence on adherence and statistical power remains underexplored in obstructive sleep apnea (OSA) trials with continuous positive airway pressure (CPAP) intervention. Using Sleep Apnea Stress Study (SASS, NCT00607893) data, we aimed to assess how excluding the run-in period affects key clinical outcomes.

Methods: We generated adherence models and estimated power considering scenarios with and without use of a run-in period. Without use of the run-in period, adherence for previously excluded patients was adjusted to 0-100% of the observed adherence post-randomization. Power estimates were based on two-sided t-tests with sample sizes reflecting randomized groups and the full potential sample, assuming inclusion of previously excluded participants.
Results: Post-randomization CPAP adherence among participants who completed the 2-week run-in period was 58%. Without the run-in, adherence for the previously excluded group post-randomization ranged from 47% (0% adjusted adherence) to 59% (100% assuming adherence equivalent to randomized participants). Power to detect a large standardized effect size(0.8) in clinical outcome biomarkers of soluble interleukin-6 receptor and augmentation index increased from 0.80 (with run-in and observed adherence) to 0.93 (without run-in and 100% adjusted adherence). Power for systolic blood pressure (SBP) detection rose from 0.34 (with run-in and observed adherence) to 0.47 (without run-in and 100% adjusted adherence). Without the run-in period, if sample size subsequently increased to include previously excluded participants, statistical power was enhanced, even if previously excluded participants maintained the same post-randomization adherence. If sample size was fixed, including previously excluded participants modestly improved power only when adherence approximated that of randomized participants. Under other adherence scenarios, power was diminished. Observed SBP differences were smaller than hypothesized, which may contribute to reduced power for SBP detection under these models.
Conclusion: Run-in period exclusion potentially enhances statistical power, particularly with larger sample size or high adherence among previously excluded participants. However, advantages diminish when adherence is lower among the excluded cohort. Findings underscore the need for careful consideration of anticipated adherence and sample size adjustments when integrating the run-in period in CPAP clinical trials in OSA.

INNOVATIONS IN TIME SERIES DATA INTEGRATION IN A POLYSOMNOGRAPHIC FOUNDATIONAL MODEL INFORMING RISK GROUPS

Matheus Lima Diniz Araujo[1], Catherine Heinzinger[1], Erhan Bilal[2], Kristen Beck[3], Samer Ghosn[4], Nancy Foldvary-Schaefer[1], Carl Saab[4], Jeffrey L. Rogers[2], Reena Mehra[5]
[1] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [2] Digital Health, IBM T.J. Watson Research Center, Yorktown Heights, NY, [3] Digital Health, IBM Almaden Research Center, San Jose, CA, [4] Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [5] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, Seattle, WA

Introduction: Despite the abundance of polysomnography (PSG) data, the limited summary metrics used in existing approaches may not provide the most informative insights for clinical decision-making. We hypothesized that a new data-driven clustering method using the entire multimodal raw PSG data could enable a precise risk stratification approach. We leveraged a new clinical data set to facilitate this data-driven approach and create a novel Foundation Model.
Methods: We utilized 10,000 PSGs conducted at the Cleveland (1/2012-12/2022) and custom artificial intelligence techniques that incorporate time-series data, to develop a Foundation Model from raw PSG data. We optimized this new model to classify sleep stages, respiratory events, and oxygen desaturations. Resulting embeddings were used to cluster patients into distinct risk groups with a k-means algorithm. Baseline characteristics were compared between risk groups using chi-square tests for categorical variables and Welch's ANOVA for continuous variables. Means and standard deviations are reported.
Results: Optimal stratification of embeddings was achieved with five clusters. Resulting risk groups (RG) had a graded increase in age, male predominance, cardiovascular risk factors, and sleep-disordered breathing(SDB) severity from RG1(n=3,357) to RG5(n=363). Males were more prevalent in RG4(n=1,144; 60.8%) and RG5(66.4%) and least in RG2(n=1,877; 37.6%). Body mass index was lowest in RG2(32.7±9.1kg/m2) and highest in RG5(35.4±10.4kg/m2). RG4 and RG5 were the oldest(58.6±16.1years) and RG2 the youngest(44.0±15.0years). RG1 had intermediate SDB with apnea hypopnea index (AHI:12.4±12.4), total sleep time (TST:328±61.1min), and risk (hypertension:59.8%,diabetes II:32.7%), and lowest cognitive impairment(14.1%). RG2 had the mildest SDB (AHI:5.4±6.4), longest TST (342±71.6min), and lowest cardiovascular risk (hypertension:47.5%,diabetes II:24.7%). RG3(n=2,867) had intermediate SDB and risk. RG4 had more abnormal PSG measures (AHI:22.7±13.2, TST:201±73.9min), more risk (hypertension:75.6%,diabetes II:65.2%), and highest major adverse cardiovascular events (43.6%) but lowest migraine (11.5%). RG5 had the most severe SDB (AHI:37.3±39.0), lowest TST (98.4±89.0min), and high risk (hypertension:77.4%,diabetes II:44.6%). All p-values were < 0.001.
Conclusion: We created a Polysomnographic Foundational Model to stratify patients into risk groups characterized by different comorbidities not completely explained by traditional measures. RG4 and RG5 exhibited more severe SDB and unique clinical characteristics that prompt future investigation and warrant more attention from healthcare providers.

RELATIONSHIP BETWEEN SLEEP AND POSTOPERATIVE DELIRIUM IN CARDIAC SURGERIES: A SCOPING REVIEW

Hesam Varpaei[1], Lorraine Robbins[1], Pallav Deka[1], Fabrice Mowbray[1], Stuart Quan[2]
[1] Michigan State University, [2] Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Harvard Medical School.

Introduction: Perioperative sleep disturbance is a risk factor for postoperative delirium (POD). The two-fold aim of this study is to: evaluate the relationship between perioperative sleep disturbance and POD after cardiac surgeries (CS); and examine sleep recovery after cardiac surgeries in patients with and without POD.
Methods: We followed the Arksey and O'Malley framework for scoping review. Following the PRISMA statement and using keywords, we electronically searched five different electronical databases (PubMed, Cumulated Index to Nursing and

Allied Health Literature, Web of Science, Scopus, EMBASE). The search was conducted in July 2024 with no date limitation. Original English articles that assessed sleep and POD in patients who had CS were eligible.
Results: Of the 14 included studies (28.5% interventional), most studies were from Iran (29%) followed by China (29%) and the US (21%). Reports indicated that the incidence of POD ranged from 5.3% to 50%. Patients who developed POD during hospitalization had significantly higher postoperative self-reported sleep disturbances after 3 years. Also, POD patients had a significantly higher Pittsburg Sleep Quality index (>5) one year after surgery. Preoperatively, high apnea-hypopnea index, low sleep efficiency, short sleep duration, and a high non-rapid eye movement arousal index predicted POD, indicating patients with poor sleep quality and insomnia are more likely to develop POD after CS. Although dexmedetomidine (an anesthetic) did not improve sleep quality 30, 60, 90, and 180 days after surgery compared to a placebo, it did help prevent POD. However, melatonin (3 mg) improved sleep quality when compared to Oxazepam (10 mg) after surgery.
Conclusion: Poor sleep quality and insomnia are the most common perioperative sleep disturbances and risk factors for POD. Melatonin improved post-surgery (in hospital) sleep quality but had no impact on POD. In contrast, dexmedetomidine prevented POD but did not improve post-hospital discharge sleep quality. Patients may need at least one month to achieve preoperative sleep quality, which may not necessarily be classified as good-quality sleep. Therefore, full sleep recovery may take 3 to 6 months post-CS. More research on the effectiveness of non-pharmacological interventions targeting sleep improvement, such as earplugs and eye masks after surgery, is warranted.

SLEEP QUALITY AND RESPIRATORY DISTURBANCE IN PATIENTS WITH CARDIOVASCULAR CONDITIONS AND TYPE 2 DIABETES MELLITUS

Nayana Williams[1], Jeremy Weingarten[2], Boris Dubrovsky[1], John Cunningham[1]
[1] NewYork-Presbyterian Brooklyn Methodist Hospital, [2] Well Cornell Medicine/NewYork-Presbyterian Brooklyn Methodist hospital

Introduction: Increased likelihood of poor sleep and OSA have been associated with both cardiovascular conditions (CVC) and type 2 diabetes mellitus (T2DM). A CV-T2DM comorbidity may be associated with a greater risk for sleep and respiratory disturbances. In this study, polysomnographic (PSG) measures and Pittsburgh Sleep Quality Index (PSQI) were compared between 4 patient groups: CVC, T2DM, CVC-T2DM, and controls.
Methods: From 1678 consecutive diagnostic PSGs, patients were excluded with < 120 minutes of total sleep time (TST), history of shift work and significant psychiatric and medical conditions other than CVC and T2DM. This yielded 36 CVC patients (18 women, 7 white, M[age]=55.3±13.7, M[BMI]=33.3±8.6), 57 T2DM patients (37 women, 8 white, M[age]=57.7±11.9, M[BMI]=34.8±6.2), 10 CV-T2DM patients (4 women, 3 white, M[age]=63.5±14.5, M[BMI]=29.1±3.7), and 271 controls (151 women, 90 white, M[age]=49.3±15.1, M[BMI]=34.6±7.8). MANCOVA was used for between-group comparisons of TST, N1%, N3%, REM%, sleep latency, REM latency, sleep efficiency, wake after sleep onset, awakenings, arousal index, AHI, SpO290% nadir, time (minutes) below SpO290%, and PSQI. Covariates were sex, age and BMI.
Results: MANCOVA revealed significant group effects on PSQI (p=0.02) and, of all PSG variables, on time below SpO290% (p=0.05). LSD post-hoc comparisons with controls revealed higher PSQI in CVC patients (M[CVC]=10.4±4.6 vs. M[Controls]=8.4±3.4 (p=0.01), and longer time below SpO290% in CVC-T2DM patients (M[CVC-T2DM]=30.1±70.0 vs. M[Controls]=8.1±28.7 (p=0.04). No other between-group comparisons were significant. Mean group AHI and SpO290% nadir values were, respectively: AHI: M[CVC]=16.1±19.9, M[T2DM]=21.7±24.4, M[CVC-T2DM]=12.9±11.9, M[Controls]=15.8±20.5; SpO2% nadir: M[CVC]=83.5±11.1, M[T2DM]=82.9±10.2, M[CVC-T2DM]=83.0±9.6, M[Controls]=85.6±8.0.
Conclusion: PSG-defined sleep and respiratory disturbance variables were essentially the same in these small samples of CVC, T2DM and comorbid CVC-T2DM patients, and did not differ from controls, with one exception: CVC-T2DM patients spent more time with SpO2 below 90% relative to controls, suggesting the possibility of a cumulative effect of CVC-T2DM comorbidity on respiratory parameters. As PSQI was higher in the CVC group in comparison with controls, subjective sleep quality in these patients may relate to factors other than PSG variables.

OBESITY/OSA PHENOTYPES RELATIVE TO HYPERTENSION AND DIABETES: A CROSS-SECTIONAL STUDY IN A MEXICAN POPULATION

Matilde Valencia-Flores[1], Victoria Santiago Ayala[2], Montserrat Resendiz-Garcia[3], Jorge Oseguera Moguel[4], Aldo Torre[3], Gabriela Gaytán Cervantes[5], Carlos A. Aguilar-Salinas[6], Donald Bliwise[7]
[1] Sleep Laboratory, Neurology Department, UNAM-INCMNSZ, [2] Sleep Laboratory, Department of Neurology and Psychiatry, [3] INCMNSZ, [4] Department of Cardiology, INCMNSZ, [5] Sleep Laboratory, Department of Neurology and Psychiatry, INCMNSZ, [6] Research Unit in Metabolic Diseases, INCMNSZ, [7] Emory University School of Medicine

Introduction: A strong association between obstructive sleep apnea (OSA) and obesity has been well documented, however, not all obese OSA patients show similar comorbidities. Two of the most common comorbidities shown by such patients are hypertension and diabetes. Hypertension accompanying OSA may reflect increased sympathetic nervous system activity, decreased baroreflex sensitivity, vascular endothelial dysfunction, and altered metabolism of salt and water, all of which have been demonstrated to accompany disordered breathing during sleep. In addition to OSA, other aspects of sleep architecture and disrupted chronobiology, including short duration sleep, sleep-related movement disorders (restless legs syndrome (RLS)/ periodic limb movements of sleep (PLMS), bruxism), and circadian rhythm disruption have been associated with prevalent and/or incident hypertension. The objective of this work was to explore/ examine whether visceral fat and sleep measures would differentiate patients with obesity and obstructive sleep apnea (OSA)/phenotypes. A secondary objective was to determine which sleep and metabolic variables predicted hypertension in obese patients.

Methods: An observational, cross-sectional study was conducted comparing three obesity/phenotypes: 1) Obesity/OSA without hypertension or diabetes; 2) Obesity/OSA with hypertension; 3) Obesity/OSA with hypertension and diabetes. Polysomnographic (PSG) measures of sleep and self-reported aspects of sleep together with novel measures of lipid and glucose metabolism (Metabolic Score for Visceral Fat (METS-VF), Metabolic Score for Insulin Resistance (METS-IR)) were compared between groups. Multiple regression models were used to determine which variables predicted group status.
Results: Patients with obesity/OSA and hypertension had a shorter total sleep time and a longer time of wakefulness after sleep initiation (WASO). These measures were associated with hypertensive group status using multiple regression models, which incorporated both visceral fat (METS-VF) and insulin resistance (METS-IR). Both lower total sleep time (TST) (OR=0.988, p=0.05) and higher METS-VF (OR=10.315, p=0.05) independently predicted hypertensive group status ($\chi 2$ =11.591, p=0.021; R2 = 0.218). No such associations were observed for METS-IR. Sleep measures did not differentiate the group that included diabetes.
Conclusion: Our data suggest that, in a Mexican population with marked obesity and severe sleep apnea, hypertension was related to sleep duration and continuity.

SLEEP HEALTH AND DISABILITY AMONG ADULTS WITH INFLAMMATORY BOWEL DISEASE

Samantha Conley[1], Stacy Al-Saleh[2], Melanie Schneekloth[1], Kendra Kamp[3], Melissa Pinto[1], Sunanda Kane[1], Nancy Redeker[4]
[1] Mayo Clinic, [2] Mayo Clinic Arizona, [3] University of Washington, [4] University of Connecticut

Introduction: The majority of adults with inflammatory bowel disease (IBD) experience disability which is not fully explained by disease activity. Up to 80% of adults with IBD experience poor sleep health, which is associated with disability in other populations; however, the relationship between disability and sleep health among patients with IBD is largely unexamined. The purpose of this study was to compare the sleep health characteristics of those with and without IBD-related disability.
Methods: We recruited adults (18 to 59 years old) with IBD from a single academic medical center from 2022 to 2024. We measured disease activity using the Manitoba IBD Index and sleep using the PROMIS Sleep Disturbance and PROMIS Sleep-Related Impairment scales, the Insomnia Severity Index, and 14 days of wrist-worn actigraphy (Phillips Spectrum Plus, Phillips Respironics). We asked participants how many days they missed or had at least 50% reduced productivity in paid work or household work or missed leisure activities in the last 3 months related to their IBD. Disability was defined as missing six or more day over three months. We conducted bivariate analyses and logistic regressions to study associations.
Results: Among 83 adults with IBD [mean age = 40.4 years (SD 10.7), 59 (71.1%) were female, 56 (71.1%) had Crohn's disease], and 49 (62.0%) had IBD-related disability. Patients with disability had more severe sleep disturbance (56.4 vs. 51.0, p <.001), sleep-related impairment (58.3 vs 50.3, p <.001), more severe insomnia (12.7 vs. 9.4, p =.029), and actigraph-measured higher wake after sleep onset (41.6 minutes vs. 34.0 minutes, p = 0.012) and lower sleep efficiency (85.1% vs. 87.9%, p = 0.032) compared to those without disability. After controlling for age and disease activity, sleep-related impairment (OR = 1.1, 95% CI 1.03, 1.15) was independently associated with disability.
Conclusion: Patients with IBD-related disability experience poor sleep health. Sleep related daytime impairment uniquely contributed to disability when controlling for disease activity. Sleep interventions need to be tested in adults with IBD to determine if they are effective at addressing disability in this population.

COMORBID NONRESTORATIVE SLEEP ACCELERATES MORTALITY IN COMMUNITY ADULTS WITH COMMON CHRONIC CONDITIONS

Eriya Takahashi[1], Takuya Yoshiike[1], Tomohiro Utsumi[1], Aoi Kawamura[1], Kentaro Nagao[1], Megumi Hazumi[1], Shinobu Okamura[1], Mai Fuwa[1], Shun Matsushima[1], Masahito Nangaku[1], Ayano Kimura[2], Shingo Kitamura[1], Kentaro Matsui[3], Kenichi Kuriyama[1]
[1] Department of Sleep-Wake Disorders, National Institute of Mental Health, National Center of Neurology and Psychiatry, [2] Sleep Disorders Center, National Center of Neurology and Psychiatry, [3] Department of Laboratory Medicine, National Center Hospital, National Center of Neurology and Psychiatry

Introduction: Nonrestorative sleep (NRS) is a subjective daytime symptom reflecting poor sleep quality. We recently demonstrated a longitudinal association between NRS and increased mortality in US community adults. NRS has been reported to co-occur with physical and mental conditions and to predict the development of common chronic conditions such as diabetes, hypertension, obesity, and depression. However, it remains unclear whether NRS comorbid with common chronic conditions accelerates mortality.
Methods: We analyzed data from the Multi-Ethnic Study of Atherosclerosis (MESA), a community-based cohort study in US. The analysis included data from 5,818 adults who provided self-reported sleep-related information during the follow-up period from 2005 to 2015. The sample was categorized into four groups based on the presence of NRS and specific conditions including diabetes, hypertension, obesity, and depression: (1) NRS-/chronic condition (CC)- (reference), (2) NRS+/CC-, (3) NRS-/CC+, and (4) NRS+/CC+. We compared the multivariable-adjusted hazard ratios for all-cause mortality among the four groups using Cox proportional hazards regression. We applied three different models to adjust for the known potential confounders including demographic, cardiovascular, and sleep-related variables. Furthermore, we examined the interaction between NRS and each condition by calculating the index of interaction (relative excess risk due to interaction; RERI).
Results: A total of 863 deaths (14.8%) were reported over a median (interquartile range) follow-up period of 9.4 (9.0–9.8) years. The NRS+/CC+ group had a higher mortality risk compared to the NRS-/CC- group for all conditions. Relative increases in hazard ratio of the NRS+/CC+ group compared to the NRS-/CC+ group varied across conditions: diabetes, +123%; hypertension, +33%; obesity, +85%; and depression, +62% in the fully adjusted model. Notably, the elevated mortality risk associated

with chronic conditions comorbid with NRS was independent of self-reported sleep duration and nocturnal insomnia symptoms. A significant interaction was observed between NRS and diabetes (RERI 0.98, 95% CI: 0.02–1.94).
Conclusion: Our findings suggest that NRS accelerates chronic condition-related mortality in community adults, independently of subjective sleep duration and insomnia symptoms. These results underscore the clinical and epidemiological importance of addressing NRS.

CO-MORBID INSOMNIA AND OBSTRUCTIVE SLEEP APNEA AUGMENTS CARDIAC AUTONOMIC BURDEN TO INCREASE ALL-CAUSE MORTALITY

Hua Qin[1], Fernando Vaquerizo-Villar[2], Jan W. Kantelhardt[3], Thomas Penzel[4], Xiaowen Zhang[1]
[1] Guangzhou medical university, [2] Universidad de Valladolid, [3] Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, [4] Charité - Universitätsmedizin Berlin

Introduction: Co-morbid insomnia and sleep apnea (COMISA) is associated with increased mortality. However, it remains unclear whether COMISA exerts cumulative deleterious impact on autonomic regulation to augment incidence of deaths compared to insomnia alone and OSA alone. This study aimed to evaluate an association of heart rate variability (HRV) as a marker of autonomic burden to all-cause mortality in patients with COMISA.
Methods: 5023 participants who underwent unattended polysomnography and completed sleep questionnaires on insomnia and daytime impairment from the Sleep Heart Health Study were included. The diagnosis of COMISA required the criteria for both insomnia (difficulties initiating sleep, maintaining sleep, and/or early morning awakenings on 16-30 times/month and daytime impairment) and sleep apnea (an apnea-hypopnea index [AHI]≥15 events/h) to be met. HRV measures were computed from a 5-min ECG segment extracted during wakefulness prior to sleep and sleep using linear methods, detrended fluctuation analysis, entropy, symbolic dynamics, deceleration capacity (DC) and acceleration capacity (AC). Analysis of covariance controlling for relevant covariates was used to compare differences in HRV characteristics among control, insomnia, OSA, and COMISA groups. Multivariable-adjusted Cox analysis and receiver operating characteristic analysis were conducted to estimate the associations between HRV metrics and all-cause mortality in COMISA subgroup.
Results: Of the 5255 participants, 2697 (51.6%) were controls without insomnia or OSA, 170 (3.3%) had only insomnia, 2221 (42.5%) had only OSA, and 137 (2.6%) had COMISA. 42 deaths occurred in COMISA (30.6%). By comparisons of HRV metrics among these 4 groups, patients with COMISA were associated with elevated autonomic burdens, showing decreased parasympathetic activity during wakefulness and sleep compared to controls. In the multivariable Cox model, DC was an independent predictor associated with all-cause mortality in COMISA during wakefulness (hazard ratio [HR], 0.91; 95%CI, 0.84-0.99; P=0.026) and sleep (HR, 0.86; 95%CI, 0.77- 0.96, P=0.007). DC demonstrated favorable performance in identifying mortality risk in COMISA during wakefuless (the area under the curve, AUC, 0.78) and sleep (AUC, 0.76).
Conclusion: COMISA predisposed HRV impairments to be related to increased all-cause mortality through decreased parasympathetic function. Further studies are warranted to investigate the role of autonomic burden in clinical outcomes of COMISA.

DISTINGUISHING PATTERNS OF COMORBIDITY PROGRESSION IN OBSTRUCTIVE SLEEP APNEA USING REAL-WORLD DATA

Matthew Goodman[1], Raichel Alex[2], Scott Sands[2], Ali Azarbarzin[2], Kelly Dunham[3], Salma Batool-Anwar[1], Milena Pavlova[1], Lawrence Epstein[1], Susan Redline[4], Brian Cade[4]
[1] Brigham and Women's Hospital and Harvard Medical School, [2] Brigham and Women's Hospital and Harvard Medical School, [3] Brigham and Women's Faulkner Hospital, [4] Department of Medicine, Brigham and Women's Hospital, Harvard Medical Sch ool

Introduction: Obstructive sleep apnea (OSA) is a prevalent disorder associated with numerous comorbidities, including cardiometabolic and neuropsychiatric diseases. Heterogeneity in presentation and multi-morbidity complicates disease management. This analysis adopts a validated data-driven approach, age-dependent topic modeling (ATM; PMID 37814053), to group OSA-related diagnoses into longitudinal trajectories, elucidating comorbidity progression and its relationship with OSA.
Methods: We analyzed longitudinal electronic health records (EHR) from 38,600 OSA patients in the Mass General Brigham (MGB) system using 411 diagnoses previously associated with OSA. OSA status was ascertained with a validated algorithm incorporating EHR and available polysomnography (PSG). ATM analysis then grouped incident EHR diagnoses into age-dependent patterns (topics) optimized to predict future diagnoses from any given age. Model weights were used to calculate individualized risk scores for each topic, which were standardized and tested for association with OSA in a separate validation cohort of 7,774 OSA cases and 15,294 controls, matched 2:1 on propensity score (accounting for age, sex, BMI, ancestry, and healthcare utilization), and further adjusted for residual confounding.
Results: ATM identified 17 distinct age-dependent comorbidity topics in OSA patients. Of these, 14 were significantly associated ($p< 0.05/17$) with higher scores in OSA cases, representing greater risk for diverse conditions including neuropsychiatric, cardiometabolic, and respiratory disorders. The strongest associations were observed for: 1. A neuropsychiatric topic ($\beta=0.43$, $p< 1.88e-222$), progressing from mood disorders (early-adulthood) to insomnia (middle-age) and cognitive decline (old-age). 2. A respiratory-cardiovascular topic ($\beta=0.35$, $p< 1.35e-147$), progressing from chronic respiratory infections (childhood) to hearing loss and hypertension (middle-age), and cardio-vascular disease (old-age). For example, a 60-year-old with prior mood disorders and incident insomnia is expected to score high in the neuropsychiatric topic, a scenario observed more frequently in OSA, suggesting risk of later cognitive decline.

Conclusion: This study highlights associations between OSA and distinct multimorbidity patterns and suggests age-dependent comorbidity progression as a framework for understanding comorbidity burden in OSA. These findings have potential to guide targeted management strategies and interventions. Future work will integrate longitudinal data and OSA endotypes to further investigate disease heterogeneity and explore physiologically relevant pathways.

GENDER AND RACIAL DISPARITIES IN OBSTRUCTIVE SLEEP APNEA MORTALITY AMONG ADULTS WITH OBESITY IN THE UNITED STATES: A 22-YEAR ANALYSIS

Wajeeh Hassan[1], Javeria Javeid[1], Kalpina Kumar[2], Laiba Ahmed[1], Usman Hassan[1], Sohaba Iqbal[1], Faseeh Haider[1], Muhammad Inam[3], Imama Ahmad[4]
[1] Allama Iqbal Medical College, [2] Dow University of Health Sciences, [3] Marshall University, [4] Cleveland Clinic Pulmonary critical care medicine

Introduction: Obesity and Obstructive Sleep Apnea (OSA) are two of the most prevalent conditions in nutrition sciences and sleep medicine, respectively. Obesity is the strongest risk factor for OSA and its consequent mortality. Therefore, the objective of our study is to evaluate temporal trends and disparities in OSA mortality among adults with obesity stratified by gender, race, and age groups in the United States (US) from 1999 to 2020.
Methods: This retrospective analysis used death certificate data from the US CDC WONDER database of adults ≥25 years with obesity and OSA. Age-adjusted mortality rates (AAMRs) per 1,000,000 population, annual percent change (APC), and average annual percent change (AAPC) were calculated through Joinpoint regression. We used ICD-10 codes for OSA (G47.3) and obesity (E66).
Results: Between 1999 and 2020, a total of 67,999 deaths attributed to OSA and obesity were reported with an overall AAMR of 14.28. The AAMR increased from 1999 to 2006 [APC = 13.93*(95% CI: 7.8 to 22.5)], followed by a steady increase from 2006 to 2018 [APC = 4.89 (95% CI: -0.45 to 18.6)], and a sharp rise thereafter [APC = 13.3*(95% CI: 5.4 to 18.2)]. Men had higher AAMRs than women (17.85 vs 11.02 respectively) with AAPC of 8.49 vs 8.22 respectively. Non-Hispanic (NH) American Indians had the highest AAMRs (21.3) followed by NH African Americans (20.9), NH Whites (14.4), Hispanics (9.3), and NH Asians (3.1). Among different age groups, individuals aged 65-74 had the highest mortality rate (33.5) followed by the 75-84 years age group (28.9). Geographically, the West had the highest AAMR (16.5), followed by the Midwest (16.4), South (13.5), and Northeast (10.6). AAMRs were higher in rural areas (17.1) than urban areas (13.7).
Conclusion: An overall increasing trend in mortality was seen in adults with obesity due to OSA in the US from 1999 to 2020. There are notable disparities in mortality among NH American Indians, males over 65 years, and residents of rural and western regions. This highlights the need for early diagnosis of OSA in obese patients and timely intervention such as weight loss and CPAP in high-risk populations.

CPAP ADHERENCE TRAJECTORY AND GLYCEMIA AMONG PATIENTS WITH TYPE 2 DIABETES AND OBSTRUCTIVE SLEEP APNEA

Xiao Tan[1]
[1] Zhejiang University

Introduction: Despite evidence of a relationship among obstructive sleep apnea (OSA), metabolic dysregulation, and diabetes, it is uncertain whether long-term continuous positive airway pressure (CPAP) treatment can improve glycemia among patients with type 2 diabetes and OSA.
Methods: CPAP adherence and personal data were collected among 329 participants in the Swedish sleep apnea registry (SESAR). Glycated hemoglobin A1c (HbA1c) were obtained from the Swedish National Diabetes register (NDR) during a median follow-up of 2.2 years. Linear mixed models were used to investigate how CPAP usage changed longitudinally and how the change integrated to HbA1c's trend.
Results: Long term moderate and high CPAP adherence was associated with reduction in HbA1c compared to low adherence, with the multivariable-adjusted β coefficients of -4.567 (-7.781, -1.353), and -4.784 (-8.313, -1.255), respectively. Joint analyses with baseline and trajectories of CPAP adherence show that, compared to irregular-low users, those regular users with moderate and high trajectories over time experienced reduction in HbA1c, with the multivariable-adjusted β coefficients of -5.830 (-9.419, -2.240), and 5.316 (-8.978, -1.653), respectively.
Conclusion: Among patients with established OSA and T2D, we found evidence that moderate and high CPAP therapy over several years significantly improve HbA1c over low adherence. Early identification of patients with irregular use and low adherence could improve glycemia by further interventions.

PREVALENCE AND RISK FACTORS FOR SLEEP DISTURBANCE IN ACUTE RESPIRATORY FAILURE IN INTENSIVE CARE UNIT SURVIVORS

Sundus Imran[1], Dexter Corlett[2], Anthony J. Perkins[3], Zachary Koehler[1], Sikandar H Khan[1], Sujuan Gao[2], Babar Khan[1]
[1] Division of Pulmonary, Critical Care, Sleep, and Occupational Medicine, Indiana University School of Medicine, IN, USA, [2] Department of Internal Medicine, Indiana University School of Medicine, [3] Department of Biostatistics and Health Data Science

Introduction: Patients admitted to the intensive care unit (ICU) due to acute respiratory failure (ARF) frequently experience sleep disturbances which can persist for years. Our study aims to assess the relationship between clinical characteristics and insomnia severity in ARF ICU survivors.
Methods: This is a secondary analysis of the mobile critical care recovery program (mCCRP) clinical trial (n = 466) which included patients 18 years or older admitted with ARF requiring invasive ventilation at 4 Indiana hospital ICUs. Demographics, comorbidities, and clinical characteristics were assessed using the electronic medical record during the index admission. Severity of illness was assessed using the Acute Physiology and

Chronic Health Evaluation Score (APACHE-II). Sleep quality was assessed with the Insomnia Severity Index (ISI) at ICU discharge. ISI scores range from 0 to 28, with higher scores indicating worse insomnia. Patients who completed an ISI at discharge were included in this analysis. Logistic regression was performed to measure the relationship between demographic and clinical characteristics and odds of clinically significant insomnia.
Results: A total of 362 patients were included in the analysis. The mean age of the cohort was 55.2 years (SD 14.0), 53.6% were female, 37.6% identified as Black, and 17.7% had pre-existing sleep disorders. Of the 362 patients, 31.2% reported clinical insomnia and 29.6% reported subthreshold insomnia at ICU discharge. Patients with clinical insomnia had significantly higher pre-ICU diagnoses of anxiety (47%) compared with those with subthreshold insomnia (31%) or no insomnia (25%, p =0.001). Participants with clinical insomnia also had higher rates of pre-ICU depression (53%) compared with those with subthreshold insomnia (31%) or no insomnia (25%, p = 0.032). In a logistic regression model, patients with pre-ICU anxiety had a significantly higher odds of developing clinical insomnia (OR 2.07, 95% CI 1.17 – 3.65). Additionally, patients with a neurologic etiology for their ARF admission had higher odds of clinical insomnia (OR 3.12, 95% CI 1.35 – 7.22).
Conclusion: Insomnia was highly prevalent in our cohort. Mental health and neurological diagnoses were significant risk factors for post-ICU sleep dysfunction. Future research is needed to help determine interventions to reduce sleep disturbances during and after critical illness.

IMPACT OF DERMATOLOGICAL DISEASES ON SLEEP, INFLAMMATION, AND CARDIOMETABOLIC RISK: FINDINGS FROM THE EPISONO STUDY

Maingredy Souza[1], Ellen Xerfan[2], Daniela Rosa[3], Priscila Morelhão[4], Tathiana Alvarenga[4], Sergio Tufik[5], Monica Andersen[5]

[1] Departamento de Psicobiologia, Universidade Federal de São Paulo, São Paulo, Brazil, [2] Department of Psychobiology, Universidade Federal de São Paulo, [3] Departamento de Microbiologia, Imunologia e Parasitologia, Universidade Federal de São Paulo, [4] Sleep Institute, [5] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Dermatological diseases (DD), including dermatitis, psoriasis, and vitiligo, impact millions worldwide and are increasingly linked to sleep disturbances. Symptoms like pruritus disrupt sleep, triggering pro-inflammatory states that can worsen these conditions and their comorbidities. Despite these connections, this field remains underexplored. This study examined the influence of DD, individually and combined, on sleep parameters, the prevalence of sleep disorders, and associations with inflammatory and cardiometabolic biomarkers using data from the 4th edition of the São Paulo Epidemiological Sleep Study (EPISONO).
Methods: Data from 743 participants (20–80 years) who completed the EPISONO General Health Questionnaire were analyzed. Among these, 86 were identified with DD: dermatitis (n=59), psoriasis (n=19), vitiligo (n=8), and coexisting DD (n=8), compared to 657 Non-DD individuals. Propensity score matching (PSM) was applied to create 86 balanced pairs matched by age, sex, ethnicity, and socioeconomic status. Polysomnography (PSG), validated sleep questionnaires, and biochemical markers were assessed.
Results: Participants with DD experienced significantly poorer sleep quality compared to the Non-DD group. Excessive daytime sleepiness was 2.11 times more prevalent in individuals with dermatitis and 6.36 times higher in those with vitiligo. Psoriasis was linked to reduced mean oxygen saturation and elevated high-sensitivity C-reactive protein, reflecting an increased cardiovascular risk. No significant associations were observed between DD and sleep disorders like obstructive sleep apnea, insomnia, bruxism, or periodic limb movement disorder.
Conclusion: This study underscores the interplay between DD, sleep health, and systemic inflammation. It is the first to examine sleep patterns in vitiligo participants using PSG. These findings highlight the importance of integrating sleep assessments and systemic factors into DD management to prevent cardiovascular complications, improving health and quality of life for these patients.

THE IMPACT OF SLEEP DISTURBANCE ON DISEASE ACQUISITION; RELATIONSHIPS BETWEEN SLEEP AND MULTIMORBIDITY IN A LARGE-SCALE U.S. SAMPLE

Melissa Baker[1], Jillian Crocker[1], Ashley Stripling[1]

[1] Nova Southeastern University

Introduction: Multimorbidity, or the presence of two or more co-occurring chronic medical conditions, is increasingly prevalent and impactful within the United States (US). Given the significant personal and financial cost of multimorbidity, understanding modifiable behavioral mechanisms that increase susceptibility is essential to inform intervention strategies. Disturbed sleep has been identified as one such modifiable factor. The current study's aim is to examine the impact of sleep disturbance on multimorbidity in adults using longitudinal data from the Survey of Midlife Development in the United States (MIDUS) to better inform person centered sleep interventions and future research.
Methods: Study participants (N=565) self-reported information regarding medical history and subjective sleep quality through questionnaires administered over the phone and in-person at two timepoints (MIDUS 2: 2004-2006, MIDUS 3: 2013-2014). The speed of multimorbidity was operationalized as the difference in number of chronic medical conditions across study timepoints. Hierarchical linear regression was used to assess the association between sleep disturbances and the change in number of chronic diseases. The model was adjusted for the set of covarying demographic and clinical factors (i.e. sex, age, race, ethnicity, education, BMI) to determine the unique contribution of sleep disturbance upon speed of multimorbidity acquisition across time.
Results: The sample was predominantly female (59.4%), 66 years-old, had an average of 2.46 chronic medical conditions at

T1 and 3.26 conditions at T2. Results of the hierarchical linear regression indicated that sleep disturbances significantly predicted the rate of chronic disease accumulation after controlling for clinical and demographic factors ($R^2\Delta$ =.014, p =.005). Significant predictors included BMI in Step 1 (β =.104, p=.016) and Step 2 (β =.094, p=.027), and Sleep Disturbance in Step 2 (β=.120, p=.005).
Conclusion: Results of this analysis demonstrate that the speed at which individuals acquire chronic diseases is accelerated in the presence of disturbed sleep. Given the significant impact of multimorbidity on both individual and systemic levels, the identification of nonspecific disease factors that contribute to the acquisition of multimorbidity presents an important opportunity to develop earlier intervention and prevention protocols to help mitigate negative health consequences and promote longevity.

RISK OF METABOLIC ASSOCIATED FATTY LIVER DISEASE (MAFLD) IN PATIENTS WITH NARCOLEPSY: A COHORT STUDY

Munaza Riaz[1], Christopher Kaufmann[1], Rakesh Bhattacharjee[2], Wei-Hsuan Lo-Ciganic[3], Debbie Wilson[1], Atul Malhotra[2], Emerson Wickwire[4], Haesuk Park[1]
[1] University of Florida, [2] University of California, San Diego, [3] University of Pittsburgh, [4] University of Maryland Baltimore

Introduction: Metabolic-associated fatty liver disease (MAFLD) is a major public health concern and is closely linked to cardiometabolic dysfunction. While prior research has investigated the relationship between narcolepsy and cardiovascular disease, no studies have examined whether narcolepsy increases the risk of MAFLD, despite the overlap in known risk factors. This study aimed to determine whether narcolepsy increases the risk of MAFLD.
Methods: We conducted a retrospective cohort study using the 2005-2021 MarketScan® Commercial and Medicare Supplemental databases. We included patients with >2 outpatient claims for new narcolepsy diagnoses identified using International Classification of Diseases – Clinical Modification diagnosis codes (narcolepsy group). A comparison cohort of patients without narcolepsy and hypersomnia (non-narcolepsy group) was matched in a 1:3 ratio using propensity score (PS) matching based on baseline demographics, comorbidities, and medication use. We excluded patients with any of the following conditions during the 1-year baseline period: cardiovascular disease, hypertension, hyperlipidemia, diabetes, and MAFLD. After PS matching, we used Cox proportional hazard regression to compare risk of MAFLD between the two groups after. We also conducted subgroup analyses based on age, sex, presence of sleep apnea, and narcolepsy type.
Results: We identified 86,002 patients (22,293 with narcolepsy and 63,709 without; mean age 33.5 ± 14.0 years, 63.7% female). The incidence of MAFLD was 0.42 per 100 person-years in the narcolepsy group and 0.28 per 100 person-years in the non-narcolepsy group. After adjusting for time-fixed and time-varying covariates and relative to non-narcolepsy, narcolepsy was associated with a 48% higher risk of MAFLD (adjusted hazard ratio [aHR] 1.48; 95% confidence interval [CI] 1.28-1.73). These findings remained consistent across all subgroup analyses.
Conclusion: Compared to well-matched patients without narcolepsy, patients with narcolepsy have a significantly elevated risk of being diagnosed with MAFLD.

THE IMPACT OF CHRONIC RHINOSINUSITIS ON INSOMNIA SYMPTOMS AND SLEEP DURATION IN WORLD TRADE CENTER RESCUE AND RECOVERY WORKERS

Horacio Romero Castillo[1], Sri Saranya Ravi[1], Katarina Martillo[1], Adriana De Resende[2], Alicia Legard[3], Felix Romero Castillo[1], Anna Mullins[1], David Rapoport[1], Andrew Varga[4], Ankit Parekh[4], Rafael de la Hoz[1], Shou-en Lu[3], Fred Lin[1], Jag Sunderram[3], Indu Ayappa[5]
[1] Icahn School of Medicine at Mount Sinai, [2] Rutgers - Environmental and Occupational Health Sciences Institute, [3] Rutgers Robert Wood Johnson Medical School, [4] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [5] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Chronic rhinosinusitis (CRS) is highly prevalent in World Trade Center rescue and recovery workers (WTCRRW) and was found to be a significant risk factor for shorter subjective sleep duration, sleepiness, sleep quality, and insomnia. Symptoms of CRS such as facial pain, congestion, and rhinorrhea may impair subjects' ability to fall asleep and stay asleep. The purpose of this study is to compare objective sleep duration and variability, sleepiness, and insomnia symptoms in subjects with and without CRS.
Methods: WTCRRW underwent 2-week actigraphy. Demographics, CRS symptoms, Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS), and sleep duration were collected. CRS+ was defined as ≥3 symptoms: facial pain, post-nasal drip, nasal congestion, blocked nose, anosmia, sneezing, sore throat, or hoarseness. Actigraphy data were analyzed using Cole-Kripke algorithm to obtain mean total sleep time (aTST) in hours and coefficient of variability (CV) across nights. Unadjusted bivariate analyses were performed with significance level at p< 0.05.
Results: 70 subjects (70%M30%F, age 63.8±5.2, BMI 28.8±6.0 kg/m^2) had 14 nights (range=4-16) of actigraphy. Subjective sleep duration and aTST were correlated (r=0.5, p< 0.0001). 35 subjects were CRS+ (50%) and CRS- (50%) each. Age, sex, BMI, and employment status did not differ between groups. CRS+ subjects reported increased moderate to very severe difficulty falling and staying asleep compared to CRS- subjects (17 (48.6%) vs 8 (22.9%), p=0.04 and 19 (54.3%) vs 9 (25.7%), p=0.03 respectively). We found no difference in aTST and variability between CRS+ 6.8 (1.0), CV=18.9 (8.6) and CRS- 7.1 (0.9), CV=17.1 (7.1), p=0.3. Similarly, there were no significant differences in mean subjective sleep duration [CRS+ 7.9 (1.2) vs CRS- 8.1 (0.9), p=0.6], mean ISI [CRS+ 7.2 (5.9) vs CRS- 5.7 (5.1), p=0.3], and mean ESS [CRS+ 5.0 (3.4) vs CRS- 5.0 (3.8), p=0.9].
Conclusion: Although WTCRRW with CRS symptoms subjectively report more difficulty falling and staying asleep, we

were unable to demonstrate a difference in aTST, variability, and sleepiness between CRS groups. A larger sample size and additional measures of CRS severity and insomnia may be needed to better understand the discrepancy between subjective sleep complaints and sleep duration in patients with CRS.

SEX-BASED ASSOCIATION BETWEEN INSOMNIA AND PAIN IN PATIENTS RECOVERING FROM HIP OR KNEE JOINT ARTHROPLASTY

Manasa Kokonda[1], Emily Arentson-Lantz[2], Jessica Meers[1], Doris Escobedo[1], Julia Boyle[3], Zbigniew Gugala[4], Michael Smith[5], Jennifer Martin[6], Sara Nowakowski[1]

[1] Department of Medicine, Baylor College of Medicine, Houston, TX, USA, [2] Department of Nutrition Sciences and Health Behavior, University of Texas Medical Branch, Galveston, TX, USA, [3] Office of Research and Development & New England GRECC, VA Boston Healthcare System, [4] Department of Orthopedic Surgery and Rehabilitation, University of Texas Medical Branch, Galveston, TX, USA, [5] Johns Hopkins University, [6] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System

Introduction: A reciprocal relationship exists between sleep and pain in the context of surgery where peri-operative pain often leads to disrupted sleep, and poor sleep before surgery can increase the severity of post-operative pain. Sex differences in postoperative pain and sleep quality have also been observed with females reporting greater pain severity and worse sleep quality compared to males. The present clinical trial examined sex-based differences in insomnia severity, pain, and their relationship in osteoarthritis patients before and after hip or knee joint arthroplasty.
Methods: Patients diagnosed with insomnia scheduled for hip or knee joint arthroplasty (N=61, Mean age=67.3±7.7 years; 68% females; 62% Caucasian) completed an online survey that included Insomnia Severity Index (ISI), PROMIS Pain Intensity, and PROMIS Pain Interference +/- 2-4 weeks before and after surgery. Paired t-tests were performed to examine differences between pre- and post-surgery. Pearson correlation tests were performed to examine the association between change scores of insomnia severity and pain measures. Similar analyses were performed on subgroups by sex.
Results: PROMIS Pain Intensity significantly decreased from baseline to post-surgery (55.8±6.1 vs 53.3±6.6; P=0.04). ISI (P=0.21) and PROMIS Pain Interference (P=0.12) pre- and post-surgery were not significantly different. When analyzed by sex, PROMIS Pain Intensity scores in male participants post-surgery were significantly different from baseline (56.8±5.5 vs 52.7±5.7; P=0.04), but not for female participants (P=0.3). ISI change scores from pre- to post-surgery were significantly correlated with change scores of PROMIS Pain Intensity (r=0.4, P=0.02); ISI and PROMIS Pain Interference change scores (P=0.2) were not significantly correlated.
Conclusion: Pain intensity significantly decreased following hip or knee joint arthroplasty, despite no significant changes in pain interference or insomnia symptom severity. The change in pain intensity following surgery was largely driven by male participants who reported significant improvements, whereas women did not experience a significant change in pain intensity. Improvements in pain intensity were associated with improvements in insomnia severity following surgery.

INSOMNIA AND PERCEIVED COGNITIVE FUNCTION IN SOLID ORGAN TRANSPLANT RECIPIENTS

Stacy Al-Saleh[1], Stacie Attig[1], Candace Mansour[1], Jehan Mahmoud[1], Samantha Conley[2]

[1] Mayo Clinic Arizona, [2] Mayo Clinic

Introduction: Solid organ transplant recipients experience high rates of cognitive impairment; however, little is known about what modifiable factors contribute to cognitive impairment after transplantation, limiting evidence-based treatment options. Insomnia is a sleep disorder that is associated with poor cognitive functioning in healthy adults and is amenable to interventions, but the relationship between insomnia and cognitive impairment after organ transplantation has not been explored. The purpose of this study was to identify relationships between insomnia, sleep characteristics, and perceived cognitive function after organ transplantation.
Methods: We conducted a descriptive, cross-sectional study of adult (>18 years) transplant recipients. We used the Insomnia Severity Index to measure insomnia, 10 days of continuous wrist actigraphy (Ambulatory Monitoring Inc. MicroMotionlogger) to measure sleep characteristics, and the PROMIS Cognitive Function to elicit perceived cognitive function. Descriptive statistics, Spearman's Rho correlations, and Pearson's correlations were used to describe relationships.
Results: We enrolled 34 participants [Mean age 62.5 years (SD 10.7), 64.7% (n=22) female, 85.3% (n=29) white, 17 liver/9 heart/8 kidney, average time since transplant 4.8 years (SD 4.2)]. 73.3% had clinically significant insomnia [mean ISI: 12.9 (SD 6.9)]. Sleep characteristics were obtained using actigraphy (mean duration: 7.03 hours [SD 1.28], onset latency: 9.16 min [SD 4.90], efficiency: 89.49% [SD 8.96], wake after sleep onset: 49.61 [SD 37.37]). Perceived cognitive function for the sample was worse than that of the general population, with a mean T-score of 45.21 (SD 11.44). Lower perceived cognitive function scores were significantly associated with younger age (rs = -.416, p=.016) and shorter time since transplant (rs =-.386, p=.024). Longer wake after sleep onset (rs =.347, p=.048) and lower sleep efficiency (rs=-.358, p=.041) were associated with lower perceived cognitive function. Lower perceived cognitive function was strongly associated with higher insomnia severity scores (r=.817, p=<.001).
Conclusion: Insomnia was common in our sample of transplant recipients and was strongly correlated with worse perceived cognitive function. Future research should incorporate objective measures of cognitive functioning and should consider insomnia treatment as a potential intervention to promote optimal cognitive functioning after organ transplantation.

ASSOCIATIONS OF DAILY SLEEP DURATION AND BLOOD GLUCOSE IN PREGNANT WOMEN WITH DIABETES: AN EXPLORATORY ANALYSIS

Kimberly Savin[1], Linda Gallo[2], Vanessa Malcarne[2], Scott Roesch[2], Thomas Rutledge[3], Gregory Talavera[2], Britta Larsen[3]

[1] VA San Diego Healthcare System, [2] San Diego State University, [3] University of California San Diego

Introduction: Blood glucose management during pregnancy is crucial for individuals with diabetes, but can be complex due to metabolic and behavioral changes that occur in the prenatal period. It can be particularly challenging to maintain optimal sleep behaviors during pregnancy. Prior research has examined associations of average sleep with average blood glucose levels, but this approach obscures important knowledge about between- and within-day fluctuations in glycemia. This study examined within- and between-person associations of daily and average sleep duration with next-day fasting blood glucose levels in pregnant women with diabetes.
Methods: Participants were 8 women [mean (SD) age = 28.5 (4.1) years, gestational age = 21.1 (3.5) weeks, 75% Latina ethnicity, 25% Black race]) enrolled in a physical activity intervention. Participants were instructed to wear Fitbit Alta HR devices (Fitbit, Inc., San Francisco, CA) for up to 12 weeks, until 36 weeks gestation, or 1 week before giving birth. Devices captured sleep duration. Participants self-reported demographic information and daily morning fasting blood glucose. There were 118 observations (nights) with contemporaneous sleep and next-day blood glucose data across participants. Multilevel models were used to examine associations of sleep duration with next-day fasting blood glucose. Models were adjusted for age, gestational age, and educational attainment. Multiple imputation was used to account for missing data. Given statistical power limitations, effect size benchmarks based on past research were emphasized over p-values.
Results: Mean (SD) sleep duration was 7.0 (0.5) hours and next-day fasting blood glucose was 91.1 (4.3) mg/dL. Within-person daily sleep duration was not associated with next-day fasting blood glucose. With one hour longer average sleep duration (between-person), next-day fasting blood glucose was 4.89 mg/dL lower (γ = -4.89, SE = 3.63, a small to medium effect size, p = 0.18).
Conclusion: Our results were similar to previous research linking longer average sleep duration with better glucose management during pregnancy. Results were observed among a sample of women of minoritized racial and ethnic groups with healthy average sleep durations and fasting blood glucose levels. These findings suggest that sleep promotion may be helpful for blood glucose regulation during pregnancy, but replication in larger samples is needed.

TEMPORAL STABILITY OF SLEEP AND GLUCOSE METABOLISM AND THEIR RELATIONSHIP DURING PREGNANCY: A CROSS-LAGGED ANALYSIS

Pei Chen[1], Yueying Wang[2], Jinle Wang[3], Jiahui Zhang[3], Qin Lin[4], Bingqian Zhu[5]

[1] University of Illinois Chicago, [2] Hong Kong Polytechnic University, [3] Shanghai Jiao Tong University, [4] International Peace Maternity and Child Health Hospital, School of Medicine, Shanghai Jiao Tong University, [5] Shanghai Jiao Tong University School of Nursing

Introduction: The relationship between sleep and glucose metabolism during different trimesters remain inconsistent. The aim of this study was to temporal stability of sleep (including duration, quality, and insomnia symptom) and glucose metabolism indicators, and to analyze their longitudinal associations through cross-lagged models.
Methods: A prospective cohort study involving 216 pregnant women was conducted. Data were collected during the first (T1), second (T2), and third (T3) trimesters from March 2022 to November 2024. Sleep quality was assessed by Pittsburgh Sleep Quality Index (PSQI). Mean sleep duration was calculated from the 7-day sleep diary, and insomnia symptoms was measured by the Insomnia Severity Index (ISI). Glucose metabolism indicators included HbA1C and fasting glucose which were obtained from health records of the participants. Cross-lagged models were used to examine the longitudinal relationship between sleep and glucose metabolism. Age, education, marital status, occupation, and number of children were included as time-invariant covariates.
Results: Both HbA1C and fasting glucose demonstrated temporal stability across the three trimesters (HbA1C_T1→T2: β = 0.573, p < 0.001; T2→T3: β = 0.512, p < 0.001; fasting glucose _T1→T2: β = 16.578, p = 0.002; T2→T3: β = 0.381, p < 0.001). Average sleep duration remained stable over time (Sleep_Avg_ T1→T2: β = 0.373, p < 0.001; T2→T3: β = 0.299, p < 0.001) and sleep duration at T1 was associated with lower HbA1C (β = -0.001, p = 0.009). Both sleep quality (PSQI) and insomnia symptoms (ISI) showed temporal stability (PSQI_T1→T2: β = 0.450, p < 0.001; T2→T3: β = 0.544, p < 0.001; ISI_T1→T2: β = 0.643, p < 0.001; T2→T3: β = 0.589, p < 0.001). Additionally, higher fasting glucose _T1 was associated with lower ISI_T2 (β = -1.242, p = 0.018).
Conclusion: HbA1C and fasting glucose exhibit high temporal stability, and average sleep duration is consistently maintained and influences glycemic indicators. Education level and age modulate both sleep and glucose metabolism. Furthermore, sleep quality and insomnia symptoms are stable over time, and there may be potential interactions between sleep-related measures and blood glucose levels.

SLEEP DISTURBANCE IN INDIVIDUALS WITH AND WITHOUT MINOR MEMORY COMPLAINTS

Alexandria Muench[1], Tyree Ware[2], Julia Boyle[3], Mark Seewald[1], Knashawn Morales[1], Michael Perlis[4]

[1] University of Pennsylvania, [2] Morehouse University, [3] Office of Research and Development & New England GRECC, VA Boston Healthcare System, [4] Department of Psychiatry, University of Pennsylvania

Introduction: Prior research indicates that individuals with Mild Cognitive Impairment (MCI) or Alzheimer's Disease (AD) exhibit higher-than-normal levels of sleep disturbance. Epidemiologic studies suggest that poor sleep may be a risk factor for the progression of Alzheimer's Disease and Related Dementias (ADRD). Despite these findings, the literature is non-specific regarding the types of sleep disturbances that present in this population. We aimed to assess the various forms of sleep disturbance in individuals with and without minor memory complaints (MMC).
Methods: Data were obtained from an online sleep and health survey, with participants directed to the site via advertisements on platforms such as Facebook, Google, TV, and local newspapers. The survey includes sections on general sleep, health conditions, and chronic diseases, and takes approximately 20 minutes to complete. In 2024, three questions regarding memory function were added: (1) recent memory issues, (2) use of supplements or over-the-counter medications for memory, and (3) diagnosis or treatment for memory problems. Two groups were formed based on reported memory problems, distinguishing those with minor memory complaints (MMC) from those without. Analyses focused on sleep patterns (e.g., Time in Bed, Wake After Sleep Onset, Sleep Efficiency), insomnia severity, and frequency of sleep disorders. Bivariate contrasts were conducted with an alpha level set at $p < 0.01$.
Results: The sample included 308 participants (mean age 46.0 ± 12.9, 64% female, 14% non-white). Of these, 134 had MMC and 174 did not. The groups did not differ demographically, but those with MMC exhibited a subtle sleep phase delay (~30 minutes), increased insomnia severity (related to daytime function), and a higher frequency of parasomnic behaviors (e.g., nightmares).
Conclusion: Subjects with MMC demonstrated more severe sleep disturbance, particularly with phase delays and parasomnias. These findings suggest that sleep disturbance may occur early in cognitive decline and could serve as a potential early indicator of MCI. Given the connection between sleep and memory function, these results may offer insight into the pathophysiology of ADRD. Analyses are ongoing.

THE IMPACT OF PULMONARY REHABILITATION ON SUBJECTIVE SLEEP QUALITY

Madeleine Basist[1], Sara Khan[1], Shahidul Islam[1], Jon Javor[1], Harly Greenberg[1], Stella Hahn[1], Arunabh Talwar[1]
[1] Northwell Health

Introduction: Pulmonary rehabilitation (PR) and exercise programs have been shown to improve subjective sleep quality in patients with COPD. We hypothesized that PR would improve sleep quality in all patients irrespective of underlying chronic lung conditions using the Pittsburgh Sleep Quality Index (PSQI), a validated questionnaire to assess levels of sleep disturbance over a 1-month period.
Methods: All new PR patients at Northwell Health Pulmonary Rehabilitation in New Hyde Park, NY were invited to participate. Enrolled subjects participated in the standard PR program (3 sessions weekly for 8 weeks, total 24 sessions) and completed the PSQI at their1st, 12th, and 24th sessions. A preliminary descriptive analysis was performed on data from 28 subjects enrolled between February 2024 and October 2024. 13 subjects completed all three PSQI surveys, while 15 subjects completed at least two. Demographic and clinical characteristics were summarized using counts and percentages for categorical variables, and either mean and standard deviation or median and interquartile range for numeric variables, as appropriate. Differences between baseline and post-intervention PSQI scores were computed to estimate change at different time points and reported as medians and interquartile ranges.
Results: 28 subjects were included in this preliminary analysis. Subjects were 50% female and 50% male. Mean age was 70.6 years (SD ±10.51) with median BMI 33 kg/m2 (IQR 27.6-35.9) for females and 28.7 kg/m2 (IQR 25.9-30.7) for males. Comorbid conditions included COPD (57.1%), ILD (46.4%), pulmonary hypertension (17.9%), and obstructive sleep apnea (39.3%). Median total PSQI score was 9 at the 1st and 12th sessions and 8 at the 24th session, showing a median decrease of 1 between sessions 1 and 24. The PSQI subscores that demonstrated the greatest maximum improvement were sleep efficiency and need for medication to sleep.
Conclusion: This preliminary analysis suggests that PR may improve subjective sleep quality in patients with a range of chronic pulmonary conditions. Further long-term studies are needed to confirm these findings.

EARLY MEAL TIMING IMPROVES OVERNIGHT GLUCOSE IN PREGNANCIES COMPLICATED BY GESTATIONAL DIABETES

Hannah Cunningham[1], Matthew Butler[1], Lucy Ward[1], Amy Valent[1]
[1] Oregon Health & Science University

Introduction: Gestational diabetes (GDM) results in adverse outcomes for the pregnant individual and neonate. Lifestyle interventions for GDM to improve glucose time-in-range are critically needed. Previous research demonstrates beginning food consumption early in the day is beneficial for glucose metabolism, potentially due to circadian alignment of food ingestion to the circadian clock. This study examines how temporal eating patterns influence glucose concentrations in individuals with GDM.
Methods: This is a secondary analysis of pregnant people with GDM randomized to using continuous glucose monitoring (CGM) versus capillary-blood glucose (CBG) for management of GDM. Participants measured CBG with blinded or real-time CGM and were included in the analysis if post-prandial CBG were available to infer meal timing (n=74). Fasting glycemia was measured at study enrollment with a blood test. The cohort was median split into early (first meal before 10:56) and late eating (first meal after 10:56). The 24-hour CGM glucose profiles were compared between groups by linear and cosinor analyses, adjusted for maternal and gestational age, race, medication, and GDM history. Data are mean ± standard error.
Results: People who ate breakfast later were older on average and less likely to receive Medicaid. Early eating was significantly associated with lower fasting glycemia (92.3±1.4 vs 97.6±1.8 mg/dL; P=0.021). Over 24 h, glucose tended to increase during the day and decrease during the night. This rhythm was shifted earlier for the early eating group. Additionally, the trough glucose

concentration was lower for the early eating group. Overnight glucose (23:00-5:59) decreased in both groups by ~11.7 mg/dL. However, the early eating group had significantly lower overnight glucose (average: 77.5±0.1 vs 82.8±0.1mg/dL, P=0.037). Daytime glucose concentration did not differ between the groups.
Conclusion: These data suggest individuals with GDM who eat their first meal earlier have lower fasting glycemia and lower overnight glucose concentrations compared to individuals who eat later. Food timing, with an emphasis on early eating, is a potential intervention for individuals with GDM.

IMPACT OF A 12-WEEK EXERCISE PROGRAM ON SELF-REPORTED SLEEP PARAMETERS IN CANCER SURVIVORS

Selene Tobin[1], Christine Duffy[2], Don Dizon[2], Mary Ann Fenton[2], Zihuan Cao[2], Jared Saletin[3], Rena Wing[1], Jessica Unick[1]
[1] Alpert Medical School of Brown University, [2] Brown University Health, [3] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: Sleep disturbances are common among cancer survivors. While increased physical activity (PA) is known to improve sleep in the general population, it is unclear whether exercise can improve sleep in cancer survivors. The purpose of this study was to examine self-reported sleep problems among cancer survivors and to explore whether self-reported sleep parameters change following a 12-week PA program.
Methods: 23 adults (82.6% female; Age: 54.4 ± 7.9 years; BMI: 33.0 ± 9.4; duration since end of treatment: 665.0 ± 728.5 days) who reported being physically inactive were enrolled in a larger study designed to test the feasibility, acceptability, and preliminary efficacy of a 12-week automated Internet program aimed at increasing PA among cancer survivors. Participants were asked to complete the Pittsburgh Sleep Quality Index (PSQI) at baseline and post-intervention assessments. Subcategories of the PSQI were explored, scores for all outcomes range 0-3, with 3 indicating worse dysfunction.
Results: Participants reported high levels of sleep problems at baseline and post-intervention (Sleep duration: pre: 1.2 ± 1, post: 1.3 ± 1.1; Latency: pre: 1.7 ± 1.1, post: 1.5 ± 1.1; Disturbances: pre: 1.7 ± 0.7, post: 1.7 ± 0.7; Daytime dysfunction: pre: 0.9 ± 0.7, post: 0.7 ± 0.6, Sleep medication: pre: 0.9 ± 1.3, post: 0.9 ± 1.2; and subjective sleep quality: pre: 1.2 ± 0.9, post: 1.3 ± 0.9; scores < 1 are typically associated with the absence of sleep problems; scores expressed as m±sd). Despite an increase in objectively measured moderate-to-vigorous physical activity during the intervention (+46.3 min/wk), there were no significant changes in any PSQI subscale scores from baseline to post-intervention (p's=0.23-0.86).
Conclusion: In this sample of cancer survivors, we observed a high rate of self-reported sleep problems, consistent with previous research. Unlike the general population, however, participation in a 12-week PA program did not result in improvements in self-reported sleep quality. While replication is required in larger samples, these findings suggest that targeting PA alone may not be sufficient for modifying sleep in this population and that more comprehensive lifestyle interventions may be needed.
Support (if any): This study was funded by the Legorreta Cancer Center at Brown University.

A CROSS-STUDY ANALYSIS ON THE IMPACT OF BEHAVIORAL INSOMNIA TREATMENT ON PAIN SEVERITY IN U.S. VETERANS

Alexander Erickson[1], Alaina Gold[2], Gwendolyn Carlson[3], Monica Kelly[4], Michael Mitchell[1], Karen Josephson[1], Constance Fung[5], Cathy Alessi[6], Jennifer Martin[7]
[1] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System, [2] VA HSR Center for the Study of Healthcare Innovation, Implementation and Policy, VA Greater Los Angeles Healthcare System, [3] Department of Mental Health, VA Greater Los Angeles Healthcare System, [4] VA Geriatric Research, Education and Clinical Center, VA Greater Los Angeles Healthcare System, [5] Geriatric, Research, Education and Clinical Center, VA Greater Los Angeles, [6] VA Geriatric, Research, Education and Clinical Center, VA Greater Los Angeles Healthcare System, [7] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System

Introduction: Insomnia disorder and chronic pain are highly comorbid, and share underlying mechanisms that impact their severity. Literature regarding the impact of behavioral insomnia treatments like cognitive behavioral therapy for insomnia (CBT-I) on pain severity, especially in veterans, has been mixed.
Methods: We harmonized datasets from four randomized clinical trials, yielding a sample of 469 veterans (mean age 63 years, 65.7% male, 56.7% white, 70% not working) who engaged in structured behavioral insomnia treatments (4-5 sessions). All veterans in the sample completed baseline, posttreatment, and at least one follow-up assessment (e.g., 3-, 6-, 9-, or 12-month follow-up). Pain severity was operationalized by harmonizing items from the Brief Pain Inventory and Geriatric Pain Measure related to average pain severity the day of assessment and average pain severity in general. Pain ratings range from 0 (no pain) to 10 (severe pain). Other measures included the Insomnia Severity Index (ISI) and Pittsburgh Sleep Quality Index (PSQI). Analyses included mixed effects modeling to evaluate treatment impact.
Results: Baseline pain was mild-to-moderate across the sample (m = 4.3, SD = 2.7). Across pain variables, there was no meaningful effect of behavioral insomnia treatment on pain severity outcomes (-.02 ≤ b ≤.09, p >.05). This lack of effect is present despite significant improvement in both ISI (-.5.9 ≤ b ≤ -7.39, p<.001) and PSQI (-3.45 ≤ b ≤ -4.58, p<.001) at posttreatment and follow-up periods. No differences in effect were observable when examining demographic breakdowns of age, sex, or race.
Conclusion: Though behavioral insomnia treatments do significantly improve insomnia and sleep-related outcomes, they do not appear to meaningfully improve perceived pain severity in a sample of US veterans. This is consistent with similar literature showing a lack of meaningful improvement in pain severity, yet continues to open the door for further research into facets of pain beyond severity (e.g., interference in day-to-day living) that could be impacted by improving sleep.

TRAJECTORIES OF CHANGE IN CANCER-RELATED FATIGUE AND INSOMNIA OVER 12 WEEKS OF RADIATION THERAPY

Elizabeth Lampe[1], April Park[2], Mark Seewald[2], Gary Freedman[2], Sara Nowakowski[3], Michael Perlis[4], Alexandria Muench[2]

[1] Drexel University, [2] University of Pennsylvania, [3] Department of Medicine, Baylor College of Medicine, Houston, TX, USA, [4] Department of Psychiatry, University of Pennsylvania

Introduction: The impact of radiation therapy (RT) on insomnia and cancer-related fatigue (CRF) among individuals with cancer is not well understood. Our study aimed to 1) examine trajectories of insomnia and CRF across RT and 2) understand whether these trajectories depend on age or sex.
Methods: Patients with cancer (all types) undergoing RT were recruited immediately prior to starting treatment (N=128; Mage=58.6±12.4y, 38% female, 80% White, 2% Hispanic or Latino). Subjects were asked to report on insomnia and CRF symptoms at baseline and then every 2 weeks for 3 months. Mixed effects models accounting for linear and quadratic effects of time were used to examine change in CRF and insomnia over 12-weeks. Additional models evaluated baseline age and sex as moderators of these relationships. All models were adjusted for the presence of other interventions (e.g., surgery, medications).
Results: There was no significant linear (p=0.11) or quadratic (p=0.29) effect of time on fatigue, and sex did not moderate this effect. However, age moderated this effect (est=0.003, S.E.=0.001, p=0.03) such that those < 47y reported decreased CRF while those >72y reported increased CRF. There was also no significant linear (p=0.09) or quadratic (p=0.16) effect of time on insomnia, and sex did not moderate this effect. Again, age moderated the effect of time on insomnia (est=0.007, S.E.=0.003, p=0.03) such that those either < 47y or >72y reported reductions in insomnia symptoms with those < 47y reported greater reductions in insomnia symptoms compared to those >72y, while those between 47-72y reported slight increases in insomnia symptoms.
Conclusion: Findings indicate that those who are older (>72y) report increased CRF during and after RT compared to those who are younger (< 47y), where fatigue decreased more in this age cohort. Changes in both groups were modest. Results suggest that insomnia and CRF function independently in this population, as CRF increased while insomnia decreased within the full sample. Future research should explore additional risk- and maintenance-factors for insomnia and CRF during and after RT.
Support (if any): This work was partially supported via a trainee grant provided by Penn's Department of Radiation Oncology.

RAPID EYE MOVEMENT SLEEP-SUPPRESSING ANTIDEPRESSANT USE IS ASSOCIATED WITH ENHANCED SURVIVAL IN GUILLAIN-BARRÉ SYNDROME

Cosmo Fowler[1], Briana Makadia[1], Komal Kaur[1], Doo Choi[1], Donald Bliwise[1], Meredith Greer[1]

[1] Emory University School of Medicine

Introduction: Patients with neuromuscular conditions are most vulnerable to sleep disordered breathing during rapid eye movement (REM) sleep. Experimentally, pharmacological suppression of REM has been demonstrated to improve nocturnal hypoxia in muscular dystrophy patients. This approach has not been investigated in Gullain-Barré syndrome (GBS), a rare acquired neuromuscular condition.
Methods: We queried the TriNetX U.S. Collaborative Network (Cambridge, MA), an electronic health record (EHR) database of over 120 million US patients from 69 healthcare organizations, for patients with a diagnosis of GBS (ICD-10-CM G61.0) between 01/2003–01/2023. We defined a REM-inhibited cohort of patients prescribed 1 of several antidepressants associated with REM suppression in the year prior to GBS diagnosis, as well as a REM-non-inhibited cohort who received antidepressants not linked to REM suppression, excluding patients who received prescriptions from both classes. The primary outcome was 30-day mortality from GBS diagnosis. We calculated relative risks with 95% confidence intervals using logarithmic transformation and delta method standard errors, complemented by Kaplan-Meier survival analysis. Propensity score matching was performed using age, race, and gender.
Results: We identified 5,113 patients with GBS who met inclusion criteria, of whom 1,158 (22.7%) made up the REM-non-inhibited cohort and 3,955 (77.3%) comprised the REM-inhibited cohort. In the unmatched analysis, one-month mortality was significantly higher in the REM-non-inhibited group (3.0% vs 1.5%, absolute risk difference [ARD] 1.4%, 95% CI 0.4-2.5%), with a relative risk (RR) of 1.92 (95% CI 1.27-2.91, p=0.002). After propensity score matching (n=1,145 per group), this difference persisted (3.0% vs 1.6%, ARD 1.4%, 95% CI 0.2-2.6%), with RR 1.89 (95% CI 1.07-3.33, p=0.025). Kaplan-Meier survival curves demonstrated significantly better survival in the REM-inhibited group both before (log-rank p=0.002) and after matching (p=0.024).
Conclusion: This is the first study examining differential survival in GBS patients receiving REM-inhibiting versus REM-non-inhibiting antidepressants. These findings align with those obtained in patients with other neuromuscular disorders, where REM suppression is associated with clinical benefit. While we faced limitations inherent to studies of observational clinical EHR data and were unable to characterize the fraction of patients who may have had their outpatient medications interrupted due to illness acuity, our findings justify prospective investigation.

ASSOCIATION BETWEEN SLEEP DISTURBANCE AND PAIN-RELATED OUTCOMES AMONG FORMER PROFESSIONAL AMERICAN-STYLE FOOTBALL PLAYERS

Chen Wang[1], Rachel Grashow[1], Robert R. Edwards[2], Can Ozan Tan[3], Janet Mullington[4], Meagan M. Wasfy[5], Ross Zafonte[6], Aaron L. Baggish[5], Susan Redline[7], Suzanne Bertisch[8]

[1] Harvard T.H. Chan School of Public Health, [2] Brigham and Women's Hospital, [3] University of Twente, [4] Beth Israel Deaconess Medical Center, [5] Massachusetts General Hospital, [6] University of Missouri School of Medicine, [7] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, [8] Brigham and Women's Hospital, Harvard Medical School

Introduction: Sleep disturbances and chronic pain frequently co-occur, exhibiting a bidirectional relationship that exacerbates

both conditions. Former professional American-style football (ASF) players face unique health challenges from the physical demands and injuries sustained during their careers. This study investigates the associations between sleep disturbances and pain-related outcomes in this high-risk population.
Methods: This cross-sectional study analyzed data from 111 former professional ASF players enrolled in the Football Players Health Study at Harvard University. Sleep disturbance and sleep-related impairment were measured using PROMIS T-scores, while sleep-disordered breathing (SDB) was assessed using a single-night apnea-hypopnea index (AHI >15 events/hour). Pain outcomes included PROMIS pain interference T-scores and a 0–10 numeric rating scale for pain intensity. Weighted multivariable linear regression models were employed to evaluate associations, adjusting for demographics, physical activity, smoking status, football position, and number of professional seasons, to generalize findings to the broader Football Players Health Study cohort.
Results: The mean age of the former professional ASF players was 48.2 ± 7.8 years; 59 (53.2%) identified as Black, and 52 (46.8%) as White. The average duration of professional league play was 4.0 years, and 62 (55.9%) primarily played lineman positions. Higher PROMIS sleep disturbance scores were associated with higher pain interference (multivariable model $\beta = 0.47$; 95% CI: 0.16, 0.79; $p < 0.01$) and higher pain intensity ($\beta = 1.03$; 95% CI: 1.00, 1.06; $p = 0.02$). Similarly, sleep-related impairment scores were significantly associated with higher pain interference ($\beta = 0.69$; 95% CI: 0.43, 0.96; $p < 0.001$) and pain intensity ($\beta = 1.05$; 95% CI: 1.03, 1.07; $p < 0.001$). No significant associations were observed between SDB or higher rapid eye movement (REM) sleep percentage and pain intensity ($\beta = 1.12$, 95% CI: 0.70, 1.81, $p = 0.63$; $\beta = 1.02$, 95% CI: 0.98, 1.05, $p = 0.34$).
Conclusion: Patient-reported sleep disturbances and sleep-related impairment are significantly associated with higher pain interference and higher pain intensity among former professional ASF players. These findings underscore the opportunity for interventions to address sleep disturbances as part of comprehensive pain management strategies to reduce symptom burden and improve quality of life in this population.

EXPLORING THE BEHAVIOR OF AUTOANTIBODIES AND VITAMIN D IN A VITILIGO SAMPLE: A LINK WITH PHOTOTHERAPY AND SLEEP

Ellen Xerfan[1], Anamaria Facina[2], Monica Andersen[3], Sergio Tufik[4], Jane Tomimori[2]

[1] Department of Psychobiology, Universidade Federal de São Paulo, [2] Department of Dermatology, Universidade Federal de São Paulo, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo, [4] Universidade de Federal de São Paulo

Introduction: Poor sleep can impair immune regulation, impacting autoimmune diseases, including the skin disorder vitiligo. Several pathways possibly related to vitiligo, including hormonal, metabolic (particularly vitamin D) and autoimmune vias can be parallelly affected. Concomitant autoimmune diseases and positivity of serum markers can be triggered, including those of thyroid. Phototherapy UVB, the gold-standard treatment of vitiligo, can influence circadian rhythm synchronization and these pathways. This study aimed to investigate autoimmune and metabolic components in individuals with vitiligo; and verify their sleep profile considering these markers and phototherapy.
Methods: It was a cross-sectional study (ethically approved), enrolling 30 patients with vitiligo treated at a Dermatology Service, and 26 controls. The sleep questionnaire Pittsburgh Sleep Quality Index (PSQI) was accessed. Serum vitamin D 25(OH)D, thyroid-stimulating hormone (TSH), and autoimmune markers [antinuclear antibody (ANA), and anti-thyroid autoantibodies (anti-TPO and anti-TG)] were measured. Generalized Linear Model was used to analyze variables, and to relate them with sleep.
Results: Vitiligo group was mostly composed of women at forty decade of life, and individuals with active lesions. Phototherapy UVB was recorded in 43% of vitiligo sample. Most individuals from vitiligo (85%) and control groups (62.5%) were "poor sleepers" (PSQI>5). The descriptive PSQI mean score was slightly lower in the part of vitiligo sample that underwent phototherapy (7.2) compared with those not treated with phototherapy (8.6). The 25(OH)D levels compared between vitiligo and control groups and when associated to phototherapy were not statistically significant. Anti-TPO was frequent in the vitiligo group only. Reactive ANA was detected in 33% of vitiligo patients (and 23.1% of controls); in 46.2% of vitiligo sample treated with phototherapy, and in 23.5% of those without phototherapy. Regarding sleep, all individuals with reactive ANA were "poor sleepers".
Conclusion: Poor sleep predominated in the vitiligo group and in the part of vitiligo sample that have not been treated with phototherapy. Vitamin D was not statistically associated to phototherapy in this study. Anti-TPO and ANA were more frequent in the vitiligo sample. We raise the importance of investigating the interaction of autoimmune and metabolic components, especially vitamin D, with sleep, phototherapy and vitiligo activity.

OBSTRUCTIVE SLEEP APNEA AND ITS EFFECT ON NON-CYSTIC FIBROSIS BRONCHIECTASIS EXACERBATIONS: A NATIONAL INPATIENT SAMPLE STUDY

Pedro Arias-Sanchez[1], Juan Pablo Moreno-Graterol[1], Francisco Gallegos-Koyner[1], Puja Bhardwaj[1],

[1] SBH Health System

Introduction: A priori bronchiectasis is increasingly recognized as more frequent in patients with Chronic Obstructive Pulmonary Disease and Obstructive Sleep Apnea (OSA) overlap syndrome. It is hypothesized that bronchiectasis in this population may exacerbate hypoxia and increase systemic inflammation. Non-cystic fibrosis bronchiectasis (NCFB) is associated with a broad range of underlying conditions, but the impact of OSA on the clinical outcomes of NCFB patients, particularly during hospitalization, remains unclear.
Methods: Data was gathered using the National Inpatient Sample (NIS) Database from 2016 to 2021. Patients aged 18 or older who had an admitting diagnosis of bronchiectasis with acute exacerbation (J47.1) were included and then stratified in those who had OSA (G47.33) and those who did not. Patients who had a secondary diagnosis of cystic fibrosis were excluded. Primary outcome of interest was length of stay. Propensity score

matching using sociodemographic variables was used to adjust for confounders of this outcome.
Results: A total of 30,975 adult hospital admissions were identified between 2016 and 2021, of which 3,465 had OSA and 27,510 did not. The mean age was 70.6 years, and 68.2% of patients were female. A total of 495 patients required mechanical ventilation. After propensity score matching, 2,960 weighted admissions were included in each group, with a mean age of 68 years in the matched cohorts. There were no significant differences in length of stay between the two groups (5.2 days vs. 5.1 days, p = 0.72). Additionally, there were no significant differences in mechanical ventilation use (OR 0.44, 95% CI 0.15–1.29, p = 0.14) or mortality (OR 0.33, 95% CI 0.03–3.20, p = 0.34) between patients with NCFB and OSA compared to those without OSA.
Conclusion: No significant differences were found in length of stay, mechanical ventilation use, or mortality. These results suggest that OSA may not notably impact clinical outcomes in NCFB exacerbations in the context of acute hospital admissions.

THE DEVELOPMENT OF OBSTRUCTIVE SLEEP APNEA FOLLOWING RADIOTHERAPY AND CHEMOTHERAPY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Augustin Vannier[1], Neil Kondamuri[2], Janya Allen[3], Nihar Rama[1], Rachel Nordgren[2], Phillip LoSavio[3]
[1] University of Chicago, Pritzker School of Medicine, [2] The University of Chicago, [3] University of Chicago

Introduction: With advances in chemotherapeutic agents and targeted radiation, the quality of life of cancer patients is becoming increasingly relevant. Sleep disturbances and fatigue are a primary complaint of surviving cancer patients. While the interaction between obstructive sleep apnea OSA and oncologic treatment remains poorly understood, multiple proposed mechanisms exist. We conducted a meta-analysis of prospective and retrospective studies evaluating the development of sleep apnea in patients with any cancer type who receive chemotherapy or radiotherapy.
Methods: We aggregated and evaluated OSA following chemotherapy or radiotherapy for cancer. Subsequently we conducted meta-analysis of eligible studies to determine AHI, LSAT, ODI and ESS differences between different combinations of treatment modalities, as well as evaluation for incident OSA diagnosis following treatment. Studies were considered eligible for analysis if the application of either chemotherapy or radiotherapy could be isolated and if the study explicitly listed the rate of OSA in each treatment group.
Results: We identified 559 papers, of which 110 were duplicates. 30 articles met criteria for full text review, and 17 were eligible for meta-analysis. We did not find a significant effect on the development of OSA associated with the application of either chemotherapy or radiotherapy. We observed a modest, nonsignificant trend towards increased development of mild OSA among patients receiving radiotherapy (z=1.21 p = 0.23). The isolated effect of chemotherapy was not associated with any discernible impact on either mild (z=-0.83, p = 0.41) or moderate (z=0.00, p=1.00) OSA. Patients receiving radiotherapy did not have significantly different AHI (z=-0.19, p = 0.85), ODI (z=-0.85, p = 0.40) LSAT (z=-0.15, p = 0.89) or ESS (z=-0.46, p=0.65) compared to controls. Similarly, chemotherapy was not associated with a significantly different AHI (z=0.81, p=0.42) or LSAT (z=0.38, p=0.70).
Conclusion: We find no effect of cancer therapy on development of OSA, in contrast to the conclusion of several individual studies. Literature on the development of OSA in patients treated with chemotherapy or radiotherapy for cancer is thus far limited to small-scale studies that are not powered to detect even moderate effect sizes. Large-scale studies of multiple treatment modalities are warranted.

THE ROLE OF IRON METABOLISM IN OBSTRUCTIVE SLEEP APNEA SEVERITY IN INDIVIDUALS WITH ANDROGENETIC ALOPECIA (EPISONO)

Ellen Xerfan[1], Maingredy Souza[2], Anamaria Facina[3], Jane Tomimori[3], Sergio Tufik[4], Monica Andersen[5]
[1] Department of Psychobiology, Universidade Federal de São Paulo, [2] Departamento de Psicobiologia, Universidade Federal de São Paulo, São Paulo, Brazil, [3] Department of Dermatology, Universidade Federal de São Paulo, [4] Universidade de Federal de São Paulo, [5] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Androgenetic alopecia (AGA) is a dermatological condition related to progressive hair loss commonly manifested in men, although women can be affected. Sleep patterns and, consequently, quality of life can be impaired. Androgen-sensitive hair follicles are affected as a result from the conversion of testosterone into dihydrotestosterone by the enzyme 5-alpha-reductase. Although the hormonal etiopathogeny is well-documented in AGA, the role of iron metabolism and its relationship with polysomnography (PSG)-measured sleep parameters are not well understood in this hair condition. This study aimed to investigate how iron markers relate to sleep outcomes in individuals with AGA, emphasizing sex differences and obstructive sleep apnea (OSA) severity.
Methods: Data from the 4th Edition of the São Paulo Epidemiological Sleep Study (EPISONO) were analyzed. Participants self-reported AGA, underwent PSG, and provided blood samples for biomarkers analysis. The Propensity Score Matching (PSM) was adopted to statistical control for age, sex, and metabolic syndrome.
Results: From 747 participants, 81 were in the AGA group (17 women and 64 men) and 666 in the Non-AGA group (423 women and 243 men). After PSM, 160 participants (80 matched pairs) were retained, including 34 women (n=17/group) and 126 men (n=63/group). Prior to PSM, women from AGA group presented 2 polysomnographic parameters significantly higher compared to the Non-AGA group: apnea hypopnea index (AHI) and desaturation events. In the AGA group, significant negative correlations were identified between serum iron levels and AHI in both sexes, especially in women. Ferritin positively correlated with both AHI and the desaturation index in women, while serum iron was negatively linked to the desaturation index in men. These results remained significant after PSM. In Non-AGA men, weaker associations were found, with transferrin positively correlated with AHI and negatively with sleep efficiency.
Conclusion: Components of iron regulation, particularly serum iron and ferritin, presented a significant role in OSA severity in AGA, with stronger associations in women. These findings

highlighted the importance of consider iron metabolism in the management of OSA in individuals with AGA, in both sexes. Further examinations are warranted to explore the mechanisms underlying these metabolic associations.

ASSOCIATION OF OBSTRUCTIVE SLEEP APNEA WITH PULMONARY EMBOLISM: A LARGE-SCALE DATABASE STUDY

Saud Alawad[1], Nawaf Alsaeed[1], Ahmad Jarrar[1], Sunil Sharma[2]
[1] West Virginia University Hospital, [2] West Virginia University

Introduction: Obstructive sleep apnea (OSA) is a common sleep-related breathing condition that has been linked to thromboembolic and cardiovascular events. The prevalence of OSA in the U.S. is nearly 33.4% among men and 17% among women. Pulmonary embolism (PE) is a life-threatening disorder that may occur at augmented rates in people diagnosed with OSA. The aim of this study is to compare the PE's prevalence in patients with any sleep disorder, while also evaluating transitory results, including all-cause mortality and cardiac arrest.
Methods: A retrospective cohort study was performed using the TriNetX Global Health Research Network which offers access as EHRs from different healthcare facilities utilizing US Collaborative Network. Two cohorts were defined: Adult patients (Age 18 or above) with OSA and PE, and patients with PE but no known diagnosis of OSA or other sleep disorders. Propensity score comparison was utilized to address noteworthy variations in demographics and comorbidities between the two clusters. Data analysis was done from 2000 to present, with a one-month follow-up to evaluate the secondary outcomes of all-cause mortality and cardiac arrest.
Results: The patients with PE's who had OSA (n=3,119,120) demonstrated incidence proportion of 2.012% and the prevalence was 3.614%. While the incidence proportion in control group who diagnosed with PE without diagnosis of any sleep disorders (n=98,422,632) was 0.602% and the prevalence was 0.614%. The OSA group with PE's (n=101,031), when compared to the non-OSA group with PE's (n=554,126), demonstrated a reduced risk of all-cause mortality (RR: 0.549; 95% CI: 0:53-0.57) and cardiac arrest (RR: 0.652; 95% CI: 0.564-0.754) within a month after PE diagnosis.
Conclusion: Patients with OSA are at a high risk of developing PE compared to those without OSA. Nonetheless, cardiac arrests and mortality, seem to be significantly lower in the OSA. These findings indicate an intricate interplay between thromboembolic events and OSA, underscoring the necessity for further prospective research to affirm such relationships and the involved mechanisms.

PROBABLE OSA RISK IN COMMUNITY DWELLING ADULTS IN THE UNITED STATES: THE ROLE OF COPD AND OBESITY

Rachel Manuel[1], Safia Khan[2], Bhaskar Thakur[1]
[1] Department of Family and Community Medicine, The University of Texas Southwestern Medical Center, [2] Department of Neurology, The University of Texas Southwestern Medical Center

Introduction: Approximately 14 million US adults suffer from COPD, which is the fifth leading cause of death in the US. OSA prevalence is relatively high among adults with COPD. The coexistence of these two diseases is known as overlap syndrome, which carries an increased risk of cardiopulmonary complications. This study aims to examine the independent and combined effects of COPD and obesity on the risk of probable OSA (pOSA).
Methods: Data from three cycles (2013-14, 2015-16, and 2017-18) of the National Health and Nutrition Examination Survey was utilized to perform a cross-sectional analysis. As previously recommended, pOSA was screened based on self-reported snoring, breathing pauses, and daytime sleepiness. Weight was classified into four categories (normal, overweight, obese, and severely obese). COPD presence was determined by inquiring if subjects were told they had COPD by a health professional. The survey-based Poisson regression model was used to estimate the adjusted prevalence ratio (aPR) with 95% confidence interval (CI).
Results: The total sample population included 10,360 US adults, aged 20 years and older, with the majority being female (52%). Subjects with COPD were 52% more likely to have pOSA compared to those without COPD (aPR 1.52, 95% CI: 1.18–1.97, p = 0.002). Obesity also increased the risk of pOSA, with aPRs of 1.33 (95% CI: 1.18–1.49) for overweight, 1.70 (95% CI: 1.52–1.90) for obese, and 2.03 (95% CI: 1.80–2.28) for severely obese individuals (all $p < 0.001$). While the individual risk of pOSA increased with the severity of obesity, the combined risk across obesity categories remained consistent, with aPRs of 1.84, 1.91, and 1.86 for overweight, obese, and severely obese participants with COPD, respectively.
Conclusion: In this study, both COPD and obesity were found to be independently associated with increased likelihood of pOSA after controlling for potential covariates. The combined impact of COPD and different weight groups did not show a synergistic effect on the risk of probable OSA. Subject reported COPD and OSA may have influenced these findings. These study results confirm the importance of addressing both COPD and obesity as key factors in the management of probable OSA risk in adults.

IDENTIFYING GAPS IN EVALUATION AND TREATMENT OF INSOMNIA, OSA, AND PTSD IN WOMEN VETERANS

Gwendolyn Carlson[1], Alaina Gold[2], Alexander Erickson[3], Megan Hoch[1], Monica Kelly[4], Constance Fung[5], Cathy Alessi[6], Elizabeth Yano[7], Alison Hamilton[2], Jennifer Martin[8]

[1] Department of Mental Health, VA Greater Los Angeles Healthcare System, [2] VA HSR Center for the Study of Healthcare Innovation, Implementation and Policy, VA Greater Los Angeles Healthcare System, [3] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System, [4] VA Geriatric Research, Education and Clinical Center, VA Greater Los Angeles Healthcare System, [5] Geriatric, Research, Education and Clinical Center, VA Greater Los Angeles, [6] VA Geriatric, Research, Education and Clinical Center, VA Greater Los Angeles Healthcare System, [7] VA HSR Center for the Study of Healthcare Innovation, Implementation and Policy, VA Greater Los Angeles Healthcare System; Department of Medicine, [8] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System

Introduction: Insomnia disorder, obstructive sleep apnea (OSA), and posttraumatic stress disorder (PTSD) are highly comorbid conditions among veterans. There are clear clinical practice guidelines for the assessment/treatment of these conditions, but sleep disorders remain under documented in electronic health records (EHR) and it is unclear if women veterans are being appropriately assessed and treated for these conditions.
Methods: We sent recruitment letters to 361 veterans potentially eligible for a clinical trial of cognitive behavioral therapy for insomnia (CBT-I) for women veterans with PTSD (NCT05683132). Eighty-one women completed telephone screening which included the Insomnia Severity Index (ISI), STOP, and Primary Care PTSD Screen for DSM-5 (PC-PTSD-5). Clinical cutoff scores were used to determine probable insomnia (ISI ≥ 11), high OSA risk (STOP ≥ 2), and probable PTSD (PC-PTSD-5 ≥ 4). Prior engagement in first-line treatments was assessed for insomnia (CBT-I), OSA (positive airway pressure [PAP]), and PTSD (Cognitive Processing Therapy [CPT], Prolonged Exposure [PE], and Eye Movement Desensitization and Reprocessing [EMDR]).
Results: Among women screened, 90.1% (n = 73) had probable insomnia, 59.3% (n = 48) were at high risk for OSA, and 71.6% (n = 58) had probable PTSD. 55.6% (n = 45) had both probable insomnia and increased risk for OSA. 46.9% (n = 38) were high risk for OSA and had both probable insomnia and PTSD. Among those with probable insomnia, seven (9.6%) had received CBT-I. Among those at increased risk for OSA, 32 (66.7%) had underwent a sleep evaluation, 22 (45.8%) were diagnosed with sleep apnea and prescribed PAP, and seven (14.6%) reported PAP use in the last week. Among those with probable PTSD, 40 (69.0%) received non-medication treatment for PTSD, including 11 (19.0%) who received CPT, PE, or EMDR.
Conclusion: Few women veterans with probable insomnia received CBT-I. One third of women with high OSA risk were not previously evaluated. Most women prescribed PAP were not currently using treatment. Few women with probable PTSD received first-line non-medication treatments for PTSD. Challenges remain in increasing access to evidence-based treatments for women veterans.

SLEEP OUTCOMES FROM THE APNEA AND INSOMNIA RELIEF (AIR) PILOT TRIAL IN VETERANS WITH POSTTRAUMATIC STRESS DISORDER

Lizabeth Goldstein[1], Ali El Solh[2], Jennifer Martin[3], Thomas Neylan[4], Kathleen Sarmiento[5], Shira Maguen[1]

[1] San Francisco VA Health Care System, [2] VA Western New York, [3] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System, [4] University of California, San Francisco, [5] San Francisco VAMC

Introduction: Among Veterans with PTSD, approximately 70% have obstructive sleep apnea (OSA) and 90% have insomnia. In patients with PTSD and OSA, positive airway pressure (PAP) use is associated with not only improvements in daytime sleepiness, but also reduction in overall PTSD symptom severity. Unfortunately, patients with PTSD have lower PAP adherence than those without PTSD, and insomnia is associated with lower levels of PAP use. We developed a behavioral sleep treatment called Apnea and Insomnia Relief (AIR) to target comorbid sleep apnea and insomnia (COMISA). This six-session, telehealth-based protocol combines aspects of motivational enhancement, psychoeducation, positive airway pressure (PAP) desensitization, and cognitive behavioral therapy for insomnia.
Methods: We conducted a pilot randomized controlled trial (RCT) comparing AIR to a Sleep Education (SE) control in Veterans with PTSD and COMISA who were recommended for PAP therapy for OSA. Sleep outcomes included PAP adherence (4+ hours use, at least 70% of past seven days), insomnia symptom severity (Insomnia Severity Index; ISI), and daytime sleepiness (Epworth Sleepiness Scale; ESS).
Results: The sample (N=34) included 32 men (94%) and two women (6%); mean age was 50 years (SD=12, range 26-76) and 43% of the sample identified as a racial or ethnic minority. One participant (randomized to AIR) dropped out of the trial. At post-treatment, 41% of participants randomized to AIR met criteria for PAP adherence, compared to 13% of participants randomized to SE ($x2(1,32)=3.06$, $p=.08$). Participants randomized to AIR demonstrated greater reduction in insomnia symptom severity from pre- to post-treatment, with average reduction on the ISI of 7.12 points (SD=7.52) for AIR, versus 4.07 points (SD=4.81) for SE ($t(30)=4.50$, $p=.0001$). Participants randomized to AIR demonstrated greater reduction in daytime sleepiness from pre- to post-treatment, with average reduction on the ESS of 4.00 points (SD=5.98) for AIR, versus 2.80 points (SD=4.07) for SE ($t(31)=3.22$, $p=.003$).
Conclusion: AIR was associated with higher PAP adherence and reduced symptoms of insomnia and daytime sleepiness in Veterans with PTSD and COMISA. Additional trials are needed to establish efficacy in a larger, more diverse sample and evaluate implementation strategies to increase access to this behavioral sleep intervention.

EMOTIONAL DREAM CONTENT OF ACUTE TRAUMA PATIENTS: ASSOCIATIONS WITH INTERPERSONAL VIOLENCE, NIGHTMARES, AND PTSD

Greg Mahr[1], Anthony Reffi[2], Lily Jankowiak[1], David Moore[1], Christopher Drake[2]

[1] Henry Ford Health, [2] Henry Ford Health System

Introduction: Dreams are involved in the processing of emotions and can serve as markers of emotional distress. The authors developed a rating scale for affect in dreams and applied it to an acute trauma population.
Methods: We recruited 88 patients hospitalized within one week following traumatic injury (Mage = 39.53 ± 14.31 years, 67.0% male, 67.0% Black). Patients who recalled a dream since hospitalization recorded their dream (n = 43). An independent rater scored the dreams using a novel 33-item Affective Neuroscience Dream Rating Scale to indicate the presence of fear, rage, grief, seeking, care, play, and lust. We quantified the emotional valence of dreams by summing positive (seeking + care + play + lust) and negative emotions (fear + rage + grief) and explored their associations with interpersonal violence and clinical outcomes approximately one-month post-trauma.
Results: The emotional valence of dreams across all patients was significantly more negative (M = 4.84 ± 2.91) than positive (M = 1.26 ± 1.16), p <.001. Experiencing negatively toned dreams was associated with increased odds of being hospitalized for interpersonal violence (OR = 1.45, p =.014, 95% CI = 1.08 – 1.96) and more severe acute stress symptoms (β = 0.36, p =.021), regardless of sex. Reporting more negatively toned dreams during hospitalization prospectively predicted risk for trauma-related nightmares one month later (OR = 1.73, p =.045, 95% CI = 1.01 – 2.97), adjusting for time, and was prospectively associated with increased nightmare distress (r =.70, p <.001), night terrors (r =.37, p =.042), and PTSD status (r =.44, p =.033). The dreams of patients who went on to screen positive for PTSD one month after trauma were significantly more negative (M = 5.99) than patients without PTSD (M = 3.70), p =.038, ηp2 = 19, indicating a large effect.
Conclusion: Negative affective tone in dreams immediately after trauma predicted subsequent nightmares and future PTSD and can provide a potential tool for assessing PTSD risk in acute trauma patients.

TRANSGENDER IDENTITY MODERATES THE ASSOCIATION BETWEEN NIGHTMARE FREQUENCY AND SUICIDAL IDEATION

Regan Virnoche[1], Matthew Gratton[1], Garrett Baber[1], Nancy Hamilton[1]

[1] University of Kansas

Introduction: Frequent nightmares are known risk factors for suicidal ideation. Nightmares and suicide are both relatively understudied within minority populations. Transgender individuals experience disproportionately higher rates of sleep disturbances and suicidality, potentially due to the minority stress of transgender identity. Despite this, the intersection of transgender identity, nightmares, and suicidality has not been adequately investigated. To address this gap, we investigated the potential moderating relationship that transgender identity may play in the association between weekly nightmare frequency and suicidal ideation severity.
Methods: We used the Assessing Nocturnal Sleep/Wake Effects on Risk of Suicide (ANSWERS) data set (N = 971), accessed through the National Sleep Research Resource. Nightmare frequency was measured using the 5-item Disturbing Dream and Nightmare Severity Index (DDNSI). The 25- item Columbia Suicide Severity Ratings Scale (CSSRS) was used to asses lifetime suicidal ideation severity. Linear regression was used to determine the association between nightmare frequency and suicidal ideation while controlling for both age and race. Transgender identity was then included as an interaction term.
Results: Weekly nightmare frequency was independently associated with lifetime suicidal ideation severity (β = 0.14, 95% CI: [0.09, 0.19], p < 0.001). Further, transgender identity moderated the relationship between weekly nightmare frequency and lifetime suicidal ideation severity (β = 0.28, 95% CI: [0.02, 0.54], p = 0.035).
Conclusion: Transgender individuals with higher weekly nightmare frequency appeared to be more likely than non-transgender to have higher lifetime suicidal ideation. This finding highlights a unique mental health disparity within the transgender population, emphasizing the importance of addressing sleep disturbances and their potential contribution to suicidality. Future research should explore the role of intersecting factors, such as minority stress, using larger and more diverse samples. These findings may help prioritize targeted care for transgender individuals experiencing frequent nightmares and suicidal ideation.

FEASIBILITY OF UNATTENDED IN-HOME POLYSOMNOGRAPHY IN TRAUMA-EXPOSED VETERANS WITH CHRONIC NIGHTMARES

Melody Robinson[1], Christine So[2], Steven Woodward[3], Philip Gehrman[4], Grace Howard[5], Katherine Miller[5]

[1] University of Tulsa, [2] Washington State University, [3] National Center for PTSD- Dissemination & Training Division, [4] University of Pennsylvania, [5] Minneapolis VA Health Care System

Introduction: Trauma-related sleep disturbances warrant assessment, but limitations of laboratory studies preclude a comprehensive understanding of these phenomena. This study assessed the feasibility and acceptability of unattended home polysomnography (hPSG) for trauma-exposed Veterans with nightmares.
Methods: Signal quality and outcomes of hPSGs in Veterans enrolled in a study investigating nightmares were reviewed. Study staff applied the equipment in the home and Veterans were instructed to go to bed near their usual bedtime. A successful hPSG was defined as ≥4 hours of total recording time (TRT) with interpretable EEG, and other key channels (muscle tone, thoraco-abdominal bands, airflow, and pulse oximetry) with adequate signal quality for ≥80% of TRT. Perception of sleep quality and the occurrence of a nightmare were collected the next morning via a sleep diary. Feasibility was examined by exploring the percentage of participants with successful and failed hPSGs. To assess acceptability, significant differences in

self-reported sleep quality and nightmare reports were examined between nights with and without hPSG.
Results: Data were available from 46 Veterans. Six participants declined to proceed with the hPSG due to illness, discomfort, or neighborhood safety concerns. Of those who completed a hPSG, 23/40 (57.5%) tests were considered successful based on all pre-specified criteria. Seventy percent had ≥4 hours of interpretable EEG data. Most participants experienced loss of one or more electrodes. Unsuccessful hPSGs were mostly due to EEG recordings being less than four hours. No baseline differences were found between Veterans with and without successful hPSGs. Regarding acceptability between nights with and without the hPSG, no differences were found for nightmare occurrence, but sleep quality was significantly worse with hPSG.
Conclusion: Unattended hPSG is partially feasible and acceptable in a group of Veterans with nightmares; however, failure was common and sleep quality was poorer on nights with the hPSG. Characteristics of a trauma-exposed sample, such as increased sweating, sleep movements, and fragmented sleep, may have contributed to these results. Tools designed to be applied independently and to endure these factors should be considered for this population.

FEAR OF SLEEP PROSPECTIVELY PREDICTS NIGHTMARE SEVERITY IN ACUTE TRAUMA PATIENTS EXPOSED TO COMMUNITY VIOLENCE

Anthony Reffi[1], Lily Jankowiak[2], David Moore[2], Sattvik Basarkod[3], Tanja Jovanovic[3], Philip Cheng[4], Hsing-Fang Hsieh[5], Christopher Drake[1]

[1] Henry Ford Health System, [2] Henry Ford Health, [3] Wayne State University, [4] Henry Ford Health + Michigan State University Health Sciences, [5] University of Michigan

Introduction: Fear of sleep engenders arousal at bedtime that can promote nightmares. Living in disadvantaged neighborhoods with high rates of community violence may exacerbate fear of sleep and in turn increase nightmare risk. We tested fear of sleep among acute trauma patients as a prospective predictor of nightmares, and whether exposure to community violence moderated this relationship.
Methods: Patients hospitalized in the intensive care unit within one week following traumatic injury (N = 88; Mage = 39.53 ± SD 14.31, 67.0% male, 67.0% Black, 47.7% income ≤ $20,000). Patients completed the Fear of Sleep Inventory (FoSI) Short Form and a community violence questionnaire during hospitalization (T1; N = 88) and the Nightmare Disorder Index (NDI) approximately two months post-trauma (T2; n = 59). We computed an NDI sum score as our outcome to indicate greater nightmare severity (nightmare frequency and nightmare-related awakenings, distress, and impairment). Skin conductance response (SCR) was collected from a subsample of patients (n = 7) during the FoSI to preliminarily explore the psychophysiological correlates of this scale.
Results: Exposure to community violence exacerbated the prospective effect of fear of sleep on future nightmare severity (β = 0.51, p =.039), such that relationship between fear of sleep at T1 and nightmare severity at T2 was strongest for patients reporting exposure to higher levels of community violence in the 90 days prior to hospitalization. SCR to the FoSI was correlated with greater exposure to community violence (r = 0.76, p =.048) and the following fear-of-sleep-related safety behaviors: "I stayed up late to avoid sleeping" (r = 0.87, p =.012) and "I tried to stay as alert as I could while lying in bed," though this relationship was nonsignificant (r = 0.74, p =.060).
Conclusion: Acute trauma patients presenting with a fear of sleep may be at increased risk for posttraumatic nightmares during recovery, especially those living within neighborhoods marked by high levels of community violence. Preliminary results suggest fear of sleep and community violence exposure may share an association with sympathetic activation which, when elevated at bedtime, could increase nightmare production.

ENHANCING PRIMARY CARE DETECTION AND REFERRAL OF NIGHTMARE DISORDER: A QUALITY IMPROVEMENT PROJECT

James Kang[1], Zahari Tchopev[1], H. Samuel Scheuller[1], William Frey[1], Collin Clay[1], Aaron Burch[1], Philip Cushman[1], Amanda Radtke[1], Jaclyn Faulk[1], Mack Peterson[2], Matthew Evans[2], David Armstrong[2], Bhavna Lalvani[2], Matthew Brock[1]

[1] San Antonio Uniformed Services Health Education Consortium, [2] Wilford Hall Ambulatory Surgical Center

Introduction: Nightmare disorder (NDO) is a significant but often under-recognized condition, especially within the military population. We previously reported that 31.2% of patients referred to our military sleep disorders center have NDO, yet only 3.9% were referred for NDO. Despite the general population's NDO prevalence (2-8%), our center had no referrals for NDO from June 1 to August 31, 2024. This quality improvement (QI) project aimed to improve NDO detection and referral rates using the nightmare disorder index (NDI).
Methods: From September 6 to October 4, 2024, the Internal Medicine Clinic (IMC) at a Military Treatment Facility (MTF) integrated the NDI into routine patient intake. Patients were categorized into three groups: negative for NDO (no nightmares or nightmares without associated symptoms), possible NDO (nightmares causing symptoms), and probable NDO (nightmares causing significant symptoms, indicated by a score of 2 or greater in each NDI section of sections 2-4). Additionally, patients with a prior NDO diagnosis were classified as symptomatic or asymptomatic. Providers were instructed to review the NDIs and refer patients for NDO as clinically appropriate.
Results: Out of 614 patients screened, 580 (94.5%) completed the NDI. Among them, 460 (79.3%) screened negative, 72 (12.4%) screened positive for possible NDO, and 12 (2.1%) for probable NDO. Additionally, 35 patients had a prior NDO diagnosis, with 25 (71.4%) remaining symptomatic. Of these symptomatic patients, 10 were on pharmacologic therapy, 3 engaged in behavioral therapy, 5 received both, and 7 had no treatment. The IMC made 16 referrals to sleep medicine during this period, with 2 referrals indicating concern for NDO.
Conclusion: This quality improvement project successfully incorporated the NDI into routine primary care screening, achieving a high completion rate. The detection of possible and probable NDO is clinically significant. However, far more patients were

identified than were referred for specialty care. Future planned QI cycles will expand this project to other primary care clinics, such as Family Health and Operational Medicine, to improve referral rates and enhance NDO identification and treatment. These efforts, which are generalizable to civilian populations, aim to reduce NDO under-recognition and improve patient quality of life.

A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL OF DOXAZOSIN FOR NIGHTMARES AND SLEEP DISTURBANCE IN PTSD

Anne Richards[1], Leslie Yack[1], Anthony Santistevan[2], Emily Berg[2], Steven Batki[2], Karen Seal[2], Thomas Neylan[1]

[1] University of California, San Francisco, [2] San Francisco VA Health Care System

Introduction: Nightmares and non-nightmare sleep disturbances are a core feature of posttraumatic stress disorder. Effective treatments remain elusive. Doxazosin is an alpha-1 adrenergic blocker with demonstrated promise, but there is a dearth of evidence from randomized controlled trials on its effectiveness. We report findings from a randomized, double-blind, placebo-controlled trial evaluating the effectiveness of doxazosin for nightmares and non-nightmare sleep disturbances.

Methods: N = 65 trauma-exposed adults (60 veterans, 21 female) with full or subclinical PTSD and prominent nightmares were randomized to either placebo (N=32) or doxazosin (N = 33) titrated to a maximum dose of 10mg daily. Primary outcomes were nightmare frequency and intensity (CAPS-4), nightmare distress (NDQ), and sleep quality (PSQI). Secondary outcomes were derived from a sleep diary mobile phone application developed by our group and included the weekly number of distressing dreams, worst distressing dream severity, and properties of sleep (sleep latency, wake after sleep onset, sleep maintenance, and total sleep time). For outcomes with two measurements, baseline-adjusted ANCOVAs were used to estimate treatment differences in change from baseline. For outcomes measured at three or more time points, linear mixed effects models were used to model change from baseline. All models adjusted for baseline values of the dependent variable of interest.

Results: Compared to placebo, participants randomized to doxazosin showed greater reduction in wake after sleep onset (adjusted $p = 0.02$), greater increase in sleep maintenance (adjusted $p = 0.047$), and greater reduction in nightmare severity (adjusted $p < 0.001$) over the course of the trial as measured by a daily sleep diary. That said, validated measures of nightmare distress (CAPS-4 nightmare items, nightmare distress questionnaire) and sleep quality (Pittsburg Sleep Quality Index) did not differ significantly over the course of the trial between treatment groups (adjusted p's > 0.05), in part due to robust placebo effects in these measures.

Conclusion: Results suggest that doxazosin may be effective for improving properties of sleep quality and reducing distressing dream severity in those with PTS and highlight the utility of a daily mobile sleep diary application, in contrast with retrospective reporting, for detecting effects.

ENHANCING DIAGNOSIS OF NIGHTMARE DISORDER AT AN ACADEMIC SLEEP DISORDERS CENTER: A QUALITY IMPROVEMENT INITIATIVE

Amanda Radtke[1], Aaron Burch[1], James Kang[1], Philip Cushman[1], H. Samuel Scheuller[1], Zahari Tchopev[1], Matthew Brock[1]

[1] San Antonio Uniformed Services Health Education Consortium

Introduction: Nightmare Disorder (NDO) is estimated to impact at least 4% of the US adult population yet is reported to be much higher among service members (SMs). Our Center has previously reported 31.2% of referred SMs had probable NDO based on screening measures, yet only 3.9% reported nightmares as a reason for evaluation. No quality measures report on the rate of confirmed diagnosis, and more importantly, treatment of NDO or its sequelae. This quality improvement project sought to address the barriers to effective identification and diagnosis of NDO by implementing tiered Plan-Do-Study-Act (PDSA) cycles.

Methods: Patients referred to our academic sleep center complete a nightmare disorder index (NDI) during their intake assessment. Retrospective chart review of May 2024 was performed to establish baseline rates of probable and possible NDO based on NDI responses, as well as rates of eventual NDO diagnoses at follow-up clinic appointments. The initial intervention instituted was to include the NDI as part of baseline characteristics listed at the top of polysomnography reports to prompt the provider at follow-up to address the finding. Chart review cycles were performed to assess the efficacy of this intervention in diagnosing NDO at follow-up.

Results: During baseline assessment period of May 2024, 167 new patients completed the NDI, with 33 (19.76%) scoring in the probable, and 66 (39.52%) in the possible NDO range. Ultimately, 5 (2.99%) of these patients were diagnosed with NDO after clinical assessment. The first intervention went into effect in July 2024. Subsequently, 72 patients completed the NDI, with 10 (13.89%) probable and 26 (36.11%) possible NDO. Of these, 3 (4.17%) patients were diagnosed with NDO after clinical assessment.

Conclusion: This ongoing quality improvement project suggests the NDI is detecting probable and possible NDO at high rates in our patient population, consistent with prior reports. The baseline clinical diagnosis of NDO was concerningly low but the initial intervention improved the rate of diagnosis. Planned PDSA cycles include tracking and improving patient follow-up to better understand the sensitivity and specificity of using the NDI in our population, and educating patients and staff on the importance of appropriately diagnosing and treating NDO.

PREDICTING DREAM RECALL AND SHARING: THE ROLE OF CHILDHOOD EXPERIENCES, MENTAL HEALTH, AND DREAM PHENOMENA

Emily Feldman[1], Rebecca Essien[1], Danya Husein[1], Danica Slavish[1]

[1] University of North Texas

Introduction: Dream recall frequency (DRF), or how often individuals remember and report dreams, is influenced by factors

such as family dynamics, mental health, and cultural norms. Women tend to report higher DRF and greater distress from nightmares, while individuals with psychiatric conditions often exhibit reduced DRF. This study examined the relative contributions of childhood experiences, mental health, and current dream-related factors in predicting DRF and dream sharing.
Methods: A sample of 360 undergraduate students (mean age = 19.91; 67.7% female; 54.44% White) completed surveys, including the Perception of Parents Scale, Bedtime Routine Questionnaire, PCL-5, GHQ-12, ISI, and Mannheim Dream Questionnaire. Hierarchical linear regression analyses were conducted to identify predictors of DRF and dream sharing.
Results: Childhood nightmares were significant positive predictors of dream recall frequency (DRF; $\beta = 0.209$, $p < 0.001$) and dream sharing ($\beta = 0.208$, $p < 0.001$). Current psychological distress (GHQ-12; $\beta = -0.146$, $p = 0.010$) predicted lower DRF, while PTSD symptoms ($\beta = -0.157$, $p = 0.009$) and distress ($\beta = -0.182$, $p < 0.001$) were associated with less dream sharing. Insomnia severity ($\beta = 0.096$, $p = 0.032$), more dream sharing ($\beta = 0.458$, $p < 0.001$), higher perceived caregiver warmth ($\beta = .082$, $p = 0.048$) and fewer sleep-related phenomena ($\beta = -0.273$, $p < 0.001$) were linked to increased DRF. When accounting for family and mental health factors (Step 3), negative dream attitudes ($\beta = -0.217$, $p < 0.001$), fewer sleep-related phenomena ($\beta = -0.439$, $p < 0.001$), and more déjà vu experiences ($\beta = 0.089$, $p = 0.040$) were significantly associated with greater dream sharing. Individuals with whom participants reported sharing and receiving dreams will be discussed.
Conclusion: While childhood nightmares initially predicted greater DRF and dream sharing, sleep-related phenomena, dream sharing, and negative attitudes toward dreams emerged as the strongest predictors. These findings suggest a dynamic, multifaceted process in which early sleep experiences, current psychological factors, and dream-related attitudes interact to shape patterns of DRF and dream sharing over time.

CHANGE IN GLOBAL AND TRAUMA-RELATED SLEEP DIFFICULTIES AMONG ADULTS RECEIVING TREATMENT FOR POSTTRAUMATIC STRESS DISORDER

Isabelle Tully[1], Alexandra Klein[2], Halle Deericks[1], Noni Pinales[1], Lori Zoellner[3], Michele Bedard-Gilligan[3], Norah Feeny[1]
[1] Case Western Reserve University, [2] VA San Diego Healthcare System, [3] University of Washington

Introduction: Sleep difficulties are prevalent among individuals with posttraumatic stress disorder (PTSD). While sleep often improves following psychotherapy for PTSD, residual sleep difficulties are common. Most studies assessing sleep in the context of PTSD treatment have relied on single-item scores. This study evaluated associations between sleep difficulties and psychopathology prior to treatment and predictors of change in global and trauma-related sleep problems following PTSD treatment.
Methods: Participants (N=146, 75.3% Female, M Age=36) enrolled in a randomized trial of prolonged exposure (PE) and PE plus sertraline completed the Pittsburgh Sleep Quality Index (PSQI), PSQI PTSD Addendum (PSQI-PTSD), PTSD Symptom Scale Self-Report for DSM-IV (PSS-SR; re-experiencing, avoidance, and arousal subscales), and Quick Inventory of Depressive Symptomatology (QIDS-SR) at baseline, post-treatment, and 3-month follow-up. Sleep-related items were removed from PSS-SR and QIDS-SR scales. Correlations examined associations between baseline self-report measures. For treatment-completers, paired t-tests compared PSQI and PSQI-PTSD scores between baseline and post-treatment and between post-treatment and follow-up. Multivariate linear regression models assessed predictors of change in sleep from baseline to post-treatment.
Results: At baseline, global sleep difficulties (PSQI) were clinically elevated (M=11.77, SD=3.26) and associated with moderately higher PSS-SR avoidance (r=.26, p=.002), arousal (r=.32, p<.001), and QIDS-SR severity (r=.30, p<.001), but not PSS-SR re-experiencing. PTSD-related sleep difficulties (PSQI-PTSD) were associated with greater PSS-SR re-experiencing (r=.48, p<.001), avoidance (r=.35, p<.001), and arousal (r=.29, p<.001) and QIDS-SR severity (r=.44, p<.001). Among treatment-completers, sleep problems decreased substantially between baseline and post-treatment (PSQI: p<.001, d=1.09; PSQI-PTSD: p<.001, d=0.96); however, mean global sleep difficulty scores remained above the clinical-cutoff of 5 (M=7.90, SD=3.87). Change from post-treatment to follow-up was non-significant, suggesting maintenance of gains. When predicting change in PTSD-related, but not global, sleep difficulties, higher baseline re-experiencing symptoms (β=.38, p=.002) was the strongest predictor of improvement in trauma-related sleep difficulties (PSQI-PTSD, R-squared=.20, F(4,84)=5.18, p<.001).
Conclusion: On average, sleep difficulties decreased substantially following trauma-focused intervention, but global sleep difficulties remained elevated. This builds upon research suggesting sleep disturbance may be better conceptualized and treated as comorbid with PTSD rather than secondary. Research identifying mechanisms mediating improved sleep can inform targeted use of adjunctive, sleep-specific interventions for patients receiving trauma-focused therapy.

AT WHAT FREQUENCY DO NIGHTMARES EFFECT SUICIDE

Ainsley Pickering[1], Emma Angle[1], Victoria West Staples[1], Westley Youngren[1]
[1] University Of Missouri-Kansas City

Introduction: A robust body of research has linked nightmares to suicide. For example, research has found that nightmares predict suicidal ideation above and beyond other mental health symptoms (such as depression and post-traumatic stress disorder) and that treating nightmares may indirectly decrease the risk of suicide. Considering the established link between nightmares and suicide, our goal was to further extend the literature by examining at what frequency do nightmares become related to suicide.
Methods: Data were collected through an online survey distributed anonymously to our participants. Embedded within the survey were measures of nightmare frequency and cognitions related to suicide. After examining the data for validity, and removing outliers, our final sample size was N = 117. Bivariate linear regression analyses were used to explore the relationship between nightmare frequency and cognitions related to suicide.

Results: Experiencing nightmares several times a month (β = 6.20, p < 0.01) and several times a week (β = 5.75, p < 0.05) both significantly predicted cognitions related to suicide. In contrast, experiencing nightmares several times a year did not significantly predict cognitions related to suicide (β = 2.12, p = 0.32). Weekly frequency accounted for 6.8% of the variance in cognitions related to suicide while monthly frequency accounted for 8.4% of the variance in cognitions related to suicide.
Conclusion: Our results revealed that experiencing nightmares at weekly or monthly rate were both predictive of cognitions related to suicide, while experiencing nightmares a few times a year was not predictive of cognitions related to suicide. Of note, monthly nightmares appeared to explain the most variance in cognitions related to suicide. Overall, our results highlight that experiencing nightmares at a monthly basis may be the tipping point for when nightmares begin to impact the risk for suicide. However, our data was cross-sectional, which impacts our ability to establish a true temporal relationship. Future research should utilize longitudinal methods to further explore at what frequency do nightmares become a risk factor for suicide.

A PROPOSED METHODOLOGY TO IDENTIFY TRAUMA-ASSOCIATED SLEEP DISORDER IN VETERANS USING ELECTRONIC HEALTH RECORD DATA

Mackenzie Lind[1], Catherine McCall[1], Rebecca Hendrickson[2]
[1] VA Puget Sound Health Care System, Seattle Division, [2] VA Puget Sound Healthcare System, Seattle Division

Introduction: The proposed clinical phenotype of trauma-associated sleep disorder (TASD) includes repetitive trauma nightmares, dream enacting behaviors, and nighttime autonomic symptoms. Symptoms overlap with post-traumatic stress disorder (PTSD), rapid eye movement sleep behavior disorder (RBD) and obstructive sleep apnea (OSA). TASD is clinically relevant given high rates of post-traumatic sleep disturbances and known associations between RBD and neurodegeneration. However, TASD is not formally recognized, and more research is needed on its epidemiology and classification within clinical datasets. Here, we describe planned methods for identification of a potential TASD cohort based on electronic medical record (EMR) data which can be used to further characterize TASD.
Methods: Data was extracted from the EMR of Veterans with polysomnography studies within the national VA system (N= 1,036,952, 92% male, mean [SD] age 64.9 [13.9]) utilizing the VA Informatics and Computing Infrastructure. Sleep and psychiatric diagnoses were obtained from ICD10 codes. Full text search of clinical note data identified documented instances where the phrase "trauma associated sleep disorder" was present within a Veteran's chart, indicating that this diagnosis was likely being considered.
Results: Prevalence of related sleep and psychiatric comorbidities within the full sample were as follows: 36.1% (PTSD), 68.4% (OSA), 1.2% (RBD), 0.8% (other/unspecified parasomnia). There were 519 individuals where clinical note text search identified the term TASD; for these Veterans, prevalence of the above disorders was 86.1% (PTSD), 90.6% (OSA), 35.1% (RBD), and 38.5% (other/unspecified parasomnia).
Conclusion: Preliminary results demonstrate high prevalence of comorbid sleep and related disorders, particularly in Veterans whose clinical charts mention TASD as a diagnostic consideration. This highlights the complexity of creating a proxy variable distinguishing TASD from related diagnoses. Ongoing work will incorporate both subjective (e.g., dream enactment) and objective (e.g., autonomic parameters) clinical data to create a proxy diagnostic phenotype for TASD, which can be combined with polysomnography data to examine sleep architecture and autonomic arousal; data on prescribed medications will also be incorporated. Though preliminary, this line of research has potential to improve our understanding of mechanisms involved in disturbed sleep following trauma.

NIGHTMARES & INSOMNIA, DIFFERING IMPACTS ON SUICIDE

Victoria West Staples[1], Emma Angle[1], Todd Bishop[2], Wilfred Pigeon[3], Westley Youngren[1]
[1] University Of Missouri-Kansas City, [2] VA Center of Excellence for Suicide Prevention, [3] University of Rochester Medical Center

Introduction: Previous research has shown that both insomnia and nightmares are related to suicide. However, the literature currently disagrees about the relationship between nightmares and suicide, with some researchers suggesting that the majority of variance in nightmares predicating suicide is better explained by fear of sleep and/or insomnia. Our goal was to use a stepwise regression analysis to further explore the relationship between insomnia, nightmares, and suicide (while controlling for fear of sleep), with the aim of providing clarifying information to the aforementioned argument.
Methods: Participants (N = 218) completed an anonymous online survey which included the following measures: self-reported insomnia symptoms (Insomnia Symptom Index), frequency of trauma-related nightmares (Trauma-Related Nightmare Survey), fear of sleep (Fear of Sleep Inventory; FoS), and cognitions related suicide (Brief Suicide Cognition Scale; SCS). To examine the incremental predictive power of our variables of interest, a stepwise regression model was utilized where in step-1 FoS will be the only predictor, and in step-2 both nightmares and insomnia will be added into the regression model.
Results: In the first step of our model (with FoS as the only predictor), FoS significantly predicted SCS (b = 0.47, p < 0.01; F = 24.89, p < 0.001). In the second step of our model (adding insomnia and nightmares as predictors), nightmares (b = 3.82, p <.05) and insomnia symptoms (b = 0.89, p <.001) both independently predicted cognitions related to suicide, but FoS no longer significantly predicted SCS (p = 0.30). The second step of our model significantly explained 24.04% of the variance in SCS (F = 15.61, p < 0.001).
Conclusion: Increase in suicide cognitions was predicted by both nightmares and insomnia, even when controlling for FoS. These results lend evidence to the idea that both nightmares and insomnia independently impact suicide, and that nightmares are not just an effect of insomnia and/or FoS. This is clinically relevant as it suggests two unique variables (insomnia & suicide) that could be targeted with interventions, with the overall goal of reducing the risk of suicide.

INTEGRATED INSOMNIA/PTSD TREATMENT LED TO REDUCTIONS IN INSOMNIA, PTSD, AND PAIN INTERFERENCE AMONG VETERANS

Anne Malaktaris[1], Breanna Holloway[2], Kira Clare[3], Peter Colvonen[4]

[1] Center of Excellence for Stress and Mental Health, VA San Diego, [2] UC San Diego, [3] VA San Diego, [4] University of California, San Diego

Introduction: Among Veterans with posttraumatic stress disorder (PTSD), sleep disturbances are almost ubiquitous with 70 - 87% reporting comorbid insomnia. Chronic musculoskeletal pain (CP) likewise frequently co-occurs with PTSD; 50-70% of Veterans seeking PTSD treatment have CP, and comorbid PTSD/CP is associated with high rates of sleep disturbances. Thus, insomnia, PTSD, and pain are highly co-occurring. Though there is evidence that integrated Cognitive Behavioral Therapy for Insomnia (CBT-I) and Prolonged Exposure (PE) are effective in decreasing both insomnia and PTSD symptoms, the effects of integrated PTSD/insomnia treatment on pain over time and whether pain attenuates treatment outcomes is unknown.
Methods: We conducted secondary analyses with data from an RCT comparing integrated CBT-I + PE to a hygiene plus PE to optimize PTSD, sleep, and quality of life outcomes in N = 94 Veterans. PTSD symptom severity (PTSD Checklist; PCL-5), insomnia severity index (ISI), The Brief Pain Inventory (BPI) for pain severity, and the Patient-Reported Outcomes Measurement Information System (PROMIS) Pain Interference measures were collected at baseline, week 5, posttreatment, and 3-month follow up.
Results: Individuals with higher chronic pain severity and pain interference reported greater PTSD symptom severity (r =.33, p <.001; r =.36, p <.001, respectively) and insomnia severity at baseline (r =.34, p <.001; r =.39, p <.001, respectively). Hierarchical linear models showed that neither baseline pain severity nor pain interference hindered successful integrated insomnia + PTSD treatment trajectories (beta = 0.1, p =.22). Finally, collapsing across sleep and PE treatments, treatment resulted in clinically meaningful reduction in both pain interference and pain intensity (beta = -0.11, p =.002); results did not differ by treatment arm.
Conclusion: Integrated sleep + PE treatments were no less effective in reducing insomnia and PTSD symptom severity among Veterans with comorbid chronic pain; in fact, these treatments also led to reductions in pain severity and interference despite not including pain-specific interventions. Thus, integrated insomnia/PTSD treatments are an efficacious, parsimonious options for the common, complex clinical presentation.

INCREASED RATE OF DEMENTIA IN PTSD IS REDUCED BY ALPHA-1-ANTAGONIST PRAZOSIN TO TREAT NIGHTMARES: A RETROSPECTIVE STUDY OF VETERAN MEDICAL RECORDS

Savanah Sicard[1], Gregory Scott[1], Lee E. Neilson[1], Rebecca C. Hendrickson[2], Elaine R. Peskind[3], Murray A. Raskind[4], Jeffrey J. Iliff[5], Carolyn Tinsley[1], Jonathan Elliott[1], Miranda Lim[6]

[1] VA Portland Health Care System, [2] University of Washington, Department of Psychiatry and Behavioral Sciences, [3] University of Washington, School of Medicine, Department of Psychiatry and Behavioral Sciences, [4] University of Washington, School of Medicine Department of Psychiatry and Behavioral Sciences, [5] VISN [20] Mental Illness Research, Education, and Clinical Center, [6] Oregon Health & Science University

Introduction: Adults with post-traumatic stress disorder (PTSD) have a significantly increased risk for developing dementia. With previous work linking sleep-related glymphatic dysfunction to neurodegeneration, sleep disturbances in PTSD are a potential target for decreasing this risk. Clinical trials demonstrated prazosin, an alpha-1-antagonist, improves sleep quality by decreasing nightmares in Veterans with PTSD, and rodent trials showed prazosin improves glymphatic flow. Here, we investigate the effect of prazosin on dementia risk in clinical PTSD populations through a retrospective analysis of medical records from the nationwide VA Corporate Data Warehouse.
Methods: Records were divided into 4 groups: -PTSD/-prazosin (control, N = 300,000), -PTSD/+prazosin (N = 47,652), +PTSD/-prazosin (N = 300,000), and +PTSD/+prazosin (N = 59,778). Inverse probability of treatment weighting (IPTW) adjusted for sex, race, ethnicity, birth year, hypertension, benign prostatic hyperplasia, traumatic brain injury, and sleep disorders. ICD-9 and ICD-10 codes were used to determine diagnoses, and prescription history determined prazosin treatment. To prevent reverse causation, all independent variable diagnoses needed to occur ≥ 1 year before the dementia diagnosis, and all records needed to be ≥ 5 years long. Because many Veterans have an unknown PTSD onset date, the record start date was used as onset.
Results: Compared to controls, prazosin alone accounted for 2.6 [2.3, 2.9] 95% CI and 3.7 [3.3, 4.0] 95% CI extra cases of dementia per 1000 people after 10 and 20 years respectively, and PTSD without prazosin accounted for 7.6 [7.4, 7.9] 95% CI and 11.4 [11.1, 11.8] 95% CI extra cases of dementia after 10 and 20 years respectively. There was a significantly reduced incidence of dementia in the PTSD group that received prazosin of 4.3 [3.6, 5.0] 95% CI at 10 years, while the effect decreased at 20 years with an incidence of 10.1 [9.2, 10.9] 95% CI.
Conclusion: Prazosin may have long-term neuroprotective benefits for those with PTSD and the heightened risk for dementia in PTSD may be prevented. More research is needed on neurological and glymphatic effects of prazosin in healthy and PTSD populations.

THE SEATTLE TRAUMA AND AUTONOMIC RELATED SLEEP SYMPTOMS SCALE: A SELF-REPORT FOR NIGHTMARES AND SLEEP DISRUPTIONS WITH ASSOCIATED AUTONOMIC SYMPTOMS

Aaron Rosser[1], Garth Terry[1], Kimberly Hart[2], Sarah Campbell[1], Murray A. Raskind[3], Rebecca Hendrickson[4]

[1] University of Washington, [2] VA Puget Sound Healthcare System, [3] University of Washington, School of Medicine Department of Psychiatry and Behavioral Sciences, [4] VA Puget Sound Healthcare System, Seattle Division

Introduction: Nightmares and sleep disruption are hallmarks of posttraumatic stress disorder (PTSD), cause significant distress, and often persist after the remission of other symptoms. Autonomic dysregulation, including tachycardia, excessive sweating, and panic, have been implicated in the pathophysiology of PTSD. Existing self-report measures for nightmares and disrupted sleep primarily focus on subsets of the relevant clinical features, with relatively little emphasis on symptoms of autonomic dysregulation during sleep, restricting their ability to quantitatively assess the impact of trauma on sleep or to track treatment response. Here, we describe a new 11-item self-report measure, the Seattle Trauma and Autonomic Reactivity Sleep Symptoms Scale (STARSS), which assesses commonly encountered clinical symptomatology of trauma-associated sleep disruptions including nightmares, autonomic symptoms during sleep, and sleep-related hypervigilance.
Methods: Items of the scale were derived from a series of clinician assessments of sleep-related symptoms observed in practice and research settings of PTSD treatment to respond to prazosin, an alpha-1 adrenoceptor antagonist. Psychometric validation of the STARSS was conducted in a sample of 830 healthcare workers and first responders working during the COVID-19 pandemic. Measures of internal consistency, discriminant and convergent validity, sensitivity, specificity, and factor structure were conducted in the study sample.
Results: The STARSS was positively correlated with self-report measures covering symptom domains additional to nightmares and commonly elevated following trauma exposure, including PTSD (PCL-5; r=0.76), anxiety (GAD7; r=0.67), depression (PHQ9; r=0.63), and insomnia (ISI; r=0.54), and displayed strong internal consistency (α=0.88; ω=0.93). Underlying factors included sleep-related hyperarousal, partner/self-reported activity in sleep, and trauma dream intensity.
Conclusion: The STARSS is a brief, clinically informed questionnaire assessing autonomic and trauma-related symptoms during sleep, with strong psychometric validity. The scale is more highly correlated to PTSD symptom burden than are existing measures of insomnia and anxiety, suggesting specificity for trauma-related sleep disruption. Future work will explore the utility of the STARSS in clinical and research contexts for identifying treatment targets and tracking treatment response, as well as testing the potential for the measure to identify individuals likely to respond to specific interventions, supporting a precision medicine approach.

INCREASED ELECTROMYOGRAPHIC ACTIVITY DURING RAPID EYE MOVEMENT SLEEP IN ACTIVE DUTY WARFIGHTERS WITH POST-TRAUMATIC STRESS DISORDER

Grant Tays[1], Caddie Motoni[2], Amanda Studnicki[1], Angeliki Pollatou[1], Bradford Clemens[2], Elizabeth Metzger[1], J. Kent Werner[2]
[1] Walter Reed National Military Medical Center, [2] Uniformed Services University

Introduction: REM sleep without atonia (RSWA) is a key criteria for diagnosing REM Behavior Disorders (RBD), which has been strongly associated with Parkinson's disease and dementia. RBD prevalence is increased in the Veteran population, and further increased in Veterans that have been diagnosed with traumatic brain injury (TBI) and post-traumatic stress disorder (PTSD). PTSD and TBI share common underlying pathology that could manifest in RBD, and some data suggests RSWA is increased in these populations RSWA, therefore, may have potential to serve as a biomarker of neurodegeneration and/or sympathetic hyperactivityIn this study, we aimed to investigate whether RSWA differs between Warfighters with PTSD (PTSD+) and those without (PTSD-).
Methods: We compared polysomnography data of 7 PTSD+ active duty Warfighters from Walter Reed National Military Medical Center and compared these data to 5 healthy control Active Duty Warfighters. Following clinician graded sleep scoring, we used the RBDtector, an open-source software, to analyze EMG activity and sleep stages in the chin and tibialis anterior. In our initial analysis, we used a one-way ANOVA to determine if RSWA is higher in PTSD+ Warfighters compared to PTSD-.
Results: PTSD+ Warfighters had significantly higher phasic (0.1 – 5.0s) bouts of chin EMG activity ($p < 0.001$). Further, there was overall increased EMG activity ($p = 0.003$) in PTSD+ compared to controls. Data analysis is still ongoing to reach 150 participants in each group. Further analysis will include linear mixed effect models, controlling for age and medications such as serotonin norepinephrine reuptake inhibitors.
Conclusion: Our data show that Warfighters with PTSD had higher EMG activity during REM sleep than Warfighters without PTSD. More data will lend further insights to support these findings and provide more evidence to support the overlapping underlying neuropathologic pathways in PTSD and RBD. Such insights could enhance our understanding of the shared mechanisms underlying PTSD, RBD, and related neurodegenerative conditions.

TARGETED DREAM INCUBATION'S IMPACT ON DREAM SELF-EFFICACY & JOY

Westley Youngren[1], Emma Angle[2], Victoria West Staples[2], Sarina Soligo[1], Adam Horowitz[3], Michelle Carr[4], Guillermo Bernal[3], Robert Stickgold[5]
[1] University of Missouri Kansas City, [2] University of Missouri-Kansas City, [3] Massachusetts Institute of Technology, [4] University of Montreal, [5] Harvard Medical School

Introduction: Targeted Dream Incubation (TDI) is the process of utilizing verbal cues (such as, "while you try to fall asleep, try and think of a tree") during pre-sleep stages in order to directly shape dream content. Preliminary results have demonstrated that TDI may be able to increase dreaming self-efficacy (DSE). Our study aimed to replicate and extend initial findings by examining TDI's impact on DSE and related variables.
Methods: Fifteen participants completed the TDI protocol, which included a pre-nap assessment (baseline), a 1.5-hour nap opportunity, a post-nap assessment, and a one-week follow-up assessment. In all assessments, we measured DSE and subjective feelings related to dreaming. During the nap, when entry into hypnagogia was detected (via a portable EEG system) dream reports were collected and afterwards participants were again given the verbal cue and told to continue sleeping. Non-parametric statistics were used to examine descriptives, compare means, and explore linear relationships.

Results: Most participants (n = 12; 80%) reported at least one dream that included the cued subject (a tree). Mean comparison analyses found that post-nap DSE (M = 4.56, SD = 1.55) and one-week follow-up DSE (M = 4.45, SD = 1.69; $p < 0.05$) were both significantly higher than baseline DSE (M = 3.49, SD = 1.54; $p < 0.05$); and that joy related to dreams measured at the one-week follow-up (M = 4.36, SD = 1.55) was significantly higher than joy related to dreams measured at baseline (M = 3.14, SD = 0.66; $p < 0.05$).
Conclusion: Findings both replicate and extend prior research, by demonstrating that TDI may be a reliable method for increasing DSE. Additionally, these findings are the first of their kind to demonstrate that TDI may also impact joy related to dreaming. Both results are quite meaningful as prior research has linked self-efficacy to positive treatment outcomes, and low levels of joy have been linked to outcomes such as depression and suicide. Although statistical power was accounted for, the small sample size is still a limitation of the findings and directly impacts generalizability.

EXPLORING DREAM SELF-EFFICACY'S RELATIONSHIP WITH SUICIDE

Westley Youngren[1], Emma Angle[2], Victoria West Staples[2], Sarina Soligo[1], Adam Horowitz[3], Michelle Carr[4], Guillermo Bernal[3], Michael Grandner[5], Robert Stickgold[6]
[1] University of Missouri Kansas City, [2] University of Missouri-Kansas City, [3] Massachusetts Institute of Technology, [4] University of Montreal, [5] University of Arizona College of Medicine, [6] Harvard Medical School

Introduction: Research has begun to identify self-efficacy as a crucial variable related to positive treatment outcomes. For treatments targeting nightmares, self-efficacy related to dreaming (DSE) has been proposed to be a key mechanism of change. Additionally, a robust amount of research exists that links nightmares to suicide, suggesting that mechanisms related to trauma-related nightmares may also be related to suicide. Thus, we sought to explore the relationship between DSE and suicide in a protocol that actively attempted to increase DSE.
Methods: Fifteen participants completed our Targeted Dream Incubation (TDI) protocol, which includes cueing participants for dream reports once hypnogogic sleep is detected, then after dream reports giving participants the following cue, "while you try to fall asleep, try and think of a tree". Then after the cue is given, allowing participants to continue sleeping. The protocol included a pre-nap assessment (baseline), a 1.5-hour nap, a post-nap assessment, and a one-week follow-up assessment. In all assessments, we measured DSE. Cognitions related to suicide were measured at baseline and one-week follow-up. Non-parametric mean comparison analyses and bivariate regressions were used to analyses our aims.
Results: Post-nap DSE scores ($t = -2.11$, $p < 0.05$) and follow-up DSE scores ($t = -1.89$, $p < 0.05$) significantly increased after the TDI protocol. Pre-nap DSE ($r = -0.59$), Post-nap DSE ($r = -0.66$) and follow-up DSE ($r = -0.74$) were all significantly negatively correlated with follow-up cognitions related to suicide ($p < 0.05$). The change of DSE between baseline and follow-up was significantly negatively predictive of cognitions related to suicide ($b = -0.24$, $p < 005$).
Conclusion: Our results are the first of their kind to demonstrate the DSE is both correlated with and predictive of cognitions related to suicide. Furthermore, our results highlight that changes in DSE brought about by TDI may reduce suicidal cognitions. Future research should examine DSE, suicide, and TDI under the context of a trauma-related nightmare intervention. Although statistical power was accounted for, our small sample size was small and directly impacts generalizability. Further data collection is needed to strengthen and confirm our findings.

PERSONALITY TRAITS ARE ASSOCIATED WITH NIGHTMARE FREQUENCY AND DISTRESS

Michael Price[1], Odalis Garcia[1], Jeremy Hamm[1], Katherine Duggan[1]
[1] North Dakota State University

Introduction: Many studies involving the relationship between personality and nightmare frequency (NF), common in cross-sectional data, have only looked at neuroticism in isolation, assumed a linear relationship, or did not include nightmare disorder index (NDI) to determine if personality traits might predict NDI over NF. While neuroticism is the personality trait most commonly associated with nightmares, theoretically due to negative emotionality or emotional instability, including all five traits allows for a more holistic outlook into this relationship. Particularly, conscientiousness, agreeableness, and (low) neuroticism tend to form a higher order stability composite, whereas openness and extraversion are more related to adaptability to new experiences.
Methods: Our pre-registered data analysis comes from Wave 5 of the NDSU National COVID study, where participants completed questionnaires about the Big Five, NF, and NDI (N=436; mean age = 59.20, range 22-93; 55.96% female). Pearson correlations were used to examine bivariate associations between personality and nightmares, and Loess curves were used to evaluate possible curvilinear associations.
Results: Neuroticism was the strongest, statistically significant correlate of NF and NDI ($r = .26$ and $.25$, respectively), followed by conscientiousness ($r = -.16$ and $-.14$). Next, extraversion was correlated with NF and NDI ($r = -.11$ and $-.12$), while agreeableness was only correlated with NF ($r = -.16$, $p = .001$). Associations for openness were not statistically significant ($p \geq .26$), and we found no strong evidence of curvilinearity.
Conclusion: Our results clarify the relevance of personality for nightmares. In line with prior studies, we find moderate associations between neuroticism and nightmares, as well as three of the other Big Five traits (conscientiousness, extraversion, and agreeableness). Overall, these traits emphasize the relevance of self-regulatory personality processes for sleep. We also found similar associations for NF and distress, highlighting the relevance of self-regulatory traits for multiple dream-related sequelae. These findings highlight the need for longitudinal research on personality and nightmares, which can inform clinical work using personality as a tool to identify people at risk of nightmares and identify whether personality can be leveraged in clinical interventions.

DIFFERENTIATING TYPICAL DREAMS, DISRUPTIVE DREAMS, PERCEIVED NIGHTMARES, AND TRUE NIGHTMARES USING DISCRIMINANT FUNCTION ANALYSIS

Odalis Garcia[1], Michael Price[1], Katherine Duggan[1]
[1] North Dakota State University

Introduction: There is currently no consensus on the definition of nightmares. Most participants define nightmares as "bad dreams" with intense, distressing emotions. Per the DSM-5, nightmares are distressing dreams, but to be diagnosed with nightmare disorder, the dreams must awaken the dreamer. Surprisingly, research has not evaluated the characteristics dreamers use to categorize their nightmares. Evaluating the characteristics that distinguish between dream types can reduce ambiguity and potentially improve clinical research.
Methods: In this ongoing pre-registered study, participants (n=53) self-report their psychosocial factors, sleep, and the most recent dream. Participants are given instructions to maintain actigraphy, sleep diaries, and dream diaries for one week. Thus, participants have up to 2 dream reports across the week of the study. We utilized discriminant function analysis (DFA) to describe the differences in dream content for dreams classified as true nightmares, perceived nightmares, disruptive dreams, and typical dreams.
Results: Overall, the DFA could distinguish between dream types using one canonical correlation ($p<.0001$) which classified dreams much better than chance. However, errors were heterogeneous and were highest for classifying true nightmares, followed by perceived nightmares (33% and 30%, respectively). Adversity, positivity, negativity, and deception were important in distinguishing dream types. Follow-up contrast analyses showed dream characteristics did not significantly differentiate true nightmares from other dream types. However, when true and perceived nightmares were grouped, they were significantly more negative than disruptive and typical dreams ($p=.002$). Surprisingly, there were no significant differences between dreams that woke participants up and those that did not, as well as no differences between typical dreams and all others ($ps\geq.08$).
Conclusion: These results suggest that dream content distinguishes dream types, but not following current clinical guidelines: true (clinical) nightmares and perceived nightmares were more similar to each other than all other categories. This implies the awakening definition of nightmares is too restrictive, and that intense negativity perhaps best distinguishes clinically-meaningful nightmares from all other dream types. The definition of nightmares is important when considering the generalizability of research and screening for nightmares at the population level.
Support (if any): This research was supported in part by funding from the NSF GRFP and NIGMS (P30GM114748).

2NITEMARES: THE RELATIONSHIP BETWEEN NIGHTMARES AND INTEGRATED CBT-I AND PROLONGED EXPOSURE TREATMENTS AMONG VETERANS WITH INSOMNIA AND PTSD

Kira Clare[1], Riona Yoshida[1], Kimberly Savin[2], Abigail Mack[1], Peter Colvonen[1]
[1] VA San Diego, [2] Center of Excellence for Stress and Mental Health

Introduction: Nightmares and insomnia commonly co-occur with Posttraumatic Stress Disorder (PTSD), with 70% to 91% of individuals with PTSD reporting chronic nightmares and insomnia. Evidence suggests that even gold standard treatments for PTSD (such as Prolonged Exposure, PE) and insomnia (CBT-I) individually may not fully resolve nightmares. Our study presents secondary analyses of a randomized controlled trial of integrated CBT-I and PE (CBTI-PE), compared to sleep hygiene and PE (hygiene-PE) on nightmares.
Methods: We examined a) how nightmare frequency and maximum distress severity changed over the course of treatments (baseline, 5-week, post, and 3-month follow up); and b) if baseline nightmares interfered with the efficacy of treatment. Participants were 94 Veterans with PTSD and insomnia (23.4% female; 52.1% white; age M= 40, SD=12) with mean baseline PTSD Checklist (PCL-5) score of 55.6 (SD = 12.55) and Insomnia Severity Index (ISI) score of 20.53 (SD = 4.73). Participants completed seven-day sleep diaries including number and severity of distress from nightmares (0-10). Nightmare maximum distress was the highest severity rating.
Results: Baseline sleep diaries showed participants averaged 0.86 nightmares per night (SD = 0.89) with maximum distress of 5.69 (SD=1.47) out of 10. Neither baseline average number of nightmares nor maximum nightmare distress correlated with ISI ($r=.26$, $r=.13$, $p=.32$). Only maximum distress correlated with PTSD at baseline ($r=.41$, $p<.001$). Hierarchical linear modeling showed that the number nightmares ($\beta = -0.11$, $p =.002$) and maximum distress ($\beta =-0.46$, $p =.02$) significantly decreased over both treatments, but there were no differences between groups. Follow-up analyses suggest that PE (after week 5) had larger effects on nightmares than either sleep intervention. No baseline nightmare variables interfered with PTSD or ISI treatment outcomes.
Conclusion: CBTI-PE and hygiene-PE showed decreased nightmare frequency and severity; this may be due to the PTSD treatment. However, there were residual nightmares and maximum distress that may require further intervention. Our finding that nightmares do not have an impact on insomnia and PTSD treatment efficacy is consistent with recent literature.
Support (if any): The study was supported by Department of Veterans Affairs RRD Grant (1lK2Rx002120-01).

PREDICTORS OF SUICIDAL IDEATION WITHIN THE FIRST YEAR POSTPARTUM: WHAT'S SLEEP GOT TO DO WITH IT?

Sammy Dhaliwal[1], Katherine Sharkey[2], Philip Gehrman[3], Huynh-Nhu Le[4], Jennifer Keller[5]
[1] University of Pennsylvania, Perelman School of Medicine, [2] Warren Alpert School of Medicine at Brown University, [3] University of Pennsylvania, [4] The George Washington University, [5] The George Washington University School of Medicine

Introduction: Together, sleep disturbance and postpartum depression constitute the most prevalent pregnancy-related medical complications. Suicide is the leading cause of death in the first year postpartum. However, longitudinal follow-up of suicidal ideation is rare, especially among women who experience early, persistent sleep disturbance. We assessed the stability of suicidal ideation (SI) over the first year postpartum, and whether sleep disturbance (insomnia severity, disordered breathing)

modified the relationship between postpartum depression and SI, over time.
Methods: 324 women repeated sleep (Pittsburgh Sleep Quality Index), and mood (Edinburgh Postnatal Depression Scale) assessments at postpartum week-6, 12, 24, 36, 50. The EPDS included a single item probing suicidal ideation on a 4-point Likert scale. Among these, 49 women also completed wrist actigraphy at 6-8 weeks postpartum.
Results: Forty-seven (14.5%) women endorsed some form of SI during the first year postpartum. Within-woman, these assessments tended to peak at 9-months postpartum. Among women with accelerometer and diary data, those with later sleep onset and midpoint at 6-weeks postpartum were significantly more likely to experience more severe depression (d=.3, p<.01). Ten of these women (20%) endorsed thoughts of self-harm above "never" at some point during the first year postpartum. Women with shorter objective and self-reported sleep duration, as well as difficulty initiating and maintaining sleep were at greater risk for SI over time (Beta =.91, p<.01). Women with greater variability in night-to-night sleep patterns experienced the most severe SI at each time point assessed.
Conclusion: Both sleep timing and insomnia may predict suicidal ideation among women with mild-moderate postpartum depression symptoms. Objective accelerometer data on night-to-night patterns seemed to be the strongest predictor of frequency and severity of SI. Women with PPD would benefit from ongoing assessments of both sleep and mood throughout the first year postpartum, with the understanding that sleep may be less stigmatizing to probe.

MELANOPSIN-DRIVEN LIGHT RESPONSIVITY AND REWARD MOTIVATION IN YOUNG PEOPLE AT RISK FOR MANIA

Lauren Keller[1], Margaret Kuzemchak[1], Meredith Wallace[1], Brock Sollie[1], Nathan Elia[1], Allison Caswell[2], Simey Chan[2], Brant Hasler[1], Kathryn Roecklein[1], Adriane Soehner[1]
[1] University of Pittsburgh, [2] University of Pittsburgh Medical Cen ter

Introduction: Mania is associated with circadian and reward dysregulation, and there are strong reciprocal relationships between the circadian and reward systems. To better detect and prevent mania, it is essential to characterize potentially abnormal biobehavioral relationships between the circadian and reward systems that may confer risk for mania. Light signals conveyed through melanopsin-containing retinal ganglion cells are one of the strongest influences on the biological clock. We examined the extent to which melanopsin-driven light responsivity (via pupillometry) is associated with reward dysregulation in young people at-risk for mania.
Methods: Ninety-five participants aged 16-24yr (M=21.82, SD=2.02) spanning a spectrum of mania vulnerability (MOODS-SR-Lifetime, MOODS) completed a 24-hr lab visit. Testing included melanopsin-driven pupil responsivity (post-illumination pupil response, PIPR), reward-based aggression (Point Subtraction Aggression Paradigm, PSAP), and reward motivation (Effort Expenditure for Rewards Task, EEfRT). PIPR was estimated at 10-40sec (PIPR30) after the light stimulus, calculated as a percent of baseline. Poisson regression models assessed PIPR's associations with reward-related outcomes and moderation by lifetime mania risk (MOODS mania score), adjusting for age, sex assigned at birth, past-week depression and mania symptoms, psychotropic medication use, time spent awake, photoperiod, and MOODS depression score. Johnson-Neyman intervals were used to examine the range of significant moderation (interaction) effects.
Results: There was a significant interaction (RR=1.45. p< 0.001) between melanopsin-driven light sensitivity (PIPR30) and mania risk (MOODS-Mania) for reward-related aggression (PSAP percent steals). A Johnson-Neyman test showed that lower PIPR30 was associated with greater PSAP percent steals at low/moderate mania vulnerability (MOODS-Mania values < 16) but this relationship was reversed for individuals with higher levels of mania vulnerability (MOODS-Mania> 23). There was not a significant association between PIPR30 and reward motivation (EEfRT % hard choices; RR=0.14, p=0.643) nor a significant moderating effect of mania risk (RR=2.00. p=0.238).
Conclusion: Our interim findings indicate that, as mania risk increases, greater melanopsin-driven pupil responsivity is associated with greater reward-related aggression. This finding may reflect abnormal associations between the circadian and reward systems among individuals with elevated vulnerability to mania that, when exacerbated, contribute to irritability and aggressive behavior associated with mania/hypomania.

WEEKEND CATCH-UP SLEEP AND DEPRESSIVE SYMPTOMS IN EMERGING ADULTS: RESULTS FROM THE NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY

Melynda Casement[1], Jason Carbone[2]
[1] University of Oregon, [2] Wayne State University

Introduction: Short sleep duration and late and irregular sleep timing are associated with risk for depressive symptoms, a leading cause of disability in emerging adults. However, weekend catch-up sleep (WCS) -- compensatory sleep with later sleep timing on weekends -- has been associated with reductions in depressive symptoms in some adult samples. The present study evaluates associations between WCS and daily depressive symptoms in a large and nationally representative sample of emerging adults.
Methods: Secondary data analyses were conducted using data from 16–24-year-olds in the National Health and Nutrition Examination Survey (NHANES 2021-2023; N = 1087). Participants' reports of weekend and weekday bed- and wake-times were used to calculate WCS. Analyses were conducted with dichotomized WCS (>0 h or 2h, >0-2h,
Results: Emerging adults with WCS had 60% lower odds of daily depressive symptoms compared to those without WCS. Analyses with three categories of WCS indicated that emerging adults with WCS up to or greater than 2 hours had lower odds of depressive symptoms compared to those without WCS, but depression risk did not differ between those with WCS of >0-2 h versus >2h.
Conclusion: WCS may reduce the frequency of daily depressive symptoms in emerging adults. For emerging adults who find it difficult to get enough sleep during the week or maintain consistent bed- and wake-times, WCS can be a healthy sleep habit.

Additional research is needed to parse the relative benefits of WCS versus consistent weekday-weekend sleep duration and timing.

DAYTIME NAPPING AND DEPRESSION IN BIPOLAR DISORDER: FINDING FROM THE APPLE COHORT STUDY

yuichi Esaki[1], Kenji Obayashi[2], Keigo Saeki[2], Kiyoshi Fujita[1], Nakao Iwata[3], Tsuyoshi Kitajima[3]
[1] Okehazama Hospital, [2] Nara Medical University School of Medicine, [3] Fujita Health University School of Medicine

Introduction: The relationship between daytime napping and depression remains debatable. Thus, we investigated whether daytime napping is associated with depressive symptoms in patients with bipolar disorder.
Methods: In a cross-sectional study, we recruited 204 outpatients with bipolar disorder who were participants in the Association between Pathology of Bipolar Disorder and Light Exposure in Daily Life (APPLE) cohort study. Each participant's daytime napping was measured using an actigraph over 7 consecutive days. Depressive symptoms were evaluated using the Montgomery–Åsberg Depression Rating Scale, and scores of ≥8 points were considered indicative of a depressed state.
Results: One-hundred and ten (53.9%) participants were depressed. In multivariable logistic regression analysis, as the number of nap days, number of naps per day, and nap duration increased, the odds ratio (OR) for depressed state significantly increased. Additionally, compared to the participants who did not nap, the participants who napped on five or more days a week or who had an average nap duration over 60 min had more than three times higher ORs in the depressed state (number of nap days: OR, 3.66; 95% confidence interval [CI], 1.32–10.17; nap duration: OR, 3.14; 95% CI, 1.12–8.81).
Conclusion: We found a significant and independent association between daytime napping and depressive symptoms in patients with bipolar disorder. Further studies are needed to identify the effect of short napping on depressive symptoms in patients with bipolar disorder.

THE ROLE OF SLEEP HYGIENE IN THE COMORBIDITY OF GAD AND MDD SYMPTOMS IN AN UNDERGRADUATE SAMPLE

Anna Quesada[1], Matt Judah[2], Morgan Middlebrooks[2]
[1] University of Kansas, [2] University of Arkansas

Introduction: Major depressive disorder (MDD) and generalized anxiety disorder (GAD) are highly comorbid. These conditions commonly develop during early adulthood, and they negatively impact health and social, academic, and workplace functioning. Sleep hygiene, which includes behaviors and routines that support consolidated sleep, may be a factor in GAD/MDD comorbidity. Indeed, sleep disturbances are a symptom of both disorders. We tested the hypothesis that GAD and MDD symptoms would be more highly correlated at lower levels of sleep hygiene. Participants (N= 180) were undergraduate students recruited from the online Sona research pool from a large Southern university. Regression analyses supported the hypothesis, suggesting that the association of GAD with MDD symptoms was moderated by sleep hygiene, Specifically, the environment and behavior aspects of sleep hygiene were associated with a stronger association between GAD and MDD symptoms. The findings implicate sleep hygiene as a moderator in the comorbidity of GAD and MDD.
Methods: Participants (n= 180) were undergraduate students recruited from a large, urban university. Measures used were the Sleep Hygiene Index, Patient Health Questionnaire- 9, and Generalized Anxiety Disorder- 7. The hypothesis was tested using the Process macro.
Results: GAD symptoms were associated with depression symptoms, B =.610, 95% CI [.474,.747]. Sleep disturbing environment/behavior was associated with depression, B =.166, 95% CI [.005,.326], but irregular sleep-wake schedule was not, B = -.000, 95% CI [-.038,.037]. There was an interaction between GAD symptoms and sleep disturbing environment/behavior, B =.024, 95% CI [.001,.048], but not between GAD symptoms and irregular sleep-wake cycle, B = -.000, 95% CI [-.038,.037]. Evaluation of simple slopes indicated that the association between GAD symptoms and depression was stronger at higher levels of sleep disturbing environment/behavior.
Conclusion: In conclusion, we found that the association between GAD and MDD symptoms was stronger at higher levels of environmental and behavioral components of poor sleep hygiene. Our findings suggest that the relation between GAD and MDD symptoms was stronger in those with higher levels of sleep disturbing environment and behaviors. Comorbidity did not depend on sleep/wake cycle. Our findings have implications for GAD/MDD interventions.

INSOMNIA AFTER SPOUSAL DEATH AND ITS ASSOCIATION WITH COMPLICATED GRIEF IN LATE-LIFE

Sarah Stahl[1], Khusbu Patel[1]
[1] University of Pittsburgh

Introduction: Beavement is characterized by sleep problems including poor sleep quality, difficulty falling asleep, and short sleep duration. This study examined cross-sectional and longitudinal relationships of insomnia with maladaptive or complicated grief (CG) symptoms in acutely-bereaved older adults.
Methods: This secondary analysis used data collected from a randomized controlled trial for depression prevention in adults 60 years of age or older who experienced the death of their spouse/life partner within the previous 12 months. One hundred fifty adults were randomly assigned to a digital health intervention arm or an enhanced usual care arm. The Insomnia Severity Index and Inventory of Complicated Grief were administered at baseline and 3 months later. Linear regression analysis examined associations of insomnia with CG at baseline and over time, while controlling for well-established correlates of CG (age, time since loss, medical illness burden, and perceived loneliness). Separate regression models were fit for each CG symptom cluster: yearning and preoccupation with the deceased, anger; shock

and disbelief; estrangement from others; hallucinations of the deceased; and behavior change.
Results: Participants were a mean (SD) of 70.6 (7.1) years and bereaved 208.13 (102.42) days; 80% were women and 85% were White. Greater insomnia severity was associated with more yearning and preoccupation (t=2.175; p=0.031) and more behavior change including avoidance behaviors (t=2.334; p=0.021) at baseline. Improvement in insomnia was correlated with reductions in yearning and preoccupation over a 3-month follow-up (β=0.185; p=0.033; R2=0.293).
Conclusion: Greater insomnia severity is associated with more yearning and preoccupation with the deceased at baseline and over 3 months. Intense yearning is a key characteristic of prolonged grief disorder. This observation generates the hypothesis that behavioral interventions that directly target and modify insomnia symptoms may benefit older adults with maladaptive/complicated grief following the death of a loved one.

SHORT-TERM VARIABILITY IN SLEEP AND SUICIDAL IDEATION IN DEPRESSED OLDER ADULTS

sarah stahl[1], Hanga Galfalvy[2], Peter Franzen[1], Swathi Gujral[1], Beth Campbell[1], Meghan Wong[1], Katalin Szanto[1]
[1] University of Pittsburgh, [2] Columbia University

Introduction: Sleep disturbances are linked to suicidal ideation and depression in older adults. Depression is also linked to contemplation of suicide and suicidal behavior. While there are complex, bi-directional relationships between sleep, depression, and suicide risk, these relationships have yet to be measured in well-defined suicide risk groups in late life. This study explored the association between sleep and suicidal ideation using actigraphy and digital sleep diaries via a 3-week ecological momentary assessment protocol.
Methods: Participants included 72 older adults (M±SD=65.3±6.5 years) with clinical depression, defined by a Hamilton Rating Scale for Depression (HRSD) score≥14. Forty-six percent (n=33) of participants had a lifetime suicide attempt. Actigraphic recordings of sleep including sleep duration and sleep efficiency were measured using Philips Spectrum Plus/ Pro actiwatches. Sleep diaries were completed in the morning, including sleep quality. Clinician-administered assessments of suicidal ideation (Scale for Suicidal ideation [SSI]) and depression (HRSD) were collected weekly, for 3 weeks. Mixed effect regression models were used to assess the associations between daily/weekly measures of sleep and suicidal ideation.
Results: Results: Thirty eight percent of participants reported experiencing suicidal ideation (SSI score ≥ 2) during the 3-week protocol. Presence of suicidal ideation was significantly associated with sleep duration. On the aggregate over 3 weeks, ideators had greater sleep duration (M±SD = 441.00±77.29) relative to non-ideators (M±SD=404.82±68.94); t = -2.071,df=70: p =.042. Among ideators, longer sleep duration was significantly associated with greater severity of suicidal ideation the next day (b=0.011, SE=0.004, t=2.54, df=80, p=0.013), Poor sleep quality the night prior to completing the SSI was also associated with the presence of suicidal ideation (OR=0.71, 95% CI: 0.51-0.99, z=-2.03, p=0.043).
Conclusion: Longer sleep duration was predictive of suicidal ideation in weekly and daily models. Long sleep is a symptom of atypical depression and associated with cardiovascular disease, cancer, and cognitive decline in late life, among others. Long sleep duration may compensate for poor sleep quality, which was associated with suicidal ideation in our sample of depressed older adults. Future research should replicate the above findings and verify mechanisms linking long sleep to suicidal ideation in older adults.

THE MEDIATING ROLE OF SLEEP QUALITY IN THE ASSOCIATION BETWEEN DEPRESSION AND PAIN INTENSITY IN OLDER ADULTS

Priscila Morelhão[1], Rafael Pinto[2], Allan Porcacchia[3], Cynthia Gobbi[4], Marcia Franco[5], Viviane Kakazu[3], Sergio Tufik[6], Monica Andersen[6]
[1] Sleep Institute, [2] Universidade Federal de Minas Gerais, [3] Universidade Federal de São Paulo, [4] Universidade Estadual de Londrina, [5] Centro Universitário UNA, [6] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Chronic low back pain (LBP) is a prevalent condition in older adults, often co-occurring with depression and impaired sleep quality. While the bidirectional relationship between sleep disturbances, depression, and pain is recognized, evidence on the mediating role of sleep quality in this association is scarce. The aim of this study was to evaluate whether sleep quality mediates the relationship between depressive symptoms and pain intensity in older adults with chronic LBP.
Methods: This cohort study included 171 adults aged ≥60 years with chronic LBP. Data was collected at baseline, 6 months, and 12 months. Depressive symptoms were assessed using the Center for Epidemiologic Studies Depression Scale, pain intensity with a Numeric Pain Scale, and sleep quality with the Pittsburgh Sleep Quality Index. Mediation analysis was conducted to analyze whether sleep quality at 6 months mediated the relationship between baseline depressive symptoms and pain intensity at 12 months. Statistical significance was set at $p < 0.05$, and the bootstrap method with 1,000 resamples was used to calculate confidence intervals.
Results: The mediation analysis showed a significant indirect effect of baseline depressive symptoms on pain intensity at 12 months through sleep quality at 6 months. The total effect remained significant with 43.54% of the effect mediated by sleep quality. The direct effect between depressive symptoms and pain intensity at 12 months did not show statistical significance.
Conclusion: These findings suggest that in long term sleep quality mediates the relationship between depressive symptoms and pain intensity in older adults with chronic LBP. Interventions targeting sleep disturbances may be a potential strategy to reduce pain intensity and improve outcomes in this population.

INSOMNIA INTERVENTION ASSOCIATED WITH IMPROVEMENTS IN AFFECTIVE BRAIN FUNCTION, MOOD, AND SLEEP IN DEPRESSION

Adam Krause[1], Raquel Osorno[1], Natalie Solomon[1], Maryam Ahmadi[1], Pandora Lam[1], Olivia Magana[1], Emilija Blozyte[1], Leah Harris[1], James Gross[1], Jun Ma[2], Laura Lazzeroni[1], Jerome Yesavage[1], Rachel Manber[1], Jared Saletin[3], Andrea Goldstein-Piekarski[1]

[1] Stanford University, [2] University of Illinois Chicago, [3] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: Depression and insomnia are bidirectionally related. It is hypothesized that fronto-limbic brain function, specifically the amygdala and medial prefrontal cortex (mPFC), links sleep and mood disturbances and represents targets of insomnia-related emotional dysfunction. A primary aim of this first-phase of a two-phase mechanistic clinical trial was to test whether insomnia treatment engages these affective circuits. Secondarily, we examined treatment-related changes in emotion and sleep outcomes and their associations with changes in fronto-limbic brain function.

Methods: 47 adults (64% female; age 25-60) with depression and insomnia completed six sessions of therapist-delivered cognitive-behavioral therapy for insomnia (CBT-I). FMRI of emotional faces and regulation tasks and at-home polysomnography were acquired before and after treatment. Primary outcomes were treatment-associated changes in amygdala reactivity and amygdala-mPFC task-modulated connectivity, analyzed using linear mixed-effect modeling and FDR-correction across task-contrasts and mPFC regions-of-interest (q=0.05). Secondary outcomes included depression, anxiety, and insomnia symptoms, emotion regulation habits, N3 duration, and sleep efficiency. Secondary analyses examining associations between fronto-limbic brain function and secondary outcomes used linear regression. All models controlled for age and sex.

Results: Following treatment, participants experienced reduced amygdala reactivity to fearful faces (b=-0.17 [CI:-0.25-0.08], puncorrected=0.003, padjusted=0.008) and a trend towards increased amygdala connectivity with the subgenual anterior cingulate cortex that did not survive FDR correction (b=0.16 [CI:0.008-0.31], puncorrected=0.045, padjusted=0.23). No significant changes were observed in regions-of-interest during active emotion regulation (b< 0.05 [CI:-1.26-0.23], puncorrected>0.64). Treatment was associated with improvements in depression, anxiety, and habitual cognitive reappraisal (p's< 0.002), as well as reduced insomnia symptoms and increased N3 sleep and sleep efficiency (p's< 0.001). Despite parallel improvements in brain, mood, and sleep, amygdala reactivity changes were only associated with improvements in cognitive reappraisal (b=5.4 [CI: 0.94-9.91], p=0.019). There were no other relationships between changes in amygdala reactivity or connectivity with emotion or sleep improvements (all p's>0.293).

Conclusion: This is the first study to establish that CBT-I is associated with improved fronto-limbic brain function, mood, emotion regulation, and objective sleep quality in individuals with co-occurring insomnia and depression symptoms. However, the improvements in emotion and sleep largely do not appear to be driven by the changes in brain function.

IMPACT OF INSOMNIA SYMPTOMS ON ANXIETY, DEPRESSION AND QUALITY OF LIFE IN WOMEN: EPISONO COHORT STUDY

Leandro Lucena[1], Monica Andersen[2], Sergio Tufik[2], Helena Hachul[3]

[1] Universidade Federal de Sao Paulo, [2] Departamento de Psicobiologia, Universidade Federal de São Paulo, [3] Universidade Federal de São Paulo

Introduction: The maintenance of a good sleep is fundamental for human health. From adulthood onwards, women tend to present more sleep complaints, such as inadequate sleep time and insomnia. This study evaluated the effect of insomnia symptoms over time on women, having the level of anxiety, depression, fatigue, quality of life and sleep pattern as measuring outcomes, compared to the control group.

Methods: We used data from Sao Paulo Epidemiologic Sleep Study (EPISONO), which observed the sleep patter in a representative sample of Sao Paulo in 2007 (n=1,042), with a follow-up in 2015. Women who took part in both editions of the study were distributed in two groups: those with insomnia symptoms (GIS) and those without insomnia symptoms (GWIS), according to their responses to question from the Unifesp sleep questionnaire and the Pittsburgh Sleep Quality Index. To evaluate the effect of groups over time, the Chalder Fatigue Questionnaire, the Beck Anxiety Index, the Beck Depression Index, and the World Health Organization Quality of Life assessment were used. Additionally, full night polysomnography was used to assess the participants' sleep pattern.

Results: The GWIS comprised 70 women, and the GIS 141 women. The GWIS presented significantly less fatigue, anxiety, depression, and better results in all domains of quality of life, in both EPISONO editions. Time had a significant impact on the level of depression, regardless of groups. In relation to the sleep pattern, the sleep onset latency was increased in the GIS, regardless of time.

Conclusion: This study hypothesized that GWIS would worsen over time in terms of quality of life perception and mood. Our findings indicated that regardless of time, insomnia symptoms were associated with higher levels of anxiety, depression, fatigue, and lower perception of quality of life. Moreover, time impacted the level of depression in all participants.

DIFFERENCES OF MYELIN-RELATED VALUES AMONG DEPRESSIVE PATIENTS WITH AND WITHOUT INSOMNIA AND HEALTHY CONTROL

Jeong-Min Shim[1], Seo-Eun Cho[2], Seong-Jin Cho[2], Chang-Ki Kang[1], Seung-Gul Kang[2]

[1] Gachon University, [2] Gachon University College of Medicine

Introduction: Decreased myelin has been reported in depression and insomnia in previous studies. This study aimed to investigate whether myelin differs between major depressive disorder (MDD) patients with and without insomnia. Myelin-related differences in cortical gray and white matter regions were examined among three groups: MDD with insomnia, MDD without insomnia, and healthy controls.
Methods: Clinical evaluations and high-resolution 7T magnetic resonance imaging (MRI) were conducted on participants, including patients with clinically significant insomnia, patients with MDD without significant insomnia, and healthy controls. Sagittal brain images were obtained using the prototype multi-echo magnetization-prepared 2 rapid gradient echoes (ME-MP2RAGE) sequence. Quantitative myelin maps (q-Ratio) were derived by dividing R1 images by T2 images and were subsequently smoothed to create smoothed q-Ratio (sq-Ratio) maps. Statistical analyses were performed to identify differences in myelin-related values across major brain regions of interest among the three groups.
Results: MDD patients with insomnia exhibited significantly lower myelin-related values in specific brain regions compared to those without insomnia. While the sq-Ratio myelin-related maps showed a trend toward lower myelin values in the MDD with insomnia group compared to the other groups, this overall difference was not statistically significant. However, significant reductions in myelin-related values were observed in the olfactory cortex, superior temporal gyrus, amygdala, frontal regions, and five cerebellar regions in gray matter, as well as the inferior fronto-occipital fasciculus in white matter, in MDD with insomnia compared to MDD without insomnia.
Conclusion: This study identified significant myelin differences in specific brain regions between MDD patients with and without insomnia, highlighting the distinct neurobiological changes associated with insomnia in MDD. These findings underscore the critical role of insomnia in influencing brain myelin content and provide novel insights into the interplay between insomnia and depression, with implications for understanding the neurobiology of comorbid conditions.

EXAMINING DAILY SLEEP AND EMOTIONAL DYSREGULATION AMONG EMERGING ADULTS WITH HEAVY ALCOHOL USE PATTERNS

Eunjin Tracy[1], Derek Morgan[1], Shou Yan[1], Pei-Shu Chao[1], Shadi Ansari[1], Eunjung Kim[1], Timothy Trull[1]
[1] University of Missouri

Introduction: Emerging adults with high alcohol use patterns often experience sleep disturbances and emotional dysregulation, which frequently co-occur with anxiety. While sleep disturbances are linked with emotional dysregulation, few studies have examined within-person bidirectional associations, focusing on within-day fluctuations in emotional dysregulation, or considered the potential moderating effect of anxiety symptoms. Therefore, the current study examined the following two questions: (1) Is there a daily, bidirectional relationship between sleep (e.g., quality and duration) and emotional dysregulation? (2) Does anxiety moderate the relationship between sleep and emotional dysregulation?
Methods: Data are from a longitudinal study of heavy drinkers (N = 300, 65.4% women, Mage 24.57, range: 21-29) who completed a single 14-day ecological momentary assessment burst, documenting sleep quality and duration, positive and negative emotional states, and completed a prior survey on anxiety symptoms. Multilevel modeling was used to explore within- and between-person associations between sleep (quality and duration) and next-day emotional dysregulation, as well as the effect of emotional dysregulation on same-night sleep. The moderating effect of anxiety was also examined.
Results: Findings suggest better sleep quality was associated with lower emotional dysregulation for negative affect (b = -.06, SE =.02, 95%CI= [-.09,.-.03], p <.001). Furthermore, on days when participants experienced above-average sleep quality or duration, they reported reduced emotional dysregulation for positive affect the following day (sleep quality: b = -.05, SE =.02, 95%CI = [-.08, -.01], p =.01; sleep duration: b = -.03, SE =.01, 95%CI = [-.05, -.02], p <.001). Daily emotional dysregulation did not predict sleep outcomes, nor did anxiety symptoms moderate these associations.
Conclusion: This study sheds light on the dynamic interplay between daily sleep and emotional dysregulation in emerging adults with heavy alcohol use patterns. These findings highlight a predominantly unidirectional influence from sleep to emotional regulation, emphasizing the importance of optimizing sleep to help reduce emotional dysregulation, especially among heavy drinkers.
Support (if any): Support for this work came from National Institute on Alcohol Abuse and Alcoholism grants R01AA027824 to Tim Trull, and T32AA013526 for postdoctoral funding.

SLEEP OUTCOMES AND RELATIONSHIPS WITH ANXIETY AND DEPRESSION SYMPTOMS IN YOUTH WITH AND WITHOUT CYSTIC FIBROSIS

Jordana McMurray[1], Kim Widger[2], Anne Stephenson[3], Robyn Stremler[4]
[1] Lawrence Bloomberg Faculty of Nursing, University of Toronto, [2] Lawerence Bloomberg Faculty of Nursing, University of Toronto & The Hospital for Sick Children (Sick Kids), [3] Unity Health Toronto & Institute of Health Policy, Management and Evaluation, University of Toronto, [4] Lawrence Bloomberg Faculty of Nursing, University of Toronto & The Hospital for Sick Children (Sick Kids)

Introduction: The adolescent and young adult (AYA) developmental period is a time of risk for both sleep and mental health concerns which may be amplified for those living with cystic fibrosis (CF). This study aimed to better understand sleep, sleep disturbance, and relationships to anxiety and depression symptoms in AYA with CF.
Methods: This study examined whether significant differences exist between AYA with CF and healthy controls, aged 14-25, in actigraphic (TST, SE, WASO, number of night awakenings) or self-reported sleep outcomes (PSQI, PROMIS-SD, PROMIS-SRI, sleep diary); anxiety or depression symptoms (STAI-S, CES-D); and examined whether anxiety or depression symptoms were associated with sleep outcomes in AYA with CF. Semi-structured interviews were conducted with a subset of purposively sampled participants with CF aiming to capture maximum variation in sleep experience as defined by the PSQI. Disease characteristics were also collected from the CF National Data Registry for all CF participants. Quantitative analysis: linear regression models

were used to determine differences between groups and to examine associations between sleep and mental health outcomes. Qualitative analysis: interviews were audio-recorded, de-identified, and transcribed verbatim. Data was analyzed through content analysis, independently by two researchers using qualitative descriptive methods.
Results: This study (n=86; n=45 with CF, n=41 without CF) found no significant difference between AYA with CF and healthy controls in actigraphically-measured or self-reported sleep outcomes, or in anxiety or depression symptoms. In participants with CF, self-reported sleep quality was significantly associated with both anxiety (p< 0.001) and depression (p< 0.001) symptoms, but actigraphically-measured sleep was not. The qualitative arm (n=19) found that AYA with CF reported that CF symptoms, CF treatments, anxiety, changes in health status, and initiation of elexacaftor/tezacaftor/ ivacaftor (ETI) interfere with sleep, while, positioning, good sleep hygiene, breathing therapies, and being stable on ETI were described as benefitting sleep. AYA's with CF also discussed a desire to engage in discussions about sleep with their CF care teams.
Conclusion: Within the current context of improving treatments and care, sleep and mental health outcomes may be improving for AYA with CF. Despite potential improvements, AYA with CF still report unique sleep challenges.

ARE REM SLEEP ALTERATIONS ASSOCIATED WITH DEPRESSIVE SYMPTOMS IN PEDIATRIC NARCOLEPSY TYPE 1?

Grace Wang[1], Jennifer Worhach[1], Bo Zhang[1], Holli Sharples[1], Kiran Maski[1]
[1] Boston Children's Hospital

Introduction: Children and adolescents with pediatric Narcolepsy Type 1 (pNT1) experience short REM sleep latency and REM sleep fragmentation at night and depression is a common pNT1 co-morbidity. Notably, depressive symptoms in otherwise healthy adults and adolescents are associated with short REM latency and an increase in total REM duration (Riemmann, 2020; Pesonen et al., 2019). The relationship between these REM disturbances and depressive symptoms in adolescents with pNT1 is understudied. We hypothesize that shorter REM latency, longer REM duration, and more REM fragmentation will be more associated with depressive symptoms in pNT1 than healthy controls (HC).
Methods: We collected data from 25 pNT1 participants (not on oxybate and weaned or naïve from stimulant/wake promoting agents) and 25 HC, aged 9-20 years old. Participants completed the Child Depression Inventory (CDI), the Positive and Negative Affect Scale (PNAS), and underwent an in-lab polysomnogram. We compared survey responses and REM sleep variables (REM latency, total REM duration, and REM mean bout duration) between groups. We used linear regression controlling for age, gender, and SSRI use to determine relationships between depressive symptoms and REM sleep in our cohorts.
Results: pNT1 participants had significantly higher scores on the CDI and lower scores on the PNAS positive affect scale than HC participants (p's< 0.001). While REM latency and total REM duration did not differ significantly between groups, the pNT1 group had shorter REM mean bout durations than HC (p=0.003). Across groups, we found a main effect of total REM duration on the CDI score (F=5.556, B=-0.61, p=0.023, 95% Cl: -0.114 to -0.009), but results were not significant within groups. We found no relationship between REM latency and REM mean bout duration across or within groups with CDI or PNAS scores.
Conclusion: REM sleep alterations in pNT1 participants were not associated with increased depressive symptoms in our study. Future studies may need to include larger cohorts of pNT1 with a wider range of depressive and psychiatric symptoms to study this question in more depth.

Introduction: The public is increasingly motivated to use cannabis for sleep or anxiety. However, research on the effects of cannabis on these symptoms remains equivocal. This study examined the effects of cannabis on subjective sleep quality and objective sleep measures collected via actigraphy in an anxious sample.
Methods: Participants were in one of 4 conditions: a) no cannabis use, b) tetrahydrocannabinol (THC) dominant cannabis, c) cannabidiol (CBD) dominant cannabis, or d) a product with roughly equal proportions of THC and CBD (1:1). Cannabis using participants were further allocated to either flower or edible forms. Participants were assessed after 4 weeks of ad libitum use of their assigned product, with actigraphy monitors worn starting at the 2 week timepoint. A condition and form analysis of variance was conducted for outcomes of Pittsburgh Sleep Quality Index (PSQI) and average sleep latency, number of awakenings, and total sleep time (TST) collected by actigraphy.
Results: 150 participants used cannabis for anxiety (41 THC dominant, 48 CBD dominant, and 40 in the 1:1 condition; 50 in edible form, 79 in flower form) and 21 participants were in the no-use condition (Age M=34.72, SD=14.38; 58.67% female). Levels of anxiety at baseline were mild-moderate on the Beck Anxiety Inventory (BAI; M=13.01, SD=8.25). Participants who used cannabis in flower form ($F(1, 141)=7.53$, p=.007, $\eta^2G=0.05$) or were in the THC condition ($F(2, 141)=4.69$, p=.01, $\eta^2G=0.06$) reported the lowest average PSQI scores at the 4 week timepoint. There were no significant effects of condition or form on the outcomes of sleep latency, number of awakenings, or TST from actigraphy (p's >.05).
Conclusion: These results highlight a discrepancy between subjective and objective measurement of sleep quality parameters in participants using cannabis for anxiety. These results contrast with 30-day daily diary data previously reported by our group favoring CBD dominant edible forms of cannabis. Results may be influenced by expectancy effects or the duration of the study. More research is needed to understand the relationship between varying forms of cannabis and sleep.

AN AI-DRIVEN MODEL FOR DEPRESSION DETECTION USING SLEEP HEARTBEAT AND BREATHING SIGNALS

Dongbin Lyu[1], Xuesong Chen[2], Yichen Wang[2], Jingwei Zhao[2], Yi Fang[3], Andrew Krystal[3], Wei Chen[4], Yue Leng[5]

[1] Shanghai Mental Health Center, [2] Five Seasons Medical LLC, [3] University of California, San Francisco, [4] Sir Run Run Shaw Hospital, [5] Department of Psychiatry and Behavioral Sciences, University of California, San Francisco

Introduction: Autonomic dysfunction, marked by changes in heart rate and breathing patterns, is a core symptom of depression. However, the role of autonomic dysfunction during sleep as a marker for depression is not well understood. This study evaluates the utility of polysomnography (PSG)-derived cardiorespiratory signals for depression detection and compares their predictive value to that of sleep electroencephalography (EEG), a widely studied modality in depression research.

Methods: We examined clinical PSG data and electronic health records at Sir Run Run Shaw Hospital, collected between 2018 and 2023. Depression cases were identified using the International Classification of Diseases, 10th Revision (ICD-10) diagnosis, Hamilton Depression Rating Scale (HAMD) scores of 8 or higher, and/or chief complaints indicative of depression. Age- and sex-matched controls were sourced from the National Sleep Research Resource, selected based on physician diagnoses or validated depression scales. Predictive models were developed using a foundational model approach: electrocardiogram (ECG) and abdominal (ABD) signals were pre-trained to predict other PSG channels and annotations, followed by fine-tuning with logistic regression for depression classification. An EEG-based model was used for comparison. Data were divided into 80% training and 20% testing sets for evaluation. Model performance was evaluated using the area under the receiver operating characteristic curve (AUROC), sensitivity, and specificity.

Results: The study sample consists of 1863 depression cases (mean age 50.9 ± 15.7 years, 57.5% female) and 2547 controls (mean age 55.2 ± 15.6 years, 57.0% female). The ECG+ABD model achieved an AUROC of 0.960, with a specificity of 0.897 and sensitivity of 0.902. These results were comparable to those of the EEG-based model, which yielded an AUROC of 0.975, with specificity of 0.924 and sensitivity of 0.913.

Conclusion: Our findings demonstrate that AI-driven analysis of sleep-derived heartbeat and breathing signals can detect depression with performance comparable to that of the EEG-based model. This strategy holds promise for non-invasive monitoring to facilitate at-home depression screening, paving the way for advancements in precision mental health management.

ASSOCIATIONS BETWEEN SLEEP DISTURBANCES, DEPRESSION, AND THE RISK OF SUICIDAL IDEATION

Dae Jong Oh[1], Ji Hyun Han[1], Songyi Lee[1], Sang-Won Jeon[1]

[1] Kangbuk Samsung Hospital

Introduction: The relationship between sleep disturbances and the risk of suicidal ideation has been explored in previous research. However, it remains unclear whether specific sleep parameters contribute differently to this risk and whether the presence of depression moderates these associations.

Methods: This study is part of the Kangbuk Samsung Health Study, a prospective cohort of Korean adults who underwent annual or biannual health screenings between 2011 and 2022. A total of 49,834 participants were included after excluding those with baseline suicidal ideation or major psychiatric/neurological illnesses other than depression. Subjective sleep parameters, including sleep duration, sleep quality, and daytime dysfunction, were evaluated using the Pittsburgh Sleep Quality Index. Depression and suicidal ideation were assessed using the Center for Epidemiologic Studies Depression Scale and a self-reported questionnaire adapted from the Korea National Health and Nutrition Examination Survey.

Results: Over 302,902 person-years (mean follow-up: 6.1 ± 3.1 years), 3,695 cases of suicidal ideation were identified. Multivariate Cox proportional hazard models, adjusted for depression and confounders (age, sex, lifestyle factors, hypertension, diabetes, serum lipids, and obesity), revealed that poor sleep quality (hazard ratio [HR] = 1.24, 95% confidence interval [CI] = 1.15 – 1.35), daytime dysfunction (HR = 1.16, 95% CI = 1.07 – 1.27), and short sleep duration (HR = 1.16, 95% CI = 1.00 – 1.34) were associated with an increased risk of suicidal ideation. Among non-depressed participants (n = 45,271; 277,379 person-years), the associations with poor sleep quality (HR = 1.34, 95% CI = 1.22 – 1.46) and daytime dysfunction (HR = 1.21, 95% CI = 1.10 – 1.34) were stronger, while sleep duration was not statistically significant. Among depressed participants (n = 4,563; 25,523 person-years), none of the sleep parameters were significantly associated with suicidal ideation.

Conclusion: Individuals with sleep disturbances may be at increased risk of developing suicidality, even in the absence of depression. Specifically, careful monitoring and timely intervention to address poor sleep quality and daytime dysfunction are crucial.

AUTONOMIC DYSREGULATION DURING SLEEP IN PREMENSTRUAL DYSPHORIC DISORDER

Christophe Moderie[1], Philippe Boudreau[2], Rafael Pérez-Medina-Carballo[2], Diane B. Boivin[2]

[1] McGill University, [2] Douglas Mental Health University Institute, McGill University

Introduction: Premenstrual Dysphoric Disorder (PMDD) is a menstrual cycle-related mood disorder, frequently associated with insomnia during the luteal phase (LP). Mood disorders and sleep disturbances are independently associated with altered autonomic nervous system (ANS) function. Research suggests that the menstrual cycle modulates ANS during wakefulness, with decreased parasympathetic activity from the follicular to LP. We hypothesize disturbed ANS regulation during sleep in PMDD during the symptomatic LP. This study aimed to investigate whether menstrual cycle–related variation in ANS activity is accentuated in women with PMDD compared to controls, and how such differences might relate to anxiety and sleep quality.

Methods: Seven women (32.0 ± 5.7 years) with PMDD-related LP insomnia and five healthy controls (30.4 ± 8.2 years) underwent polysomnography every third night across one menstrual

cycle (n=96 nights). Heart rate variability (HRV) measures, including high frequency (HF), low frequency (LF), LF/HF ratio, and rMSSD, were extracted from non-rapid eye movement (NREM) sleep. Menstrual phase and group effects were evaluated using mixed-model ANOVA. Morning questionnaires assessed anxiety (visual analogue scale) and sleep quality (7-point Likert scale), which were correlated with HRV parameters.
Results: Compared to controls, PMDD participants showed significantly reduced HF ($F_{1,24}=7.4$ $p= 0.008$) and rMSSD ($F_{1,24}=16.4$, $p < 0.001$), reflecting lower vagal tone, and elevated LF/HF ratios ($F_{1,24}=35.0$, $p < 0.001$), an index of HRV reflecting sympathetic and parasympathetic nerve activity. No main effects of the menstrual phase or interaction effects were found. Anxiety was associated positively with LF/HF ratio ($r=0.32$, $p=0.02$) and negatively with rMSSD ($r=-0.42$, $p=0.003$). No significant association was found between HRV parameters and reported sleep quality.
Conclusion: These results suggest a stable, trait-like autonomic vulnerability in PMDD, independent of the menstrual phase, characterized by diminished parasympathetic activity. The lack of a menstrual phase effect may reflect differences from previous studies, which primarily assessed ANS during wakefulness, or could be due to our limited sample size. Furthermore, our findings suggest a potential relationship between autonomic dysregulation during sleep and elevated anxiety in PMDD, independent of changes in sleep quality.

ANHEDONIA LINKS SLEEP PROBLEMS AND SUICIDAL THOUGHTS: AN INTENSIVE LONGITUDINAL STUDY IN HIGH-RISK ADOLESCENTS

Kinjal Patel[1], Jaclyn Kearns[2], Dan Foti[3], Wilfred Pigeon[4], Evan Kleiman[5], Catherine Glenn[1]
[1] Old Dominion University, Department of Psychology, [2] VA Boston Healthcare System, Behavioral Science Division of the National Center for PTSD, [3] Purdue University, Department of Psychological Sciences, [4] University of Rochester Medical Center, [5] Rutgers, The State University of New Jersey, Department of Psychology

Introduction: Sleep problems refer to a broad range of difficulties associated with the onset and maintenance of sleep, and growing research indicates a robust association between sleep problems and suicidal thoughts and behaviors in adolescents. However, relatively little is known about how this risk is conferred. This study used an intensive longitudinal design to investigate anhedonia as a mechanism linking sleep problems and next-day suicidal thoughts in a clinically high-risk sample of adolescents.
Methods: Adolescents (N=48; Mage=14.96; 77.1% white, 64.6% female) completed an ecological momentary assessment study design for 28 days following discharge from acute psychiatric care for suicide risk. Daily sleep diaries were used to assess prior night total sleep time and sleep onset latency. Ecological momentary assessment was used to assess anhedonia and suicidal thoughts up to six times per day. A series of multi-level structural equation models were used to examine facets of anhedonia as parallel mediators of the association between sleep problems and next-day suicidal thoughts.
Results: Significant direct effects were found between sleep problems (i.e., shorter total sleep time, longer sleep onset latency) and consummatory anhedonia, consummatory anhedonia and suicidal thoughts, and anticipatory anhedonia and suicidal thoughts. There were significant indirect (mediated) effects between sleep problems and next-day suicidal thoughts through consummatory anhedonia, but not anticipatory anhedonia.
Conclusion: This study significantly extends prior research on the sleep problem-suicidal thoughts association by investigating how, or the processes by which, sleep problems confer risk for suicidal thoughts. Our findings revealed consummatory anhedonia significantly mediated the relation between sleep problems and suicidal thoughts. Future research is needed to replicate these findings in larger samples and investigate how modifying sleep problems and anhedonia may mitigate suicide risk in adolescents.

RELATIONSHIP BETWEEN SUBJECTIVE SLEEP QUALITY AND OBJECTIVE SLEEP PARAMETERS FROM WEARABLE EEG IN YOUTH WITH SIGNIFICANT ANXIETY AND RELATED DISORDERS

Giulia Righi[1], Phoebe Muntz[1], Kathrin Renschler[1], Aashritha Sadu[2], Grace Kupka[2], David Barker[3], Jared Saletin[4]
[1] E.P. Bradley Hospital/Warren Alpert Medical School of Brown University, [2] E.P. Bradley Hospital Sleep Research Laboratory, [3] Rhode Island Hospital / Alpert Warren Medical School of Brown University, [4] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: Sleep problems are prevalent in pediatric anxiety and related disorders (ARD), affecting nearly 90% of patients. Nevertheless, subjective sleep complaints routinely demonstrate poor agreement with objective sleep patterns derived from either actigraphy or polysomnography in non-psychiatric samples. The aim of this submission is to examine the relationship between subjective and objective metrics of sleep quality in youth with moderate-to-severe ARD.
Methods: We conducted a multi-method study involving a clinical sample of treatment-seeking youth (ages 11-17) participating in a CBT-based partial hospital program specialized in ARD. Participants complete standardized clinical interviews, sleep quality questionnaires, up to 10 nights of sleep diaries and wearable actigraphy, and at-home overnight ZMax EEG (up to 4 nights). To date, 44 participants (54% female, 86% white, mean age 15y) have completed data collection. We analyzed self-report questionnaires and three sleep stage variables from ZMax EEG scored using Dreamento): sleep efficiency (SE%; total sleep time / sleep period time), slow wave sleep (SWS%; minutes of SWS / total sleep time) and a sleep fragmentation index (SFI; the total number of awakenings or shifts to stage 1 divided by total sleep time [in hours]).
Results: Participants experienced high severity of illness as indexed by Clinical Global Impression (mean CGI = 5.4, sd = 0.8). Sleep disturbances and sleep-related impairments were present in our sample (PROMIS self-report sleep disturbance

mean = 61.01 sd = 9.74, sleep-related impairment mean = 61.9, sd = 7.84). Average SE was 77% (sd = 15%) and average SWS% was 60% (sd = 20%; range = 79%). Average SFI was 8.1/h (sd = 4.7). Subjective sleep quality was not significantly correlated to any of our objective sleep indexes (|r|'s < 0.12; p's > 0.05).
Conclusion: Our youth with moderate-to-severe ARD report clinically significant problems with sleep and sleep-related impairments. Sleep efficiency may be lower than age-matched non clinical samples. Objective indexes of sleep depth and quality were not related to subjective reports. Next steps will include expanding the analyses to include additional data and examining these relationships with specific clinical symptoms.

EXPLORING THE LINK BETWEEN SOCIAL FUNCTIONING AND DEPRESSION REDUCTION IN CBT-I

Cameron McCray[1], Elle Wernette[2], Tiffany Xu[1], Shruthi Ravindran[1], Christopher Drake[2], Philip Cheng[3]
[1] Henry Ford Sleep Research, [2] Henry Ford Health System, [3] Henry Ford Health + Michigan State University Health Sciences

Introduction: Cognitive-behavioral therapy for insomnia (CBT-I) effectively treats insomnia and reduces depression symptom severity. However, research elucidating the mechanisms driving depression reduction via CBT-I is still underway. One underexplored mechanism may be social functioning. Prior research has shown that insomnia patients reduce their social activities, likely due to fatigue. As social functioning is important to mood regulation, this may also drive depressed mood. This study investigated whether improvements in social functioning would predict reductions in depressive symptoms.
Methods: Patients with insomnia disorder (N=1321) were randomly assigned to digital CBT-I (dCBT-I, n=905) or a sleep education control (SE, n=416). Depression severity (QIDS) and social functioning (FSS and SNI) were evaluated at baseline and 1-year post-intervention. Social functioning was quantified along three dimensions: 1) relationship strain, 2) quantity of supportive relationships, and 3) frequency of social interactions. Change scores (post-treatment - baseline) were calculated for depression severity and social functioning. Linear regressions determined whether changes in social functioning predicted changes in depression symptom.
Results: Regression analyses revealed that reduced relationship strain (β = -.361, p <.001), increased number of supportive relationships (β =.151, p <.001), and increased frequency of interactions (β =.088, P <.001) following treatment were associated with improved depression symptoms. Furthermore, change in relationship strain was a significant moderator of the antidepressant effect of dCBT-I (β =.262, p <.001); those who had greater reductions in relationship strain following treatment also showed greater improvements in depression.
Conclusion: Results point to improved social functioning following CBT-I as a potentially important factor in the antidepressant effect of insomnia treatment. This effect appears to be strongest with reduced relationship strain. Future research should explore how to optimize CBT-I to enhance social functioning and support, especially for patients with both depression and insomnia.

SLEEP HEALTH PROFILES OF NIGHT SHIFT NURSES: A LATENT PROFILE ANALYSIS AND ASSOCIATIONS WITH DEPRESSION

Kelly Kim[1], Daniel Taylor[1], Jessica Dietch[2], Danica Slavish[3], Brett Messman[4], Kimberly Kelly[3], Camilo Ruggero[5]
[1] University of Arizona, [2] Oregon State University, [3] University of North Texas, [4] Pennsylvania State University, [5] The University of Texas at Dallas

Introduction: Night shift nurses are vulnerable to worse and varied sleep and depression due to the nature of their work schedules. Although sleep and depression are associated in the literature, these associations are understudied in shift workers. This study aimed to identify sleep profiles of night shift nurses and compare them across sleep and depression facets.
Methods: Night shift nurses (N=95, Mage=35.58 years, 88.42% Female) completed measures of insomnia, depression, stress, and circadian preference. They also completed 14 days of daily diaries measuring sleep and depression. Latent Profile Analysis (LPA) was run to identify distinct profiles based on sleep efficiency, duration, quality, and midpoint. One-way analyses of variance (ANOVAs) examined sleep and mental health differences across profiles.
Results: LPA suggested profiles of "less efficient and variable sleepers" (n=34), "later and good quality sleepers" (n=35), and "earlier and highly efficient sleepers" (n=26). "Less efficient and variable sleepers" had the worst sleep efficiency, quality, and duration of the profiles. "Later and good quality sleepers" had better sleep efficiency, highest quality, and latest midpoint. "Earlier and highly efficient sleepers" had the highest sleep efficiency, longest duration, and earliest midpoint. ANOVAs showed significant group differences for depression ($F(2, 1327)=106.10$, $\eta^2=0.14$), perceived stress ($F(2, 1327)=85.26$, $\eta^2=0.11$), circadian preference ($F(2, 1327)=87.01$, $\eta^2=0.25$), variability of sleep midpoint ($F(2, 1327)=169.10$, $\eta^2=0.20$), and variability of depression ($F(2, 1327)=92.35$, $\eta^2=0.12$, all p's <.001). Post-hoc tests revealed "less efficient and variable sleepers" experienced significantly higher depression, stress, and variability of sleep timing and depression than the other profiles (p's <.001). In contrast, "earlier and highly efficient sleepers" had significantly lower depression, lower variability in sleep timing, and earlier circadian preference than the other profiles (p's < 0.05).
Conclusion: Results reveal sleep profiles of night shift nurses with "less efficient and variable sleepers" reporting worst sleep and depression facets. Although they did not differ with "later and good quality sleepers" on circadian preference, the latter group showed later and less variable sleep timing, good sleep quality, and better mental health outcomes. This may suggest the importance of alignment and consistency between one's circadian preference and sleep timing on mental health.

RESILIENCE MODERATES THE RELATIONSHIP BETWEEN SLEEP DISTURBANCES AND ANXIETY SYMPTOMS IN MILITARY VETERANS

Fatima Qureshi[1], Carter Baker[1], Megan Rech[1], Annika Myers[1], Anthony Cifre[1], Cynthia Jou[1], Deborah Beidel[2], Candice Alfano[1]
[1] University of Houston, [2] University of Central Florida

Introduction: Sleep disturbances are common in military veterans and are associated with heightened anxiety symptoms. Inter-individual differences in resilience, or the ability to cope with and adapt to stress, may influence how sleep disturbances and anxiety symptoms interact, but few studies have examined resilience in relation to objective sleep measures among military veterans. This study investigated resilience as a moderator of the relationship between actigraphy-assessed sleep variables (sleep onset latency, SOL; mean wake episodes per night, MWE; and wake after sleep onset, WASO) and anxiety symptoms in this population.
Methods: Participants were N=68 treatment-seeking veterans with PTSD (74% male) who completed self-report measures of anxiety (Generalized Anxiety Disorder-7; Spitzer et al., 2006) and resilience prior to treatment (Connor-Davidson Resilience Scale; Connor & Davidson, 2003). Objective sleep data were collected for one week using actigraphy. Moderation analyses controlling for age and sex were conducted to examine the relationship between sleep disturbances and anxiety symptoms, including whether resilience moderated these relationships.
Results: The full model predicting anxiety symptoms from resilience, SOL, and resilience x SOL was significant, R^2 =.252, F(5, 62), p=.003. SOL significantly predicted anxiety symptoms at low (-1 SD) resilience levels (b=.08, t=2.29, p=.03), but not at medium or high levels. Similarly, the model examining resilience, MWE, and their interaction on anxiety symptoms was significant, R^2=0.345, F(5,62)=6.521, p <.001, including a positive relationship between MWE and anxiety symptoms at medium resilience levels (b=0.37, t=3.21, p< 0.001), and high resilience levels (b=0.68, t=4.02, p< 0.001), but not at low levels. WASO alone was not a significant predictor of anxiety symptoms, but its interaction with resilience was significant R^2=0.307, F(5,62)=5.483, p< 0.001 in that greater resilience reduced the strength of the association between increased WASO and higher anxiety symptoms (b=0.002, t=2.24, p=0.029).
Conclusion: Findings suggest that higher levels of resilience may buffer against the adverse effects of poor sleep on anxiety symptoms among military veterans. Clinically, interventions targeting resilience may help mitigate impairment associated with both poor sleep and anxiety in PTSD sufferers. As resilience has been operationalized in various ways, future research should explore the precise mechanisms underlying these interactions in veterans.

ELECTRICAL VESTIBULAR NERVE STIMULATION (VENS) FOR DEPRESSION AND ITS EFFECT ON INSOMNIA SEVERITY: FINDINGS FROM A RANDOMIZED, SHAM-CONTROLLED TRIAL

Jason McKeown[1], Sai Sailesh Kumar Goothy[2], Rohit Singh[2], Joseph Reel[3], Rachel Robinson[3], Sinead Watson[3]
[1] Stanford University, [2] NRI Institute of Medical Sciences, [3] Neurovalens Ltd.

Introduction: The bi-directional relationship between sleep and depression is well reported, with up to 70% of individuals with major depressive disorder (MDD) experiencing insomnia, and pre-existing insomnia doubling the risk of developing depression. The aim was to explore the impact of an electrical vestibular nerve stimulation (VeNS) treatment for depression on insomnia symptoms.
Methods: The study was a double-blind randomised, sham-controlled trial (RCT) that evaluated the efficacy and safety of VeNS on MDD. The study was undertaken in Andhra Pradesh, India (ID: NCT06051864) and included adults (18-80 years) with MDD (Patient Health Questionnaire (PHQ-9) score ≥10) at screening who were on anti-depressant medication (SSRI or SNRI) to treat depression for at least 1 year. Eligible participants who provided written consent, were randomly assigned to receive an active device (n=31) or a sham device (n=31). All participants attended the clinic to complete up to 5 stimulation sessions per week, over a period of 8 weeks, with each session lasting 30 minutes. The primary outcome was change in Beck's Depression Inventory (BDI-II) score from baseline to week 8. A secondary outcome was change in Insomnia Severity Index (ISI) at 8 weeks.
Results: A total of 62 participants (mean age: 43.1±5.0 yrs; 45% female) were recruited with two participants not completing the study. An ITT analysis showed that the active group, compared to the sham group, reported a greater mean reduction in BDI-II scores (-9.0 [95% CI: -10.45, -7.55] vs -2.61 [95% CI: -4.08, -1.14], p< 0.001; respectively) as well as a greater mean reduction in ISI scores (-6.29 [95% CI: -7.27, -5.31] vs. -2.23 [95% CI: -3.40, -1.05], p< 0.001; respectively). Additionally, 61% (n=19) of the active group, compared with 16% (n=6) of the sham group (p< 0.001) achieved a ≥6 point reduction in ISI which is considered clinically meaningful. No adverse events were reported in the active group.
Conclusion: The findings suggest that VeNS not only offers a significant reduction in depressive symptoms but also has a clinically meaningful impact on improving insomnia. This dual benefit highlights VeNS as a potential therapeutic option for adults struggling with both depression and insomnia.

SOCIAL DESIRABILITY, SELF-REPORTED SLEEP DISTURBANCE, AND MENTAL HEALTH IN COLLEGE STUDENTS

Emme Tucker[1], Lauren Elmore[1], Cordell Stover[1], Sarah Emert[1], Kelly Kim[2], Alisa Huskey[3], Daniel Taylor[2]
[1] Idaho State University, [2] University of Arizona, [3] The University of Arizona

Introduction: The validity of self-report measures may be impacted when individuals feel obligated to respond in a way that represents themselves favorably. This is known as social-desirability bias. Prior research has examined social desirability effects on academic achievement reports (e.g., GPA) and financial behavior. However, little research has explored the role of social desirability in self-reported mental health. This study aims to investigate the effect of social desirability on multiple mental health screeners.
Methods: College students (N=1886; Mage=20.54 years, 57% female, 73.80% Caucasian) from two universities completed self-report questionnaires on the following domains: social desirability (SDRS-5), sleep disturbance (ASSQ-SDS), generalized anxiety disorder (GAD-7), major depressive disorder (PHQ-9), and posttraumatic stress disorder (PC-PTSD-5). Multivariate multiple regression was used to examine social desirability on the total scores of the mental health screeners.
Results: The overall multivariate multiple regression model was significant, F(4,1331) = 5.507, p <.001, Wilks' lamba = 0.984. Social desirability predicted symptoms of PTSD (PCL-5, F(1,

1334) = 14.985, p <.001, B = -1.378), generalized anxiety (GAD-7, F(1, 1334) = 16.375, p <.001, B = -.462), and major depression (PHQ-9, F(1, 1334) = 19.461, p <.001, B = -.550), but not sleep disturbance (ASSQ-SDS, F(1, 1334) = 2.549, p =.111, B = -.109).
Conclusion: The results of this study highlight the role that social desirability plays in self-reported sleep disturbance and mental health symptomology. While social desirability significantly predicted lower scores on self-reported mental health symptoms, its effect on sleep disturbances was not statistically significant. This suggests that sleep-related concerns may be perceived differently or are potentially less stigmatized than other mental health concerns. Future research may explore whether the relationship between social desirability and sleep reporting varies based on symptom severity, chronicity, or comorbid mental health concerns.

COMPARING ACTIGRAPHY SCORING PROTOCOLS IN ADOLESCENTS WITH ANXIETY AND RELATED DISORDERS (ARD)

Grace Kupka[1], Aashritha Sadu[1], Kathrin Renschler[2], Phoebe Muntz[2], David Barker[3], Mary Carskadon[3], Giulia Righi[2], Jared Saletin[3]

[1] E.P. Bradley Hospital Sleep Research Laboratory, [2] E.P. Bradley Hospital/Warren Alpert Medical School of Brown University, [3] Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University

Introduction: Estimating sleep from actigraphy is a challenge in psychiatric populations where criteria may be susceptible to altered physical activity. Expert-consensus procedures may introduce bias. Alternative scoring protocols may resolve ambiguities, avoid the need for consensus, and increase reproducibility. This study compared two scoring procedures in a treatment-seeking sample of adolescents with ARD.
Methods: Thirty-six adolescents (24 F; ages 13-17yrs [m±sd: 15±1.7yrs]) diagnosed with ARD wore a patch activity monitor on their dominant triceps and completed sleep diaries for 8.7±3.1 nights resulting in 180 unique nights. Sleep was estimated in 1-minute epochs (Sadeh); sleep periods were scored with sleep diaries using two scoring protocols: (1) "3-5" (onset at first of 3 consecutive minutes of sleep; offset at last of 5 consecutive minutes of sleep); and (2) "15-15" (onset at first of 15 consecutive minutes of sleep; offset at last of 15 consecutive minutes of sleep). We tabulated nights requiring group consensus (e.g., ambiguity of sleep within an hour before, or after, the major sleep episode). We examined differences in sleep period time and total sleep time (in minutes) and sleep midpoint, onset, and offset (in decimalized clock-hour) from five randomly selected weeknights.
Results: 15-15 scoring produced fewer nights requiring consensus (70 nights, average: 17% per participant) compared to 3-5 scoring (147 nights, average: 30% per participant). 15-15 scoring reduced estimated sleep period time by 30.2±51.1 minutes (3-5: 543.4±86.2 min; 15-15: 513.2±71.9 min; difference 95%CI: [-46.91, -13.54]; p=.001), but not total sleep time (3-5: 448.7±69.7 min; 15-15: 443.5±66.2 min; difference: -5.2±33.5 minutes [-16.2, 5.8]; p=.39). 15-15 scoring shifted estimated sleep midpoint 0.25±0.4 hours earlier versus the 3-5 rule [3-5: 4.5h±0.7h; 15-15: 4.3h±0.6h; difference 95%CI: [-0.39h,-0.11h], p=.001). The two procedures did not shift estimates (p's>.42) of sleep onset (3-5: 19.6h±4.3h, 15-15: 19.4h±4.6h) or offset (3-5: 7.5h±1.3h, 15:15: 7.4h±1.2h).
Conclusion: The 15-15 scoring protocol reduced ambiguities and the need for consensus compared to the 3-5 protocol in a psychiatric adolescent sample. It affected estimates of sleep period time and sleep midpoint but not total sleep time. These data indicate that alternative scoring may be considered in populations where symptoms may contribute to sedentary activity.

SLEEPING LESS THAN USUAL IS ASSOCIATED WITH GREATER NEXT DAY DEPRESSION AND NEGATIVE REACTIVITY TO INTERPERSONAL EVENTS AMONG SUICIDAL ADOLESCENTS

Delainey Wescott[1], Tina Goldstein[2], Noelle Rode[1], Dawn Rice[1], Kimberly Poling[1], Peter Franzen[1]

[1] University of Pittsburgh, [2] University of Pittsburgh School of Medicine, Psychiatry Department

Introduction: Daily changes in sleep can impact emotional functioning and may contribute to depression symptomatology and suicidality. The current study examined daily and longitudinal changes in sleep and next-day depression in a high-risk adolescent and young adult sample with severe psychopathology, and examined whether daily changes in sleep impacted next-day interpersonal affective reactivity.
Methods: Participants (N=198, ages 13-23, 82% White, 76% female) were enrolled in an intensive outpatient treatment program for depression and suicidality. Participants wore an actigraph and completed daily ratings of depression, sleep, and positive and negative reactivity to interpersonal events throughout treatment (M=60 days, SD=22 days). Clinicians rated weekly depression severity. Multilevel models tested changes in sleep and next-day depression and examined daily relationships between total sleep time (TST), next-day depression, and event reactivity. Covariates included age, sex, study day, clinician-rated depression, and weekday/weekend.
Results: Over the course of treatment, self-reported TST increased (b=0.01; SE=0.01; p< 0.001) and depression decreased (b=-0.06; SE=0.02; p=0.02), although actigraphy-assessed TST did not change (b=0.01; SE=0.01; p=0.16). At the daily level, sleeping less than usual was related to worse next-day depression from diaries (b=-0.29; SE=0.13; p=0.02) but not actigraphy (b=-0.19; SE=0.14; p=0.18). There was a significant cross-level interaction, with the effects of TST on next day depression were amplified for participants with greater clinician-rated depression severity for both diary (b=-0.22; SE=0.10; p=0.03) and actigraphy-assessed TST (b=-0.32; SE=0.13; p=0.01). Further, sleeping less than usual was associated with greater next-day negative event reactivity (diary: b=-0.32; SE=0.13; p=0.01|actigraphy: b=-0.81; SE=0.19; p< 0.001), but not positivity event reactivity (diary: b=-0.02; SE=0.13; p=0.83|actigraphy: b=-0.26; SE=0.15; p=0.14).
Conclusion: Sleeping less than usual negatively impacted next-day depressive symptom severity, particularly for individuals with moderate-to-severe depression. Short sleep may perpetuate depression through increased negative reactivity to interpersonal events, although mediation models are needed to test causality.

Notably, self-reported total sleep time increased throughout an intensive treatment program focused on depression and suicidality. Future work is needed to examine whether increases in sleep duration underlie depressive symptom improvement in this high-risk sample, and/or whether targeted interventions to improve sleep may hasten symptom improvement.

A NOVEL ECG-BASED MACHINE LEARNING PIPELINE FOR SCREENING MAJOR DEPRESSIVE EPISODES IN SLEEP DISORDER PATIENTS

Massimiliano Grassi[1], Silvia Dacco[1], Melissa Bruner[1], Archie Defillo[1]
[1] Medibio Limited

Introduction: Major Depressive Episodes are a significant global health challenge, often co-occurring with sleep disorders. Accurate and efficient screening for current MDE (cMDE) in patients undergoing evaluation for sleep disturbances could improve diagnostic efficiency and treatment outcomes. Traditional diagnostic methods for cMDE, such as clinical interviews and questionnaires, are resource-intensive and require significant clinical expertise. Advances in machine learning (ML) and physiological data analysis have opened new avenues for leveraging objective signals like ECG to screen for cMDE. Polysomnography routinely captures ECG signals, providing a unique opportunity to explore their potential in identifying autonomic and sleep-related patterns indicative of depressive symptoms. This project aims to investigate the accuracy of a pipeline of ML algorithms that allow screening for cMDE using only ECG as a physiological signal in subjects undergoing in-patient polysomnography.
Methods: 296 subjects from a recently completed prospective, single-arm, non-randomized cohort study have been used to investigate the screening performance of the cMDE determination pipeline compared to the MINI neuropsychiatric interview. All subjects recruited in this study were referred for inpatient polysomnography due to suspected sleep disorders. The cMDE determination pipeline begins with a deep learning algorithm that classifies sleep stages using only the lead-II ECG signal. Subsequently, heart rate (HR) and heart rate variability (HRV) metrics are computed across the identified sleep stages, and macrostructure indices derived from the ECG-based sleep staging are calculated. Finally, HR and HRV metrics and macrostructure indices are combined with the responses to items 1 and 2 of the PHQ-9 questionnaire and used as input for an ML algorithm to perform the final cMDE determination.
Results: The observed sensitivity relative to the MINI cMDE determination was 80.85% (95% CI: 66.74%-90.85%), the specificity was 71.37% (95% CI: 65.31%-76.91%), the positive predictive value was 34.86% (95% CI: 25.99%-44.58%), and the negative predictive value was 95.16% (95% CI: 91.01%-97.76%).
Conclusion: The proposed machine learning pipeline leveraging the ECG as a physiological signal demonstrates promising potential as a screening tool for cMDE in patients undergoing polysomnography for suspected sleep disorders.

A SCREENING ALTERNATIVE FOR DEPRESSIVE EPISODES IN COMISA: A COMPARATIVE EVALUATION OF A NOVEL SOFTWARE COMPARED TO NEUROPSYCHOMETRIC ASSESSMENTS

Silvia Dacco[1], Massimiliano Grassi[1], Melissa Bruner[1], Archie Defillo[1]
[1] Medibio Limited

Introduction: In recent years, numerous studies have focused on enhancing the understanding of sleep disorders within military, veteran, and civilian populations. Among these, insomnia and obstructive sleep apnea (OSA) have emerged as the two most prevalent sleep disorders affecting both military personnel and civilians. The term COMISA was introduced to describe the co-occurrence of insomnia and OSA, highlighting the significant burden associated with this dual condition. Research has shown that COMISA is associated with more severe mental health challenges compared to insomnia or OSA alone. The aim of this study is to investigate the agreement between the determination for current Major Depressive Episodes (cMDE) made by the MEB-001 software (Medibio Limited) and the MINI's cMDE diagnosis across specific clinical subgroups. These include individuals with suspected insomnia but no confirmed sleep apnea, individuals with confirmed sleep apnea but no suspected insomnia, and those with COMISA.
Methods: This study analyzes data from the recently completed prospective, single-arm, non-randomized cohort study. The subjects recruited in this study were referred for an inpatient polysomnography for suspected sleep disorders.
Results: In a preliminary analysis, in the subgroup of subjects with insomnia but no confirmed sleep apnea (n=55), the observed sensitivity relative to the MINI cMDE determination was 90.91% (95% CI: 58.72%-99.97%), the specificity was 61.36% (95% CI: 45.50%-75.64%), the PPV was 34.17% (95% CI: 9.69%-53.48%), and the NPV was 96.43% (95% CI: 81.65%-99.91%). Instead, in the COMISA sub-group (n=147), the observed sensitivity relative to the MINI cMDE determination was 88.46% (95% CI: 69.85%-97.55%), the specificity was 71.07% (95% CI: 62.13%-78.95%), the PPV was 39.66% (95% CI: 27.05%-53.36%) and the NPV was 96.63% (95% CI: 90.46%-99.30%).
Conclusion: The MEB-001 software demonstrated strong sensitivity and high negative predictive value for detecting current Major Depressive Episodes (cMDE) across clinical subgroups, particularly in individuals with COMISA and insomnia without sleep apnea.

EFFICACY AND USAGE OF HYPOGLOSSAL NERVE STIMULATION IN PATIENTS WITH COMORBID OBSTRUCTIVE SLEEP APNEA AND POST-TRAUMATIC STRESS DISORDER

Reena Dhanda Patil[1]
[1] University of Cincinnati/Cincinnati VA Medical Center

Introduction: Hypoglossal nerve stimulation (HGNS) is an effective treatment for patients with obstructive sleep apnea (OSA)

patients, whose positive airway pressure (PAP) intolerance may be related to comorbidities such as post-traumatic stress disorder (PTSD). We aimed to determine the prevalence of PTSD in our study population and compare efficacy, quality of life, and usage outcomes in patients with and without a history of PTSD after HGNS implantation.

Methods: The ADHERE registry collected data before and after HGNS (Inspire Medical, Golden Valley, MN), including baseline medical and psychiatric comorbidities. Patients were categorized into two groups based on the presence or absence of PTSD at baseline. Patients with comorbidity data and at least one of the following data points at final visit were included: apnea hypopnea index (AHI), Epworth Sleepiness Scale (ESS), nightly therapy usage (NTU), Clinical Global Impression, and patient satisfaction. Two-sided t-tests were used to determine outcome differences between the groups. One sided t-tests with pre-defined non-inferiority margins were used to determine non-inferiority between the groups.

Results: 37 of 2725 patients who completed a final follow-up visit (1.36%) reported a baseline history of PTSD. Patients with PTSD were younger (PTSD: 55.23±12.57; No PTSD: 61.03±10.75) and had a higher BMI (PTSD: 30.66±3.37; No PTSD: 29.15±3.65) than those without PTSD. Average final visit AHI was similar between both groups (PTSD: 15.75±12.06; no PTSD: 16.22±14.84). AHI and ESS reduction from baseline to final visit and the final NTU for patients with PTSD (AHI Reduction: 20.33±15.32, ESS Reduction: 5.74±4.9, NTU: 6.07±2) were non-inferior to those without PTSD (AHI Reduction: 18.84 ±18.44, ESS Reduction: 4.21±5.12, NTU: 5.76±2.24), as the confidence interval for the difference between the groups was within the margin of acceptability (AHI reduction: 7.5; ESS reduction: 2; NTU: 0.5).

Conclusion: Comorbid PTSD/OSA within the ADHERE registry was lower than reported in the medical literature. However, patients with a baseline history of PTSD received significant benefit from HGNS in terms of AHI and ESS reduction; nightly usage for patients with PTSD was non-inferior compared to those without PTSD. HGNS may be a helpful alternative treatment for patients with PTSD who cannot tolerate PAP.

PREDICTION OF DEPRESSIVE SYMPTOMS BASED ON SLEEP PATTERNS

Seojung Kim[1], Eunsun Park[2], Ji Hui Hong[3], Il Han Choo[3], Jaehyo Jung[4], Seong Jae Kim[5]

[1] Oakwood Friends School, Poughkeepsie, NY, USA, [2] Department of Counselling Psychology, Chosun University, Gwangju, South Korea, [3] Department of Psychiatry, College of Medicine, Chosun University, Gwangju, South Korea, [4] AI Healthcare Research Center, Chosun University, Gwangju, South Korea, [5] Department of Psychiatry, Chosun University School of Medicine, Gwangju, South Korea

Introduction: Irregular sleep schedules can affect mood and risk of developing symptoms of depression. Particularly, individuals with depression tend to sleep more than usual, which appears to be an attempt to avoid emotional distress. Depression and sleep problems are closely linked, but there is a lack of studies on how specific changes in sleep patterns occur in depression. Receiver operating characteristic analysis was performed to examine whether which sleep parameters can discriminate between the individuals with depression and those with non-depression.

Methods: Participants above 50 years old were recruited at Chosun University Hospital. The Korean Version of the Patient Health Questionnaire-9(PHQ-9) was administered. Actigraphy monitorings were conducted at home, and the following sleep parameters were included: bedtime(BT), wake time, time in bed(TIB), total sleep time, sleep onset latency, sleep efficiency, wake time after sleep onset, and fragmentation index. Participants with the PHQ-9 score ≥ 10 were classified into depression group(DG). Thirteen DG(67.46 ±9.3 years) and 6 non-depression group(NDG)(70.0±6.4years) were finally selected.

Results: The DG had significantly higher scores in the PHQ-9 and MDRS compared to the NDG ($p< 0.01$). There were significant differences in the BT and TIB of sleep parameters between the NDG and DG, showing the DG had earlier BT and longer TIB compared to the NDG ($p< 0.05$). The TIB among the sleep parameters were derived as indicators for discriminating depression ($p=0.04$). The area under the ROC for the TIB was 0.795 (cut-off scores ≥ 9h: 58m, sensitivity= 0.62, specificity=0.83).

Conclusion: We found the changes of sleep habits in individuals with depressive symptoms, including earlier bedtimes and longer time in bed, compared to those without symptoms.In particular, the TIB for individuals with depressive symptoms was more than 2 hours longer and was identified as a predictor of depression, suggesting that longer TIB is a risk factor for depression.

SLEEP PREDICTS TIME TO SEVERE DEPRESSIVE SYMPTOMS AND SUICIDAL IDEATION IN A LONGITUDINAL STUDY OF ADOLESCENTS

Peter Franzen[1], Tina Goldstein[2], Margaret Kuzemchak[1], Meredith Wallace[1], Daniel Buysse[3]

[1] University of Pittsburgh, [2] University of Pittsburgh School of Medicine, Psychiatry Department, [3] University of Pittsburgh School of Medicine

Introduction: Sleep and depression have bi-directional relationships. While most individuals with major depression have sleep quality complaints, and insomnia/hypersomnia are core symptoms, poor sleep health is a risk factor for the onset of depression. This may be particularly relevant during adolescence, a time of rapid changes in sleep and circadian rhythms coincident with escalating risk for the development of major depression and suicidality.

Methods: We enrolled 197 never-depressed youth in grades 7–9 (ages 11.7–15.9 years old; N=95 Female [F]; N=102 Male [M]) in the Pittsburgh Sleep in Teens Study—a longitudinal study measuring sleep (Sleep Timing Questionnaire), insomnia (Insomnia Severity Index), depression symptoms (Center for Epidemiologic Studies Depression [CES-D] scale), and suicidal ideation (Suicidal Ideation Questionnaire-Junior) every 3 months. Here we report on data through 1.5 years of follow-up. Survival analyses were used to predict time to severe depressive

symptoms (CES-D>23 with the sleep item removed) and time to endorsing suicidal ideation with Cox proportional hazard models, adjusting for sex and summer/school year.
Results: Over the 1.5 year follow-up, 19% (27% F; 11% M) developed severe depressive symptoms (CES-D>23), 17% (19% F; 15% M) developed suicidal ideation, and 36% (45% F; 28% M) developed elevated insomnia symptoms (ISI>8). Shorter sleep duration (Hazard Ratio [HR]=0.61 [95% CI: 0.48; 0.77]; p< 0.001), lower sleep efficiency (HR=3.12 [2.05; 4.74]; p< 0.001), longer sleep onset latency (HR=4.14 [2.15; 7.99; p< 0.001), and more insomnia (HR=1.39 [1.29; 1.51]; p< 0.001) were all robust predictors of time to severe depression. Shorter sleep duration (HR=0.65 [0.49; 0.86]; p=0.002), lower sleep efficiency (HR=2.39 [1.52; 3.76]; p< 0.001), longer sleep onset latency (HR=3.44 [1.56; 7.61]; p=0.002), and more insomnia (HR=1.12 [1.03; 1.21]; p=0.005) also predicted time to first occurrence of suicidal ideation. Sleep timing (midsleep) did not predict time to depression (p=0.12) or suicidal ideation (p=0.75).
Conclusion: Multiple sleep health dimensions were associated with the risk of developing severe depressive symptoms and suicidal ideation over 1.5 years in a sample of never-depressed adolescents. Trials testing preventative interventions are needed to see if risk for depression and suicidal thoughts can be ameliorated during this high-risk developmental period.

SLEEP MEASURES BEFORE AND AFTER TREATMENT IN PSYCHIATRIC POPULATIONS

Frank Sgambati[1], Luu Pham[2], Jonathan Jun[1], Una McCann[3]
[1] Johns Hopkins University, [2] Division of Pulmonary and Critical Care, Johns Hopkins University School of Medicine, [3] Johns Hopkins School of Medicine

Introduction: Sleep problems are prevalent in psychiatric populations, and may serve as a marker or mediator of disease severity. However, systematic measurements of subjective and objective sleep parameters are lacking in this population. We hypothesize that patients under treatment for psychiatric conditions would (1) exhibit a high prevalence of poor sleep quality at baseline, (2) show improvement in sleep over the course of treatment, and (3) exhibit associations between changes in sleep quality and psychiatric symptom severity.
Methods: We collected longitudinal subjective and objective (wrist actigraphy) measures of sleep in patients at the Johns Hopkins Intensive Outpatient Program for Adults (IOPA), which provides acute intensive treatment for patients with psychiatric disorders. From May 2018 until February 2020, we recruited consecutive IOPA patients. Depression, Anxiety and Stress Scale-21 (DASS-21) and actigraphy were collected at the first (baseline) and final two weeks of treatment. Sleep was estimated from actigraphy with Tudor-Locke and Cole-Kripke algorithms. By examining the distribution of sleep periods as a function of time of day, we summarized sleep timing and duration and examined their association with DASS-21 scores at both timepoints and change before and after intervention.
Results: Of 38 consented patients, complete data was available in 27 (Female:Male; 14:13; 42±15 yo) {mean±std}. At baseline, scores of depression (20.2±7.7), anxiety (12.9±7.7) and stress (19.3±9.4) fell at treatment completion, by ({mean±std/p-value}: 5.6±10.6/0.01; 3.5±6.4/0.01; 3.4±8.5/0.05, respectively). At baseline, self reported measures of sleep differed with objective measures by 22.3±109.4 minutes. DASS scores were associated with later median sleep onset time ({rho/p-value}: 0.48/0.01; 0.39/0.04; 0.43/0.02, respectively). Increased depression scores were associated with lesser sleep efficiency (-0.40/0.04) and greater movement index (0.43/0.03). PrePost reductions in DASS delta depression was associated with increased delta total sleep time (TST) (0.43/0.03). Delta stress associated with an increase in delta TST and time in bed (0.42/0.03; 0.42/0.03).
Conclusion: The IOPA is an acute intensive program treating severe psychiatric symptoms. Improvements in symptoms and sleep duration and timing have been demonstrated in these patients. Improvements in sleep may mediate psychiatric symptom improvements.

THE LACK OF CORRELATION BETWEEN POLYSOMNOGRAPHIC AND SELF-REPORTED MEASURES OF SLEEP DISTURBANCE IN PATIENTS WITH HISTORY OF DEPRESSION

Emy Villatoro[1], Boris Dubrovsky[1], Jeremy Weingarten[2], John Cunningham[1]
[1] NewYork-Presbyterian Brooklyn Methodist Hospital, [2] Well Cornell Medicine/NewYork-Presbyterian Brooklyn Methodist hospital

Introduction: Depression is associated with poor subjective sleep on Insomnia Severity Index (ISI) and Pittsburgh Sleep Quality Index (PSQI), and with polysomnographic (PSG) sleep disturbances. However, how physiological variables relate to self-reported sleep remains unclear. This analysis compares PSG and self-reported sleep measures between patients with vs. without depression history, and correlates self-reported and PSG measures.
Methods: From 1666 consecutive clinical baseline adult PSG studies, 201 patients were selected who had ≥120 minutes of total sleep time (TST), AHI< 5.0, no history of shift work or significant pain, neurological, cardiac, pulmonary, endocrine and psychiatric diagnoses, except depression (with or without anxiety). Only 18 patients (10 women, 16 white) with depression met other inclusion criteria; 17 of them were taking various mood stabilizers. MANCOVA, with sex, age and BMI covariates, was used to compare patients with vs. without depression history on PSQI, ISI, Center for Epidemiological Studies Depressions Scale Revised (CESDR), TST, N1%, N3%, REM%, SL, REM latency (REMLat) sleep efficiency (SE), WASO, number of awakenings (AW) and total arousal index (TAI). PSG variables showing between-group differences were used to predict ISI and PSQI in multiple regression models.
Results: Depression group had higher CESDR (M[Depression]=28.8±16.6 vs. M[No-Deprression]=12.7±10.6, p< 0.001), ISI (M[Deprression]=17.4±6.1 vs. M[No-Deprression]=12.1±6.4, p=0.001), PSQI (M[Deprression]=11.4±4.8 vs. M[No-Deprression]=8.7±3.7, p=0.009), more frequent AW (M[Deprression]=32.7±23.2 vs. M[No-Deprression]=28.0±12.0, p=0.02) and TAI (M[Deprression]=29.5±19.1 vs. M[No-Deprression]=22.4±12.7, p=0.01), lower N3% (M[Deprression]=14.1±9.1 vs. M[No-Deprression]=19.6±6.4, p< 0.001), longer REMLat (M[Deprression]=164.6±110.3 vs. M[No-Deprression]=107.7±62.3, p=0.006) and marginally longer SL

(M[Deprression]=47.9±38.6 vs. M[No-Deprression]=29.9±32.2, p=0.055). In multiple regressions, no PSG variables predicted ISI or PSQI in either group or in both groups combined (all p values >0.09).
Conclusion: This small sample of depressed patients without major medical or psychiatric comorbidities evidenced both subjective and objective sleep disturbance, in comparison with non-depressed patients. However, PSG variables do not appear to account for subjective sleep disturbance as measured by ISI and PSQI. These results suggest a complex relationship between depression and different measures of sleep. Effect of depression on subjective sleep may be mediated by factors other than PSG variables, including antidepressant use and daytime symptoms.

THE RELATIONSHIP BETWEEN OSA AND DEPRESSIVE SYMPTOMATOLOGY MAY DEPEND ON THE HISTORY OF DEPRESSION

Nandini Miryala[1], Boris Dubrovsky[1], Jeremy Weingarten[2], John Cunningham[1]
[1] NewYork-Presbyterian Brooklyn Methodist Hospital, [2] Well Cornell Medicine/NewYork-Presbyterian Brooklyn Methodist hospital

Introduction: Depression has been associated with OSA, and causal effects of apnea-related sleep fragmentation and hypoxemia on mood have been proposed. However, the nature of the relationship remains unclear and may be modulated by demographic variables. This study related mood and polysomnographic (PSG) measures in patients undergoing OSA evaluation.
Methods: From 1676 consecutive clinical baseline PSG studies, we excluded those with < 120 minutes of total sleep time (TST), history of shift work, significant pain, neurological, cardiac, pulmonary, endocrine and psychiatric diagnoses other than depression with or without anxiety. The sample included 36 patients with depression (20 women, 27 white, M[age]=45.6±15.3, 34 taking antidepressants), and 546 without depression/anxiety (297 women, 173 white, M[age]=48.7±15.7). A logistic regression was used to predict the presence of depression from OSA diagnosis (AHI≥5/hr), with sex, age and BMI covariates. In a general linear model (GLM), the score on the Center for Epidemiological Studies Depressions Scale Revised (CESDR) was predicted from AHI, SpO2% nadir, time below SpO90%, TST, sleep efficiency, sleep latency, REM latency, awakenings, wake after sleep onset, total arousal index, N1%, N3%, REM%, OSA, and OSA-by-depression interaction.
Results: In the logistic regression, depression was significantly predicted by OSA alone (p=0.03), but not after the demographic covariates were introduced (p=0.32). In the GLM, no PSG variables predicted CESDR; however, the OSA-by-depression interaction was significant (p< 0.001). Among patients without depression, the presence of OSA was associated with marginally lower CESDR (M[OSA]=10.9±11.1 vs. M[No-OSA]=12.7±10.4, p=0.065). In patients with depression, CESDR scores were not related to OSA (M[OSA]=25.8±12.8 vs. M[No-OSA]=24.6±16.6, p=0.82). Mean group AHI and CESDR scores were, respectively, AHI: M[Depression]=8.63±11.9 vs. M[No-depression]=15.0±20.6 (n.s.), CESDR: M[Depression]=25.9±15.1 vs. M[No-depression]=11.6±10.8 (p< 0.001).
Conclusion: In this sample of patients without significant comorbid conditions, history of depression did not relate the presence or severity of OSA after controlling for demographic variables. The relationship between OSA and CESDR appeared to be modulated by depression. Patients without depression had a tendency towards lower CESDR scores when OSA was present. In patients with depression, CESDR scores were nearly identical with or without OSA. Antidepressant use may have masked the OSA-CESDR relationship.

RELATIONSHIP BETWEEN PAIN AND DEPRESSIVE SYMPTOMATOLOGY IN OSA PATIENTS IS MODULATED BY THE CLINICAL HISTORY OF DEPRESSION

Douglas Walker[1], Jeremy Weingarten[2], Joel St. Germain[1], Boris Dubrovsky[1], John Cunningham[1]
[1] NewYork-Presbyterian Brooklyn Methodist Hospital, [2] Well Cornell Medicine/NewYork-Presbyterian Brooklyn Methodist hospital

Introduction: Prior studies reported altered pain perception in OSA, possibly due sleep fragmentation and hypoxemia. Additionally, OSA may impact mood, which also relates to pain perception. This study examined effects of polysomnographic (PSG) and mood variables on pain reports in patients evaluated for OSA.
Methods: Clinical histories of 1676 adults undergoing consecutive baseline PSG studies were used to exclude patients with chronic pain, neurological, cardiac, pulmonary, endocrine, psychiatric conditions other than depression (with or without anxiety), shift work and < 120 minutes of total sleep time (TST). Remaining sample included 546 patients without depression (297 women, 173 white, M[age]=48.7±15.7) and 36 with depression (20 women, 27 white, M[age]=45.6±15.3, 34 taking antidepressants). A general linear model, with sex, age and BMI covariates, predicted self-reported pain intensity over the preceding 6 months (PI, 0-10 scale) from TST, sleep latency, sleep efficiency, REM latency, awakenings, wake after sleep onset, arousal index, N1%, N3%, REM%, AHI, SpO2% nadir, time below SpO90%, OSA(AHI≥5/hr), Center for Epidemiological Studies Depressions Scale Revised (CESDR) score, and interactions: OSA-by-depression, OSA-by-CESDR and depression-by-CESDR.
Results: PI was associated with CESDR (p=0.013); however, the depression-by-CESDR interaction was significant (p=0.008). In patients without depression, CESDR predicted PI (p< 0.001, R2=11%). Patients with the history of depression showed no PI-CESDR relationship (p=0.8, R2< 0.01%). PI was not significantly related to any PSG variables. Mean group PI, CESDR and AHI values were, respectively, PI: M[Depression]=1.9±2.6 vs. M[No-depression]=2.5±2.7 (n.s.), CESDR: M[Depression]=25.9±15.1 vs. M[No-depression]=11.6±10.8 (p< 0.001); AHI: M[Depression]=8.63±11.9 vs. M[No-depression]=15.0±20.6 (n.s.).
Conclusion: Depressive symptoms and pain intensity were directly related only in patients without clinical history depression. The use of antidepressant medications in patients with depression may alter the relationship between CESDR and pain. As PSG measures of OSA and sleep architecture were unrelated to reports of pain in this sample, the possibility of a mediating role of depressive symptoms in the relationship between OSA and pain may be explored in the future.

DIFFERENCES IN SLEEP SCHEDULING IN VETERANS WITH PTSD AND HIGH VERSUS LOW RISK FOR SUICIDE

Steven Woodward[1], Laura Ong[2], Diana Villasenor[3], Ned Arsenault[3], Wilfred Pigeon[4], Christina Khan[5], Rebecca Bernert[6]

[1] National Center for PTSD- Dissemination & Training Division, [2] NIU, [3] NCPTSD, [4] University of Rochester, [5] Department of Psychiatry, Stanford University, [6] Resiliency Systems, LLC

Introduction: Sleep disturbances confer excess risk for suicidal ideation and behavior. This raises the question of whether long-term sleep monitoring with internet-enabled "non-wearable" devices imposing little burden might aid surveillance programs designed to promote timely interventions. Here we report proof-of-concept and preliminary group level data.
Methods: High-risk participants were identified using lists maintained by the Department of Veterans Affairs (REACH VET and HRS-PRF), maintained to facilitate surveillance for suicidality and other adverse outcomes. Both High- and Low-Risk participants were also diagnosed with PTSD per the EHR. Recruitment proceeded through treating clinicians. Consenting participants were mailed a piezoelectric, mattress-top sensor (RestOn Smart Sleep Monitor Model Z400T), a tablet computer, cables, and instructions. Participants were coached over the phone to connect the tablet computer to the internet after which staff used a remote-control utility to complete installation. Raw actigraphic data were automatically transferred daily to a cloud site from where they were downloaded, processed, and reviewed. Participants underwent weekly telephone assessments for one (Low Risk) or two (High Risk) months tracking suicidal ideation and sleep-related behaviors.
Results: The following results contrasted 54 High-Risk Veterans and 21 Low-Risk Veterans. Demographic and psychometric distinctions between the groups were minor except for the presence of comorbid MDD (72% vs 14%), suicidal symptoms (DSI-SI: 8.3 vs 4.9) and cognitions (SCSS: 15.2 vs 10.6), all higher in the High-Risk group. High-Risk participants went to bed at 21:51, more than one hour earlier than Low-Risk participants (23:02, $t(50) = -2.59$, $p = 0.013$). The groups did not differ on out-of-bed time (07:12 vs 07:57, $t(30) = -1.02$, $p = 0.32$). In-bed time variability, quantified as RMSSD within assessment weeks, did not distinguish the groups (108 versus 105 minutes, $t(21) = 0.11$, $p = 0.92$); however, out-of-bed time RMSSD was larger in the High-Risk group (118 versus 84 minutes, $t(47) = 2.37$, $p = 0.022$).
Conclusion: In contrast to the Romier meta-analysis finding reduced TST in suicidality, we observed earlier bedtimes and more variable arousal times. The former is compatible with social withdrawal. The latter is compatible with prior findings of Bernert.

IMPACT OF MEDICATION USE ON REM SLEEP WITHOUT ATONIA: DIFFERENTIATING MEDICATION EFFECT FROM DEPRESSION DIAGNOSIS

Jad El Ahdab[1], Carlos Rodriguez[1], Matheus Lima Diniz Araujo[2], James Bena[3], Shannon Morrison[1], Noah Andrews[1], Michael Saribalas[1], Nancy Foldvary-Schaefer[2]

[1] Cleveland Clinic, [2] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, [3] Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic, Cleveland, OH

Introduction: REM Sleep without Atonia (RSWA) is the polysomnographic biomarker of REM Sleep Behavior Disorder (RBD). RSWA is associated with serotonergic (SSRIs/SNRIs) antidepressants (ADs). The effects of other ADs and depression on RSWA are unknown. We analyzed the relationship between AD use and RSWA by depression diagnosis status aiming to determine whether RSWA is influenced by the diagnosis of depression, serotonergic agents, or ADs in general.
Methods: Polysomnograms at Cleveland Clinic (September 2018-October 2024) with >10% REM sleep and RSWA scoring by chin and flexor digitorum superficialis signals were included. Cases were categorized by depression status (yes=923; no=564), then stratified by AD use including any AD (SSRIs-386, SNRIs-181, bupropion-145, trazodone-117, tricyclic AD-60, mirtazapine-29), serotonergic (SSRI/SNRI), non-serotonergic (bupropion-n=145, mirtazapine-n=), and AD-free (n=653), and finally by gender. RSWA was quantified by AASM V2.6 criteria. Wilcoxon rank sum tests compared RSWA% between depression and medication status groups. Results are shown as median (IQR).
Results: A total of 1,487 were included: mean age 52.9±16.7, 47.2% female. Depression (vs no depression) was predominantly present in females (56.7% vs. 31.7%, $p< 0.001$) but had similar RSWA% (3.9[0.5, 14.6] vs 4.2[0.0, 18.0], $p=0.72$). RSWA% was 6.3[1.1,19.2], 6.7[1.3, 18.3], 0.7[0.0, 6.3], and 2.9[0.0, 11.4] in any AD, serotonergic, non-serotonergic, and drug free AD groups, respectively ($p< 0.001$). Serotonergic and AD-free groups without depression had higher RSWA% than those with depression (11.8[3.4, 31.5]/3.2[0.0, 14] vs 7.4[1.5, 20]/2.5[0.0, 9.4], $p=0.04$/$p=0.038$). For serotonergic ADs, this relationship was present only in women. RSWA did not differ in the any AD and non-serotonergic group by depression status ($p=0.56$).
Conclusion: RSWA is influenced by AD use rather than depression itself. Serotonergic agents are associated with higher RSWA% than non-serotonergic ADs, particularly in patients without depression. A possible explanation is that RSWA may be mediated by serotonin, as patients without depression, and thus without serotonergic depletion, appear more sensitive to the effects of serotonergic ADs. Our findings support the use of non-serotonergic agents over serotonergic agents, if clinically appropriate in populations at risk for RBD and α-synucleinopathies. This work has important implications on quantification of RSWA for the diagnosis of RBD.

THE ROLE OF INTERINDIVIDUAL SLEEP VARIABILITY AND SLEEP STAGES IN PRODROMAL PSYCHOSIS SYMPTOMS

Rebecca Essien[1], Emily Feldman[1], Amanda Bates[1], Danica Slavish[1]

[1] University of North Texas

Introduction: Changes in sleep architecture have been noted as a key aspect of the pathophysiology of schizophrenia, early psychosis and At Risk Mental States (ARMS). We aimed to assess the association between sleep metrics and prodromal psychosis symptoms.

Methods: This investigation utilized two-year follow up data (M age = 11.96) from the Adolescent Brain Cognitive Development (ABCD) Study, a longitudinal study examining brain development and health of children from ages 9-19. The sample was composed of participants (n = 5808, 48.79% female) who completed Fitbit sleep tracking and the Prodromal Psychosis Scale (PBQ).
Results: Linear regression analyses indicated that higher sleep variability across the study period was associated with an increased symptom count ($\beta = 0.12$, $p < 0.001$) and symptom severity ($\beta = 0.12$, $p < 0.001$). Lower average weekend sleep duration was linked to greater symptom count ($\beta = -0.09$, $p = 0.0385$). Greater awakenings and more time spent in light sleep were negatively associated with symptom count (awakenings: $\beta = -0.08$, $p < 0.001$; light sleep: $\beta = -0.08$, $p < 0.001$) and severity (awakenings: $\beta = -0.08$, $p < 0.001$; light sleep: $\beta = -0.05$, $p = 0.003$). Weekend sleep duration magnified the impact of sleep variability on psychosis symptoms ($\beta = 0.05$, $p = 0.0342$). Significant interactions were observed between awakenings, light sleep, and deep sleep. No additional significant associations were identified between other sleep stages and prodromal symptoms.
Conclusion: These findings highlight the importance of sleep consistency and adequacy in mitigating psychotic symptomatology. Although the examination of sleep stages in relation to prodromal symptoms is limited by methodology, it is possible that associations between sleep stages and psychosis may become more pronounced in older adolescents as the propensity for psychosis increases. Further research is needed to explore the long-term impact of sleep disruptions on psychotic symptom progression and to consider interventions for youth with an ARMS targeting sleep consistency.

THE DYNAMIC INTERPLAY BETWEEN UNDERGRADUATES' ECONOMIC STRESSORS AND SLEEP CAPTURED THROUGH MULTI-NIGHT AMBULATORY SLEEP EEG

Jack Peltz[1], Grecia Gamez[2], Nesrine Ramadan[2], Osiris Powley[2], Anita Licata[2]
[1] State University of New York at Brockport, [2] SUNY Brockport

Introduction: With 43% of college students obtaining less than the recommended 7-9 hours of nightly sleep and with over 75% reporting feeling tired/sleepy across the week (ACHA, 2023), this population is at significant risk for mental health, physical, and academic problems (Gaultney, 2010). These risks are exacerbated for students experiencing stress due to socio-economic challenges, which has been shown to impact both their sleep and mental health (Peltz et al., 2021). Research has tended to focus on links between deficient sleep and negative outcomes via self-report and actigraphy, but these methodologies do not measure the basic properties of sleep characterized through electroencephalography (EEG). Furthermore, sleep EEG measurement has relied on clinic-based polysomnography, which diminishes ecological validity. To build on prior research (e.g., Pesonen et al., 2021) and address this gap, this study used ambulatory sleep EEG to examine the dynamic links between college students' experiences of economic strain/stress, their sleep architecture, and self-reported sleep quality.
Methods: The sample's (N=157, 77.1% female) mean age was 20.3 years (SD=3.2), and 64.3% of participants were white, with 18.5% Black, 8.3% Hispanic/Latinx, 5.7% Asian/Pacific Islander, and 3.1% multi-racial/"other." Approximately 29.3% were considered first-generation students, and 68.8% maintained part/full-time employment while attending school. Baseline measures included economic strain, anxiety symptoms, and demographic controls. Sleep architecture was assessed with the Muse S (Interaxon, Inc.) across 10 consecutive nights, which measured, in addition to sleep stages, sleep onset latency and total sleep time (TST). Sleep quality was self-reported each morning through an online sleep diary.
Results: Multilevel structural equation modeling was conducted in Mplus (v. 8.8, Muthen & Muthen, 2022) and demonstrated two significant mediational pathways. Controlling for other effects in the model, higher economic strain was associated with less N3 sleep, which, in turn, predicted lower sleep quality. Furthermore, first-generation status predicted lower TST, and nightly decreases in TST were associated with corresponding decreases in sleep quality.
Conclusion: Our results highlight the negative impact of economic stress and first-generation status on undergraduates' sleep architecture and resulting sleep quality. This study underscores the negative impact of socio-economic stressors on undergraduates' sleep and introduces critical opportunities for interventions.

LONGITUDINAL STUDY OF ATTENTION DEFICIT AND HYPERACTIVITY DISORDER (ADHD) IN THE US ADULT GENERAL POPULATION

Maurice Ohayon[1], Stephanie Duhoux[2], Marie-Lise Cote[3]
[1] Stanford University, [2] EVALRI, [3] Centre d'evaluation & de Statistique (C.E.S.)

Introduction: Attention Deficit and Hyperactivity Disorder (ADHD) is becoming more acknowledged as a common problem among adults, garnering greater interest from researchers lately. The consequences of undiagnosed or untreated ADHD in adults can be significant. Numerous individuals face challenges in their work and everyday activities, resulting in increased stress. This, in turn, can cause sleep issues, making it harder to maintain concentration.
Methods: The initial study involved 15,929 participants across 15 US States. The longitudinal research took place in eight of the most densely populated states. During the first wave of interviews (W1), 12,218 subjects were contacted via phone, and 10,930 returned for the follow-up interview (W2) three years later. Analyses focused solely on those who participated in both W1 and W2 (N=10,930). ADHD was identified using DSM-5 criteria.
Results: At W1, 5.7% of participants met the ADHD criteria, but this percentage fell to 4.5% at W2. The disorder was more common in men than in women (6.6% compared to 5.0%; $p< 0.001$), and the rates decreased among individuals aged 55 and older (6.2% to 7.8% for those under 55, 5.3% for those aged 55 to 64, and 2.6% for those 65 and above; $p< 0.001$). ADHD was persistent in 47.4% of the cases across both interviews. After adjusting for age and gender, and controlling for the presence of a mental disorder and sleep duration, ADHD continued to be a strong indicator for insomnia symptoms (AOR: 1.69; 95% C.I.: 1.4-2.0), severe fatigue (AOR: 2.97; 95% C.I.: 2.2-4.0), and significant daytime sleepiness (AOR: 2.45; 95% C.I.: 1.9-3.2). At

W2, a sleep duration of less than 7 hours (AOR: 1.66; 95% C.I.: 1.2-2.3), trouble falling asleep (AOR: 3.41; 95% C.I.: 2.0-5.8), and moderate (AOR: 3.39; 95% C.I.: 2.0-5.7) or severe fatigue (AOR: 4.5; 95% C.I.: 2.6-7.9) at the initial interview were predictors of ADHD incidence.
Conclusion: The rate of ADHD in adults within the general population started at 5.7%, but this figure declined over three years. There is a significant link to sleep issues, as it can predict insomnia, fatigue, and significant sleepiness, and is also related to reduced sleep duration.

DECREASED SLEEP SPINDLE DENSITY IS ASSOCIATED WITH SUICIDALITY IN YOUNG ADULTS: THE PENN STATE CHILD COHORT

Jidong Fang[1], Christina Stetter[1], Anthony Rahawi[1], Melany Morales-Ghinaglia[2], Susan Calhoun[1], Alexandros Vgontzas[3], Duanping Liao[1], Edward Bixler[1], Lan Kong[4], Julio Fernandez-Mendoza[1]

[1] Penn State College of Medicine, [2] Northwestern University, [3] Sleep Research and Treatment Center, Penn State College of Medicine, [4] Department of Public Health Sciences, Penn State College of Medicine

Introduction: Sleep spindle deficits have been observed in different forms of psychopathology. Young adulthood is a developmental stage associated with increased rates of psychopathology and suicidality. Whether deficits in sleep spindle density (SSD) are associated with increased suicidality in young adults remains unknown.
Methods: A total of 246 participants from the Penn State Child Cohort, a population-based sample, underwent 9-hour in-lab polysomnography in young adulthood (age range 20-30y; 52% female, 24% racial/ethnic minority). We extracted SSD during N2 using MSS software. Suicidality was assessed via five items tapping lifetime, past-6-months, past-month and past-week suicidal attempts and/or ideation (SAI). Logistic regression models tested the association of SSD with SAI in young adulthood, while adjusting for sex, age, race/ethnicity, insomnia symptoms, body mass, apnea/hypopnea and periodic limb movements indices as well as prior SAI in childhood (age range 5-12y).
Results: SSD was negatively associated with SAI (OR=0.76, 95%CI=0.59-0.98, p=0.033). Young adults with less than 4 spindles per minute during N2 were associated with a 2.69-fold (95%CI=1.09-6.66) increased odds of SAI (p=0.033) than those with 4 spindles or more per minute.
Conclusion: Our data provide evidence linking deficits in spindle density with suicidality in young adults. Future studies should examine whether abnormal developmental declines in SSD drive the observed association with increased suicidality in young adulthood.

EXPLORING THE RELATIONSHIP BETWEEN NARCOLEPSY AND CANNABIS USE DISORDER

Mohit Chhatpar[1], Salwa Sadiq-Ali[1], Tina Thomas[1]

[1] Indiana Regional Medical Center

Introduction: The human sleep cycle consists of four stages—three NREM phases and one REM phase—regulated by neuromodulators, many acting on the lateral hypothalamus. Disruptions to this cycle can result in sleep disorders, including narcolepsy. Narcolepsy is a chronic disorder affecting sleep-wake cycle control, causing excessive daytime sleepiness and other symptoms. It is categorized into two types: Type 1, associated with cataplexy and decreased hypocretin (a hypothalamic neuromodulator), and Type 2, which lacks these features. Diagnosis typically involves clinical history and sleep studies. Cannabis, known for its psychoactive component THC, can also disrupt sleep. This meta-analysis evaluates the relationship between cannabis use disorder and narcolepsy, aiming to contribute to the existing body of literature.
Methods: A comprehensive PubMed search yielded 13 studies on cannabis use and narcolepsy. Only one examined adult cannabis use and hypersomnia using urine toxicology and sleep studies. A similar pediatric study was identified via Google Scholar. Additional literature on excessive daytime sleepiness, the hypocretin pathway, the endocannabinoid pathway, and cannabis use was also reviewed.
Results: Though literature is limited, this analysis highlights a relationship between cannabis use and narcolepsy. Endogenous cannabinoids, which act on the same receptors as those in cannabis, inhibit hypocretin-secreting neurons, reducing arousal and increasing sedation. The frequency and severity of cannabis use influenced symptom severity and disrupted sleep phases. Studies noted THC's sedating effects and CBD's wakefulness-promoting effects. Retrospective studies on adults and pediatric patients revealed narcolepsy-consistent sleep study results in THC-positive individuals.
Conclusion: Cannabis use can complicate clinical history and sleep study interpretations, impacting the sleep cycle and associated neuronal pathways. These findings underscore a relationship between cannabis use disorder and narcolepsy, emphasizing the need for a patient-centered approach in evaluation and management to account for this potential confounder.

SLEEP DURATION AND ABSTINENCE IN PATIENTS UNDERGOING METHADONE MAINTENANCE THERAPY OVER A 5-WEEK PERIOD

Jaime Devine[1], Lindsay Schwartz[1], Derek Reed[1], Steven Hursh[1]

[1] Institutes for Behavior Resources, INC

Introduction: Poor sleep is a risk factor for relapse in patients undergoing methadone maintenance therapy (MMT) for opioid use disorder (OUD). The aim of this pilot study was to examine the relationship between habitual sleep duration and opioid use over a 5-week period in MMT patients at the Institutes for Behavior Resources (IBR) Recovery Enhanced by Access to Comprehensive Healthcare (REACH) out-patient clinic in Baltimore, Maryland.
Methods: N=19 opioid-dependent patients MMT wore MotionLogger actigraphs (AMI) continuously and provided a weekly urine sample for up to five weeks. Patients were split between those who tested positive for opioids at least once during the study period (Test+) and those who consistently tested negative (Test-). Changes in weekly average total sleep time (TST) and changes in average TST between the first and last two weeks

of the study were compared between Test- and Test+ groups using paired samples t-tests and analysis of variance (ANOVA).
Results: Patients' average TST over the course of the entire study period was less than 5 hours per 24-hour period (292±81 minutes). However, TST increased an average of 23±106 min per 24-hour period between the first 2 weeks of the study period (273±118 min) and the final 2 weeks of the study period (297±78 min) across all patients. Patients were unevenly split between Test+ (n=6) and Test- (n=13) groups. Test- patients had longer TST than Test+ patients during the first two weeks of the study (288±125 min vs. 243±104 min), the final two weeks of the study (299±71 min vs. 292±100 min), and across all study days (298±80 min vs. 279±89 min). Test+ patients had a greater increase in TST over time (49±25 min) than Test- patients (11±34 min).
Conclusion: These data suggest that abstinence from opioid use may be related to habitual sleep duration at intake for MMT patients and that time in treatment may be related to increased sleep duration, particularly for individuals with worse sleep at intake. A larger study population and a longer observation period is needed in order to confirm the relationship between sleep duration and treatment outcomes.

SLEEP OF CAREGIVING FAMILY MEMBERS FOR ADULTS WITH SERIOUS MENTAL ILLNESS

Nicole Gumport[1], Isabelle Tully[2], Rachel Manber[1]
[1] Stanford University, [2] Case Western Reserve University

Introduction: Inadequate sleep is common concern among caregivers. Evidence is drawn mostly from caregivers of patients with dementia and physical ailments. However, research into sleep impairment among familial caregivers of patients with serious mental illness (SMI) is based on data from fewer than 150 participants and suggests high rates of sleep impairment. Sleep is important for caregivers as it is linked to both physical and mental health. Poor sleep contributes to diminished resources for coping with stress, low mood, and decreased wellbeing, which may exacerbate burdens caregivers are already facing. Existing interventions for sleep health may not address the unique challenges that caregivers of family with SMI experience. The current study aims to describe sleep difficulties among caregivers of family with SMI with the goal of informing development of a targeted sleep health intervention.
Methods: We conducted qualitative focus groups with 38 caregivers of an adult family member with SMI (92% women, 87% White, mean age=62 years). Participants also completed the Insomnia Severity Index (ISI), PROMIS Sleep Disturbance (PROMIS-SD), PROMIS Sleep-Related Impairment (PROMIS-SRI), Patient Health Questionnaire-4 (PHQ-4), Burden Scale for Family Caregivers- Short Version (BSFC), and measures describing their caregiving experience.
Results: Caregivers provided care most commonly for a family member with schizophrenia, schizoaffective disorder, bipolar disorder, anxiety, and/or depression. Caregivers cared for an adult offspring (81.6%), sibling (7.9%), spouse/partner (7.9%), or parent (2.6%). Mean insomnia severity (ISI) was 11.3 (SD=4.8), mean PROMIS-SD was 52.7 (SD=3.8), mean PROMIS-SRI was 56.6 (SD=7.0), and mean PHQ-4 was 4.8, SD=3.5). 28% reported waking up during the night to provide care more than once a week. Caregiver burden was high (mean BSFC=20.8, SD=4.6). One theme that emerged was waking up with a racing mind about concerns related to caregiving during the night.
Conclusion: Caregivers for SMI experience high degrees of burden and at least mild degrees of sleep difficulties and impairment due to caregiving. Data suggest caregivers of SMI might benefit from a targeted intervention to improve their sleep.

ARE DYSMENORRHEA, SLEEP DURATION AND DEPRESSION ASSOCIATED WITH MISCARRIAGE? A CROSS-SECTIONAL STUDY FROM EPISONO

Isabela Ishikura[1], Allan Porcacchia[1], Helena Hachul[1], Sergio Tufik[2], Monica Andersen[2]
[1] Universidade Federal de São Paulo, [2] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Being pregnant has been a challenge for many women. Almost 30% of the pregnancies end in miscarriage. It became prevalent in our society, and, regardless of the chromosomal abnormalities, it might be impacted by lifestyle, gynecological dysfunctions and sleep restriction. Our study aimed to identify the association of miscarriage occurrence with sleep duration, and dysmenorrhea and depression symptoms in women.
Methods: A total of 283 women participants of the epidemiological sleep study (EPISONO) from São Paulo city, Brazil, were included in this study. They responded to an institutional women questionnaire to obtain information about miscarriage occurrence and dysmenorrhea symptoms. To evaluate depression symptoms, the participants responded to the Beck Depression Inventory and underwent a full-night polysomnography exam to assess the sleep duration and wake after sleep onset (WASO). For evaluation of the sleep quality, participants responded to Pittsburgh Sleep Quality Index (PSQI).
Results: Considering the occurrence of miscarriage (yes or no) as the dependent variable, the results of the binary logistic regression model revealed that the following factors exhibited statistically significant association with miscarriage: age (OR=1.10; 95%CI=1.062-1.154; p< 0.001), dysmenorrhea (OR=1.83; 95%CI=1.009-3.340; p=0.047), total sleep time (OR=1.004; 95%CI=1.000-1.008; p=0.028), and moderate depression symptoms (OR=5.74; 95%CI=1.889-17.447; p=0.002). No statistically significant associations were observed in relation to body mass index, WASO and PSQI scores.
Conclusion: Our findings suggest that women who are trying to become pregnant should be screened in relation to sleep, and depression and dysmenorrhea symptoms to increase the risk of success in pregnancy attempts.

RISK IN TOBACCO CONSUMPTION IS AFFECTED BY WORK AND SLEEP VARIABLES: A CROSS-SECTIONAL EPIDEMIOLOGICAL STUDY

Vinícius Dokkedal-Silva[1], Guilherme Fernandes[2], Priscila Morelhão[3], Laís Berro[4], Jose Carlos Galduroz[1], Sergio Tufik[1], Monica Andersen[1]

[1] Departamento de Psicobiologia, Universidade Federal de São Paulo, [2] Universidade Federal de São Paulo, [3] Sleep Institute, [4] University of Mississippi Medical Center

Introduction: Substance misuse may lead to adverse developments in the health of the individual and constitutes a critical concern for health services and an elusive matter in the scientific community. Sleep and workplace environment variables have been assessed previously as contributing factors, but investigations covering both at the same time are still scarce. Therefore, we aimed at evaluating how sleep and workplace modulate risk in the consumption of substances.
Methods: 1,042 volunteers from the EPISONO 2007, a large-scale epidemiological study mapping sleep in dwellers from São Paulo, Brazil were included. Volunteers answered questionnaires evaluating their general health and underwent a full-night polysomnographic exam. We assessed how the score of the ASSIST questionnaire, used to gauge risk in the use of substances, was connected to variables concerning work and sleep conditions. These variables covered subjective and objective sleep, as well as questions about work characteristics, including working hours, number of jobs, amount of physical and mental effort, demand for precision of movements and working positions.
Results: Analyses focused in tobacco, cocaine and cannabis data. More time awake after sleep onset (WASO) was significantly associated with a rise of 0.054 in the ASSIST score for cocaine risk. Lower demand of movement precision in the job was significantly associated with augmented risk in the consumption of cannabis in 0.849. Greater total sleep time and necessity of more physical effort in the job were significantly associated, respectively, with a 0.014 and 1.786 increase in ASSIST score for tobacco risk.
Conclusion: We identified a concomitant effect of both sleep and work variables on risk in tobacco consumption, emphasizing the importance of a multifactorial approach when addressing use of this substance. It was found that poor sleep participates in the risk for cocaine usage and how work characteristic may affect risk for cannabis. These results reinforce the need for expansion in research in this area, contributing to the understanding on the network connecting work, sleep and substance use.
Support (if any): Our studies are supported by grants from the Associacão Fundo de Incentivo à Pesquisa (AFIP). JCFG, ST and MLA are Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) fellowship recipients.

[1] University of Missouri, [2] Washington State University, [3] University of California San Francisco, [4] University of South Florida

Introduction: Compared to the civilian population, Veterans often report higher levels of fatigue and sleep disturbances, which are frequently accompanied by self-medication with alcohol. However, the daily bidirectional dynamics between sleep and fatigue in the context of substance use remain underexplored. This study examined daily alcohol consumption as a moderator of the association between sleep and fatigue among heavy-drinking Veterans.
Methods: Heavy-drinking Veterans experiencing sleep disturbances were recruited from an insomnia treatment trial. Participants (N=130; 85.5% male; mean age=38.70 years) completed 14 days of morning sleep diaries. Diaries captured sleep parameters [quality, duration, sleep efficiency (SE), wake after sleep onset (WASO), sleep onset latency (SOL)], alcohol consumption (in standard drinks), and fatigue. Multilevel modeling was used to assess within- and between-person effects of sleep on next-day fatigue and vice versa, with daily alcohol use (0=no, 1=yes) as a moderator.
Results: Within persons, better sleep quality (b= -2.56, SE=0.64, 95% CI= [-3.82, -1.31], p <.001) and longer sleep duration (b=-0.94, SE=0.30, 95% CI= [-1.54, -0.34], p=.002) predicted lower next-day fatigue. Alcohol moderated the relationship between fatigue and same-night sleep parameters. Specifically, on days of alcohol use, higher fatigue was associated with lower sleep quality (z= -2.13, p = 0.03) and SE (z= -2.15, p=0.03). These relationships were nonsignificant on alcohol-free days (sleep quality: z=1.15, p=0.25; SE: z=1.00, p=0.32).
Conclusion: Sleep quality and duration influence next-day fatigue irrespective of alcohol use. However, fatigue adversely affects same-day sleep quality and SE only when alcohol is consumed. This suggests that alcohol use may compound fatigue's negative effects on sleep at the daily level. Findings can be incorporated into Veteran health education that alcohol use is contraindicated for sleep, particularly when one is already fatigued.

DELTA-8 TETRAHYDROCANNABINOL (THC) USE AND ITS ASSOCIATION WITH SLEEP DIFFICULTIES:INSIGHTS FROM HERBAL HEART STUDY

Amrit Baral[1], Bria-Necole Diggs[1], Ranya Marrakchi El Fellah[2], Kylee Krivijanski[2], Michelle Thompson[1], Girardin Jean-Louis[1], Denise Vidot[2]

[1] University of Miami Miller School of Medicine, [2] School of Nursing and Health Studies, University of Miami

Introduction: Delta-8 tetrahydrocannabinol (THC), a lesser-studied cannabinoid, has gained popularity in the U.S. due to its psychoactive effects, widespread availability, federal legality, and increasing consumer demand. Despite its growing use, there is a significant lack of research examining its impact on sleep. This analysis addresses this gap by exploring the association between self-reported sleep difficulties and Delta-8 THC use.

Methods: Data were drawn from the ongoing Herbal Heart Study (N=200), which investigates cannabis use and subclinical cardiovascular risk among 18-35-year-olds in South Florida. The primary exposure was self-reported lifetime use of Delta-8 THC. Main outcomes included self-reported (a) difficulty falling asleep, and (b) difficulty staying asleep in the past month. A composite variable, "poor sleep," was created for participants reporting either sleep difficulty. Sleep satisfaction was assessed using the WHO Quality of Life questionnaire and categorized as satisfied, unsatisfied, or neutral. Chi-squared/Fisher's Exact tests compared Delta-8 use prevalence across sleep variables. Multivariable logistic regression examined the association between Delta-8 use and poor sleep, adjusting for sociodemographic, behavioral, and mental health factors.
Results: Of the total sample (mean age: 25.2 years, SD=4.8), 65% were female, the majority were Hispanic (54.5%) followed by non-Hispanic White (18.5%), and non-Hispanic Black (17.5%). Delta-8 THC use was reported by 38.5% of participants. Overall, 23.0% of the sample reported difficulty falling asleep, and 16.5% reported difficulty staying asleep. Sleep issues were more common among Delta-8 consumers, with a higher prevalence of difficulty falling asleep (32.5% vs. 17.1%, $p = 0.01$), staying asleep (26.0% vs. 10.6%, $p < 0.01$), and poor sleep overall (41.6% vs. 21.1%, $p < 0.01$), though self-reported sleep satisfaction did not differ. Multivariable logistic regression analysis showed that Delta-8 consumers had nearly three-fold higher odds of poor sleep (AOR: 2.96; 95%CI: 1.27-6.9) compared to non-consumers.
Conclusion: Delta-8 THC consumers had a notably higher likelihood of reporting sleep difficulties compared to non-consumers. These results highlight the need for further exploration into the sleep-related effects of Delta-8 THC use.

POOR SLEEP QUALITY AND SUICIDAL IDEATION: CONSIDERING THE ROLE OF OCCUPATIONAL STRESS

Songyi Lee[1], Ji Hyun Han[1], Sang-Won Jeon[1], Dae Jong Oh[1]
[1] Kangbuk Samsung Hospital

Introduction: The link between sleep quality and suicidal ideation has been explored, but it is unclear how occupational stress affects the relationship between them. The aim of this study was to identify the association between poor sleep quality and suicidal ideation among workers in various occupations and to determine how occupational stress is related to this association.
Methods: This cross-sectional study collected data from 13,684 participants aged 19 to 65 who underwent mental health screening at 25 companies and public institutions. Sleep quality and occupational stress were assessed using the Pittsburgh Sleep Quality Index and Korean Occupational Stress Scale (KOSS), respectively. Sub-categories of KOSS include job demands, insufficient job control, interpersonal conflict, job insecurity, organizational system, lack of reward, and occupational climate. Suicidal ideation was assessed using the National Health and Nutrition Examination Survey.
Results: The 15.2% (n=2,077) of total participants had suicidal ideation. The 23.2% (n=1,244) of participants with poor sleep quality had suicidal ideation, whereas only 10% (n=833) of those with good sleep quality had suicidal ideation. Poor sleep quality was associated with an increased risk of suicidal ideation even after adjusting for occupational stress, depression, and other covariates (odds ratio [OR] = 1.26, 95% confidence interval [CI] = 1.13-1.42). When occupational stress was high, poor sleep quality was associated with 32% increased risk of suicidal ideation (OR = 1.32, 95% CI = 1.11-1.57). Among participants with poor sleep quality, high occupational stress was associated with the risk of suicidal ideation (OR = 1.52, 95% CI = 1.32-1.75). When we analyzed by the sub-categories of occupational stress, lack of reward and job insecurity were associated with 37% (OR = 1.37, 95% CI = 1.16-1.61) and 14% (OR = 1.14, 95% CI = 0.99-1.32) increased risk of suicidal ideation, respectively.
Conclusion: Poor sleep quality is independently associated with suicidal ideation among workers. Particular attention should be paid to employees with poor sleep quality who also have high levels of lack of reward and job insecurity.

THE ROLE OF SOCIAL MEDIA USAGE IN SLEEP AND DEPRESSION IN SUICIDAL ADOLESCENTS

Aliyah Syed[1], Jessica Hamilton[2], John Merranko[1], Tina Goldstein[3], Peter Franzen[4]
[1] UPMC, [2] Rutgers University, Department of Psychiatry, [3] University of Pittsburgh School of Medicine, Psychiatry Department, [4] University of Pittsburgh

Introduction: Social media use during adolescence may impact both sleep and depression. Social media usage could have impairing effects on mood and sleep duration and quality, and positive effects through obtaining support. Few studies have examined these relationships in clinical populations of adolescents with severe psychiatric disorders.
Methods: 143 adolescents (mean age 15.8 years, 76.9% Female) with suicidal ideation and major depression being treated in an Intensive Outpatient Program (IOP) completed social media and sleep questionnaires at baseline and monthly for up to 2 months. The social media questionnaire consisted of items regarding social media experiences, addiction, and frequency of use before bed. Monthly self-reports of sleep were measured with the Patient-Reported Outcomes Measurement Information System (PROMIS) Sleep Disturbance and Sleep Related Impairment scales, and depression through the Mood and Feelings Questionnaire (MFQ). Sleep and and social media were examined as predictors of depression severity through Pearson correlations.
Results: Nearly 72% of the sample reported social media use 2 hours before bed on most days, with 69% of adolescents using social media in bed and 44% using social media while intending to fall asleep. Negative, stressful interactions on social media were significantly associated with more depression ($r=.30$, $p< 0.01$) and sleep related impairment ($r =.27$, $p< 0.01$) within the same month. Social media addiction was significantly associated with depression ($r=.30$, $p< 0.01$) and sleep impairment ($r=0.318$, $p< 0.01$) within the same month. Duration of social media use after intent to fall asleep was significantly associated with depression ($r=.214$, $p< 0.05$), sleep disturbance ($r=.20$, $p< 0.05$), and sleep impairment ($r=.25$, $p< 0.01$) within the same month. Positive interactions on social media were notably only related to sleep impairment ($r=.214$, $p< 0.05$). No significant longitudinal associations between lagged social media use predictors and depression and sleep were found.

Conclusion: This study contributes to growing evidence regarding relationships between social media use, depression severity, and sleep-related issues in high-risk youth. Longitudinal studies further analyzing this relationship could reveal a specific pathway or mediation. Understanding social media's impact on adolescents affect and sleep health may help inform interventions specifically catered to depressed and suicidal youth.

NIGHTMARES AND SELF-INJURIOUS THOUGHTS AMONG HIGH-RISK ADOLESCENTS: EXAMINING NEGATIVE AFFECT AS A POTENTIAL MECHANISM

Kinjal Patel[1], Annabelle Mournet[2], Abigail Luce[1], Richard Liu[3], Evan Kleiman[2], Catherine Glenn[1]

[1] Old Dominion University, Department of Psychology, [2] Rutgers, The State University of New Jersey, Department of Psychology, [3] Harvard Medical School

Introduction: Self-injurious thoughts and behaviors (SITBs) are a critical public health concern among adolescents. Emerging research identifies nightmares—a sleep problem characterized by vivid, dysphoric dreams—as a promising proximal and modifiable risk factor for SITBs. However, little is known about the mechanisms through which nightmares may confer risk for SITBs among youth. This study aimed to address this gap by investigating whether negative affect intensity mediates the relationship between nightmares and SITBs in a sample of clinically high-risk adolescents.
Methods: Adolescents (N=86; ages 12–18) were recruited after discharge from acute psychiatric care settings (e.g., psychiatric inpatient hospitalization) and assessed using a 28-day ecological momentary assessment (EMA) design. Nightmare presence and intensity were assessed each morning, while negative affect (NA), suicidal thoughts, and non-suicidal self-injurious (NSSI) thoughts were measured multiple times per day. Multilevel structural equation modeling was employed to examine within- and between-person effects.
Results: Results revealed significant between-person mediation effects: adolescents who experienced more frequent or intense nightmares reported greater NA intensity, which in turn was associated with greater suicidal and NSSI thought intensity. Notably, these associations were observed at the between-person level but not within-person level, suggesting that the risk associated with nightmares and NA may be more reflective of stable individual differences rather than short-term, dynamic fluctuations.
Conclusion: These findings represent one of the first attempts to examine a mechanistic pathway linking nightmares to SITBs in adolescents, using temporally sensitive data collected during the critical period following discharge from acute psychiatric care—a time of heightened risk for SITBs. The findings have important clinical implications. Targeted interventions to reduce nightmare frequency and intensity may hold promise for mitigating SITB risk among high-risk adolescents. In sum, this study advances the understanding of how nightmares and NA intensity contribute to SITBs, providing a foundation for targeted, evidence-based interventions aimed at reducing suicide risk among vulnerable youth.

PERSONALITY TRAITS ARE NOT AN ADEQUATE PREDICTOR OF FOOD CRAVINGS DURING SLEEP DEPRIVATION

Matthew Larger[1], Kathryn Kennedy[1], David Negelspach[1], William Killgore[1]

[1] The University of Arizona

Introduction: Previous evidence has found an association between trait neuroticism and eating behavior. We hypothesized that individuals who indicated a higher degree of neuroticism would consume higher quantities of foods high in fat and sugar under sleep-deprived conditions.
Methods: A group of healthy participants (n=46; 50% female; mean age 25 years; mean body mass index (BMI) 24 kg/m2) were brought into the laboratory for a period of 30 hours of total sleep restriction. A series of neurocognitive tasks were administered at baseline, including the NEO Personality Inventory (NEO-PI). Participants were shown images of food and non-food items five times during the sleep deprivation period (approximately every 3 hours) and asked how much they wanted to eat the items on an ordinal scale (1-7). Foods were categorized as: "high-fat non-sweet", "high-fat sweet", "high-fat", "low-fat non-sweet", "low-fat sweet", "low-fat", "non-sweet", and "sweet". The "high-fat sweet" category was operationalized as the focus for unhealthy food cravings.
Results: A multivariate regression was used with NEO-PI neuroticism and interactions with other NEO-PI domains scores as predictors and the mean high-fat sweet rating across all five test intervals as the outcome due to consistency in ratings across the sleep deprivation period. No significant associations were found for NEO-PI neuroticism or interactions with other domains and high-fat sweet scores ($p=0.933$, $R2=0.061$) when adjusted for age and BMI.
Conclusion: Personality traits alone were not reliable predictors for high-fat sweet food ratings in this sample. Further research is needed to determine whether personality traits better predict actual food intake, and where discrepancies arise between self-reported hunger/food ratings and energy intake.

DOMESTIC VIOLENCE EXPOSURE ASSOCIATED WITH CURRENT SLEEP HEALTH

Suzanne Gorovoy[1], Elizabeth Rasmussen[2], Kelly Baron[3], Wendy Troxel[4], Michael Grandner[1]

[1] University of Arizona College of Medicine, [2] University of Arizona, [3] University of Utah, [4] RAND Corporation

Introduction: Domestic violence exposure (DVE) is a pervasive public health issue with profound effects on physical and mental health. Emerging evidence highlights the significant impact of DVE on sleep health, a critical determinant of overall well-being. This abstract examines the relationship between DVE and current sleep health.
Methods: Data were from the Sleep and Healthy Activity, Diet, Environment, and Socialization (SHADES) Study, consisting of N=1007 adults age 22-60. Domestic violence was assessed with the HITS scale, asking how often a partner would "physically

hurt you," "insult or talk down to you," "threaten you with harm," "scream or curse at you." Sleep health variables included insomnia (Insomnia Severity Index [ISI]), sleep duration (NHANES), sleep quality (Pittsburgh Sleep Quality Index [PSQI]), sleep control (Brief Index of Sleep Control [BRISC]), sleepiness (Epworth Sleepiness Scale [ESS]), sleep apnea risk (STOP-BANG), and items to capture habitual sleep latency (SL) and wake after sleep onset (WASO), and frequency of nightmares and loud snoring. Covariates included age, sex, race/ethnicity, education, income, relationship status, home type (single-family vs shared), and overall environmental safety. Analyses examined each HITS item and composite score. Results are expressed as unstandardized linear coefficients (B) or ordinal odds ratios (oOR).

Results: In fully adjusted models, history of physical abuse was associated with insomnia (B=1.7pts), sleep latency (B=7.5mins), sleep quality (B=0.8pts), sleepiness (B=1.4pts), and STOP-BANG score (oOR=1.4). History of verbal abuse was associated with insomnia (B=1.1pts), sleep duration (B=-11.9mins), sleep quality (B=0.6pts), sleepiness (B=0.7pts), nightmares (oOR=1.2), loud snoring (oOR=1.3), and STOP-BANG score (oOR=1.3). History of threats was associated with insomnia (B=1.7pts), sleep quality (B=0.8pts), sleepiness (B=1.2pts), nightmares (oOR=1.4), loud snoring (oOR=1.3), and STOP-BANG score (oOR=1.4). History of screaming was associated with insomnia (B=1.2pts), sleep duration (B=-8.4mins), sleep quality (B=0.8pts), control (B=-0.1), sleepiness (B=0.6pts), nightmares (oOR=1.3), loud snoring (oOR=1.3), and STOP-BANG score (oOR=1.4). HITS total score was associated with insomnia (B=0.5pts), sleep duration (B=-3.8mins), sleep quality (B=0.3pts), sleepiness (B=0.3pts), nightmares (oOR=1.1), loud snoring (oOR=1.1), and STOP-BANG score (oOR=1.1).

Conclusion: Exposure to various forms of abuse is associated with poorer sleep health across multiple dimensions. Future work should evaluate the benefit of adding sleep to DV interventions.

PREVALENCE OF PSYCHIATRIC CONDITIONS IN A LARGE SLEEP CLINIC POPULATION

Michael Mangold[1], Ankit Parekh[2], Sajila Wickramaratne[1], Zachary Roberts[1]

[1] Icahn School of Medicine at Mount Sinai, [2] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Psychiatric conditions often affect sleep, and sleep disorders can also affect mental health. The prevalence of psychiatric conditions in patients evaluated for sleep disorders is not well-established. This study reviews electronic medical records (EMRs) from a major metropolitan health system to assess the burden of psychiatric conditions in patients with suspected sleep disorders who underwent nocturnal polysomnography.

Methods: We analyzed EMR data for patients who underwent a sleep study between October 2016 and August 2023. Psychiatric diagnoses (ICD-10 F-Codes) within six months prior to the sleep study were extracted. Descriptive statistics summarized diagnoses and demographic variables, including sex, age, and AHI data for patients with F-Codes.

Results: Of 6,462 patients who completed a polysomnographic study, 310 (4.8%) had at least one F-Code diagnosis. Of these, 158 (51.0%) were female, with a mean age of 45.25 years (range: 19-82). Among all patients, 112 (1.73%) had a Nonorganic Sleep Disorder (F51), 240 (3.71%) had other F-Code diagnoses, and 70 (1.08%) had an isolated F51 code. Forty=two (0.65%) had both F51 and another F-Code diagnosis. The most common non-sleep diagnoses included Anxiety (F41, N=116, 1.80%), Non-Bipolar Mood disorders (F32-F39, N=92, 1.42%), Stress disorders (F43, N=37, 0.57%), Substance Use disorders (F11-19, N=30, 0.46%), particularly Nicotine Use (F17.2, N=23, 0.36%), and Somatoform disorders (F45, N=23, 0.36%). Among patients with any F-Code, the median AHI was 9.10 (IQR 2.64–21.57). For those with an F51 code, median AHI was 7.82 (2.68-22.04), and for those with no F51 diagnosis, median AHI was 10.34 (2.56-20.11). Patients with an AHI >5 consistently had a higher burden of psychiatric illness than those with an AHI < 5 for each F-Code.

Conclusion: Psychiatric diagnoses, especially nonorganic sleep, anxiety, mood disorders, and substance use, are common in patients undergoing sleep evaluation. However, these rates are lower than national averages, suggesting potential gaps in diagnostic practices. Median AHI values fell within the mild to moderate obstructive sleep apnea range. Those with an AHI >5 had a higher burden of psychiatric illness on average, although further research is needed. A key limitation is the six-month time frame for psychiatric data collection.

IDENTIFYING ADOLESCENTS AT RISK FOR SUICIDE USING OBSERVED CLASSROOM BEHAVIOR INDICATIVE OF EXCESSIVE DAYTIME SLEEPINESS

Reut Gruber[1], Gail Sommerville[1], Rosalie Barbeau[2], Sujata Saha[3]

[1] Attention, Behaviour and Sleep Lab, The Douglas Research Center, [2] Attention, Behaviour and Sleep Lab, The Douglas Research Center, [3] Heritage Regional High School

Introduction: Suicide is the second leading cause of death among teenagers. Unfortunately, many at-risk adolescents do not seek help, making it challenging for educators and mental health professionals to identify those in need of support. Adolescents at high risk for suicide exhibit higher daytime sleepiness compared to their low-risk counterparts. The present study therefore evaluated the validity of categorizing adolescents into high and low suicide risk groups based on observed classroom behaviors indicative of excessive daytime sleepiness.

Methods: Participants: 188 adolescents (M= 14.32 years, SD = 1.88; 59 boys). Measures: Suicidality was assessed using Item 9 of the Beck Depression Inventory: Participants responding "I do not have any thoughts of killing myself" were classified as low risk, while those indicating "I have thoughts of killing myself, but I would not carry them out," "I would like to kill myself," or "I would kill myself if I had the chance" were classified as high risk. Daytime sleepiness was assessed using the Sleepiness subscale of the School Sleep Habits Survey, which asks respondents to indicate whether they had struggled to remain awake in ten different situations.

Results: Discriminant function analysis and group classification were used to predict group membership. One discriminant function was extracted, accounting for 100% of the total variance. The function significantly discriminated between the groups (Wilks' Lambda =.94, $\chi^2(2) = 11.36$, $p < .003$), indicating strong group separation. Falling asleep in a face-to-face conversation with

another person and in class were the strongest variables for differentiating between the two groups. Group classification resulted in 82.2% accuracy for predicting the level of adolescent suicidality.
Conclusion: Classroom behaviors indicative of excessive daytime sleepiness can effectively differentiate between adolescents at high and low risk for suicide. Engaging with students who fall asleep in class may assist educators and clinicians in identifying adolescents at risk for suicide. By recognizing these behaviors, schools can play a pivotal role in early identification and intervention efforts. Understanding the sources of sleepiness and implementing appropriate interventions have the potential to significantly reduce the risk of suicide within this vulnerable population.

HIGH SUICIDE RISK IN ADOLESCENTS WITHOUT SLEEP DISTURBANCES IS ASSOCIATED WITH HIGHER DAYTIME SLEEPINESS AND LATER RISE TIME

Reut Gruber[1], Sujata Saha[2], Rosalie Barbeau[3], Gail Sommerville[1]
[1] Attention, Behaviour and Sleep Lab, The Douglas Research Center, [2] Heritage Regional High School, [3] Attention, Behaviour and Sleep Lab, The Douglas Research Center

Introduction: Suicide is a leading cause of death among adolescents. Although sleep disturbances are well-documented risk factors for suicidal thoughts and behaviors, little research has examined the association between sleep and suicide risk among adolescents without sleep disorders, particularly in community samples. To fill this gap, the present study compared sleep and circadian parameters of adolescents without sleep disturbances who showed high and low levels of suicidality.
Methods: 188 adolescents (M= 14.32 years, SD = 1.88; 59 boys) scoring in the normal range on the Sleep Disorders Inventory–Adolescent Form were recruited from high schools in Quebec. They wore actigraphs at home for six consecutive nights, completed a sleep diary nightly, and completed the Epworth Sleepiness Scale and the Munich Chronotype Questionnaire (MCTQ). Demographic information was obtained from their parents. Suicidality was assessed based on the participants' response to the 9th item of the Beck Depression Inventory. If they responded "I do not have any thoughts of killing myself," they were classified as having low suicide risk, whereas if they responded "I have thoughts of killing myself, but I would not carry them out" or "I would like to kill myself" or "I would kill myself if I had the chance," they were classified as having high suicide risk.
Results: Thirty-three adolescents (17.6%; 27 girls, 6 boys) reported suicidal ideation whereas 155 (82.4%; 102 girls, 53 boys) reported no suicidal ideation. MANCOVAs revealed significantly higher daytime sleepiness and significantly later rise time in the group with high suicide risk compared to those with low risk. There were no significant group differences in sleep duration, quality, chronotype, or circadian preferences.
Conclusion: In this community sample of adolescents without sleep disturbances, adolescents at risk for suicide showed higher daytime sleepiness and later rise times during the school year. These findings highlight the importance of improved awareness of signs of daytime sleepiness among adolescents and point to the potential benefits of including sleep health promotion as an important component of interventions aimed at lowering youth suicide risk. Limitations. The cross-sectional design of this study limits determination of causality.

PROLONGED GRIEF AND RELATED HEALTH FACTORS MODIFY THE RELATIONSHIP BETWEEN BEDROOM LIGHT EXPOSURE AND SLEEP FRAGMENTATION

Takuya Yoshiike[1], Tomohiro Utsumi[1], Tomoki Yajima[2], Kentaro Nagao[1], Aoi Kawamura[1], Srishti Tripathi[2], Eriya Takahashi[2], Masahito Nangaku[1], Shingo Kitamura[1], Kentaro Matsui[3], Satomi Nakajima[4], Kenichi Kuriyama[1]
[1] Department of Sleep-Wake Disorders, National Institute of Mental Health, National Center of Neurology and Psychiatry, [2] National Center of Neurology and Psychiatry, [3] Department of Laboratory Medicine, National Center Hospital, National Center of Neurology and Psychiatry, [4] Musashino University

Introduction: Light information critically influences sleep and emotion regulation. Nighttime light exposure has been suggested to disrupt sleep and predict poor health outcomes. However, little is known about how sleep changes after bereavement and how sleep changes contribute to prolonged grief. We examined the association between nighttime light exposure and sleep continuity in bereaved adults.
Methods: In this cross-sectional study, 30 adults who had been bereaved for at least one year, wore a wrist actigraphy for seven consecutive nights. Bedroom light intensity from bedtime to rising time (BLI, lux) and sleep continuity variables were estimated from the wrist actigraphy. We tested the association between BLI and natural log-transformed sleep continuity measures and explored factors that modify this relationship in multivariable-adjusted generalized linear models.
Results: Nearly 40% of participants were diagnosed with current prolonged grief disorder (PGD), even after a median of 2.5 years since the loss. The mean BLI was 3.72 lux. Overall, higher BLI was associated with lower sleep continuity, independently of psychological, physical, and sleep covariates, including total sleep time, sleep midpoint, and season. This was particularly evident for sleep fragmentation index (B = 0.076; 95% CI, 0.029–0.122; exp[B] = 1.079), indicating that every 1-unit increase in BLI was associated with a 7.9% increase in sleep fragmentation index. Moreover, the association between BLI and sleep fragmentation was more robust in participants with current PGD, those who had lost a child or spouse, and those whose loss was violent or sudden than in those without each of these characteristics. Similarly, depressive symptoms, hypnotic use, and regular alcohol drinking also modified the relationship between BLI and sleep fragmentation.
Conclusion: These data strengthen the evidence for nighttime light exposure and sleep fragmentation. Our findings suggest that post-loss stress and vulnerability factors interact to disrupt sleep through increased light sensitivity at night. Further research is needed to determine the role of sleep fragmentation in the maintenance of and recovery from grief.

REST BEST: NAVIGATING SLEEP SOLUTIONS FOR PERSONS WITH OPIOID USE DISORDER THROUGH AN ENGAGING MHEALTH APP

Allison Wilkerson[1], Brooklynn Bailey[2], Rick Simmons[2], Angela Moreland-Johnson[2], Kenneth Ruggiero[2], Sarah Book[2], Aimee McRae-Clark[2]

[1] Medical University of South Carolin, [2] Medical University of South Carolina

Introduction: Sleep disorders are highly prevalent among individuals undergoing treatment for opioid use disorder (OUD) with medications for OUD (MOUD) and often remain largely untreated. There is a critical need for effective interventions for sleep disorders that can be integrated into ongoing MOUD treatment with minimal burden and risk to both providers and patients. This project aims to develop an mHealth, MOUD-adjacent program in the form of a smartphone application, RestBest, to guide patients through a brief, structured transdiagnostic program for sleep problems.
Methods: This study employed a two-phase approach: 1) Qualitative interviews were conducted with 15 adults (5 newly beginning MOUD, 5 stabilized on MOUD, and 5 MOUD providers) to review storyboards and create an initial build of RestBest; 2) The initial build was then tested with 10 adults who recently initiated or modified their MOUD prescription. Participants completed daily in-app sleep logs over 4 weeks and engaged with 6 chapters of animated videos that included basic sleep habits, the science of sleep and substance use, sleep scheduling, daytime functioning, bedtime relaxation, and specialty topics (e.g., nightmares, sleep apnea). Program completion was followed by the System Usability Scale (SUS), the mHealth App Usability Questionnaire (MAUQ), and a qualitative interview.
Results: Initial interviews highlighted the need for a comprehensive sleep survey, a preference for educational animated videos over text or lecture-style formats, and a desire for a personalized dashboard with sleep variables and practice points. The mean SUS score was 89.19, and mean MAUQ was 109, indicating "excellent" usability and a positive user experience with the app. Interviews revealed a desire for customization of content based on the type of sleep problems, visual tracking of MOUD adherence on the dashboard, and additional specialty topics (e.g., shift work).
Conclusion: Initial testing of RestBest indicates high usability and positive reception among users. The findings underscore the importance of customizable content addressing numerous types of sleep problems in creating effective mHealth interventions for sleep disorders in individuals receiving MOUD. Future directions include a randomized controlled trial with multidimensional measures of sleep to determine efficacy of the intervention on sleep quantity and quality.

ETHNIC DIFFERENCES IN SLEEP PATTERNS AMONG CANNABIS CONSUMERS IN THE HERBAL HEART STUDY

Ciné Brown[1], Amrit Baral[1], Bria-Necole Diggs[1], Kylee Krivijanski[2], Ranya Marrakchi El Fellah[2], Girardin Jean-Louis[1], Denise Vidot[2]

[1] University of Miami Miller School of Medicine, [2] School of Nursing and Health Studies, University of Miami

Introduction: There is a dearth of research exploring sleep difficulties/satisfaction among ethnically-diverse younger cannabis consumers - a vulnerable population with increasing cannabis use. We examined self-reported sleep difficulties by cannabis use (CU) and Hispanic origin.
Methods: Data are from 18-to-35-year-olds in the Herbal Heart Study cohort (N=200). Cannabis was self-reported, confirmed via urine, and categorized as low-to-moderate (< 20-days/month) and high-frequency (>20-days/month). Self-reported difficulties were falling (DFA) and staying asleep (DSA) over the past month; "poor sleep" included those with either. Sleep satisfaction was measured via WHO Quality of Life and classified as satisfied, neutral, or unsatisfied. Differences by CU and ethnicity were assessed using Chi-squared/Fisher exact tests.
Results: Of participants (mean age: 25.2 years, SD=4.8; 65.0% female, 54.5% Hispanic), 63.0% were CUs; 74.6% of which were high-frequency CUs. Overall, 23.0% reported DFA, 16.5% DSA, 29.0% poor sleep and 23.0% reported sleep dissatisfaction. DSA was more prevalent among CUs vs non-CUs (20.6% vs. 9.5%, $p = 0.04$), particularly among Hispanics (24.0% vs. 8.6%, $p = 0.049$). Frequent CUs reported higher DSA than non-frequent CUs (26.0% vs. 3.1%, $p < 0.01$). There were no differences found by sex.
Conclusion: Frequent cannabis consumers had higher prevalence difficulty staying asleep, particularly among Hispanic/Latinos. These findings underscore the need in further investigating the relationship between frequent cannabis use, sleep disturbances, and racial/ethnic disparities.

SLEEP DISTURBANCE MEDIATES THE RELATIONSHIP BETWEEN PERCEIVED STRESS AND DRUG USE IN COLLEGE ATHLETES

Emme Tucker[1], Lauren Elmore[1], Cordell Stover[1], Sarah Emert[1], Alisa Huskey[2], Kelly Kim[3], Daniel Taylor[3]

[1] Idaho State University, [2] The University of Arizona, [3] University of Arizona

Introduction: Sleep difficulties are common among college student athletes and can significantly affect their physical and mental well-being. The Athlete Sleep Screening Questionnaire (ASSQ) is a screener for detecting sleep disturbances. Research has shown that poor sleep quality mediates the relationship between stress and maladaptive health behaviors like poor diet and alcohol misuse. The present study explores the mediating effect of sleep difficulties on perceived stress and drug use in college student athletes.
Methods: College students (N=1886; Mage=20.54 years, 57% female, 73.80% Caucasian) from two universities completed self-report questionnaires on the following domains: sleep disturbance (ASSQ-SDS), perceived stress (PSS), and drug use (CAGE-AID). Mediation analysis was used to investigate the effect of sleep disturbances on perceived stress and drug use.
Results: The overall regression model was significant, $F(3, 1352) = 21.9656$, $p < .001$, R-squared=.0465. Sleep disturbance severity significantly predicted drug use, $B = -.0834$, $SE = .0420$, $t = -1.9869$, $p = .047$. Perceived stress did not significantly predict drug use, $B = -.0102$, $SE = .0153$, $t = -.6654$, $p = .5059$. The

interaction between sleep disturbance severity and perceived stress significantly predicted drug use, B =.0056, SE =.0019, t = 2.9244, p =.0035, Delta R-Squared=.0060, F(1, 1352) = 8.5519.
Conclusion: The results of this analysis highlight the mediating role that sleep disturbance has on reported perceived stress and drug use. Additionally, higher levels of sleep disturbance are associated with increased drug use. Athletes experiencing more sleep difficulties may have a heightened vulnerability to drug use when exposed to stress. Previous research suggests that strategies like sleep hygiene education, relaxation techniques, mindfulness, and CBTi are effective in improving sleep. Improving sleep quality may mitigate the negative effects of stress on drug use behavior, a critical focus for student health initiatives.

HABITUAL INSUFFICIENT SLEEP ASSOCIATED WITH SUBSTANCE USE BEHAVIORS IN COLLEGE STUDENT ATHLETES

Mira Marwah[1], Chloe Warlick[2], Amy Athey[3], Subhajit Chakravorty[4], William Killgore[5], Pamela Alfonso-Miller[6], Suzanne Gorovoy[7], Michael Grandner[7]
[1] University of Arizona, [2] Northwestern University Feinberg School of Medicine, [3] Athey Performance, [4] Corporal Michael J. Crescenz VA Medical Center, [5] The University of Arizona, [6] Northumbria University, [7] University of Arizona College of Medicine

Introduction: Sleep problems are common among student athletes, who are often over-scheduled while balancing responsibilities. Insufficient sleep may be a risk factor for substance use in this population.
Methods: Data were collected from 8,683 athletes using the National College Health Assessment conducted between 2011-2014. Insufficient sleep was assessed as number of nights students did not "get enough sleep so that you felt rested when you woke up," coded as <=2, 3-4, or >=5 nights per week. Students were asked whether they used the following in the past 30 days: cigarettes, hookahs, cigars/cloves, smokeless tobacco, alcohol, marijuana, cocaine, methamphetamine, other amphetamines, sedatives, hallucinogens, steroids, opiates, inhalants, ecstasy, club drugs, or other drugs and whether "the typical student at your school" used these substances in the past 30 days. Multinomial logistic regression analyses examined sleep variables relative to use (Past or Present vs None) and typical use (More or Less vs Same).
Results: Insufficient sleep at least 5 nights per week was associated with increased use of cigarettes in the past (RRR=1.46) and present (RRR=1.52), hookahs in the past (RRR=1.29) and present (RRR=1.43), cigars/cloves in the past (RRR=1.37) and present (RRR=1.40), smokeless tobacco in the past (RRR=1.36) and present (RRR=1.48), alcohol in the present (RRR=1.34), marijuana in the past (RRR=1.34) and present (RRR=1.35), amphetamines in the present (RRR=1.64), sedatives in the past (RRR=1.79) and present (RRR=2.35), and inhalants in the past (RRR=2.07). Student athletes who reported at least 5 nights per week of insufficient sleep were more likely to report less-than typical use of smokeless tobacco (RRR=1.14), cocaine (RRR=1.14), methamphetamine (RRR=1.14), amphetamines (RRR=1.19), sedatives (RRR=1.26), hallucinogens (RRR=1.26), steroids (RRR=1.27), opioids (RRR=1.23), inhalants (RRR=1.20), MDMA (RRR=1.28), other club drugs (RRR=1.31), and other drugs (RRR=1.23), and less likely to report that their alcohol use was less than typical (RRR=0.77). They were also more likely to report that their use of sedatives was more than typical (RRR=2.73).
Conclusion: Substance use among student athletes is linked to insufficient sleep. Addressing insufficient sleep through focused interventions should be evaluated to determine whether they decrease substance use in this population.

ADVERSE CHILDHOOD EXPERIENCES ASSOCIATED WITH UNHEALTHY SLEEP IN THE SOUTHERN COMMUNITY COHORT STUDY

Caroline Castleman[1], Hui Shi[2], Maureen Sanderson[3], Loren Lipworth[2], Kelsie Full[4]
[1] Vanderbilt University School of Medicine, [2] Vanderbilt University Medical Center, [3] Meharry Medical College, [4] Division of Epidemiology, Department of Medicine, Vanderbilt University Medical Center

Introduction: Adverse childhood experiences (ACEs) are potentially traumatic events that occur before age 18, including abuse, neglect or witnessing violence in the home or community. ACE exposure has been associated with poor sleep and chronic diseases in adulthood. Leveraging data from the Southern Community Cohort Study (SCCS), a large cohort of predominantly low-income adults, we investigated ACE exposure in childhood with sleep duration in adulthood.
Methods: The SCCS enrolled predominantly Black adults age 40-79 from 12 southeastern US states between 2002-2009. SCCS participants self-reported sleep duration at baseline. The follow-up survey conducted from 2012-2015 included a 10-item ACEs scale. Sleep duration was categorized as short (< 7 hours), healthy (7-9 hours), or long (>9 hours). Odds ratios (ORs) and confidence intervals (CIs) were calculated to estimate the association between ACEs and sleep duration, adjusting for age, sex, and income.
Results: Of 32,959 participants (mean age 52.9 years), 18,901 (57%) reported at least one ACE, 62% identified as Black, and 46% had income <$15,000/year. Compared to zero ACE exposure, exposure to at least one ACE was associated with short (1.19 [1.13, 1.25]) and long (1.15 [1.06, 1.24]) sleep at baseline. Individuals with 4 or more ACEs were 1.32 times more likely to report short sleep than those without ACEs (1.23, 1.42). Abuse-related ACEs were associated with lower odds of short sleep (0.84 [0.74, 0.94]), while ACEs related to household dysfunction were associated with increased odds of short (1.22 [1.16, 1.28]) and long sleep (1.16 [1.07, 1.25]).
Conclusion: Among over 30,000 predominately low-income adults in the southeastern US, ACE exposure was associated with short and long sleep in adulthood. Greater ACE exposure (4+) was associated with greater odds of short sleep than lower ACE exposure. This pattern could reflect a trend toward shorter sleep

with increasing ACEs. Further research should work to identify mechanisms connecting ACEs and abnormal sleep duration.

UNDERSTANDING BEDTIME PROCRASTINATION IN THE MILITARY POPULATION

Aaron Burch[1], Lauren Cornell[2], Jordan Ellis[3], Claudia Holtz[4], Tarjani Shukla[2], Dianna Herrera[2], H. Samuel Scheuller[1], Zahari Tchopev[1], Philip Cushman[1], James Kang[1], Amanda Radtke[1], Matthew Brock[1]

[1] San Antonio Uniformed Services Health Education Consortium, [2] DHA Lackland 59th MDW, [3] DHA Andrews 316th MDG, [4] USAF [559] MDG

Introduction: Bedtime procrastination (BP) is considered a form of self-harm. BP contributes to insufficient sleep leading to multiple negative cognitive and physiologic sequelae. The prevalence of BP is not currently established among military service members (SMs), yet similar contributors to insufficient sleep such as insomnia are high, ranging from 27-74%. There are clinically validated tools that aid in the evaluation of factors contributing to BP, which are not currently employed in our clinic. This quality improvement project sought to incorporate phased Plan-Do-Study-Act (PDSA) cycles to improve the assessment and disposition of referred patients' sleep complaints by incorporating three BP questionnaires and educating clinic providers on their interpretation and implementation in routine patient care.

Methods: Our academic military sleep disorders center incorporated validated BP scales into standard new patient intake questionnaires. These included the Bedtime Procrastination Scale (BPS) (max score 45), While-in-Bed Procrastination Scale (WIBPS) (max score 35), While-in-Bed-Smartphone-use-Induced Sleep Procrastination Scale (WSPS) (max score 30) and 1 single-item measure: "Did you use smartphone in bed before sleep last night?". Responses were collected for two weeks as part of the initial PDSA cycle.

Results: The BP scales were successfully incorporated into our patient intake process. Surveys were collected from 112 (23 female (20.54%), mean age = 36.1 years, age range 18-62) SMs from all branches of the military. The average scores on the BPS, WIBPS and WSPS were 24.2± 6.8, 12.9±5.0, and 12.8± 4.8, respectively. A total of 67 (59.8%) respondents endorsed smartphone use in bed on the previous night.

Conclusion: Methods of evaluating patients who suffer sleep loss due to bedtime procrastination are not currently standardized or regularly implemented. We successfully implemented BP questionnaires with a high completion rate and found that BP and in-bed smartphone use is highly prevalent in our patient population. Better methods of characterizing the behavioral patterns and coping mechanisms which negatively impact soldier health and operational readiness can help providers achieve greater clinical success by targeting the barriers to sleep. Additional QI cycles will educate patients about BP and educate providers on using the responses for personalized interventions.

CHANGES IN ACTIGRAPHY-DERIVED SLEEP DURATION AND TIMING ARE ASSOCIATED WITH IMPROVED PTSD SYMPTOM SEVERITY DURING TREATMENT

Alannah Miranda[1], Breanna Holloway[2], Kira Clare[3], Laura Straus[4], Peter Colvonen[1]

[1] University of California, San Diego, [2] UC San Diego, [3] VA San Diego, [4] Palo Alto VA Medical Center

Introduction: Insomnia is highly co-occurring with posttraumatic stress disorder (PTSD) and is a major contributing factor to PTSD symptom severity. Research suggests insomnia also negatively impacts emotional processes, thus could reduce the efficacy of PTSD treatment. Sleep duration, timing and regularity likely contribute to PTSD symptom severity and PTSD treatment outcomes. This study aimed to examine whether changes in sleep duration, timing and regularity predicted improvement in PTSD symptom severity in a cohort of Veterans with PTSD (N=22) undergoing only the CBT-I part of an integrated treatment of Cognitive Behavioral Therapy for Insomnia and Prolonged Exposure Therapy (i.e., 2NITE protocol). We also explored whether emotional regulation mediated the relationship between sleep and PTSD.

Methods: PTSD symptom severity (PTSD Checklist; PCL-5) was assessed at baseline and during week 5, at the end of CBT-I, but before PE started. Participant sleep was monitored via actigraphy for one week at baseline and during week 5. Mean total sleep time (TST), mean sleep midpoint (mSM) and standard deviation of sleep midpoint (sdSM) were calculated at each time point. Emotional regulation (Difficulties in Emotion Regulation Scale; DERS) was assessed at baseline. A linear regression was performed using treatment condition and change in sleep variables (Week 5-Baseline) as the predictors and change in PCL-5 scores (dPCL) as the outcome variable.

Results: The overall model significantly predicted dPCL ($F(4,17)=4.27$, $p< 0.05$, $R2=0.38$). However, only TST (□ = 0.11, 95% CI = -0.05, 0.18, p =.001) and sdSM (□ = -0.12, 95% CI = -0.21, -0.02, p =.02) significantly contributed to the prediction model. Mediated regression analyses were performed using baseline DERS score as the mediating variable. Baseline DERS score did not significantly mediate the relationship between dPCL and change in sleep variables.

Conclusion: These results indicate that increases in sleep duration and regularity were associated with improvements in PTSD symptom severity. Baseline DERS scores were not observed to mediate the relationship between sleep and PTSD symptoms. Future analyses may explore the relationship specific domains of emotion regulation and other dimensions of sleep health.

RELATIONSHIP BETWEEN SELF-REPORTED SLEEP DISTURBANCES AND COGNITION IN OLDER CHINESE AMERICANS: A PILOT MEDIATION ANALYSIS

Li Zhou[1], Ankit Parekh[2], Jessica Spat-lemus[1], Tianxu Xia[1], Amy Aloysi[1], Judith Neugroschl[1], Yiyu Cao[1], Linghsi Liu[1], Hiuyu Au[1], Shreya Upendra[1], Mahmood Mohamed[1], Lorene Leung[1], Joanne Lim[1], Clara Li[1]

[1] Icahn School of Medicine at Mount Sinai, [2] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai

Introduction: Sleep disturbance/disorders are common among immigrants in the United States, yet few studies focus on older Chinese Americans and their link to Alzheimer's Disease and Alzheimer's Disease Related Dementias (AD/ADRD). While physical and mental health are known to affect cognition, it is unclear whether they mediate the relationship between sleep disturbances and cognition. This study aimed to: 1) investigate the association between self-reported sleep disturbances and both objective and subjective cognitive functions in older Chinese Americans; and 2) explore whether this relationship is mediated by immigration experiences or physical and mental health.

Methods: Data were extracted from a pilot study at the Mount Sinai's ADRC, which focused on community-based recruitment of older Chinese Americans. Ninety-five participants aged 72.1 years on average (± 6.7), with either normal cognition or mild cognitive impairment, completed the Pittsburgh Sleep Quality Index (PSQI). The cognitive test battery and cognitive function instrument (CFI) were used to evaluate objective and subjective cognitive functions, respectively. Information about immigration experiences, such as acculturation, age at immigration, were collected through questionnaires. Participants' physical (cardiovascular and cerebrovascular diseases) and mental health (depressive and anxiety disorders/symptoms) were assessed using the National Alzheimer's Coordinating Center Uniform Data Set version 3.0. Mediation analysis was conducted to investigate how immigration experiences and physical/mental health might mediate the relationship between sleep disturbances and cognition.

Results: The mean global PSQI score was 11.7±3.0, indicating poor sleep quality among older Chinese Americans. Higher global PSQI scores were associated with more subjective cognitive impairment (CFI scores: $\beta = 0.35$, $p = 0.01$) and poorer performance on the digit symbol substitution test ($\beta = -1.1$, $p = 0.011$). Mediation analysis showed that depressive symptoms, but not immigration experiences and physical health, mediated the relationship between self-reported sleep disturbances (global PSQI score) and subjective cognitive impairment (CFI score) ($p = 0.006$).

Conclusion: The findings from this pilot study highlight the need for further research to understand the contributory role of sleep disturbances and mental health in AD/ADRD risk in this historically underrepresented population to develop targeted preventions and improve health disparities.

SLEEP TRAJECTORIES ACROSS THREE COGNITIVE-AGING PATHWAYS IN COMMUNITY DWELLING OLDER ADULTS

Afsara Zaheed[1], Amanda Tapia[2], Nina Oryshkewych[1], Bradley Wheeler[1], Meryl Butters[1], Daniel Buysse[3], Yue Leng[4], Lisa Barnes[5], Andrew Lim[6], Lan Yu[1], Adriane Soehner[1], Meredith Wallace[1]

[1] University of Pittsburgh, [2] Mayo Clinic, [3] University of Pittsburgh School of Medicine, [4] Department of Psychiatry and Behavioral Sciences, University of California, San Francisco, [5] Rush University Medical Center, [6] University of Toronto

Introduction: Comparing sleep and rest-activity rhythms (RARs) across the spectrum of cognitive aging can reveal novel risk factors and potential mechanisms underlying dementia disorders. However, our current understanding is restricted by differences in sleep measurement, limited longitudinal data, and heterogeneous cognitive aging processes. We aimed to determine (1) which sleep/RAR features exhibit meaningful changes within three distinct cognitive pathways; and (2) which sleep/RAR features differ between cognitive aging pathways prior to and after the onset of mild cognitive impairment (MCI) and/or dementia.

Methods: Longitudinal self-reported sleep and actigraphy data were obtained from 1,449 participants in the Rush Memory and Aging Project (mean age= 81.2±7.1 years, 75.2% female, 5.2% Black, 94.8% White). We applied flexible cubic spline models to quantify differences in the levels and trajectories of sleep amount (self-reported duration; actigraphy rest interval length and alpha), regularity (actigraphy interdaily stability, intradaily variability, and midpoint standard deviation), and timing (self-reported midpoint; actigraphy midpoint and acrophase) within and between three cognitive aging pathways over 12 years: Normal Cognitive Aging ('Normal'), Progression to MCI ('Stable MCI'), and Progression to Dementia ('Dementia'). Models were adjusted for key sociodemographic and health variables.

Results: Sleep amount was lowest in the Dementia pathway prior to MCI or dementia, but increased with age, most rapidly following dementia. The greatest effect was observed in self-reported duration (standardized mean change, d[95%CI]=0.912 [0.47, 1.36]. Regularity declined across all pathways, most rapidly after cognitive diagnoses, with the largest increases in intradaily variability occurring among the Stable MCI (d=0.97 [0.70, 1.23]) and Dementia paths (d=1.11 [0.84, 1.38). Shifts toward earlier sleep timing were observed in actigraphy measures across all three pathways ($-0.54 \leq d \leq -0.31$).

Conclusion: Shorter sleep amount in cognitively healthy older adults may be a risk factor or prodromal indicator of dementia, while longer sleep amounts and decreasing regularity following dementia may reflect neurodegeneration. Advances in sleep timing may be less useful as a clinical indicator of future cognitive impairment or decline. Differences between self-reported and actigraphy-measured sleep/RAR outcomes may reflect distinct underlying mechanisms, warranting further research.

SLEEP DIFFERENCES ACROSS SUSPECTED TAUOPATHIES AND COGNITIVELY UNIMPAIRED OLDER ADULTS

Leslie Yack[1], Natalie Pandher[1], Harli Grant[1], Hilary Heuer[1], Esther Li[1], Rowan Salonar[1], Kaitlin Cassaletto[1], Howard Rosen[1], Marilu Gorno-Tempini[1], Gil Rabinovici[1], Adam Boxer[1], Joel Kramer[1], Lea Grinberg[1], Thomas Neylan[1], Christine Walsh[1]

[1] University of California, San Francisco

Introduction: Sleep disturbances are common in neurodegenerative diseases, yet their presentation across tauopathies remains unclear. Our previous work identified differing sleep/wake patterns in two tauopathies: progressive supranuclear palsy (PSP) and mild cognitive impairment (MCI)/Alzheimer's disease (AD) compared to cognitively unimpaired older adults (CU) using single-overnight EEG recordings. Our goal is to extend this research by studying 1) multiple nights in PSP, AD, and CU, and 2) two additional tauopathies: traumatic encephalopathy syndrome (TES) due to probable chronic traumatic encephalopathy (CTE), and corticobasal syndrome (CBS) due to probable corticobasal degeneration. We hypothesize that altered sleep characteristics will vary across tauopathies and CU.
Methods: Participants with PSP (n=20), AD (n=20), CBS (n=15), TES (n=20), and CU (n=22) wore a self-applied frontal-EEG device (Sleep Profiler, Advanced Brain Monitoring, Inc.) for 3 nights. Measures of interest included total sleep time (TST), sleep stages (N1, N2, N3, REM), wake after sleep onset (WASO), and EEG spectral power frequency bands (delta, theta, alpha, sigma, beta) during sleep. Data were analyzed using ANCOVA to control for age and sex.
Results: Building on our prior research, we found that PSP had less TST and less time in REM across multiple nights compared to CU, more N2 compared to MCI/AD and CU, and higher WASO compared to AD, CBS, TES and CU. Individuals with TES had more N1, lower alpha power, higher sigma power, and lower beta power compared to CU. CBS showed no significant differences, apart from having less WASO than PSP. No group differences were observed in N3.
Conclusion: Overall, we found different sleep/wake patterns and microstructure from spectral analysis across tauopathies and CU. PSP and TES (particularly in spectral power) show notable sleep alterations, while nighttime sleep is less affected in CBS and MCI/AD. Further research is needed to explore daytime sleep/wake differences and extend these findings in larger cohorts. Unique sleep characteristics may serve as potential biomarkers for identifying individuals at risk across tauopathies and help guide potential therapeutic interventions.

SLEEP IN SLOW AND FAST GENETIC CARRIERS OF PRION DISEASES

Christine Walsh[1], Leslie Yack[2], Natalie Pandher[1], Esther Li[1], Theresa Driscoll[2], Supratik Nandi[2], Thomas Neylan[1], Michael Geschwind[2]

[1] University of California, San Francisco, [2] UCSF

Introduction: Genetic prion diseases (gPrD) are caused by more than 40 mutations in the prion protein gene (PRNP). Each mutation can generally be subdivided into two types, Fast vs. Slow gPrD, based on their average progression rate or disease duration. Fast mutation carriers (FAST) typically progress very rapidly (less than 2 years). Slow mutation carriers (SLOW) have a longer disease duration (usually greater than 3 years). Although sleep has been well characterized in the D178N-129M mutation causing fatal familial insomnia, it is unclear how sleep is affected in SLOW and other FAST.
Methods: We assessed sleep using a frontal EEG Sleep Profiler□ device in SLOW (n=4, all female, mean 47 years), FAST (n=8, 4 female, mean 47 years) and non-carrier gPrD controls (NC, n=7, 6 female, mean 50 years).
Results: In comparison to NC, SLOW spend significantly less time in REM sleep (REM, $p < 0.05$), whereas FAST had shorter latencies to REM ($p < 0.05$) though similar latencies to nonREM stage 3 sleep (N3). FAST had longer sleep duration ($p < 0.05$) and shorter REM latencies ($p < 0.05$) than SLOW with no difference in latency to N3. Overall, SLOW and FAST spent similar amounts of time in nonREM stage 1 sleep, nonREM stage 2 sleep and N3. SLOW, however, spent less time in REM than FAST ($p < 0.05$). To ensure the differences between FAST and SLOW were not driven by sex, we analyzed only females (4 FAST, 4 SLOW, 6 NC). Overall, the results were similar. In comparison to NC females, SLOW females spent less time in REM ($p < 0.05$), whereas FAST females tended to have shorter latencies to REM ($p=0.07$). SLOW females slept shorter amounts than FAST females ($p < 0.05$) and tended to take longer to enter REM ($p=0.06$).
Conclusion: Overall, our findings suggest that sleep/wake patterns differ between gPrD groups and with NCs. Larger cohorts are being studied to confirm these findings. Further research is needed to understand how these patterns change with disease progression.

SLEEP DEFICIENCIES AND THE SPEED OF COGNITIVE DECLINE IN INDIVIDUALS WITH MILD COGNITIVE IMPAIRMENT

Lichuan Ye[1], Jack Johnson[1], Ning Zhang[1]

[1] Northeastern University

Introduction: Mild cognitive impairment (MCI) is a critical stage in the Alzheimer's Disease and Related Dementias (ADRD) continuum. The speed of cognitive decline from MCI to dementia is highly variable. Little is known, however, whether sleep deficiencies (e.g., short sleep duration, disturbed sleep) accelerate this decline process. This study aimed to examine whether individuals who experienced sleep deficiencies prior to the onset of MCI were at an increased risk of faster cognitive decline.
Methods: This retrospective cohort study utilizes survey data from the Health and Retirement Study of Americans aged 50 and older, a national representative, biennial survey from 2006 to 2020. Cognition was assessed using the validated Telephone Interview for Cognitive Status (TICS) and categorized as normal cognition (TICS ≥ 12), MCI (6 < TICS < 12), and ADRD (TICS ≤ 6). Onset of MCI was defined as the transition from normal cognition in the preceding wave to MCI in the index wave. The

speed of progression from MCI to ADRD was measured as the number of waves or years between the onset of MCI and the observation of ADRD. Sleep deficiencies was defined as experiencing sleep disturbance or reporting a sleep duration ≤3 hours frequently. Other variables include age, gender, race/ethnicity, and Carlson comorbidity index. Linear regression and survival analysis were employed.
Results: A total of 8,378 adults with MCI were included in the study, with approximately 40% experiencing sleep deficiency prior to the onset of MCI. There were 2,523 (31%) of these individuals progressing to ADRD during the study period. About 63% of those who progressed to ADRD experienced sleep deficiencies before onset of MCI, compared to 39% of those who did not progress. Moreover, the average number of years of ADRD progression was shorter for those with sleep deficiencies than those without sleep deficiency (4 years vs. 8 years).
Conclusion: Our preliminary analyses shed light on the important role sleep plays in the speed of cognitive decline. Ongoing confirmative analyses will confirm the results taking account of other relevant demographic and clinical factors, including obstructive sleep apnea and its treatment.

LOWER FREQUENCY OF HEADPULSE SLEEP BURSTS IN SUBJECTS WITH MILD COGNITIVE IMPAIRMENT

Christine Walsh[1], Thomas Neylan[1], Leslie Yack[2], Steven Woodward[3], Esther Li[1], Lea Grinberg[1], Dominica Randazzo[2], Eliot Lee[2], Paul Lovoi[2], Wade Smith[2]

[1] University of California, San Francisco, [2] UCSF, [3] National Center for PTSD- Dissemination & Training Division

Introduction: We discovered a novel signal termed "Headpulse Sleep Bursts" (HPSB) whereby the "headpulse" (HP, a phenomenon measurable in humans using highly sensitive accelerometers in contact with the head) transiently and periodically increases in amplitude for a few seconds during sleep attempts, independent of sleep stage. HPSB have been observed in all subjects tested we have measured. Human neurodegenerative disorders are hypothesized to be caused by lack of brain protein clearance during sleep. We report here on the frequency of sleep bursts in a cohort of subjects with Mild Cognitive Impairment (MCI) to see if HPSB are less frequent compared to controls.
Methods: 4 MCI individuals (1 female; median age 56 years (IQR 51-62)) did concomitant HP and SP recordings. HP was recorded using a UCSF-designed headband with force transducers on the right temporal scalp (analyzed through MATLAB). Sleep Profiler (Advanced Brain Monitoring Inc) was used to assess sleep in 30s epochs. The SP/HP data were aligned and analyzed in register.
Results: Five nights of concomitant recordings of at least 4hrs of sleep were recorded for a total of 39.2 hours. Like controls (n=22) all MCI patients (n=4) exhibited HPSB; however, the frequency and pattern during various sleep stages in MCI patients differed compared to controls. Compared to controls, HPSB in MCI were 26.5% ($P = 0.036$) less frequent compared to the awake state prior to sleep onset, and this difference was dominated by a 45.8% ($p = 0.044$) reduction in stage N2 sleep and 41.4% ($P = 0.063$) in stages N1-N3.
Conclusion: This is the first report of HPSB phenomenon in humans with a form of neurodegenerative disease. HPBS were observed in MCI patients and controls. However, MCI patients had fewer HPSB, and when they occurred were particularly suppressed in non-REM sleep. If HPSB are produced by an active glymphatic drainage system, the observation that fewer HPSB are found in MCI patients supports the hypothesis that neurodegeneration is associated with lesser glymphatic activity. We are continuing to record from a larger cohort of subjects with neurodegenerative diseases.

COGNITIVE IMPAIRMENT AND SLEEP DISTURBANCES IN WORLD TRADE CENTER (WTC) RESCUE AND RECOVERY WORKERS AND VOLUNTEERS

Katarina Martillo[1], Sri Saranya Ravi[1], Horacio Romero Castillo[1], Adriana De Resende[2], Alicia Legard[3], Felix Romero Castillo[1], Iris Udasin[4], Shou-en Lu[3], Ricardo Osorio[5], David Rapoport[1], Rafael de la Hoz[1], Jag Sunderram[3], Andrew Varga[6], Indu Ayappa[7], Anna Mullins[1]

[1] Icahn School of Medicine at Mount Sinai, [2] Rutgers - Environmental and Occupational Health Sciences Institute, [3] Rutgers Robert Wood Johnson Medical School, [4] Rutgers School of Public Health and 4Environmental & Occupational Health Sciences Institute, Piscataway, NJ, United States, [5] Department of Psychiatry, New York University Grossman School of Medicine, [6] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [7] Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai

Introduction: World Trade Center rescue and recovery workers and volunteers (WTCRRWV) have elevated levels of poor sleep quality, insomnia symptoms and Obstructive Sleep Apnea (OSA). Increasing evidence of early onset of cognitive deficits in some of these workers highlights the importance of early identification of cognitive impairment. We aim to describe cognitive impairment in this heterogeneous population with a broad range of education levels using multiple assessment methods and investigate potential relationships between cognition and sleep disturbance.
Methods: 206 WTCRRWV completed sleep and mood questionnaires (Insomnia Severity Index, Epworth Sleepiness Scale, Functional Outcomes of Sleep Questionnaire), at-home or in-lab polysomnography and Montreal Cognitive Assessment (MoCA). Identification of cognitive impairment with sex, age, and education adjusted (SAE) MoCA norms (< 9th percentile) were compared to raw scores with 1 point added for ≤12 years education (raw score < 26 indicates impairment). Subset of 73 underwent UDS-3 Neuropsychological Battery (12% Spanish). UDS-3 norms were applied to 4 cognitive domains (memory, executive & visuospatial, attention and language) to investigate potential domain specific impairments. MoCA raw, SAE adjusted, and UDS-3 domain percentiles were investigated according to OSA, sleep macrostructure and symptoms of insomnia, sleepiness, and functional sleep outcomes.
Results: 50% of WTCRRWV (n=206, age=59±8 [37-77 years], 80% male, 67% white, 9% black, 29% Hispanic/Latino) demonstrated impairment using raw MoCA scores versus 12% with SAE norms. UDS-3 norms (n=73) indicated that 42% exhibited

low average performance (< 25th percentile) on memory and 16% on language domain [3% with mild impairment (< 9th percentile)]. 50% report symptoms of insomnia and 42% have OSA. No apparent association found between insomnia, sleepiness, OSA severity, sleep macrostructure and raw, adjusted MoCA or UDS-3 domain scores.
Conclusion: MoCA raw cut-off scores suggest widespread cognitive impairments in WTCRRWV compared to SAE norms and likely overestimate impairments. No associations were found between sleep and cognition as assessed here. Future work will examine this complex relationship using sleep-dependent emotional and spatial memory paradigms. AI models that combine symptomatology with physiology and include risk factors such as environmental exposure and social vulnerability may more accurately confer cognitive impairment in this cohort.

LONGITUDINAL EFFECT OF SLOW WAVE SLEEP ON PLASMA ALZHEIMER'S DISEASE BIOMARKERS IN COGNITIVELY NORMAL OLDER ADULTS

Jeongyeon Hwang[1], Luisa F. Figueredo[2], Daphne Valencia[3], Esther Blessing[2], Omonigho Michael Bubu[2], Ankit Parekh[4], Korey Kam[4], Ricardo Osorio[2], Andrew Varga[4]

[1] Department of Neurology, Icahn School of Medicine at Mount Sinai, [2] Department of Psychiatry, New York University Grossman School of Medicine, [3] Icahn School of Medicine at Mount Sinai, [4] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai

Introduction: There has been emerging evidence on the bidirectional relationship between sleep and Alzheimer's disease (AD) pathology. However, there has been sparse data using plasma AD biomarkers despite its advantages of high accessibility and safety when sampling. This study aims to examine the longitudinal effect of slow wave sleep (SWS) on plasma beta-amyloid (Aβ) 42/40 ratio and phosphorylated-tau 217 (p-tau 217) in cognitively normal older adults.
Methods: Sixty-three community-dwelling cognitively normal adults aged between 55 and 90, with Mini-Mental State Exam scores of 25 or more, were recruited at the New York University Brain Aging & Sleep Center. All participants completed a baseline polysomnogram and had repeated plasma collections at least 2 years apart. Plasma Aβ 42 and 40 were measured via mass spectrometry (Araclon Biotech, Spain). Plasma p-tau 217 was measured in a subset of 22 subjects by the single-molecule array technology (Quanterix Corp., USA). Spearman's correlation analysis was performed. Multiple regression analyses were done with the dependent variable as log-transformed changes in plasma biomarkers divided by year interval (log [Δ Aβ42/40pre-post] or [Δ p-tau 217post-pre] / year interval), after adjusting for age, sex, and apolipoprotein ε4 (APOE4) status.
Results: Subjects were 66.3 ± 7.3 years old, 71.4 % female, and 41.5 % APOE4 positive. SWS duration was 73.6 ± 45.6 minutes (20.6 ± 13.1% of total sleep time). The mean follow-up interval was 3.3 ± 2.0 years. SWS duration and %SWS were associated with annualized log Δ Aβ42/40 ($t = -2.917$, $p = 0.005$; $t = -3.026$, $p = 0.004$). In 22 subjects who had repeated plasma p-tau 217, SWS duration and %SWS were correlated with annualized log Δ p-tau 217 ($\rho = -0.441$, $p = 0.040$; $\rho = -0.457$, $p = 0.032$), but not associated after adjusting for covariates ($t = -1.323$, $p = 0.210$; $t = -1.901$, $p = 0.082$).
Conclusion: In cognitively normal older adults, short SWS duration and low SWS percentage may predict faster annualized plasma Aβ42/40 ratio decline and p-tau 217 increase longitudinally, reflective of increased cortical amyloid plaque and tau tangle load respectively, in the preclinical stage of Alzheimer's disease.

ATTENUATED MELANOPSIN-MEDIATED POST-ILLUMINATION PUPILLARY RESPONSE ACROSS THE ALPHA-SYNUCLEINOPATHY SPECTRUM

Joey Chan[1], Bei Huang[2], Anne Chan[3], Karen Ma[3], Ngan-yin Chan[1], Man-ho Li[2], Joshua Tsoh[3], Shirley Li[4], Kelvin Chong[2], Kathryn Roecklein[5], Yun-Kwok Wing[1]

[1] Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, [2] The Chinese University of Hong Kong, [3] Prince of Wales Hospital, [4] Sleep Research Clinic and Laboratory, Department of Psychology, The University of Hong Kong, Hong Kong SAR, [5] University of Pittsburgh

Introduction: Circadian disruptions are common in patients with Parkinson's disease (PD). Degeneration and dysfunction in the melanopsin-containing intrinsically photosensitive retinal ganglion cells (ipRGCs) have been postulated as a potential mechanism. This study aims to investigate ipRGC function by chromatic pupillometry in healthy controls, patients with RBD (a prodromal stage of PD), and PD.
Methods: Patients with video-polysomnography confirmed RBD, PD, and age-matched healthy controls (HC) were recruited. Chromatic pupillometry was conducted using one-second of blue light (432nm) and one-second of red light (622nm) with continuous pupil tracking. The post-illumination pupillary response is defined as the pupil size at 6-second post-stimulus (PIPR6s) and the average pupil size for 30-second beginning 10-second after light stimulus (PIPR30s), both normalized to baseline pupil size. Net PIPR is calculated by subtracting the response to red from the response to blue. Group differences were compared by one-way ANOVA followed by post-hoc Tukey HSD tests. The effect of "group" on PIPR was further examined by ANCOVA adjusting for age, gender and visual acuity.
Results: A total of 135 participants (mean age ± SD=64.1 ± 5.8 years, Male =56%) were recruited with 45 in each of the HC, RBD and PD group, respectively. There was no significant difference in age and visual acuity. The PIPR6s to blue light was 22.5 ± 11.0%, 28.4 ± 11.6%, and 34.0 ± 10.6%, respectively, and was the most attenuated in PD, followed by RBD and HC ($p < 0.001$). Similar results were found with the Net PIPR6s (12.9 ± 9.5% vs 18.5 ± 10.8% vs 23.8 ± 9.4%, $p < 0.001$, post-hoc: PD< RBD< HC) and Net PIPR30s (3.3 ± 7.8% vs 4.7 ± 7.7% vs 7.5 ± 6.2%, P=0.026, post-hoc: PD< HC). The group effect on Net PIPR6s ($p < 0.001$) and Net PIPR30s (p=0.042) remained significant after adjusting for age, gender and visual acuity.
Conclusion: Our study demonstrated a progressive attenuation of PIPR across the spectrum of alpha-synucleinopathy,

suggesting ipRGC dysfunction occurs early and PIPR may represent a clinical advance for screening of prodromal PD.

LONGITUDINAL CHANGES IN RESTING-STATE EEG IN ISOLATED REM SLEEP BEHAVIOR DISORDER

Jung Kyung Hong[1], In-Young Yoon[1], Minji Lee[2]
[1] Seoul National University Bundang Hospital, [2] Soonchunhyang University Seoul Hospital

Introduction: Patients with isolated REM sleep behavior disorder (iRBD), a prodromal alpha-synucleinopathy, has been reported to show electroencephalographic (EEG) slowing compared to healthy controls. However, longitudinal studies examining brain activity changes in iRBD are scarce. This study aimed to identify longitudinal changes in brain activity using resting-state quantitative EEG (qEEG) and their clinical significance in iRBD.
Methods: Patients diagnosed with iRBD between 2014 and 2015 who underwent waking 64-channel EEG at both baseline and 5-year follow-up were included. Patients with mild cognitive impairment (MCI) at baseline were excluded, and included patients were divided into two groups, based on cognitive status at 5 years (non-MCI and 5yr-MCI groups). EEG spectral analysis was conducted using fast Fourier transform, with relative power values calculated for five frequency bands (delta, theta, alpha, beta, and high-beta) across five cerebral regions (frontal, temporal, central, parietal, and occipital). Longitudinal qEEG analyses were performed using generalized estimating equations (GEE), adjusting for clonazepam use.
Results: Fifty-one iRBD patients without baseline MCI (72.5% male, mean age 65.9 ± 5.7 years) were analyzed. After five years, six patients (11.8%) developed MCI. At baseline, the non-MCI group had significantly higher high-beta power than the 5yr-MCI group (frontal, temporal and parietal: $p = 0.002$; central: $p = 0.025$; occipital: $p = 0.006$). Longitudinally, the 5yr-MCI group showed significant increases in theta (frontal, central, and occipital: $p < 0.001$; temporal: $p = 0.015$; parietal: $p = 0.005$), delta (parietal: $p = 0.021$; occipital: $p < 0.001$), and beta (temporal and central: $p < 0.001$) power and decreases in alpha power (all regions: $p < 0.001$) at follow-up compared to baseline. In contrast, the non-MCI group exhibited minimal changes in brain activity over time.
Conclusion: EEG slowing occurs in iRBD patients as cognitive decline develops. Reduced fast activity, such as high-beta power, may serve as a biomarker for predicting future cognitive impairment in iRBD.

FREQUENCY AND LONGITUDINAL COURSE OF AUTONOMIC REFLEX TESTING ABNORMALITIES IN ISOLATED REM SLEEP BEHAVIOR DISORDER

Hash Brown Taha[1], Jennifer Zitser[2], Mitchell Miglis[3]
[1] University of Southern California, [2] Tel Aviv Sourasky Medical Center, Affiliate of Sackler Faculty of Medicine, Tel-Aviv University, [3] Stanford University

Introduction: Autonomic dysfunction is common across the α-synucleinopathies including isolated RBD (iRBD), however the presence, severity and distribution of autonomic dysfunction as a risk factor for phenoconversion in iRBD remains unclear. We aimed to characterize autonomic reflex testing (ART) abnormalities in a cohort of participants with iRBD and assess their potential as biomarkers for predicting phenoconversion risk.
Methods: We performed ART on 45 individuals with iRBD and evaluated the ability of individual ART components (sympathetic cholinergic, cardiovagal, sympathetic adrenergic) to predict phenoconversion using univariate and multivariate predictive models, both alone and combined with measures of olfaction, cognition, motor function, and skin biopsy assessment of dermal α-synuclein.
Results: Forty-one individuals with iRBD were enrolled (age 66.7 ± 7.4 yrs, 27% female), and followed annually for an average of 2.9 ± 2.4 yrs, with four participants lost to follow-up. Eight participants with iRBD phenoconverted during their follow-up period (3 Parkinson's disease, 4 dementia with Lewy bodies and 1 multiple system atrophy), yielding a phenoconversion rate of 6.6% per year. Eighty seven percent of iRBD participants had an abnormal baseline ART, and 100% had an abnormal follow-up ART. A combination of MDS-UPDRS III score and cardiovagal dysfunction (abnormal heart rate variability with deep breathing) best predicted phenoconversion (AUC = 0.77, 95% CI: 0.59–0.94).
Conclusion: ANS dysfunction was common and spanned all domains of autonomic function. Baseline cardiovagal dysfunction was most affected and predictive of phenoconversion, especially if combined with motor examination. Longitudinal studies with larger sample sizes are needed to confirm these findings.

THE SYN-SLEEP STUDY: DETECTION OF CUTANEOUS PHOSPHORYLATED ALPHA-SYNUCLEIN IN REM SLEEP BEHAVIOR DISORDER

Todd Levine[1], Bailey Bellaire[1], Christopher Gibbons[1], Roy Freeman[2]
[1] CND Life Sciences, [2] Beth Israel Deaconess Medical Center

Introduction: REM sleep behavior disorder (RBD) is a prodromal neurodegenerative disease characterized by the deposition of phosphorylated alpha-synuclein (P-SYN) within the central and peripheral nervous system. RBD has a high risk of phenoconversion to a clinically apparent synucleinopathy (including Parkinson's disease (PD), multiple system atrophy (MSA) or dementia with Lewy bodies (DLB)) with >90% of patients converting over 15 years. The goals of this longitudinal, prospective study are 1) to determine rates of P-SYN deposition in RBD and quantify changes in PSYN deposition over time and 2) to determine if the pattern of P-SYN deposition is a predictor of phenoconversion to a central synucleinopathy.
Methods: After informed consent, detailed neurologic examinations, cognitive evaluation, orthostatic vital signs and questionnaires were completed. Medical history, ancillary testing and polysomnograms were reviewed. Skin biopsies at the distal leg, distal thigh and posterior cervical sites were performed. Dual immunohistochemical immunostaining of the skin biopsies for nerve fibers (protein gene product 9.5) and P-SYN was

completed using standard methodology. Quantitative measures of P-SYN and nerve fiber density were measured blinded to any clinical data.
Results: To date, 76 subjects (30% female) have been enrolled from 10 study sites across the United States with an anticipated total enrollment of 80 subjects. The mean age of the enrolled subjects is 67.8±8.9 years. Of the 76 enrolled subjects, 57/76 are P-SYN positive (75%). P-SYN positive subjects tended to be older (68.7±7.6 (P-SYN+) vs. 63.8±11.9 (P-SYN-). There were no differences in P-SYN positivity in patients who demonstrated REM sleep without atonia on polysomnogram (PSG) and those whose diagnosis was confirmed using the REM sleep behavior disorder questionnaire (RBDSQ) (30/41 with PSG [73%] vs 27/35 using the RBDSQ [77%]).
Conclusion: Skin biopsies are a simple, low-risk outpatient procedure to test for P-SYN as a diagnostic biomarker for prodromal synucleinopathies. At initial study visit, 75% of RBD cases contain P-SYN with equal rates of P-SYN positivity in those with and without polysomnography confirmed RBD. Longitudinal reassessment of these subjects is in progress to determine if quantification of P-SYN can serve as a biomarker of disease progression and phenoconversion.

OBSERVATIONAL STUDY OF HEADPULSE SLEEP BURSTS IN A LARGER COHORT OF NORMAL SUBJECTS

Christine Walsh[1], Thomas Neylan[1], Leslie Yack[2], Natalie Pandher[1], Steven Woodward[3], Esther Li[1], Lea Grinberg[1], Dominica Randazzo[2], Eliot Lee[2], Paul Lovoi[2], Wade Smith[2]
[1] University of California, San Francisco, [2] UCSF, [3] National Center for PTSD- Dissemination & Training Division

Introduction: The "headpulse" (HP) is: a novel biological phenomenon; generated by cardiac contractile forces impacting the human head and dissipated by the brain; measurable using accelerometers with a time-domain varying signal; does not occur in sitting adults. Our goal was to characterize night-time HP patterns and to determine prevalence and occurrence during sleep (SP) stages.
Methods: Cognitively healthy subjects (N=22, 10 female) underwent 50 HP device recordings during sleep, with 25 simultaneous HP and SP recordings. HP was recorded using a UCSF-designed headband with force transducers on the right temporal scalp (analyzed through MATLAB). Sleep Profiler (Advanced Brain Monitoring Inc) was used to assess sleep in 30 sec epochs. The SP/HP data were aligned and analyzed in register.
Results: A total of 252 hours of combined HP and SP recordings were obtained from subjects (median age 45 years (IQR 25-68)). Transient increases in HP forces began just prior to sleep onset, with increased magnitudes over the sleep period now termed HeadPulse Sleep Bursts (HPSB). HPSB were present in all 22 subjects. The number of HPSB in subjects with at least 4hrs of sleep had a median range of 142 [92-220], a median frequency of 0.42 HPSB/min (IQR 0.31-0.62), or 0.007 Hz. Two subjects had remarkably periodic HPSB, occurring every 50 seconds or every 2 minutes. HPSB occurred at a differential rate of: 1 (laying down, wake prior to sleep onset): 1.30 (N1): 0.80 (N2): 0.92 (N3): 0.82 (N1-N3): 0.87 (REM); none of these differences were significant (t-test).
Conclusion: This is the second, but larger report of HPSB occurring in all cognitively healthy humans, independent of sleep stage. HPSB began during wake while attempting sleep n all subjects and are not present in awake, upright subjects not preparing for sleep. The relative low frequency of these bursts, 0.31 – 0.62/min range (0.005 – 0.01 HZ) has no parallel in human sleep but matches the MRI-assessed rate of CSF transient reversal flow in the cerebral aqueduct in sleeping humans. Thus HPSB could be a novel biomarker.

FEASIBILITY OF 48-H AMBULATORY BP ASSESSMENT IN LATINOS WITH DEMENTIA

Mili Jimenez Gallardo[1], Andrea Castillo Suárez[1], Peng Li[2], Ramon C. Hermida[3], Michael Smolensky[4], Claudia Duran-Aniotz[5], Andrea Slachevsky[6], Maria Behrens[7], David Aguillon[8], Hernando Santamaria-Garcia[9], Adolfo M. García[10], Diana Matallana[11], Agustín Ibáñez[12], Kun Hu[2], Shahab Haghayegh[1]
[1] Massachusetts General Hospital/Harvard Medical School, [2] Massachusetts General Hospital/ Harvard Medical School, [3] Universidade de Vigo (atlanTTic), [4] The University of Texas at Austin (Cockrell School of Engineering), [5] Universidad Adolfo Ibañez (BrainLat), [6] Geroscience Center for Brain Health and Metabolism (GERO),, [7] Clínica Alemana-University Desarrollo, [8] Universidad de Chile (Centro de Investigación Clínica Avanzada), [9] Universidad de Antioquia (Grupo de Neurociencias de Antioquia), [10] Universidad de San Andrés (Cognitive Neuroscience Center), [11] Pontificia Universidad Javeriana (School of Medicine), [12] Global Brain Health Institute, University of California San Francisco

Introduction: Ambulatory blood pressure (BP) monitoring encapsulates 24-h BP patterns across the sleep-wake cycle and provides a comprehensive assessment of BP regulation with certain features, such as sleep-time dipping, that can better predict health outcomes than traditional office BP measurements. However, 24-h BP patterns remain understudied in Latino populations, especially older adults. This pilot study investigated the feasibility of continuously ambulatory BP monitoring blood pressure with portable devices in Latinos with dementia.
Methods: Eight participants (4 with Alzheimer's disease, 1 with Frontotemporal dementia, 3 controls; age range 45.8-80.3 years) from the ReDLat cohort (Multi-Partner Consortium to Expand Dementia Research in Latin America) were enrolled for a 48-h ambulatory BP assessment with hourly measurements using a portable arm-cuff device. Participants also answered six questions to evaluate: (1) device adaption, (2) measurement frequency tolerability, (3) study duration acceptability, (4) perceived value of the assessment, (5) willingness to perform the assessment again, and (6) likelihood of recommending the assessment to others.
Results: The study yielded high-quality recordings with minimal missing BP measurements (range: 0%-14.1%; mean: 8.9%). Device adaptation improved over time, with 75% (6/8) reporting better tolerance on the second day and 25% (2/8) reporting consistently good tolerance across both days. All participants reported that hourly BP measurement was tolerable, and majority (7/8, 87.5%) found 48-h monitoring acceptable. Seven participants (87.5%) believed that the assessment was valuable, were

willing to participate again, and likely recommend to others the assessment.
Conclusion: Our findings demonstrate that 48-hour ambulatory BP monitoring is feasible and well-tolerated among older Latino adults with mild to moderate dementia in Latin American settings. Further feasibility testing should be performed in large samples and other populations, including individuals at later stages of dementia and in different countries.

FEASIBILITY OF AMBULATORY SLEEP ASSESSMENT IN CHILDREN WITH LENNOX-GASTAUT SYNDROME

Gita Gupta[1], Louise O'Brien[2], Fauziya Hassan[3], Stephanie Rau[4], Arushi Gupta[2], Raayed Saeed[2], Renee Shellhaas[5]
[1] Johns Hopkins University, [2] University of Michigan, [3] Sleep Disorders Center, Division of Pulmonary Medicine, Department of Pediatrics, University of Michigan, [4] Division of Pediatric Neurology, Department of Pediatrics, University of Michigan, [5] Department of Neurology, Washington University in St. Louis

Introduction: Disordered sleep is reportedly common in children with Lennox-Gastaut Syndrome (LGS), a severe and often intractable epilepsy syndrome. Despite the potentially severe sequelae, the sleep of children with LGS has not been systematically studied. To inform future study design, we conducted a pilot study to determine what methods of ambulatory sleep assessment are most feasible in this population.
Methods: Families were invited to participate in a polysomnogram, a home sleep apnea test (WatchPAT), use an Apple Watch nightly, and fill out daily sleep logs, for up to 4-weeks. Polysomnograms and WatchPATs were completed within a 1-month period. The Pediatric Sleep Questionnaire was administered at the beginning and end of the study. Participants rated convenience, ease of use, perceived accuracy, how time consuming a modality was, comfort, and their most preferred method on a Likert scale ('1' = strongly disagree and '5' = strongly agree for the listed domains; '1' = most preferred and '5' = least preferred for preference rating).
Results: 15 participants (mean age of child 12.2±3.1 years; 58% female) filled out the feasibility questionnaire. Participants remained in the study for 16.9±7.0 days and wore an Apple Watch for 13.8±9.1 days. Parents found questionnaires to be the most convenient option (4.1 ± 0.9), closely followed by the Apple Watch device (not the app; 3.7±1.6); whereas the WatchPAT and polysomnograms were considered the least convenient options (2.4±2.1 and 2.4±2.0 respectively). The Apple Watch device was the most preferred modality (1.6±1.0) and the polysomnogram was the least preferred modality (4.1±1.4). The WatchPAT was preferred (3.3±1.4) compared to the polysomnogram. Two out of three participants' sleep apnea tests yielded similar results (AHI 0.1; pRDI 2.8, AHI 26.5; pRDI 25) whereas one yielded dissimilar results (AHI 7, pRDI 26.5).
Conclusion: It may be feasible to conduct a longitudinal study of sleep in children with LGS over 2 weeks. WatchPATs might be a feasible alternative to a polysomnogram in appropriate scenarios. With optimization of the sleep measurement app, the Apple Watch device could be a highly preferred option for ambulatory sleep assessment.

CHARACTERISTICS OF SLEEP DISTURBANCE IN PATIENTS WITH MOYAMOYA

Mudassar Ahmad[1], James Klaas[2], Giuseppe Lanzino[2], Stuart McCarter[2], Erik StLouis[2], Lorenzo Rinaldo[2], Diego Carvalho[2]
[1] Mayo Clinic, Rochester MN, [2] Mayo Clinic

Introduction: Moyamoya is characterized by idiopathic, progressive, large intracranial arterial steno-occlusion, affecting the anterior circulation of the brain. Common presentations include strokes, seizures, and headaches, which have been associated with poor sleep quality and sleep disorders in the general population. However, to our knowledge, sleep quality has not been previously investigated in Moyamoya disease. The aim of this study was to characterize self-reported sleep quality, sleepiness, sleep disorder diagnoses in patients with Moyamoya syndrome, and to explore possible association between sleep disturbance and quality of life in these patients.
Methods: We analyzed consecutive patients with Moyamoya evaluated at our institution who completed the Pittsburgh Sleep Quality Index (PSQI) and the Epworth Sleepiness Scale (ESS). We also abstracted the Patient-Reported Outcomes Measurement Information System (PROMIS) to measure person-centered physical, mental and social wellbeing.
Results: We studied 23 patients with mean age 41.8 ± 12.1 years old having disease duration of 3 ± 4.4 years. 15 (65.2%) had ischemic strokes. Mean total PSQI score was 6.9 ± 2.9, and 17 (73.9%) had poor sleep quality (PSQI>5). Mean sleep efficiency was reduced at 80 ± 17%. Although Median ESS was 6 (IQR 3.25 – 8), most patients (91.3%) reported at least mild daytime dysfunction (Component 7≥1). Mean PSQI component scores (0 – 3 severity, 3 is worse) were 1.29 ± 0.62 (subjective quality), 1.1 ± 0.73 (sleep latency), 1.04 ± 0.83 (sleep duration), 0.87 ± 1.01 (sleep efficiency), 1.22 ± 0.52 (sleep disturbances), 0.3 ± 0.88 (sleep medication), and 1.1 ± 0.52 (daytime dysfunction). The total PSQI score was positively correlated with PROMIS score (r=0.47, p=0.044). Only one patient was diagnosed with obstructive sleep apnea and three with chronic insomnia.
Conclusion: Poor sleep quality appears to be a frequent problem in patients with Moyamoya disease. Sleep disturbance severity was similar to previous findings in clinical stroke populations. The apparent mismatch between subjective sleep disturbance and sleep disorder diagnoses suggest that sleep disorders are likely underdiagnosed in Moyamoya patients. The relationship between PSQI and PROMIS scores suggests that sleep disturbance may significantly affect quality of life in these patients.

ASSOCIATION BETWEEN SLEEP DURATION AND PSYCHOMOTOR VIGILANCE TEST METRICS

Michael Koenig[1], Nathan Nesbitt[1], Emmanuel Mignot[2], Anne Morse[3], Ulysses Magalang[4], Brendan Keenan[5], Allan Pack[6]
[1] The Ohio State University Wexner Medical Center, [2] Stanford University, [3] Geisinger Commonwealth School of Medicine Geisinger Medical Center Janet Weis Children's Hospital,, [4] The

Ohio State University, [5] University of Pennsylvania, [6] University of Pennsylvania Perelman School of Medicine

Introduction: Previous studies suggest an association between short and long sleep duration and adverse health outcomes, including impaired cognitive function. Using sleep diary and psychomotor vigilance test (PVT) data, we evaluated the relationship between sleep duration and vigilance/alertness.
Methods: De-identified data from adults enrolled in the Stanford Technology Analytics and Genomics in Sleep (STAGES) study was obtained from the National Sleep Research Resource. Data included demographics, questionnaires, polysomnography, sleep diaries, and a 3-minute PVT. Average sleep duration per night was calculated for each patient using sleep diary entries over two weeks. The primary outcomes from the PVT were the mean reciprocal of the response time (mean RRT) and the number of 355 msec lapses. Analysis of covariance (ANCOVA) was used to compare PVT outcomes among five groups based on average sleep duration: < 6 (n=33), 6-7 (n=100), 7-8 (n=272), 8-9 (n=254), and ≥ 9 (n=106) hours. Covariates included age, sex, body mass index (BMI), apnea-hypopnea index (AHI), Patient Health Questionnaire-9 (PHQ-9), time PVT was taken, and educational level.
Results: A total of 765 patients [44% male; age 45.2±14.6 years; BMI 31.3±9.10 kg/m2; AHI 16.2±22.0 events/hour; mean±SD] were included. The mean sleep duration was 7.88±1.12 hours/night. In covariate-adjusted analyses, both mean RRT (p=0.005) and number of 355 msec lapses (p=0.001) significantly differed based on average sleep duration. Slower response speed and more lapses occurred in patients with short (< 6 hours; mean [95% CI] of 3.16 [3.05, 3.27] 1/s and 13.6 [9.50, 17.8] lapses) and long (≥ 9 hours; 3.14 [3.08, 3.21] 1/s and 14.7 [12.3, 17.1] lapses) sleep duration, compared to those sleeping 6-7 (3.30 [3.24, 3.35] 1/s and 8.89 [7.28, 10.5] lapses), 7-8 (3.24 [3.20, 3.27] 1/s and 11.1 [9.92, 12.4] lapses) or 8-9 (3.24 [3.20, 3.27] 1/s and 10.5 [9.38, 11.6] lapses) hours.
Conclusion: These data suggest that individuals who report either short (< 6 hours) or long (≥ 9 hours) sleep duration have worse alertness and vigilance based on PVT. This is consistent with the "U-shaped" relationship reported between sleep duration and other health outcomes in prior studies.

MORNING BRIGHT LIGHT THERAPY IMPROVES SLEEP AND SYSTEMIC INFLAMMATORY PROFILES IN VETERANS AND NON-VETERANS WITH OR WITHOUT TRAUMATIC BRAIN INJURY

Jessica Brewer[1], Jonathan Elliott[1], Savanah Sicard[1], Hannah Cunningham[2], Andrea Hildebrand[2], Allison Keil[1], Brittany Ligman[1], Mohini Bryant-Ekstrand[1], Jessica Gill[3], Bradley Dengler[4], Miranda Lim[2]
[1] VA Portland Health Care System, [2] Oregon Health & Science University, [3] John's Hopkins University, School of Nursing, [4] Military Traumatic Brain Injury Initiative

Introduction: Sleep-wake disturbances frequently present in Veterans with mild traumatic brain injury (mTBI). These TBI-related sleep impairments confer significant burden and commonly exacerbate other functional impairments. Therapies to improve sleep following mTBI are limited and studies in Veterans are even more scarce. In our previous pilot work, morning bright light therapy (MBLT) was found to be a feasible behavioral sleep intervention in Veterans with a history of mTBI; however, this was single-arm, open-label, and non-randomized, and therefore was not intended to establish efficacy. The present study extends this preliminary work as a fully powered, sham-controlled, participant-masked randomized controlled trial.
Methods: Veterans and non-Veterans with and without TBI were randomized in a 2:1 allocation ratio to: 1) active: MBLT (n=93), and 2) sham: deactivated negative ion generator (n=46); each with identical engagement parameters (60-min duration; within 2-hrs of waking; daily). Participant masking via deception balanced expectancy assumptions across arms. Assessments were completed following a 14-day baseline (pre-intervention), 28-days of device engagement (post-intervention), and 28-days after the post-intervention assessment (follow-up). Outcomes included self-reported sleep (validated questionnaires and a daily sleep diary), objective sleep via wrist-based actigraphy, and peripheral proteomic profiling examining 250 inflammatory and 120 neurodegenerative biomarkers via NUcleic acid Linked Immuno-Sandwich Assay (NULISA) with Next Generation Sequencing.
Results: MBLT was associated with significant improvements in self-reported sleep (insomnia severity index (14±20%), and increased actigraphy-derived total sleep time (47±65 min). This was associated with increased time in bed (59±67 min), an earlier bedtime (77±125 min) without change in wake time, and corresponding earlier mid-sleep time (37±72 min) consistent with a potential circadian phase advancement. Peripheral plasma assays demonstrate sweeping reductions in ~20 proinflammatory cytokines and several pro-thrombotic clotting factors, as well as relevant neurodegenerative markers (e.g., pTau-217). No changes were observed in the sham arm.
Conclusion: MBLT improved actigraphy-derived sleep outcomes in Veterans and non-Veterans with and without traumatic brain injury. Objective and subjective sleep, mood, pain management, and blood-based pro-inflammatory cytokines improved post-MBLT intervention. These results lead us to believe that MBLT could be used as a cost-effective and universal support therapy to those with disrupted sleep.

SLEEPOVER PROTOCOL: A FULLY REMOTE, MULTIMODAL SLEEP PHENOTYPING PACKAGE TO BENCHMARK DISEASE PROGRESSION AND RESPONSE TO THERAPY

Savanah Sicard[1], Jonathan Elliott[1], Hannah Cunningham[2], Katherine Powers[1], Cosette Olivo[1], Jessica Brewer[1], Miranda Lim[2]
[1] VA Portland Health Care System, [2] Oregon Health & Science University

Introduction: Previous work supports sleep disturbances as a benchmark of disease progression. To understand this relationship between sleep and health, efforts are emerging to observe sleep in clinical populations and to test sleep therapies. However, obtaining a detailed and long-term measure of sleep in human studies can prove challenging. Measuring sleep in a laboratory setting can provide a detailed description of sleep for short periods of time but interferes with natural sleep patterns, while

current remote approaches, such as sleep logs, can increase longitudinal feasibility but decrease the depth of data. To address this, we have developed SLEEp Phenotyping of Vitals, EEG, and Rhythms (SLEEPoVER), a protocol incorporating multiple measures to provide a detailed description of natural sleep patterns derived from months to years of remote data collection.
Methods: SLEEPoVER utilizes 5 measures concurrently in a single comprehensive package. Daily sleep diaries administered via text message and electronic questionnaires provide subjective measures of sleep, together with continuous wrist-based actigraphy, an under-the-mattress piezo-based sensor, and in-home unattended Type III polysomnography (PSG) provide objective sleep measures. Feasibility of this combined approach is presented from data collected within individuals over ~6 months.
Results: There were 94 participants. Sleep diaries had the highest overall data completeness of 93%, followed by PSG at 90%, subjective sleep questionnaires at 85%, mattress sensors at 62%, and actigraphy at 57%.
Conclusion: These findings demonstrate the feasibility of sleep diaries, questionnaires and in-home polysomnography to be used in conjunction for longitudinal and remote observation of sleep in clinical populations. Technical complications limited data completeness of actigraphy and mattress sensor devices independent from adherence to the protocol. Future work will utilize these multimodal sleep measures to generate comprehensive phenotypes for classification of disease progression and response to sleep therapies.

CAREGIVER RELATIONSHIP, BURDEN, AND SLEEP PROBLEMS: PATIENT SLEEP DISTURBANCES ON SPOUSE CAREGIVERS VS. CHILD CAREGIVERS

Danielle Paisley[1], Diviya Khullar[2], Jessie Song[1], Anna Papazyan[3], Mary-Lynn Brecht[4], Jennifer Martin[5], Brent Mausbach[6], Raeanne Moore[6], Yeonsu Song[7]
[1] UCLA, [2] University of California, Los Angeles,, [3] University of California, Los Angeles, [4] University of California Los Angeles, [5] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System, [6] University of California, San Diego, [7] School of Nursing, University of California Los Angeles

Introduction: Caregiving for people living with cognitive impairment often imposes significant physical and emotional burdens on caregivers. These challenges are compounded when care recipients experience sleep problems, which can disrupt caregivers' sleep. This study aimed to explore the relationship between sleep problems in care recipients and caregivers, as well as caregiving characteristics.
Methods: Data were collected from 177 caregivers who participated in a phone screening for an ongoing clinical trial (NCT05452031) evaluating a dyadic sleep intervention for people with dementia and their caregivers. Sleep problems in care recipients were assessed using the Neuropsychiatric Inventory (NPI) sleep subscale. Caregiver sleep quality was measured using the Pittsburgh Sleep Quality Index (PSQI). Caregiver burden was assessed based on the number of activities of daily living (ADLs) and instrumental ADLs (IADLs) requiring assistance. Caregiver type (spouse, adult child, or other) was also collected. Data were analyzed using Pearson correlations and Student's t-tests.
Results: Caregivers of care recipients who experienced early morning awakenings (PSQI: 9.9 ± 4.5vs. 7.7 ± 3.7, $p = 0.027$) and nighttime behaviors (PSQI: 10.0 ± 3.2 vs. 7.5 ± 4.4) reported significantly poorer sleep quality, indicated by higher PSQI scores. The number of sleep problems reported by care recipients was positively correlated with ADL/IADL assistance ($r = 0.33$, $p < 0.001$), suggesting that caregivers managing frequent sleep disturbances face a heavier caregiving load. Adult child caregivers reported significantly more sleep problems in their care recipients compared to spousal caregivers (3.5 ± 2.0 vs. 2.9 ± 1.7 respectively, $p = 0.040$).
Conclusion: Sleep problems in care recipients are associated with poor sleep quality in caregivers, highlighting the importance of addressing sleep issues within the caregiving dyad. The findings also reveal the differential impact of sleep disturbances on caregiver burden, particularly based on the caregiver's relationship to the care recipient. Adult child caregivers report both more sleep disturbances in their care recipients and a higher caregiving load compared to spouses. These findings emphasize the need for tailored interventions to alleviate caregiver burden, especially for adult child caregivers.

RATIONALE AND STUDY DESIGN OF SAMELISANT (SUVN-G3031) FOR THE TREATMENT OF CATAPLEXY IN TYPE 1 NARCOLEPSY PATIENTS

Ramakrishna Nirogi[1], Vinod Kumar Goyal[1], Jyothsna Ravula[1], Pradeep Jayarajan[1], Satish Jetta[1], Anil Shinde[1], Veera Raghava Chowdary Palacharla[1], Santosh Kumar Pandey[1], Abdul Rasheed Mohammed[1], Rajesh Kumar Badange[1], Renny Abraham[1], Surendra Petlu[1]
[1] Suven Life Sciences

Introduction: Samelisant (SUVN-G3031) is potent and selective histamine 3 receptor inverse agonist, which works by modulating the histamine system, a key part of the brain's sleep-wake regulation. Samelisant demonstrated wake-promoting and anticataplectic effects, in animal models relevant to narcolepsy.
Methods: Samelisant was evaluated in orexin knockout mice and orexin-B SAP lesioned rats for its effects on sleep/ wake and cataplexy using electroencephalography (EEG). Samelisant produced significant reduction in cataplectic like episodes in orexin knockout mice, similarly significant decrease in direct wake to REM sleep (DREM) episodes was observed in orexin-B SAP lesioned rats. Based on the evidence from animal studies, Samelisant is being evaluated in a Phase 2 proof-of-concept study in the USA and Canada to treat cataplexy in NT1 patients.
Results: This study is a placebo-controlled, double blind randomized, parallel-group study. The study will recruit about 129 NT1 patients with an established diagnosis of NT1 according to the ICSD-3 or DSM-5-TR. After a prescreening period of 4-weeks, eligible patients will follow a titration schedule to gradually increase their dose of the investigational product for initial three weeks followed by stable dose treatment for additional five weeks. The primary endpoint of the study will be to evaluate change from Baseline in weekly cataplexy rate on Day 56. Secondary endpoints will include change from Baseline in Clinical Global Impression Scale-Severity (CGI-S) score and Epworth Sleepiness Scale (ESS) score on Day 56.

Other exploratory endpoints will be change from Baseline in Clinical Global Impression of Change (CGI-C), Patient Global Impression of Change (PGI-C), Narcolepsy Severity Scale (NSS) score and 5-level EQ-5D version (EQ-5D-5L) on Day 56.
Conclusion: Outcomes from animal models of narcolepsy suggest that Samelisant may have anticataplectic effects. The Phase-2 study results may inform the therapeutic utility of Samelisant for the treatment cataplexy in NT1 patients.

LONGITUDINAL SLEEP PHENOTYPING OF AUTISTIC INDIVIDUALS USING A NON-CONTACT BIOMOTION SENSOR IN THE HOME ENVIRONMENT

Devon Hansen[1], Lucia Peixoto[2], Annette Estes[3]
[1] Washington State University, [2] Sleep and Performance Research Center, Washington State University, [3] University of Washington

Introduction: Sleep problems occur at a higher rate in autism spectrum disorder (ASD) than in typical development (TD). Polysomnography (PSG) is the gold-standard for collecting objective sleep data, but it is labor-intensive, intrusive, requires patients to stay overnight in an unfamiliar environment, and typically limited to one night of recording decreasing its validity and scalability to larger cohorts of ASD individuals. We tested a non-contact biomotion sensor, the SleepScore Max (SSM) to determine the acceptability of longitudinal use and feasibility of estimating sleep characteristics in ASD and TD youth in the home.
Methods: 7 ASD (M=13.0y, SD=2.2y, with community ASD diagnosis) and 6 TD (M=13.3y, SD=2.3 y) individuals completed 2 weeks of at-home sleep monitoring using the device. Participants were between age 8-15 years, living with a caregiver, sleeping alone, and >80lbs. Caregivers completed an acceptability questionnaire at the end of the study. Sleep metrics were analyzed using repeated-measures ANOVA with fixed effects of group (ASD vs TD), day, and their interaction. Pairwise comparisons of standard deviations determined differences in night-to-night variability between groups.
Results: The ASD group exhibited more deep sleep ($F=21.52$, $p<0.001$), longer sleep onset latency ($F=5.13$, $p=0.025$), and increased total wake time ($F=4.56$, $p=0.034$), whereas the TD group had more light sleep ($F=5.58$, $p=0.019$), and total interruptions ($F=12.79$, $p<0.001$). Pairwise comparisons determined that the ASD group had greater night-to-night variability in REM sleep ($t=-2.7$, $p=0.021$). Caregivers reported the device to be highly acceptable (M=6.44; SD=1), reasonable to use (M=6.31; SD=1) and causing little to no discomfort (M=1.7; SD=1.2) on a 1-7 Likert scale.
Conclusion: Our results agree with previous PSG studies showing an increase in sleep onset latency and an increase in deep sleep in autistic individuals. These results provide preliminary evidence that a non-contact biomotion sensor can accurately measure and differentiate sleep between ASD and NT individuals in a naturalistic and sensory friendly manner with high levels of acceptability and low participant burden. Non-contact sensors show great promise for long-term longitudinal characterization of sleep in the home to evaluate outcomes of sleep focused interventions.

SLEEP QUALITY IN INPATIENTS HOSPITALIZED WITH AN ACQUIRED BRAIN INJURY: A QUALITATIVE EXPLORATION

Poppy Gardiner[1], Frank Jackson[2], Gregory Carter[2], Gabriela León[1], Ellie Bruce[1], Matthew Layton[1]
[1] Elson S. Floyd College of Medicine, Washington State University, Spokane, Washington, USA, [2] Providence St. Luke's Rehabilitation Medical Center, Spokane, Washington, USA

Introduction: Sleep is essential for recovery from severe medical conditions, yet disturbed sleep is a pervasive issue during hospitalization. Over half of inpatients with an Acquired Brain Injury (ABI) (Traumatic Brain Injury (TBI) or non-TBI, e.g., stroke) experience disturbed sleep while hospitalized, with insomnia and fragmented night-time sleep frequently reported. Sleep disturbances can delay neurorehabilitation and lead to excessive daytime sleepiness, presenting a significant barrier to ABI recovery and therapy engagement. Despite this, research regarding ABI and sleep quality among inpatients remains sparse, with more efforts needed to identify effective areas for intervention. A recommended first-step in intervention development is to conduct qualitative research with the target population. In inpatient ABI, this qualitative data is lacking. To address this, the current study aimed to explore inpatient perspectives of sleep quality during hospitalization for ABI.
Methods: As part of a broader qualitative project involving hospital staff and outpatients, N=13 inpatients with ABI (66±17y; 10 males) were recruited from a large rehabilitation hospital in Washington, USA. N=7 inpatients had ischemic stroke, N=4 had TBI, and N=2 had other non-TBI. On average, participants were 20 days post-ABI and 9 days post-admission, having received primary emergency care in other facilities. Semi-structured interviews were conducted to explore the nature and prevalence of sleep/wake disturbances, factors contributing to these disturbances, and current nighttime care practices.
Results: Reflexive thematic analysis revealed five key themes: Insomnia Symptoms; Nighttime Care Provision; Pain, Mental Health, and Other Comorbidities; The Hospital Environment; and Daytime Therapy Engagement.
Conclusion: Study findings can inform the future development of sleep interventions for inpatients with ABI. Interventions could include clustering nighttime care (e.g., conducting observations and administering medication simultaneously) to reduce nighttime disruptions and alleviate insomnia symptoms. Interventions should also look to address pain, mental health, and other comorbidities which influence sleep quality. The hospital environment (primarily, excessive noise and light) emerged as a significant concern, highlighting an inpatient-specific issue. A cyclical relationship between nighttime sleep quality and daytime therapy engagement was also explored. Ongoing data collection will provide further insights, with the results and conclusions presented here representing an early snapshot of the broader study.

MILD TRAUMATIC BRAIN INJURIES AND THE INTERACTION BETWEEN SLEEP AND COGNITIVE DYSFUNCTION

Lauren Elmore[1], Sarah Emert[1], Alisa Huskey[2], Emme Tucker[1], Cordell Stover[1], William Killgore[2]

[1] Idaho State University, [2] The University of Arizona

Introduction: Mild Traumatic Brain Injuries (mTBIs) are associated with symptoms such as headaches, fatigue, mood changes, cognitive dysfunction, hindering executive functioning, attention, processing speed, and memory. Prior research has also implicated mTBIs in the development of sleep dysfunction and circadian rhythm disorders, and this has been associated with further neurocognitive degeneration. However, a lack of research exists examining how sleep dysfunction in individuals with mTBIs impacts specific cognitive domains. This study aims to examine the relationship and influence that sleep has on mTBI symptomology and cognitive dysfunction.
Methods: Adults with mTBIs (N= 167; Mage=24.41 years, 59% female) completed self-report questionnaires that assessed symptomology associated with mTBIs (RPCSQ), sleep (DSIQ), and personality (PAI; used to assess thought dysfunction). Participants also completed cognitive testing to assess executive functioning (D-KEFS). A multivariate analysis of variance assessed concussive symptomology's association with cognitive domains and sleep disturbance. Moderation analyses assessed sleep's influence on the relation between symptomology and cognitive dysfunction.
Results: There was a significant effect on cognitive dysfunction and sleep based on mTBI symptomology: PAI Thought dysfunction: $F(1, 42) = 2.015$, $p = .002$, partial $\eta 2 = .463$ D-KEFS Number-Letter Switching: $F(1, 42) = 2.129$, $p = .001$, partial $\eta 2 = .477$ D-KEFS Color Word Interference: $F(1, 42) = 2.115$, $p = .001$, partial $\eta 2 = .476$ Sleep disturbance: $F(1, 42) = 1.929$, $p = .004$, partial $\eta 2 = .453$ Sleep disturbance did not moderate the relationship between mTBI symptomology and cognitive task performance.
Conclusion: Results of this study replicate previous research that suggests mTBIs impact sleep and cognitive domains, like concentration, confusion, disorganization, and executive functioning. Despite previous literature on sleep and cognition, it indicates sleep does not moderate the relationship between mTBIs and cognitive dysfunction, suggesting an alternative relational mechanism. Future research should examine sleep's role in cognitive dysfunction in mTBIs given its potential neurodegenerative effects.

PRESENCE AND IMPACT OF BLAST-INDUCED TRAUMATIC BRAIN INJURY ON SLEEP HEALTH IN POST-9/11 VETERANS

Harshitha Mergey Devender[1], Mahrukh Riaz[1], Thomas Alexander[2], John Konikkara[1], Steven Cassady[1], Montserrat Diaz-Abad[3], Anays Sotolongo[2], Mehrdad Arjomandi[4], Silpa Krefft[5], John Osterholzer[6], Bradley Richmond[7], Michael Falvo[2], Danielle Glick[3]

[1] Baltimore VA Medical Center, [2] VA New Jersey Health Care System, [3] University of Maryland School of Medicine, [4] San Francisco VA Medical Center, [5] Rocky Mountain VA Medical Center, [6] Ann Arbor VA Medical Center, [7] Nashville VA Medical Center

Introduction: In the post-9/11 conflicts in Southwest Asia and Afghanistan, traumatic brain injury (TBI) and blast exposure have been recognized as signature injuries. This is often accompanied by psychological health issues such a post traumatic stress disorder (PTSD). We have previously shown this group suffers from insufficient and disturbed sleep. The present study aims to examine the impact of blast-related TBI on sleep quality and psychological health.
Methods: Veterans enrolled in the Post-Deployment Cardiopulmonary Evaluation Network (PDCEN) underwent evaluation at five separate VA sites for unexplained dyspnea. Included in this in-depth evaluation were questionnaires inclusive of demographic information, the Brief Traumatic Brain Injury Scale (BTBIS), the Pittsburgh Sleep Quality Index (PSQI), and emotional health evaluations. The group was dichotomized based on the likely presence of blast-related TBI, defined as a positive BTBIS screen. Sleep dysfunction was defined as having a total PSQI score greater than or equal to 10. A multivariable logistic regression model was used to examine the association between TBI and sleep dysfunction, adjusted for age, sex, body mass index (BMI), race, anxiety, depression, and PTSD.
Results: A total of 301 veterans completed questionnaires. Respondents were aged 46 ± 9 years and mostly white males with an average BMI of 31.5 ± 7.1 kg/m2. Most veterans served in the Army or multiple branches of the military. Sleep quality was overall abnormal with 73% having PSQI >10, average PSQI 12.3 ± 4.4, and mean sleep duration of 5.2 ± 4.1 hours. Blast-related TBI was present in 86 veterans (28.6%) and associated with increased odds of having sleep dysfunction (aOR 2.8, 95% CI 1.2-6.8), with average PSQI 13.6 ± 4.0 among those with blast-related TBI and 11.8 ± 4.5 among those without ($p = 0.003$). Anxiety, depression, and PTSD were also more common when TBI was present, though only depression met significance.
Conclusion: In this group of post-9/11 veterans with exposure to burn pits and other airborne hazards, the presence of blast-induced TBI was associated with an increased risk of sleep disturbance and mood disorder. Future analysis will focus on the impact of blast-induced TBI on sleep disordered breathing.

AMINO ACID SUPPLEMENTATION IMPROVES SLEEP IN OLDER ADULTS WITH TRAUMATIC BRAIN INJURY AT RISK FOR NEURODEGENERATION

Hannah Cunningham[1], Jonathan Elliott[2], Cosette Olivo[2], Savanah Sicard[2], Jessica Brewer[2], Katherine Powers[2], Sarah Happ[2], Andrea Hildebrand[1], Akiva Cohen[3], Miranda Lim[1]

[1] Oregon Health & Science University, [2] VA Portland Health Care System, [3] Perelman School of Medicine, Anesthesiology and Critical Care Medicine, University of Pennsylvania

Introduction: Older adults with a history of traumatic brain injury (TBI) are more likely to experience chronic sleep disturbances and cognitive impairments, elevating their risk of future

neurodegeneration. Interventions to mitigate sleep and cognitive disturbances are critically needed. Our prior preclinical work demonstrated dietary supplementation with branched chain amino acids (BCAA: leucine, isoleucine, and valine), precursors to de novo glutamate production, restore orexin/hypocretin neuron function, sleep-wake regulation, and memory in rodent models of TBI. The present study aims to translate this potential therapeutic approach to humans with a history of TBI.

Methods: Veterans with TBI (n=157) were recruited (135 eligible, 115 enrolled, with 106 allocated 1:1:1:1), in this double-blind, placebo-controlled randomized clinical trial comparing dietary BCAA supplementation at three dosages (high: 60g/day, medium: 40g/day, and low: 20g/day) with placebo (rice protein, 60g/day) for 12-weeks. Primary outcomes included feasibility/acceptability metrics, sleep (self-report, wrist-based actigraphy, overnight polysomnography) and neuropsychological testing, which were collected at baseline and 4-, 8-, and 12-weeks of intervention. Follow-up questionnaire-based assessments were collected at 4 and 12-weeks post-intervention.

Results: Of the 106 Veterans allocated/randomized, 49 have completed data collection (13 high, 8 medium, 14 low, and 14 placebo), 29 have withdrawn, and 57 are presently active. This interim analysis considers only the 78 who have completed or withdrawn (i.e., 65% of the 120 target sample). We demonstrate overall retention of 63%, with most attrition by week 4 (15.7%; no difference across study arms). Protocol compliance was 95% for full adherence to intervention (5-7 days/week), and ~98% reported being very to extremely satisfied, with most complaints attributed to gastrointestinal discomfort. In the high dose group, pre vs. post BCAA supplementation showed improved self-reported sleep (insomnia severity index scores, 13.6±2.8 to 8.9±2.9, $p < 0.05$) and actigraphy measures: total sleep time (6:23±1:04 vs. 7:04±1:08 hh:mm, $p < 0.05$), sleep onset latency (19.5±16.1 vs. 6.0±9.1 minutes, $p < 0.05$), and wake-after-sleep onset (65.7±26.0 vs. 47.8±23.1 minutes, $p < 0.05$).

Conclusion: Dietary BCAA supplementation is a feasible and acceptable home-based intervention to improve sleep in older adults with a history of TBI. Ongoing work will yield effectiveness data related cognitive function, BCAA dosing and treatment duration.

IMPROVING EQUITABLE ACCESS TO OSA CARE FOR HOSPITALIZED TRAUMATIC BRAIN INJURY VIA STAKEHOLDER-IDENTIFIED DETERMINANTS TO IMPLEMENTATION

Natalie Gilmore[1], Deveney Ching[2], Shannon Miles[2], Marc Silva[2], Alexa Watach[3], Risa Nakase-Richardson[2]

[1] James A. Haley Veterans' Hospital, Tampa, FL, [2] James A. Haley Veterans' Hospital, [3] University of Pennsylvania

Introduction: Despite high obstructive sleep apnea (OSA) prevalence (68%) during a time of critical neural repair following hospitalized traumatic brain injury (TBI), OSA screening and diagnosis is uncommon in TBI healthcare settings. Unrecognized OSA is problematic given its association with increased morbidity and early mortality. A recent multicenter comparativeness effectiveness trial (NCT 03033901) identified the best screening and diagnostic approach for use during inpatient rehabilitation following TBI. To support access to OSA management for a disabled population that experiences healthcare disparity, the study team leveraged stakeholder engagement to identify determinants (factors that facilitate or hinder) clinical translation of findings (OSA screening, diagnosis).

Methods: Stakeholders involved in the trial (n = 37) comprising individuals with lived experience of TBI; providers (rehabilitation, sleep medicine), researchers, industry representatives, healthcare administrators and policy professionals were asked to identify key considerations for translating findings into real-world practice. At trial conclusion, respondents were asked to answer, "What are the key things we need to consider to move the study results into real-world practice?" via a graffiti wall technique. Rapid content analysis was used to generate themes and validated by a third rater with TBI and OSA expertise.

Results: Responses resulted in the identification of seven determinants to OSA screening and diagnostic tool implementation during inpatient rehabilitation. Thematic analysis revealed the following needs: 1) Improve societal understanding of the importance of sleep, 2) Increase motivation/understanding of the need for OSA identification and treatment, 3) Research to identify the impact of OSA on TBI outcomes; 4) Understanding the cost to implementation of OSA management in inpatient settings, 5) Improve reimbursement for OSA management during inpatient rehabilitation, 6) Address logistical considerations of implementing screening, diagnosis, and treatment during hospitalization, and 7) Develop/adapt interventions to improve positive airway pressure compliance in a disabled population (hospitalized TBI) at risk for healthcare disparity.

Conclusion: This study identified determinants of clinical translation of screening and diagnostic tools for OSA in TBI from multiple stakeholder perspectives. These findings will inform future patient-, provider-, system-, and policy-level interventions to reduce healthcare disparity in TBI by improving access to high-quality OSA care.

IMPACT ON PATIENTS' PERCEIVED SLEEP QUALITY BY BED LOCATION IN THE INPATIENT NEUROLOGY UNIT

Christine Ly[1], Sullafa Kadura[1]

[1] University of Rochester Medical Center

Introduction: While sleep plays a critical role in restoration of health and wellbeing, sleep disruptions during hospitalization prolong the recovery period and increase mortality. Our recent survey-based observational study revealed differences in perspectives on sleep disruptions in the neurology unit between patients and staff. In this study, we will further investigate how patients' sleep quality is affected by bed location in the inpatient neurology unit.

Methods: We analyzed the data from a previously performed survey-based observational study on a 25-bed inpatient neurology unit at an academic medical center from April 2021 to October 2022. The unit was analyzed in three main areas: corridor, front, and back. Questionnaires used to assess patients' previous night's sleep included the Consensus Sleep Diary (CSD), the Karolinska Sleep Diary (KSD), and the Potential Hospital Sleep Disruptions and Noises Questionnaire (PHSDNQ). Nurses were asked which rooms they perceived to have the most disruptions. We used unpaired t-tests for statistical analysis.

Results: 224 out of 256 responses were analyzed. Of the 112 patients in shared rooms, 58 stayed in beds by the door while 54

were in beds by the window. Patients in shared rooms perceived their sleep to be more disrupted by medical interventions (vital signs, tests, and neurologic checks) compared to those in private rooms (1.971 ± 0.1.057, 1.58 ± 0.938, p = 0.004). Overall, there were no significant differences in sleep quality between shared and private rooms. Although nurses reported the front rooms closest to the nursing station to be the most disrupted, patients perceived no differences between the corridor, front, or back rooms. Interestingly, in the front shared rooms, patients perceived better sleep quality based on the KSD (sleep quality, restorative, restful, sleep throughout) in the bed by the door than by the window (3.356 ± 1.278, 2.553 ±1.079, p = 0.028). Additionally, perceived total sleep time (minutes) was higher for those by the door than window (417.69 ± 174.71, 304.74 ±146.38, p = 0.023).
Conclusion: There continues to be differences between perceived disruptions between the staff and the patients in the inpatient neurology unit. Further studies are needed to improve sleep quality in the neurology unit.

PREVALENCE OF STROKE AND TIA IN INSOMNIACS AND SLEEP EVALUATION DIFFERENCES: A TERTIARY CENTER PERSPECTIVE

Amna Sohail[1], Emily Fisher[1], Saagar Sheth[1], Chad Aldridge[1]
[1] University of Virginia

Introduction: Sleep is essential for neuronal, metabolic and vascular health. Insomnia increases stroke risk through development of hypertension, diabetes mellitus and hyperlipidemia. Stroke causes insomnia by altering sleep architecture. Insomniacs had a 54% stroke risk with a prevalence of 2.71% over 4 years in the community. About 50% of stroke patients have insomnia and only 7% undergo appropriate evaluation.
Methods: To evaluate the prevalence of stroke and Transient Ischemic Attack (TIA) in insomniacs and differences in sleep evaluation in those with cerebrovascular events, we performed a retrospective chart review. ICD 10 codes were utilized to identify insomniacs over last 6 years, aged 18 to 89 years. Based on reported prevalence of stroke in insomniacs, 651 patient charts were randomly selected from the 7000 identified.
Results: Prevalence of any stroke and TIA was 9.98%, 95% CI [7.7%-12.4%]. Ischemic stroke and TIA were the common cerebrovascular events (92%). Pre-stroke insomnia was present in 55% patients. Insomniacs with any cerebrovascular event were older (69 (56,80) vs 59 (42,69), p< 0.001). Sleep study was done in 76% insomniacs seen in a sleep clinic compared to 0.3% who were only seen by a primary care provider. Insomniacs with elevated BMI (p< 0.001), atrial fibrillation (p< 0.001), hypertension (p=0.011), diabetes mellitus (p< 0.001), hyperlipidemia (p< 0.001) or a cerebrovascular event (p=0.03) were frequently evaluated with a sleep study. About 71% of insomniacs with any cerebrovascular event were evaluated by sleep specialist and 54% underwent a sleep study. About 13% of insomniacs with an additional sleep disorder had a cerebrovascular event. About 31% with any stroke or TIA had both sleep apnea and insomnia disorder. The odds of having any stroke or TIA did not significantly increase by having an additional sleep disorder (OR 1.71, 95% CI [0.95, 3.08]).
Conclusion: Prevalence of stroke and TIA is higher in insomniacs at tertiary centers. They are more often evaluated by sleep specialists and undergo a sleep study. This may be due to better access to sleep clinics and increased awareness of the negative effects of insomnia on vascular health amongst primary care providers resulting in higher sleep disorder screening, especially in stroke survivors.

WHAT FACTORS INFLUENCE SLEEP HEALTH DURING RECOVERY AFTER STROKE?

George Fulk[1], Karen Klingman[2], Emily Peterson[1]
[1] Emory University, [2] SUNY Upstate Medical University

Introduction: People post stroke (PPS) exhibit a variety of sleep disorders. PPS with poor sleep health (SH) often have worse outcomes. However, the factors that may contribute to poor SH in PPS are poorly understood. The purpose of study was to explore factors that influence SH after stroke.
Methods: Data were collected at 10- (in the hospital), 60-, and 90-days post stroke. SH was assessed based on the components of the Ru-SATED scale by combining data from actigraphy: regularity, timing, efficiency, and duration of sleep; and self-report of satisfaction and alertness. This provided a surrogate Ru-SATED (S-Ru-SATED) SH score between 0 and 12, with higher scores indicating better SH. Common stroke outcomes were taken at each time point: Montreal Cognitive Assessment (MOCA), Barthel Index (BI), Patient Health Questionnaire 9 (PHQ-9), and self-selected gait speed (GS). To assess the relationship between the S-RU-SATED and potentially predictive covariates, we used a cumulative link mixed model. This method combines features of ordinal regression with mixed effects modeling. We estimated the cumulative probabilities of the response falling into or below each category of the S-Ru-SATED as a function of fixed effects (fixed predictive covariates included PHQ-9, BI, GS, MOCA, sex, age, and time post-stroke), and subject-specific random effects which captures the variability across subjects accounting for time dependencies in the data.
Results: Data from 90 PPS were used in the analysis. For the fixed effects, PHQ-9 had a significant negative estimate of -0.1327 (p < 0.001), indicating that for each unit increase in PHQ-9, the odds of being in a higher category of S-Ru-SATED decreased by approximately 12.4% holding other variables constant. The other predictors were not statistically significant.
Conclusion: Our findings suggest that people with greater levels of depression may have poorer sleep health during the first 3 months after stroke. Interestingly, differences between 60/90 days versus inpatient periods did not significantly influence SH. We would expect that SH would improve once participants were out of the hospital. Addressing depression early after stroke may be an important to improve SH in people who are recovering after stroke.

COMPOSITIONAL DATA ANALYSIS TO EXPLORE THE ASSOCIATION BETWEEN SLEEP, ACTIVITY, AND SEDENTARY BEHAVIOR AFTER STROKE

George Fulk[1], Karen Klingman[2], Emily Peterson[1]
[1] Emory University, [2] SUNY Upstate Medical University

Introduction: People post stroke (PPS) often exhibit impaired sleep, lower levels of activity, and high levels of sedentary behavior. The impact of these behaviors on stroke outcomes has traditionally been explored singularly. Compositional data analysis (CoDA) offers a unique method that combines 24-hour behaviors into a composition, which then can used for analysis. The purpose of this study was to use CoDA to analyze the composition of sleep, active, and sedentary behaviors and to explore its association with stroke related quality of life (S-QOL).
Methods: This was a cross-sectional study at 60 days post stroke. Participants wore an activity monitor (AM) for 7 days that measured time in sleep, active, and sedentary behaviors. Participants reported their S-QOL using the Stroke Impact Scale-16 (SIS-16). Depression (PHQ-9), gait speed (GS), and age were also measured as potential confounding covariates. CoDA was used to explore the composition of sleep, activity, and sedentary behaviors and the association between the composition of these behaviors and S-QOL. Multiple linear regression (MLR) analyses were performed using the transformed isometric log-ratios of the composition of behaviors with depression, gait speed, and age as covariates to explore the association between S-QOL and the composition.
Results: 58 participants wore an AM for 5.4 (1.4) days. The compositional mean of sleep, active, and sedentary behaviors in a 24-hour period was 36.4% in sleep, 8.3% in active, and 55.3% in sedentary behaviors. The composition of behaviors was significantly associated with S-QOL (p=0.0004), r2 of 0.69. Gait speed (p=0.0002) and depression (p=0.0003) were significant co-variates.
Conclusion: Participants spent most of their day in sedentary behaviors. CoDA provides a unique method to assess the composition of behaviors across a 24-hour period in people with stroke that may be more appropriate than examining each individual behavior because changing time in one behavior necessitates change in one of the other two behaviors across a 24-hour period. The composition of sleep, activity, and sedentary behaviors was significantly associated with S-QOL. Developing interventions to improve sleep and increase time in active behaviors may improve S-QOL

SEVERITY OF OBSTRUCTIVE SLEEP APNEA SEVERITY AND EARLY CPAP USE IS ASSOCIATED WITH CPAP ADHERENCE IN A STROKE REHABILITATION POPULATION

Brian Wall[1], Martha Billings[1], Michael Nash[1], Sandeep Khot[1], Sofia Grande[1], Chuck Bombardier[1], Maggie Ramirez[1], Devin Brown[2], Belqeis Abatiyow[1], Teresa Bryant[1]
[1] University of Washington, [2] University of Michigan

Introduction: Continuous Positive Airway Pressure (CPAP) therapy is a common and effective treatment for obstructive sleep apnea (OSA). Among patients with stroke and OSA, CPAP therapy is associated with reduced stroke risk and improved recovery but is limited by generally poor adherence. We aimed to explore the association between clinical factors and the first 3 months of CPAP use within a stroke rehabilitation population who were provided with enhanced CPAP support.
Methods: Stroke patients admitted to inpatient rehabilitation (IPR) were enrolled and tested for OSA with a portable sleep apnea test. Eligible participants were provided CPAP for 3 months along with a multicomponent CPAP adherence intervention, including technical support, motivational interviewing, and mobile health interventions. Associations between demographics, stroke severity, and OSA-related factors and average CPAP use over 3 months were evaluated using t-tests.
Results: Thirty-three of 36 participants met criteria for OSA [mean age= 58 ± 11 years, 67% male, 52% non-Hispanic white (NHW)]. The mean respiratory event index (REI) was 21/hour and mean NIH Stroke Scale score was 6. Three participants withdrew from the study during IPR. Among the 30 remaining participants, mean nightly CPAP use over 3 months was 3.1 hours. Mean nightly CPAP use during IPR (3.3 ± 0.9 hours over a mean of 12.6 ± 2.4 days) was predictive of mean CPAP use after IPR (3.0 ± 1.1 hours), p = 0.01 (linear model). Mean nightly CPAP use was 4.8 hours among those with REI ≥ 30 compared to 2.4 hours among participants with REI< 30 (p=0.04). Mean CPAP use did not differ by stroke severity, oxygen desaturation index, age, gender or obesity.
Conclusion: In this study of enhanced CPAP support initiated during stroke IPR, OSA severity, but not stroke severity, was associated with CPAP use over a 3-month period. CPAP use during IPR was associated with CPAP use after IPR. Further investigations regarding the relationships of stroke, sleep apnea, and CPAP adherence are warranted to improve outcomes for patients with these common, and often comorbid, conditions.

OSA IS ASSOCIATED WITH INCREASED INCIDENCE OF PARKINSON'S DISEASE AND IS MITIGATED BY CPAP TREATMENT

Jasmine May[1], Isabella Montano[2], Lee Neilson[3], Yeilim Cho[4], Jeff Iliff[5], Jonathan Elliott[3], Gregory Scott[3], Miranda Lim[6]
[1] Oregon Healthy and Science University Hospital, [2] Oregon Health and Science University, [3] VA Portland Health Care System, [4] University of Washington, School of Medicine, Department of Psychiatry and Behavioral Sciences, [5] University of Washington School of Medicine, [6] Oregon Health & Science University

Introduction: Prior work has demonstrated an association between Obstructive Sleep Apnea (OSA) and development of Parkinson's Disease (PD), but these studies were limited by small sample size, limited duration, confounding by large-effect covariates (e.g. age, race, smoking, comorbidities), and an inaccurate ICD-code-based definition of PD with positive predictive values below 50%. Herein we measure the impact of OSA and OSA treatment on subsequent incidence of PD by using the nationwide records of the US Department of Veterans Affairs, which spans 20+ years, includes 20+ million veterans, allows for adjustment of important covariates, and leverages accurate and validated definitions of PD.
Methods: OSA was defined by ICD-10 code G47.33 (OSA+) along with two validated PD diagnosis case definitions (PPV 76% and 90%). Outcomes included PD and death from any cause. CPAP use was captured in a free-text health record field called the HealthFactor. "CPAP+ Early" was defined as mentions of CPAP within 2 years of OSA diagnosis; "CPAP+ Late" indicated >2 years since OSA diagnosis.
Results: 1,552,505 OSA+ and 9,759,246 OSA- Veterans were identified. After weighting analysis and controlling for confounders (balancing of birthyear/age, sex, smoking status, race,

ethnicity, pseudo-randomization by covariates, and adjustment for competing risk of death) we found that OSA significantly increased the incidence of PD with 1.8 [1.4, 2.3] 95% CI, $p < 0.001$) extra cases of PD per 1000 people at 5 years after OSA onset. "CPAP+ Late" had a similar incidence of PD to CPAP-. In contrast, "CPAP+ Early" had lower incidence of PD, with a reduction of 2.3 cases of PD ($p < 0.001$) 5 years after OSA.
Conclusion: OSA may be a modifiable risk factor for the development of PD and potentially other synucleinopathies. Future work will involve optimizing and validating ascertainment of OSA diagnosis and CPAP usage.

ELECTROCARDIOGRAPHIC MEASURES OF AUTONOMIC FUNCTION AND HEART-BRAIN SYNCHRONIZATION DURING SLEEP AND RISK OF INCIDENT PARKINSON'S DISEASE

Sasha Milton[1], Haoqi Sun[2], Robert Thomas[2], Farhad Kaffashi[3], Kenneth Loparo[3], M. Brandon Westover[2], Yue Leng[1]

[1] Department of Psychiatry and Behavioral Sciences, University of California, San Francisco, [2] Beth Israel Deaconess Medical Center, [3] Case Western Reserve University

Introduction: Sleep disruptions and autonomic dysfunction are common in prodromal Parkinson's disease (PD). Evidence suggests a possible breakdown of heart-brain communication in PD. It remains unclear whether electrocardiographic measures of autonomic function, autonomic balance, and heart-brain synchronization during sleep are associated with PD risk.
Methods: We examined 5864 Massachusetts General Hospital patients (median [range] age=49.0 [18-97] years; 51.9% female) without PD, dopaminergic medication use, or REM sleep behavior disorder who underwent polysomnography. Incident PD was determined using natural language processing of medical notes. From the polysomnography-electrocardiogram, we calculated average whole-night, REM-specific, and NREM-specific five-minute heart rate variability (HRV; SDNN, RMSSD, PNN50, HF, LF, VLF, and LF/HF) and cardiopulmonary coupling (CPC; synchronization between HRV and electrocardiogram-derived respiration; log high [HFC], low [LFC], and very low [VLFC] frequency coupling power) metrics. Metrics are influenced differentially by overall autonomic function, parasympathetic activity, and long-term dynamics (sympathetic, baroreflex, and other activity). Some (e.g. REM VLFC) are associated with specific sleep stages in health, reflecting heart-brain synchronization. We performed principal component (PC) analysis to quantify underlying influences on HRV/CPC. We examined associations between tertiles of PCs and incident PD using Fine-Gray and Cox models with death as a competing risk.
Results: Across a median (IQR) follow-up time of 8.9 (5.5) years, 360 (6.1%) adults developed PD. After adjustment for age, sex, race, education, body mass index, and smoking, the lowest tertile of PC1 (overall autonomic function; 53.3% variance explained; strong positive loadings for all metrics except LF/HF [not influenced by overall HRV]; HR [95% CI]=1.32 [1.01,1.71]), PC2 (autonomic balance; 13.4% variance explained; strong positive loadings for long-term dynamics metrics, small loadings for overall HRV metrics, and negative loadings for parasympathetic metrics; HR [95% CI]=1.37 [1.04,1.80]), and PC4 (heart-brain synchronization in REM; 4.9% variance explained; strong positive loadings for REM-specific versions of metrics associated with healthy REM, including VLFC; HR [95% CI]=1.30 [1.01,1.68]) showed increased PD risk relative to the highest tertile.
Conclusion: Adults with decreased overall autonomic function, reduced sympathetic, baroreflex, or other activity relative to parasympathetic activity during sleep, or heart-brain desynchronization in REM may exhibit increased PD risk.

REM SLEEP APNEA AND PARKINSON'S DISEASE RISK: INSIGHTS FROM A RETROSPECTIVE SLEEP CLINIC COHORT

Yi Fang[1], Sasha Milton[2], Haoqi Sun[3], Robert Thomas[3], M. Brandon Westover[3], Yue Leng[2]

[1] University of California, San Francisco, [2] Department of Psychiatry and Behavioral Sciences, University of California, San Francisco, [3] Beth Israel Deaconess Medical Center

Introduction: Sleep apnea is common in Parkinson's disease (PD), but its role in incident PD remains unclear. Preclinical studies suggest intermittent mild hypoxia may have neuroprotective effects, whereas severe hypoxia could exacerbate neurodegeneration. Rapid Eye Movement (REM) and non-REM (NREM) sleep apnea may have distinct effects on PD risk or be influenced by PD pathophysiology differently. This study examines the associations between overall, REM, and NREM sleep apnea and PD risk.
Methods: This retrospective cohort included individuals aged ≥30 years who underwent polysomnography (PSG) at Massachusetts General Hospital. Participants had no PD diagnosis at baseline and met quality criteria (total sleep time ≥4 hours, REM and NREM ≥30 minutes). Sleep apnea, measured using the apnea hypopnea index (AHI), was stratified into REM and NREM stages and categorized as normal (AHI< 5), mild (5≤AHI< 15), moderate (15≤AHI< 30), and severe (AHI≥30). Demographics, comorbidities, and PD diagnoses were extracted from electronic medical records using natural language processing. Cox regression with death as a competing risk was used to examine associations between AHI and PD risk, adjusting for age, sex, race, body mass index, smoking, diabetes, and hypertension. Sensitivity analyses excluded participants with REM sleep behavior disorder (RBD) or diagnosed with PD within five years of PSG.
Results: Among 4,661 individuals (age 52.2 ± 12.9 years, 2390 [51.3%] female, 878 [18.8%] non-White) followed for 8.88 ± 3.62 years, 305 (6.55%) developed PD. After full adjustment, mild REM sleep apnea was associated with a reduced risk of PD compared to normal REM AHI (HR = 0.492, 95% CI: 0.312–0.774, P = 0.002). Moderate (HR = 0.690, 95% CI: 0.454–1.048, P = 0.082) and severe REM sleep apnea (HR = 0.718, 95% CI: 0.508–1.016, P = 0.062) showed trends toward reduced PD risk but were not statistically significant. These findings remained robust in sensitivity analyses. NREM and overall AHI showed no significant associations with PD risk.

Conclusion: Our observation suggests that mild REM sleep apnea may trigger neuroprotective responses. Further studies are needed to validate these findings and explore the underlying mechanisms.

ALTERED THETA-DELTA TEMPORAL RELATIONSHIP REVEALS IMPAIRED NREM ARCHITECTURE AND DISTINCT SPECTRAL PATTERNS IN PARKINSON'S DISEASE COGNITIVE SUBTYPES

Tina Naik[1], Omonigho Michael Bubu[2], Dean Krusienski[1], Brian Berman[1]

[1] Virginia Commonwealth University, [2] Department of Psychiatry, New York University Grossman School of Medicine

Introduction: Conventional, discretized quantitative electroencephalography (qEEG) analyses fail to capture disruptions in the continuous oscillatory dynamics of sleep homeostasis. Recent studies have observed abnormal anterior theta rhythms superimposed on delta during deeper stages of NREM in Parkinson's Disease (PD) reflecting altered sleep architecture, however, the temporal theta-delta relationship has not been characterized. Here we characterize sleep architecture by exploring relevant bandpower time course relationships that underlie the altered sleep spectrum in PD. We also explored their potential to distinguish PD cognitive subtypes.

Methods: Polysomnography electroencephalography (EEG) data were collected from 51 participants (PD=36, controls=15; mean ages PD: 68 ± 6, controls: 64 ± 8; sex PD: 17M/19F, controls: 5M/10F) as part of a broader study evaluating alterations to sleep architecture in PD. PD subtypes included mild cognitive impairment (PD-MCI, n=12) and PD with normal cognition (PD-NC, n=24). EEG (F3-M2) was preprocessed in MATLAB, temporally aligned with hypnogram data, and assessed using multitaper analysis to compute bandpower per sleep stage (N2, N3, N2+N3) across 30-second epochs. Spearman's correlation coefficients for the theta-delta time course relationship were calculated across sleep stages. Stage-based bandpower time-course plots were created to visualize sleep architecture oscillatory dynamics. Group differences were evaluated with Wilcoxon rank-sum tests with Benjamini-Hochberg correction for multiple comparisons (adjusted $p < 0.05$).

Results: In controls, bandpower time-course plots reflect a positive theta-delta relationship and progressive cyclic dissipation over NREM, indicating preserved oscillatory homeostasis. A significant negative (inverse) theta-delta relationship during N2 (p=0.007), N3 (p=0.015), and N2+N3 (p=0.015) was found in PD compared to controls. Exploratory analyses of PD subtypes compared to controls revealed negative theta-delta relationship during N2 (PD-MCI: p=0.003; PD-NC: p=0.030), N3 (PD-NC: p=0.036), and N2+N3 (PD-MCI: p=0.009).

Conclusion: Findings reveal an abnormal theta-delta relationship during deeper NREM, supporting the presence of a distinct mechanism of disrupted sleep time-course dynamics. A negative theta-delta correlation in PD reflects altered oscillatory homeostasis and distinguishes subtypes: N3 dominance in PD-NC and N2 dominance in PD-MCI. Future work will assess regional theta-delta relationships and associations with disease severity measures to enhance diagnostic utility.

MULTITAPER SPECTRAL ANALYSIS REVEALS ALTERED OSCILLATORY HOMEOSTASIS AND DISTINCT SPECTRAL PATTERNS IN PARKINSON'S DISEASE COGNITIVE SUBTYPES

Tina Naik[1], Dean Krusienski[1], Omonigho Michael Bubu[2], Brian Berman[1]

[1] Virginia Commonwealth University, [2] Department of Psychiatry, New York University Grossman School of Medicine

Introduction: Sleep disturbances and cognitive decline in Parkinson's disease (PD) are common, yet the neurophysiological mechanisms linking both remain unclear. Notably, EEG bandpower ratios characterize the inter-bandpower relationships reflecting sleep homeostasis and potential reliable EEG biomarkers of neurological disorders. We utilized an optimized multitaper spectral analysis of deeper NREM sleep, with a focus on bandpower ratios, to elucidate potential underlying neurophysiological sleep oscillatory homeostatic mechanisms in PD cognitive decline.

Methods: Polysomnography electroencephalography (EEG) data were collected from 51 participants (PD=36, controls=15; mean ages PD: 68 ± 6, controls: 64 ± 8; sex PD: 17M/19F, controls: 5M/10F) as part of a broader study evaluating alterations to sleep architecture in PD. PD subtypes included mild cognitive impairment (PD-MCI, n=12) and PD with normal cognition (PD-NC, n=24). EEG (F3-M2, C3-M2) was preprocessed in MATLAB, temporally aligned with hypnogram data, and assessed using multitaper analysis to compute bandpower per sleep stage (N2, N3, N2+N3) in 30-second epochs. Group differences were evaluated with Wilcoxon rank-sum tests with Benjamini-Hochberg correction for multiple comparisons (adjusted $p < 0.05$).

Results: Overall, bandpower differences were observed during N3 in PD compared to controls, with reduced delta (frontal: p=0.012; central: p=0.019), increased theta (frontal: p=0.007; central: p=0.009), increased sigma (frontal: p=0.025), and increased beta (frontal: p=0.025; central: p=0.028). Bandpower ratios in N3 revealed increased theta/delta (frontal: p=0.009; central: p=0.022) and reduced delta/sigma (frontal: p=0.022). PD subtypes' analyses showed that PD-MCI and PD-NC compared to controls (frontal) had reduced delta during N3 in both groups (PD-MCI: p=0.019; PD-NC: p=0.009). Theta was increased in PD-MCI during N2 (p=0.002), N3 (p=0.001), and N2+N3 (p=0.0006), and in PD-NC during N3 (p=0.009). Sigma was reduced in PD-MCI during N2 (p=0.015) but increased in PD-NC during N3 (p=0.009).

Conclusion: Significant stage-specific bandpower alterations in PD-sleep reveal disrupted oscillatory homeostasis in sleep EEG features (delta, theta, sigma) exemplified by spectral ratios during N3. Subtype analyses suggest distinct spectral patterns: increased theta and reduced sigma during N2 (PD-MCI) and reduced delta, increased theta and sigma in N3 (PD-NC). These findings highlight distinct bandpower features potentially underlying neurophysiological sleep oscillatory homeostatic mechanisms in PD cognitive decline.

REM-SLEEP BEHAVIOR DISORDER AND COGNITIVE CHANGES IN PARKINSON'S DISEASE AND ROLE OF DOPAMINE TRANSPORTER BINDING

Hyun (Monica) Kim[1], Yumeng Qi[1], Terry Goldberg[1], Seonjoo Lee[1]
[1] Columbia University

Introduction: REM-sleep behavior disorder (RBD) is a robust prodromal marker of Parkinson's disease (PD) and is strongly predictive of worse progression and outcome of non-motor symptoms, including cognitive impairment. Nonetheless, little is known about the RBD's interaction with striatal dopamine transporter binding, a key neurobiological mechanism in PD. The current study used epidemiologic dataset of PD and examined the association between RBD, dopamine transporter binding, and changes in cognitive performance with the aim of elucidating the potential interaction between RBD and dopamine system on cognition.
Methods: Sample included 1,143 individuals (mean age 62.72 □9.5, 38% female, 32% with RBD) with PD from the Parkinson's Progression Markers Initiative (PPMI), a large-scale dataset focusing on PD progression and underlying mechanisms. The presence of RBD was determined using the 10-item RBD Screening Questionnaire. Dopamine transporter (DaT) single-photon emission computed tomography were extracted for the putamen and the caudate to measure dopamine transporter availability. Cognitive outcomes included the measures of memory, attention, working memory, and executive functions. The regression analyses were performed to determine the effect of RBD on cognitive performance, and RBD x DaT interaction term was added to test the moderating role of DaT.
Results: RBD was significantly associated with the Symbol Digit Modalities Test (SDMT, B= -1.8, P=0.002) but not with other cognitive measures (Ps□0.13), after adjusting for age, sex, education level, and PD duration. While there was no significant interaction between RBD and DaT measure from any observed regions on SDMT (Ps □ 0.20), RBD's association with SDMT remained significant after adding DaT in the analytic model.
Conclusion: RBD was significantly associated with a measure of working memory and processing speed, independently from dopamine transporter activity. No interaction between RBD and striatal dopamine binding was observed. Our findings indicate that RBD alone is a robust and strong predictor of cognitive decline in PD, regardless of dopaminergic uptake in the striatum. Early detection and management of RBD would be important to slow the progression of PD and related cognitive impairment.

SLEEPINESS IN PARKINSON'S DISEASE: A RETROSPECTIVE ANALYSIS OF POLYSOMNOGRAM FINDINGS

Mary Hollist[1], Heidi Roth[2], Nathan Walker[2], Katelyn Bricker[2], Zheng Fan[2], Vaughn Bradley[2]
[1] University of North Carolina- Chapel Hill, [2] UNC

Introduction: Patients with Parkinson's disease (PD) have a variety of sleep problems, including excessive daytime sleepiness (EDS). EDS, is one of the prominent non-motor symptoms in PD that has impact on the quality of life. While several factors contribute to sleepiness in Parkinson's disease, in this study, we examine sleep characteristics seen on polysomnograms (PSG) to see if these contribute to the perceived daytime sleepiness in PD.
Methods: 43 patients with PD were identified in the UNC sleep database with having PSG data for review. Subjective daytime sleepiness was assessed with the use of the Epworth Sleepiness Scale (ESS) defined as ≥ 10. Sleep characteristics including total sleep time (TST), sleep efficiency (SE), sleep latency (SOL), REM latency, wake after sleep onset (WASO), and sleep stage percentages as well as findings of AHI, periodic limb movements (PLMS), and excessive EMG in REM sleep were compared between the groups with EDS versus no EDS. Groups were compared using t-test for continuous variables and Chi square test for categorical variables.
Results: Subjects with EDS (n = 23) had mean ESS of 12.78 and those without EDS (n = 20) had mean ESS of 4.95. TST, SE, SOL, WASO, AHI, PLMS, and the finding of excessive EMG in REM sleep were not different between groups. When sleep stages were evaluated, there was no significant difference between groups, except, those with EDS ≥10 had greater time in Stage N3 (52.5 vs 17.8 minutes) (p=0.043).
Conclusion: In our Parkinson's Disease patients, those with EDS had greater number of minutes in stage N3 sleep. Although this is not a large sample, the findings could suggest that for some patients with PD and excessive daytime sleepiness the homeostatic drive may be involved in the symptoms. Yet, further investigation is needed to confirm this possible relationship.

EFFECTS OF TDCS ON SLEEP DISTURBANCES, MOOD, AND AROUSAL LEVELS IN PARKINSON'S DISEASE: INSIGHTS FROM SMART DEVICE MONITORING

Ho-Kyoung Yoon[1], Do-Young Kwon[2], Boram Chae[2], Jae-Ha Song[1]
[1] Korea University, [2] Korea University Ansan Hospital

Introduction: This study aims to investigate the effects of sequential transcranial direct current stimulation (tDCS) treatments on sleep disturbances and their interplay with mood and motor symptoms in Parkinson's disease (PD) patients, with smart devices used to objectively monitor sleep patterns and activity levels.
Methods: Twenty PD patients with depressive symptoms participated in ten sessions of tDCS treatment. Clinical assessments included the Unified Parkinson's Disease Rating Scale (UPDRS), Montgomery-Åsberg Depression Rating Scale (MADRS), State-Trait Anxiety Inventory (STAI), Apathy Scale (AS), and Parkinson's Disease Questionnaire-39 items (PDQ-39). Smart devices recorded sleep duration, patterns, and daily activity levels. Pre- and post-tDCS data were analyzed using paired t-tests, Pearson's correlation, and regression analyses to evaluate changes in sleep, mood, and motor outcomes.
Results: Although smart device data indicated no significant changes in total sleep duration post-tDCS, there was a significant increase in step counts (p = 0.012), suggesting an elevation in arousal levels. This increased arousal was correlated with mood improvements, as demonstrated by changes in MADRS scores (r = -0.47, p = 0.04). Regression analysis showed that changes in depressive symptoms explained 21.8% of the variance in step count (R^2 = 0.218, p = 0.04). However, no direct relationship

was found between motor symptom improvements (UPDRS) and sleep duration.
Conclusion: While tDCS did not extend total sleep duration, the observed increase in step counts implies heightened arousal levels, potentially driven by improved mood. Smart device monitoring provided objective data on activity and sleep, supporting its use in comprehensive PD management. These findings underscore the importance of evaluating arousal levels and mood as interconnected components influencing sleep and daily activity in PD patients.

VALIDATION OF A NOVEL METHOD FOR IDENTIFYING SLEEP-DISORDERED BREATHING IN SPINAL CORD INJURY

Stefan Vukovic[1], Rebekah Lee[1], Victoria Claydon[1]
[1] Simon Fraser University

Introduction: Spinal cord injury (SCI) is associated with complex health outcomes and can result in wide-ranging autonomic dysfunctions, many of which may complicate sleep. Indeed, most individuals with SCI experience poor sleep and some form of symptomatic sleep-disordered breathing (SDB: involuntary breath-holds during sleep causing transient hypoxia). Unmanaged SDB can progressively worsen functions of daily living and overall health, and there remains significant need for improved SDB evaluation in populations with SCI. Clinical sleep disorder diagnoses are necessary for treatment, but current assessments are prohibitive and require specialized in-laboratory testing that can be uncomfortable, impractical, and inaccessible for individuals with SCI.
Methods: We aimed to develop an at-home sleep testing protocol to assess SDB using two novel wearable technologies which noninvasively record overnight vital signs and sleep staging. Our validations compared Astroskin (form-fitting vest and headband) monitoring to simultaneous recordings using relevant gold-standard criteria. We then paired this with Fitbit (smartwatch) sleep staging to enable alignment of vital signs and sleep stages. Our design was initially evaluated in overnight sleep recordings from matched pairs of four individuals with SCI and four healthy controls.
Results: In healthy controls, the monitoring technology shows promise in providing dynamic readings of nocturnal blood oxygen saturation (SpO2; bias -2.95±2.7%; r=0.943; p< 0.0001), skin temperature (bias -0.3±0.4°C; r=0.997; p< 0.0001), respiration (r=0.967; p< 0.0001), 3-lead ECG, and body position. Over longer duration recordings, baseline blood pressure values met industry standards (bias -4.46±7.7mmHg; r=0.117; p=0.004), but dynamic blood pressure responses were captured poorly. In a case series examining preliminary results of one night of sleep in matched pairs, participants with SCI spent a greater proportion of their sleep in desaturated states (SpO2 ≤94%) compared to their matched controls. Interestingly, these nocturnal desaturations did not culminate in differences in time spent in varying sleep stages.
Conclusion: This study provides valuable insight into the use of novel wearable technologies to address known challenges and limitations of current home sleep apnea assessment methods. Our preliminary findings successfully track nocturnal desaturations and changes in sleep staging. These data show the utility of providing more accessible at-home evaluation of SDB in people with SCI.

SLEEP ROUTINES AND SLEEP DISTURBANCES AFTER SPINAL CORD INJURY: INSIGHTS FROM A COMMUNITY SURVEY

Rebekah Lee[1], Chris McBride[2], Victoria Claydon[1]
[1] Simon Fraser University, [2] Spinal Cord Injury British Columbia

Introduction: Many individuals with spinal cord injury (SCI) face a constellation of sleep disturbances that interfere with sleep initiation and/or continuity. While poor sleep is widely documented post-SCI, sleep management is often deprioritized for clinical attention. Given the potential for reciprocal impacts between sleep disturbances and additive effects on sleep outcomes, we aimed to characterise sleep routines and elucidate relationships between sleep disturbances and sleep outcomes in individuals living with SCI.
Methods: We conducted an online survey with community partner SCI British Columbia for Canadians (≥19 years old) living with SCI, inclusive of all lesion levels and sensorimotor-completeness. Survey questions pertained to sleep routines, support, and disturbances assessed by frequency, severity, and management. Established questionnaires evaluated poor sleep quality (Pittsburg Sleep Quality Index [PSQI]; score≥5), daytime sleepiness (Epworth Sleepiness Scale [ESS]; score≥10), and fatigue (Fatigue Severity Score [FSS]; score≥36).
Results: We report responses from 170 individuals with SCI (aged 43.4±13.6 years, 122 male, 14.5±11.8 years injured). Most (74%) participants manage their sleep independently. However, 28.8% use non-prescription substances to support sleep, which may reflect that 67.1% of participants have not reviewed their sleep care with a healthcare provider since initial discharge. In the past 6 months, 73.5% experienced ≥1 regular sleep disturbance, 55.2% of whom reported ≥3 disturbances. These included nociceptive pain (45.6%), anxiety (44.8%), bladder care (40.0%), spasticity (37.6%), turn routines (34.4%), neuropathic pain (30.4%), thermal discomfort (29.6%), autonomic dysreflexia (episodic hypertension; 23.1%), sleep apnea (20.8%), and bowel care (19.2%). Poor quality sleep was reported by 75.3% of respondents (PSQI 8.3±4.1), with 37.7% experiencing high fatigue (FSS 30.4±15.3), and 29.4% experiencing excessive daytime sleepiness (ESS 7.1±4.6). Compared to those without, individuals with ≥1 sleep disturbance reported higher PSQI (OR=14.9, p< 0.001), FSS (OR=6.0, p< 0.001), and ESS (OR=2.0, p< 0.05) scores, with all scores highly correlated with each other, with sleep duration, and the number of sleep disturbances experienced (p< 0.005).
Conclusion: Sleep disturbances post-SCI are highly prevalent, often occur in combination, and emerge as a determinant of global sleep health. Thus, sleep care presents as a clinical and research target with potential to improve quality of life for those living with SCI.

EXTERNAL VALIDATION OF ACTIGRAPHY-BASED IRBD CLASSIFIER USING A DIFFERENT ACTIGRAPH

Li Zhou[1], Andreas Brink-Kjær[2], Ankit Parekh[3], Katarina Mary Gunter[4], Salonee Marwaha[1], Bei Huang[5], Shi Tang[5], Siyi Gong[5], Yuhua Yang[5], Jianzhang Ni[5], Ningning Li[5], Zhixuan He[5], Yun-Kwok Wing[6], Emmanuel During[7]

[1] Icahn School of Medicine at Mount Sinai, [2] Technical University of Denmark, [3] Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, [4] University of Oxford, [5] The Chinese University of Hong Kong, [6] Li Chiu Kong Family Sleep Assessment Unit, Department of Psychiatry, Faculty of Medicine, The Chinese University of Hong Kong, [7] Mt Sinai

Introduction: Wrist-worn actigraphs have shown significant promise in detecting isolated REM sleep behavior disorder (iRBD). We previously developed a fully automated classifier for iRBD in the Stanford cohort using the AX-6 device (1-s epochs), which achieved a sensitivity of 95.2% and specificity of 85.7% by analyzing motion data during the sleep period. However, its generalizability across populations and other actigraphy devices remains unclear. Therefore, this study aimed to externally validate the Stanford iRBD classifier in the larger Hong Kong cohort using the Philips Actiwatch device (60-s epochs) (Actiwatch Spectrum Plus).

Methods: Eight healthy volunteers (28.4 ± 3.8 years, 62.5% female) were recruited to develop a conversion pipeline between Actiwatch and AX-6. They wore both devices continuously for three days on their nondominant hand. Activity counts were mapped from Actiwatch to AX-6 and optimized using linear and nonlinear regression models. The best mapping was evaluated using leave-one-out cross validation. The Stanford iRBD classifier was then applied to the Hong Kong dataset comprising 234 video-polysomnography confirmed iRBD patients and 123 control subjects. Olfactory function was assessed using an objective olfactory test on the subjects in Hong Kong dataset.

Results: We found strong correlations between the converted activity counts of Actiwatch (both linear and nonlinear) and AX-6 (ρ: 0.917–0.921). The linear regression model provided the best nighttime correlation of activity counts ($\rho = 0.833$) and the lowest mean absolute error in iRBD prediction scores. After conversion of the activity counts, the Stanford iRBD classifier achieved a sensitivity of 63.2%, a specificity of 90.2%, and an AUC of 0.86 in the Hong Kong cohort. Adding objective evidence of hyposmia to the actigraphy-based iRBD prediction reduced sensitivity to 46.5% (95% CI: 39.6%, 53.4%) but improved specificity to 99.0% (95% CI: 97.2%, 100%).

Conclusion: Our original iRBD classifier performed satisfactorily on a fully independent dataset with reduced sensitivity but increased specificity, despite the differences in both population and device used. This finding supports the generalizability of our iRBD classifier, which could serve as a useful screening tool for iRBD worldwide.

SLEEP HEALTH DISPARITY: FINDINGS FROM A RETROSPECTIVE ANALYSIS WITH ENGLISH- VERSUS SPANISH-SPEAKING OSA PATIENTS

Eloy Espinoza[1], Ravivarma Sagiraju[2], Matthew Zheng[3], Seung Kim[2], Joseph Ramzy[2]

[1] St Luke's University Healthcare Center, [2] St. Luke's University Health Network, [3] St Luke's University Healthcare Network

Introduction: Hispanics comprise the largest minority in the U.S., with a higher prevalence of obstructive sleep apnea (OSA). Social and sleep determinants of health in Hispanics, such as shift work, low income, and language barrier, increase the risk of poor health outcomes. Despite its clinical relevance, there is scant data on sleep health disparities in Spanish-speaking OSA patients, leaving a gap in the sleep research. This comparative study aimed to determine whether Spanish-speaking patients have higher rates of OSA, missed follow-up visits, and associated comorbidities, and to identify sleep health disparity while proposing mitigation efforts.
Methods: This single-center retrospective study was conducted on 200 patients who underwent polysomnography in 2022 at a large academic center in the U.S. The patients were categorized based on self-reported ethnicity and primary language.
Results: One hundred Spanish-speaking patients (SSP) (61 women, mean age 53.6, +/- 17.6 years, mean BMI 31.8 +/- 6.6) and 100 English-speaking patients (ESP) (47 women, mean age 53.4, +/- 17.8 years, mean BMI 35.9, +/- 8.4). OSA was diagnosed in 77 SSP and 72 ESP. The mean apnea-hypopnea index (AHI) was 19.0 +/-23.9 in SSP and 18.0 +/- 23.6 in ESP. SSP had significantly higher rates of OSA-associated comorbidities, including heart failure, hypertension, diabetes mellitus, and stroke (OR 0.424, 95% CI). Missed follow-up rates were markedly higher among SSP (65.2%) compared to ESP (34.8%) (OR 0.231). Among the Spanish-speaking patients (SSP), 29 had Medicare, 47 had Medicaid, and 24 had commercial insurance. Among the ESP, 26 had Medicare, 21 had Medicaid, and 53 had commercial insurance.
Conclusion: Spanish-speaking patients demonstrated worse OSA, worse follow-up rates, and higher OSA-related comorbidities compared to English-speaking patients. The observed disparities suggest that language barriers may significantly impact patient outcomes in obstructive sleep apnea, underscoring the importance of enhanced communication strategies to improve care for Spanish-speaking OSA patients.

IMPLEMENTABILITY OF A PERINATAL SLEEP CLINIC

Atena Gutierrez Chavez[1], Tiffany Xu[1], Mika Hirata[1], David Kalmbach[1], Philip Cheng[2], Christopher Drake[3], D'Angela Pitts[4]

[1] Henry Ford Sleep Research, [2] Henry Ford Health + Michigan State University Health Sciences, [3] Henry Ford Health System, [4] Department of Obstetrics and Gynecology, Henry Ford Health

Introduction: Sleep problems have been historically viewed as a normal feature of pregnancy, but a burgeoning literature highlights the high prevalence and morbidity of prenatal insomnia. Half of pregnant women report speaking to their prenatal care provider about their sleep problems. However, care access is severely limited as most health systems do not have clearly identified clinics in which prenatal insomnia is managed. In 2023, Henry Ford Health (HFH) implemented the Perinatal Sleep Clinic (PSC), a telemedicine clinic co-directed by a clinical psychologist and obstetrician. As pregnant women with sleep disorders are not routinely treated in the HFH sleep clinic or behavioral health clinic, the PSC was intended to address an unmet patient need. The present study evaluated the implementability of the PSC in a large health system.
Methods: ~10,000 live births occur annually at HFH. The PSC launched to treat pregnant women with insomnia. We reviewed electronic medical records to describe patient throughput from January 2023 through November 2024. We surveyed 53 stakeholders within and outside of HFH who had roles in health system leadership and/or clinical care in the areas of obstetrics-gynecology, maternal-fetal medicine, perinatal mental health, and/or sleep medicine. Surveys included the Acceptability of Intervention Measure (AIM), Intervention Appropriateness Measure (IAM), and Feasibility of Intervention Measure (FIM). Scale scores range from 1-5 with higher scores indicating more favorable implementation ratings.
Results: In 2 years, the PSC treated 110 pregnant women with insomnia. Among our surveyed stakeholders, 74.5% were employed by HFH. Stakeholders rated the PSC as highly acceptable (AIM: 4.52±.67), highly appropriate (IAM: 4.61±.57), and highly feasible at HFH (FIM: 4.23±.68). Additionally, stakeholders rated the clinic favorably for providing an unmet clinical need (4.65±.52) and providing an important clinical service (4.65±.59). Most stakeholders (82.4%) indicated that the clinic should be hybrid, offering both telemedicine and in-person care options.
Conclusion: As women increasingly seek help for their sleep during pregnancy, clinic resources must be made available for these patients. Leadership and provider stakeholders supported the acceptability, appropriateness, and feasibility of the PSC (ideally, as a hybrid clinic), thereby supporting its implementation in a large health system.

RECEIPT OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS AMONG RURAL PATIENTS WITH OBSTRUCTIVE SLEEP APNEA AND EXCESS WEIGHT

Aristotle Leonhard[1], Kevin Josey[2], Robert Plumley[3], Jason Castaneda[1], Mark Chee[1], Fernando Picazo[1], Sophia Hayes[1], Kevin Duan[4], Matthew Triplette[1], David Au[1], Laura Feemster[1], Lucas Donovan[1]

[1] Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, [2] Department of Biostatistics and Informatics, Colorado School of Public Health, [3] VA Puget Sound Healthcare System, Seattle Division, Health Services Research, [4] Division of Respiratory Medicine, University of British Columbia

Introduction: Patients living in rural areas have a greater burden of obstructive sleep apnea (OSA) and other weight-related comorbidities. Simultaneously, highly effective services for weight management (e.g., bariatric surgery) are resource intensive and limited to urban centers. New Glucagon-Like Peptide-1

Receptor Agonists (GLP-1RAs) are highly effective for weight loss, decrease OSA severity, and comprise a scalable solution to potentially meet the needs of rural areas. We aimed to test the association of rurality with the initiation of GLP-1RAs among patients with OSA and excess weight.
Methods: We used electronic health record data from the Veterans Health Administration to identify patients meeting the following criteria: 1) sleep study between October 1, 2017 and May 1, 2023, 2) diagnosis of OSA, 3) body mass index ≥ 27 kg/m2, and 4) participation in a lifestyle-based weight management program. We defined rurality by Rural Urban Commuting Area Codes, census tract-based codes that we collapsed into a binary variable of rural vs urban. The outcome was the receipt of a GLP-1RA approved for chronic weight loss (liraglutide, semaglutide, or tirzepatide) within one year of meeting inclusion criteria. We performed a mixed effects logistic regression accounting for patient and site level factors including demographics, comorbidities, and drive time to care.
Results: 68,862 patients met the inclusion criteria, and 17,929 (26.0%) lived in rural areas. Overall, 8.7% of patients living in rural areas received a GLP-1RA, relative to 7.8% of urban peers. However, after accounting for patient and site level confounders, patients living in rural areas had ~10% lower odds of receipt of a GLP-1RA (OR 0.91, 95%CI 0.83-0.98). This trend remained similar in sensitivity analyses which 1) stratify data by diabetes diagnoses and 2) considered receipt of other weight management medications.
Conclusion: Among patients with OSA and excess weight, after adjustment for confounding variables, those living in rural areas appear to be less likely to receive GLP-1RAs relative to urban peers. Gaps in the delivery of these promising medications may potentiate disparities in health-related outcomes. New strategies are needed to overcome barriers to the delivery of GLP-1RAs to patients with OSA and excess weight.

TIME OF DAY AND SUICIDE RISK SCREENING OUTCOMES IN VETERANS HEALTH ADMINISTRATION EMERGENCY DEPARTMENTS

Daniel Reis[1], Trisha Hostetter[1], Jeri Forster[1], Nazanin Bahraini[1]
[1] Rocky Mountain MIRECC for Veteran Suicide Prevention

Introduction: Nocturnal wakefulness is a risk factor for suicide. After adjusting for the proportion of the population awake at each given hour, Veterans are most likely to die by suicide between 12-3 am. It is unclear if self-reported suicidal thoughts and behaviors also follow such a daily rhythm in healthcare settings. The present study examined the relationship between time of day and positive suicide risk screens in emergency departments within the Veterans Health Administration (VHA).
Methods: This was an analysis of VHA medical record data from calendar year 2023. Responses on the Columbia-Suicide Severity Rating Scale (C-SSRS) screener were extracted for all veterans who completed their first screen of the year in a VHA emergency department. Risk of a positive suicide screen was modeled using Poisson regression with robust errors. Time of day was modeled using either cyclic b-splines and cosinor harmonic terms, with the model fit of the different approaches compared using the Bayesian Information Criterion.
Results: Data were available for 708,256 veterans, of whom 4,630 (0.7%) had a positive C-SSRS screen. Modeling time-of-day with cosinor harmonic terms (24-, 12-, and 8-hour harmonics) demonstrated better model fit than with cyclic b-splines (ΔBIC = -13.03). Risk of a positive C-SSRS screen was strongly associated with the time of day ($\chi 2$ = 429.4, df = 6, p <.001), with the lowest risk observed at 7:48 am (0.28%) and the highest risk observed at 1:30 am (1.02%; relative risk = 3.60).
Conclusion: Consistent with suicide rate data, risk of a positive suicide screen demonstrated a clear daily rhythm, with a nadir in the morning and a peak in the late nighttime. A steady rise in positive screening risk was observed from morning through night. These findings provide further support that nocturnal wakefulness is a risk factor for suicidal thoughts and behaviors. Addressing sleep difficulties among veterans may therefore help reduce suicide risk.
Support (if any): This study is based on work supported by the US Department of Veterans Affairs and the Rocky Mountain Mental Illness Research, Education, and Clinical Center

TECHNOLOGY-ENABLED SCREENING TARGETING OBSTRUCTIVE SLEEP APNEA (TEST-OSA) IN PRIMARY CARE OLDER PATIENTS

Minjee Kim[1], Han Luu[1], Guisselle Wismer[1], Andrew Cooper[1], Carolyn Hagler[1], Kenya Alcantara[1], Pooja Krishnan[2], Julia Benavente[1], Leah Welty[1], Kenzie Cameron[1], Jeffrey Linder[1], Phyllis Zee[1], Michael Wolf[1]
[1] Northwestern University Feinberg School of Medicine, [2] Northwestern University

Introduction: Undiagnosed obstructive Sleep Apnea (OSA) is prevalent among older adults and poses health risks. The feasibility and effectiveness of routine OSA screening in primary care remain underexplored.
Methods: We developed and pilot-tested an electronic health record (EHR)-embedded OSA screening strategy across 10 primary care clinics within a large health system (9/6/2023-6/30/2024). Patients aged 65+ without prior OSA diagnosis were invited to complete an OSA screener ('STOP') via patient portal before Medicare Annual Wellness Visits. Screening results and next-step recommendations were auto-populated in the EHR for clinician review. Fidelity data were extracted from EHR through 12/16/2024 to allow sleep study completion. Acceptability, feasibility, and implementation barriers were examined via semi-structured interviews (21 high-risk patients and 7 clinicians), supplemented by a clinician close-out survey.
Results: Of 1105 eligible patients, 48.1% (n=532; age 73.5±6.1; 49.4% female; 86.3% non-Hispanic White; BMI 27.3±5.2) completed the screener, with 30.1% (n=160/532) identified as high-risk for OSA. High-risk patients had higher BMI (28.2 [IQR 25.1-31.7] vs. 26.4 [23.6-29.2], p< 0.001) and more comorbidities (4 [3-6] vs. 3 [2-5], p< 0.001) than low-risk patients. Sleep studies were ordered for 35.6% (n=57/160) of high-risk patients, with 52.6% (30/57) completing them at a median of 60 days (range: 8-153). Clinicians reported consistently discussing screening results but cited patient refusal as the main barrier to ordering studies. Barriers for patients included limited awareness of OSA significance and misconceptions about diagnostic procedures and treatments. Among patients who completed sleep studies, 76.7% (n=23/30) received new diagnoses, including OSA (n=20 overall; n=10 moderate-to-severe), periodic limb movement disorder (n=4), and non-obstructive hypoxia (n=3). Treatment

recommendations included specialty referral (n=20), positive airway pressure therapy (n=13), and positional therapy (n=3). Overall, 14.4% of high-risk patients (n=23/160) and 4.3% of all screened patients (n=23/532) received new diagnoses prompting clinical intervention. Both clinicians and patients reported minimal burden from the process.
Conclusion: An EHR-integrated OSA screening strategy for older adults was feasible in primary care, diagnosing one OSA case per 27 patients screened. Future studies should focus on strategies to promote screening among non-portal users and to improve patient education about the health impacts, diagnostic procedures, and treatment options of OSA.

EFFECTS OF MORNING AND EVENING ACUTE EXERCISES ON OBJECTIVE SLEEP QUALITY AND NOCTURNAL BLOOD PRESSURE IN YOUNG MEN

Ryota Kobayashi[1], Hideyuki Negoro[2]
[1] Teikyo University of Science, [2] Brigham and Women's Hospital and Harvard Medical School

Introduction: Elevated blood pressure (BP) during sleep is an independent risk factor for cardiovascular disease (Kario et al., 2017). Although morning exercise has shown to improve sleep quality than evening exercise (Yamanaka et al., 2015), but the effects of acute morning and evening aerobic exercise on sleep quality and nocturnal BP have not been fully characterized. This study aimed to examine the effects of morning and evening acute aerobic exercises on sleep quality and nocturnal BP in healthy young men.
Methods: This randomized controlled crossover study included 15 young men (age; 24.4 ± 4 years, height; 172 ± 6 cm, weight; 63 ± 8 kg) who underwent three sessions; a morning acute exercise (ME) condition (cycling at 65% of preliminary heart rate for 30 min starting at 9:30 AM), an evening acute exercise (EE) condition (the same exercise as the ME condition starting at 5:30 PM), and a no exercise control (CON) condition. BP (oscillometric method), autonomic function (spectral analysis of heart rate variability), and sleep quality (zero-cross method) were assessed.
Results: Systolic BP, wake time after sleep onset, sleep efficiency during nighttime sleep, and frequency of nighttime sleep were lower in the ME condition than in the CON condition ($P < 0.05$), with no difference in the EE condition. The high-frequency component (parasympathetic activity index) of nocturnal sleep was higher in the ME condition than in the CON condition ($P < 0.05$), with no difference in the EE condition.
Conclusion: The findings suggest that acute morning aerobic exercise improves sleep quality, increases parasympathetic nervous system activity, and decreases nocturnal BP. The study results may help sustain the public's willingness to exercise in clinical settings to improve sleep quality and prevent hypertension.

WHAT INFLUENCES SLEEP STUDY COMPLETION AMONG PEOPLE WITH HIV IN CARE?

Zainab Al-Tameemi[1], Stephanie Ruderman[1], Vishesh Kapur[1], Heidi Crane[1]
[1] University of Washington

Introduction: People with HIV (PWH) face a substantially higher prevalence of obstructive sleep apnea (OSA) than the general population, with rates ranging from 20% to 70% in PWH compared to 9% to 38% in the general population. Fatigue, also highly prevalent in PWH, can be caused by OSA. Despite its high prevalence and potential impact on quality of life, OSA is underdiagnosed in PWH and sleep studies to diagnose OSA are underutilized. We investigated characteristics associated with sleep study performance among PWH engaged in care.
Methods: Demographic and clinical characteristics, comorbidities, and patient-reported outcomes (e.g., fatigue) were compared between PWH at Madison Clinic at the University of Washington who underwent sleep studies between 2008 and 2023 and those who did not. We used relative risk regression models to estimate associations between HIV factors (CD4 count and viral load) and fatigue and having received a sleep study, adjusted for demographic and clinical characteristics and comorbidities.
Results: Among 3,977 PWH, 165 (4%) completed a sleep study. Compared to those who did not receive sleep studies, PWH who underwent sleep studies were slightly older (mean age 50 vs. 48), had higher BMI, and better immunity, with higher mean CD4 cell counts (635 vs. 568) and greater HIV viral suppression (97% suppressed vs. 85%). PWH who received a sleep study had a greater prevalence of comorbidities such as diabetes (16% vs. 11%), dyslipidemia (41% vs. 27%), and hypertension (47% vs. 32%), as well as self-reported bothersome fatigue (79% vs. 55%). In adjusted models, we observed a 2.90-times (95% CI: 1.90-4.43) greater likelihood of having received a sleep study among PWH with bothersome fatigue, compared to those without.
Conclusion: We observed that PWH who received a sleep study had better HIV control (higher CD4 count and viral suppression), and a greater burden of fatigue and comorbidities often associated with OSA, than PWH who did not receive a sleep study. This suggests that healthcare providers and patients are more likely to prioritize evaluation of OSA in this context

IMPROVING ACCESS TO NIGHTMARE THERAPY: A QI INITIATIVE FOR VETERANS

Lefulesele Kholoane[1], Roberta Jacobs[2], Nichole Mogharreban[2], Yihan Li[2], Elizabeth Parsons[2]
[1] University of Washington, [2] VA Puget Sound Healthcare System

Introduction: One in ten US Veterans endorse trauma-related nightmares in their lifetime. Imagery rehearsal therapy is an effective and time-efficient therapy which is not widely accessible. We sought to evaluate if a group format could improve access to treatment.
Methods: This quality improvement project utilized Plan-Do-Study-Act methodology to evaluate impact on access to care by creating a group format for narrative-enhanced imagery rehearsal therapy (N-IRT). Retrospective review of administrative data identified trends in wait times and clinic utilization. To explore contributors to low group utilization, we performed a secondary root-cause analysis using stakeholder brainstorming sessions and chart review.
Results: N-IRT group was first offered in July 2023. In January 2024, we revised our triage workflow, including N-IRT group eligibility criteria, to encourage group enrollment and improve wait times for individual appointments. After these updates, wait time

for an individual sleep psychologist appointment decreased from 79.3 days in January 2024 to 28.9 days by March 2024. Between January and October 2024, median N-IRT group size was 3 patients. We achieved our target of 4+ patients enrolled in N-IRT group for 5 out of 10 months (50%). Between 09/01/24-10/31/2024, 20 referrals for N-IRT were received, yet only 4 patients (20%) attended N-IRT group. Of the sixteen patients who did not attend N-IRT group, 5 had scheduling issues and 11 were excluded at nurse triage. Nurse triage notes cited a variety of reasons for exclusion from group, including patient preference for individual care (N=3), request for multiple services (N=2), pending sleep medicine evaluation (N=2), medical complexity (N=1), inability to reach the patient (N=2), or lack of dream recall (N=1).
Conclusion: Multiple interventions were necessary to achieve target wait times for nightmare therapy. Barriers to group-based nightmare therapy included scheduling issues, medical complexity/contraindications, and patient preference for individual care. Tackling these barriers will likely require a multifactorial approach that includes patient and referring provider education.
Support (if any): This non-research operations project was conducted in accordance with VHA Program Guide 1200.21. The views expressed are solely those of the authors and do not represent the views of the US Department of Veterans Affairs or the US Government.

SLEEP AND PILLOWS: A NEW APPROACH TO IMPROVE NECK PAIN WITH SOMATIC SYMPTOMS USING STRICTLY ADJUSTED-HEIGHT PILLOWS

SHUORI YAMADA[1], TOHRU HOSHI[2], Michio Toda[3], Takahiro Tsuge[4], Kokoro Yamada[5], Ko Matsudaira[6], Hiroyuki Oka[6]
[1] 16 Go Orthopaedic Clinic, [2] Tokyo University of Technology, [3] Department of Orthopaedic Surgery, Kurashiki Medical Center, [4] Department of Rehabilitation, Kurashiki Medical Center, [5] The University of California San Diego, [6] Department of Medical Research and Management for Musculoskeletal Pain, 22nd Century Medical & Research Center, Faculty of Medicine, The University of Tokyo

Introduction: Neck pain causes significant negative physical and psychological effects and has a high prevalence worldwide. Cervical spine alignment is strongly associated with neck pain. It is suggested that improper pillow usage induces neck pain during sleep and awakeness and poor sleep quality by changing cervical spine alignment. Some orthopedic surgeons research the relationship between cervical alignment and pillows but have not determined the best requirements of pillows, such as materials, height, and shape, to improve neck pain and sleep. This study tries to longitudinally analyze whether strictly adjusted-height pillows improve clinical outcomes including neck pain and somatic symptoms assessed by the SSS-8. Moreover, we identify any factors related to neck pain improvement and treatment satisfaction.
Methods: A total of 84 participants with chief complaints of neck pain with somatic symptoms were evaluated using the numerical rating scale (NRS) and the Somatic Symptom Scale-8 (SSS-8). The SSS-8 is a self-administered questionnaire to assess the levels of somatic symptoms such as stomach or bowel problems, back pain, pain in the limbs or joints, headaches, chest pain or shortness of breath, dizziness, feeling tired or having low energy, and having trouble sleeping. We adjusted the height of customized pillows to fit each individual patient by millimeters using the SSS-Method and collected data at the baseline, after two weeks, and after three months. The SSS-Method determines only one optimal pillow height common to the three positions, supine, lateral, and turning over.
Results: Forty-two participants (50%) achieved the minimal clinically important difference for neck pain with a decrease of three points or higher in the NRS. The baseline neck pain scores were significantly higher in the group that achieved the minimal clinically important difference. The three-month change in the NRS and SSS-8 was significantly greater in participants who were satisfied with treatment. A significant positive association existed between improvement in the NRS and the SSS-8 at three months.
Conclusion: Strictly adjusted-height pillows using the SSS method significantly improved both physical neck pain and somatic symptoms. Adjusting pillow height for individuals is a potentially important requirement of pillow parameters.

ADDRESSING OSA CARE IN RURAL COMMUNITIES: DEVELOPMENT OF THE WEST VIRGINIA OSA ACADEMIC MENTORING PARTNERSHIP

Robert Stansbury[1], Nicole Stout[2], Toni rudisill[3], Judith Feinberg[3], Geri Dino[3], Sunil Sharma[3], Edward Rojas[3], Patrick Strollo[4]
[1] West Virginia University School of Medicine, [2] American Cancer Society, [3] West Virginia University, [4] Department of Medicine, University of Pittsburgh Medical Center

Introduction: This study used implementation science and community engaged research methods to address a significant care gap for obstructive sleep apnea (OSA) in West Virginia (WV). To this end, we designed an intervention to support primary care providers (PCPs) who treat patients in rural WV. Our overall project is grounded in context-sensitive approaches to address the unique challenges of OSA management in the rural primary care setting. Here we describe the pre-implementation work that identified the determinants of implementation in rural settings and the selection of strategies that led to the initial program; these strategies will inform our prospective implementation effectiveness study.
Methods: We used the VA Quality and Enhancement and Research Initiative (QUERI) Implementation Roadmap to inform program development. Barriers and facilitators identified in our previous research were mapped to the domains of the Consolidated Framework for Implementation Research (CFIR) to inform our implementation plan. We derived Expert Recommendations for Implementing Change (ERIC) strategies from the CFIR mapping exercise to identify the strategies that would improve implementation outcomes in rural primary care.
Results: Themes identified from our previous mixed methods community engagement study with PCPs were reviewed and mapped to CFIR domains and coded as implementation barriers or facilitators. Based on this work we identified ERIC strategies that were most likely to facilitate implementation of our intervention. The implementation strategy category identified as most important for the OSA care program implementation was "Develop stakeholder interrelationships." Other important

strategy categories included "Provide interactive assistance" and "Support for clinicians" in the targeted rural communities.
Conclusion: Leveraging a community-engaged approach and using implementation science informed the development of a novel program to support PCPs in OSA management that is tailored to the realities of rural primary care. This program, the West Virginia Obstructive Sleep Apnea Academic Mentoring Partnership (WV OSA AMP), is well-positioned to address the care disparity for OSA in rural communities in a sustainable way. More information on WV OSA AMP is available at: https://wvrha.org/wvosaamp/.
Support (if any): NIH K23 HL161437-0A1. This study was also funded but an AASM Foundation Strategic Grant (SR2332), but funding was declined by the PI due to overlap with NIH grant.

INITIAL IMPLEMENTATION OUTCOMES OF THE WEST VIRGINIA OBSTRUCTIVE SLEEP APNEA ACADEMIC MENTORING PARTNERSHIP

Robert Stansbury[1], Toni rudisill[2], Judith Feinberg[2], Nicole Stout[3], Sunil Sharma[2], Geri Dino[2], Edward Rojas[2], Patrick Strollo[4]
[1] West Virginia University School of Medicine, [2] West Virginia University, [3] American Cancer Society, [4] Department of Medicine, University of Pittsburgh Medical Center

Introduction: There is a critical need to create sustainable interventions for the nearly 80% of patients with undiagnosed obstructive sleep apnea (OSA), particularly in rural communities where notable health disparities exist. The West Virginia OSA Academic Mentoring Partnership (WV OSA AMP) was developed to address this care gap and sustainably engage rural primary care providers in the management of OSA. This study analyzed acceptability and feasibility outcomes from the initial cohort of providers enrolled in WV OSA AMP.
Methods: WV OSA AMP was developed from implementation science/community engagement methodologies utilizing the VA Quality Enhancement Initiative to develop a roadmap for implementation of the training and support intervention. This study assessed initial feasibility and acceptability outcomes of the WV OSA AMP based on post-training questionnaires. The Feasibility of Implementation Measure (FIM) and the Acceptability of Implementation Measure (AIM) are validated measures that use a 5-point Likert scale to assess agreement across participant perspectives on the feasibility and acceptability of the program.
Results: Of the 14 participants, seven have completed the post training surveys. Analysis of the AIM revealed an average score of 4.7 out of 5 across all domains. No respondents disagreed or completely disagreed with items relating to the acceptability of the intervention. Analysis of the FIM revealed an average score of 4.7 in the domains of: 1) the intervention seems implementable, 2) the intervention seems possible, and 3) the intervention seems doable. An average score of 4.6 was recorded in the domain 'this intervention seems easy to use'.
Conclusion: Our results demonstrate high levels of acceptability and feasibility in the initial cohort of WV OSA AMP participants. These findings support the notion that community engagement and implementation science can lead to effective programs that address care disparity for sleep disorders in disadvantaged areas. The next WV OSA AMP sessions are scheduled for January 30 and April 30, 2025. We plan to repeat these assessments and be able to analyze outcomes in a larger sample. We will also perform a qualitative analysis of semi-structured interviews with participants.
Support (if any): Supported by NIH K23 HL161437-0A1. AASM Foundation (SR2332) funded, declined by PI due to overlap.

LINKING ELECTRONIC HEALTH RECORD METRICS TO PATIENT-REPORTED SLEEP QUALITY IN HOSPITAL SETTINGS: A NOVEL APPROACH

Sullafa Kadura[1], Lisa Pink[1], Samia Lopa[2], Diego Mazzotti[3], Gevher Karboga[1], Wilfred Pigeon[1]
[1] University of Rochester Medical Center, [2] University of Rochester, [3] University of Kansas Medical Center

Introduction: Sleep disruptions are common in hospitalized patients, often caused by patient-staff interactions (PSIs) like vital sign checks and testing. While outpatient sleep is commonly assessed using polysomnography and patient-reported outcomes (PROs), these methods are impractical in inpatient settings. Consequently, inpatient sleep disturbances are typically inferred rather than directly measured. To address this gap, we developed two electronic health record (EHR)-derived metrics—the longest uninterrupted sleep opportunity (LUSO) and interruptive episodes—to quantify sleep disruptions from PSIs. This study evaluates whether these metrics correlate with sleep PROs.
Methods: Sleep PROs were obtained via the Consensus Sleep Diary and the Potential Hospital Sleep Disruptions and Noises Questionnaire for 247 inpatient nights from a neurology unit (April 2021–October 2022). Using established methods, we calculated LUSO and interruptive episode counts for each surveyed night. Associations between EHR-derived metrics and PROs were analyzed using univariate and multivariable models, adjusting for age, gender, and race.
Results: Longer LUSO was associated with fewer patient-reported disruptions from medical interventions ($\beta=-0.16$, 95% CI: −0.24, −0.09, $p< 0.0001$) and increased total sleep time (TST; $\beta=18.28$ minutes, 95% CI: 7.19, 29.37, $p=0.001$). Higher interruptive episode counts were associated with greater perceived disruptions ($\beta=0.18$, 95% CI: 0.10, 0.27, $p< 0.0001$) and shorter TST ($\beta=-23.10$ minutes, 95% CI: −36.00, −10.50, $p=0.0004$). Multivariate analysis confirmed these associations, with longer LUSO linked to lower perceived disruptions ($\beta=-0.19$, 95% CI: −0.29, −0.10, $p=0.008$) and higher episode counts linked to greater disruptions ($\beta=0.21$, 95% CI: 0.09, 0.32, $p=0.003$). A trend toward greater patient-reported medical disruption was observed among stroke patients ($\beta=0.50$, 95% CI: −0.01, 1.01, $p=0.054$). However, the association between episode count and patient-reported medical interventions did not differ significantly between stroke and non-stroke patients.
Conclusion: EHR-derived metrics, LUSO, and interruptive episodes are significantly associated with sleep PROs, suggesting their potential as proxies for inpatient sleep quality. Additionally, a trend toward greater perceived medical disruption was observed among stroke patients, though the association between LUSO and interruptive episodes did not differ by stroke status. These findings underscore the need for targeted strategies to address vulnerable populations, such as stroke patients.

DOES SLEEP QUALITY AND DURATION HAVE ANY EFFECT ON THE RECOVERY OF HOSPITALIZED PATIENTS- USING THE NHANES DATA SET

Sneha Ottra[1], Mark Kelley[1]
[1] LECOM

Introduction: This study aims to explore the relationship between sleep quality and duration and the recovery outcomes of hospitalized patients. Data was sourced from the National Health and Nutrition Examination Survey (NHANES) for the years 2005-2020.
Methods: Seven NHANES datasets(2005-2006, 2007-2008, 2009-2010, 2011-2012, 2013-2014, 2015-2016, and 2017-2020) were compiled, focusing on sleep disorders, hospital utilization, medical conditions, body measures, and demographics. The data was pre-processed using Python, filtering study IDs to ensure consistency across datasets. The final dataset included 931 rows and 19 columns after excluding incomplete responses and focusing on patients with overnight hospital stays. Recovery was defined as a binary variable based on self-reported general health condition, categorized as "Recovered" (Good, Very Good, Excellent) or "Not Recovered" (Poor, Fair).
Results: Logistic regression was employed to assess the impact of average sleep duration on recovery. An initial model using only sleep duration as the predictor showed an accuracy of 56.68%. A more comprehensive model incorporating additional variables (e.g., sleep quality, number of hospital nights, age, ethnicity) improved accuracy to 66.31%. However, this model exhibited a high false positive rate, indicating it often incorrectly predicted recovery. The model's sensitivity (true positive rate) was 86.8%, accurately predicting recovery in 86.8% of cases within the test data. Specificity (true negative rate) was 39.5%, indicating a high rate of false positives. Key predictors identified through recursive feature elimination included sleep quality, number of hospital nights, age, and ethnicity. Average sleep duration did not significantly impact recovery ($p = 0.66$).
Conclusion: The study found that while sleep quality and certain demographic factors significantly influence recovery, average sleep duration alone is not a strong predictor. The logistic regression model requires further refinement to reduce false positives and improve specificity before it can be effectively used in clinical practice.

TEN-YEARS' HEALTH CARE UTILIZATIONS DUE TO OBESITY HYPOVENTILATION SYNDROME AMONG HIGH-RISK MORTALITY IN U.S. HOSPITALS

Yonsu Kim[1], Younghoon Kwon[2], Yelim Cho[3], Hayden Leung[4], Ji Yoo[4]
[1] School of Public Health, University of Nevada, Las Vegas, [2] University of Washington, [3] VA Puget Sound Health Care System, [4] Kirk Kerkorian School of Medicine at UNLV

Introduction: Only the top 5% of health-care utilizations account for 60% of health-care expenditures in the U.S., with most costs occurring in the last year of life from hospital inpatient services for example, obesity hypoventilation syndrome (OHS). This study aims at examining (1) health care utilization trends among OHS admission with high-risk mortality group and (2) associated factors of health care utilizations over the past decade.
Methods: This was a retrospective study that analyzed the National Inpatient Sample between 2012 and 2021. Adults 18+ years with OHS and high-risk mortality were identified. OHS was defined as International Classification of Diseases, 9th/10th revisions. High-risk mortality was defined as the All-Patient Refined Diagnosis-Related Group (APR-DRG) Risk of Mortality ("rating of 3-4 subclasses). Total charges were the main measurement of health care utilizations and were adjusted by applying for the Consumer Price Index (CPI) rate since 2012. We performed multivariate regression analyses by treating total charges as a dependent variable, respectively as well as year as an independent variable.
Results: A total of 279,067 hospital admissions were identified. Rate of OHS with high-risk mortality per total 100,000 hospital admissions were increased from 960.4 in 2012 to 1,445.7 in 2021 ($p < .001$). Although mean hospital LOS had been shorter from 11.8 days in 2012 to 7.4 days, mean total charges had been remarkably uptrends from $65,846.0 in 2012 to $118,121.39 in 2021. Younger age (estimate $191.3 per year-old), more severe APR-DRG (estimate $32,720.1), Hispanics ($20,877.7) compared to Whites, private insurance holder ($6,959.4) compared to government insurance holder, and prolonged hospital length of stay (estimate $9,549.6 per day), and year 2021 (estimate $30,205.5) compared to year 2012 were associated with higher total charges (all $p < .001$; R-square 0.43; coefficient variance 124.3).
Conclusion: Health care utilizations of hospital care for OHS with high-risk mortality are uptrends along with more frequent hospital admission encounters. Workforce education for non-sleep special professionals is urgently warranted to advance quality and efficiency of care. Especially, health care professionals serving racial and ethnic minorities are prioritized to enhance their competencies of managing OHS individuals with high-risk mortality.

SUSTAINED USE AND PERCEIVED BENEFITS OF THE CBT FOR NIGHTMARES TRAINING PROGRAM AMONG VHA PROVIDERS

Jessica Carlile[1], Shilpa Trivedi[2], Joanne Davis[3], Courtney Bolstad[4], Katherine Miller[5]
[1] VA Pittsburgh Healthcare System, [2] Veterans Integrated Service Network [19] Clinical Resource Hub, [3] University of Tulsa, [4] Birmingham VA Health Care System, [5] Minneapolis VA Health Care System

Introduction: Chronic nightmares significantly impact Veterans' sleep, trauma symptoms, and quality of life. Training and consultation in Cognitive Behavioral Therapy for Nightmares (CBT-N) were introduced within the United States Veterans Health Administration (VHA) to mitigate Veterans' nightmare severity and to improve overall functioning. This study aims to determine the long-term viability of the CBT-N training program within VHA by evaluating the trained providers' sustained delivery of CBT-N, along with their perceptions of benefits and barriers to implementation.

Methods: An online survey was administered to VHA providers (N = 100) who had completed the CBT-N training program at least six months prior to the study. The survey assessed providers' continued use of CBT-N, perceptions of its clinical impact, and barriers to implementation. A response rate of 65% was achieved, with quantitative and qualitative responses analyzed to identify trends and themes.
Results: Ninety-five percent of providers reported continued delivery of CBT-N, and 100% indicated intent to use it in the future. Providers reported overall positive perceptions of CBT-N's effectiveness, with improvements noted in Veterans' nightmare frequency and/or severity, and related domains, including sleep health, trauma symptoms, and quality of life. A quarter of providers identified no barriers to use. Reported barriers stemmed primarily from facility-related constraints (e.g., session length/frequency issues, patient population appropriateness) and Veteran-related factors (e.g., scheduling conflicts, Veterans' shared decision-making preferences).
Conclusion: CBT-N training within the VHA demonstrates high rates of sustained use and generally positive provider perceptions of its clinical impact. Barriers related to inner facility settings and Veteran-specific factors highlight the need for adaptive strategies to optimize implementation while maintaining treatment fidelity. Recommendations include tailoring session protocols to fit facility constraints and enhancing training to address shared decision-making scenarios. Tracking direct Veteran outcomes and refining implementation supports could further expand the reach and impact of the CBT-N training program.
Support (if any): Time for this research was supported in part by the US Department of Veterans Affairs, Veterans Health Administration, Clinical Research and Development Service-IK2CX001874-PI: Katherine Miller.

INFLUENCE OF SOCIAL MEDIA ON PROMOTING HEALTHY SCHOOL HOURS FOR ADOLESCENTS

Chloe Conner[1], Ethan O'Neill[1], Madelyn Beckett[1], Paola Pascual-Ferra[1], Terra Ziporyn[2], Amy Wolfson[1]
[1] Loyola University Maryland, [2] Start School Later

Introduction: Misaligned sleep-wake schedules in adolescents, largely due to inappropriately early school start times, are associated with significant consequences including attention problems, mental health symptoms, and motor vehicle crashes. To date, however, most U.S. secondary schools still start before 8:30 a.m., and only California and Florida have enacted legislation to ensure developmentally appropriate school start times. Social media's potential to shape public opinion and influence policy decisions (Ausat, 2023) led us to use frame analysis (Entman, 1993) to examine social media discourse surrounding adolescent sleep health and to compare use of anecdotal and scientific evidence (Borgida & Nisbett, 1977).
Methods: We reviewed 395 social media posts across 6 social media platforms (i.e., Facebook, Instagram, TikTok, X/Twitter, YouTube, and LinkedIn) using key words such as "school start time" and "later school start." A coding scheme was developed to include basic social media analytics, identity of the post creator, and whether the content included anecdotal and/or scientific evidence. For the frame analysis, coders looked for posts concerning impact on student health, student learning, teachers, safety, economics, transportation, extracurriculars, and/or other topics. Coders were trained to ensure inter-rater reliability (κ =.62).
Results: Over half the posts (59%) were from accounts owned by news organizations or media professionals (i.e., journalists, podcasters, or bloggers), followed by celebrities or influencers (9%). While 62% of posts suggested support for starting school later, 24% explicitly supported and 4% explicitly opposed it. Impact on students' health (69%) and learning (45%) were the frames most frequently employed by post creators. Nearly a quarter (24%) of posts used anecdotal evidence, 33% included a scientific explanation (however brief), and 31% cited or included a link to a research study.
Conclusion: Social media analysis can be a powerful tool to understand public discourse surrounding adolescent sleep health, including who is driving the conversation, what frames are being used, and types of evidence presented. Sleep scientists and clinicians might similarly use social media to play a larger role in educating the public and influencing public opinion regarding adolescent sleep health and healthy school hours.

IMPROVING EFFICIENCY OF HOME SLEEP APNEA TESTING PATHWAY TO ENHANCE ACCESS AND SLEEP CARE DELIVERY

Norah Aung[1], Aumi Brahmbhatt[1], Lauren Frigge[2], Paul Seim[2], Robert Meister[2], Matthew Murphy[2], Steven Baller[2], Muna Irfan[2]
[1] Hennepin Health Care/ Va Minneapolis, [2] Va Minneapolis

Introduction: A high volume of sleep apnea referrals requiring home sleep apnea studies (HSAT) can result in significant operational expenses, creating a need to explore cost-effective solutions. Due to disproportionate resources, some patients were diverted to external facilities in community clinics. In the context of understaffing, increased expenditure, and the high volume of need for HSATs, it was essential to streamline the process of timely delivery of HSTs.
Methods: Baseline data for HSAT completion time and cost spent on external HSAT was obtained over one quarter of the Fiscal year. A process of vendor-based distribution & delivery service of the HSAT was created and implemented. Post-intervention data collection was done after the subsequent quarter.
Results: The total cost of completing external HSATs in the pre-intervention quarter was $463,708.55, which included expense of community HSAT referrals of $391,253, and overtime for processing HSATs of $15,741.44. With the vendor-based distribution of HSATs to patients in the next quarter, the total cost was reduced to $57,884 solely for community HSAT referrals. In addition to this, the wait time for patients to complete an HST was reduced from 6-8 months to 4-6 weeks, despite the same FTE resources in the sleep clinic. The process resulted in a reduction of the cost and burden of time on staff members, to fulfill the need of high-volume testing without compromising quality. The improved work process helped the Registered Polysomnographic Technologists/ Respiratory Therapists focus on sleep patients' clinical needs.
Conclusion: The implementation of vendor-based delivery for home sleep apnea testing studies can significantly enhance patient care and operational efficiency by reducing costs spent on external testing, sleep testing time, free clinical staff time, and expediting the delivery of care and ultimately the sleep for our patients. This QI project demonstrates the operational advantage of implementation of a vendor-based HSAT distribution model resulting in reduced expense, faster turnaround times, and improved resource allocation.

A MAIL-BASED CAMPAIGN TO PROMOTE DIGITAL CBT-I AMONG VETERANS IN RURAL AREAS WITH COMORBIDITIES

Adam Bramoweth[1], Faith Luyster[2], Caroline Hough[1], Monique Boudreaux-Kelly[1], Jennifer McCoy[1]

[1] VA Pittsburgh Healthcare System, [2] University of Pittsburgh School of Nursing

Introduction: Insomnia is common among Veterans, and Insomnia Coach, a Veterans Affairs (VA)-developed mobile app for cognitive behavioral therapy for insomnia (CBT-I), may be useful for Veterans with limited access to provider-delivered care. Increasing awareness of Insomnia Coach could improve access among Veterans most vulnerable to care inequities. This project aimed to evaluate the impact of a mail-based campaign to inform Veterans about Insomnia Coach, with targeted outreach to Veterans with insomnia living in rural areas and with comorbid psychiatric and medical comorbidities.
Methods: Using the VA Corporate Data Warehouse, we identified VA Medical Centers (VAMCs) with high proportions of Veterans living in rural areas. In collaboration with the VA Office of Connected Care, we also identified VAMCs with active Virtual Health Resource Centers, which were established to assist Veterans to successfully engage in telehealth services. For participating VAMCs, letters introducing Insomnia Coach and containing a unique access code were sent to eligible Veterans with insomnia (based on ICD-10 codes and/or prescription sleep medications), depression, COPD and/or asthma, and no engagement with CBT-I in the past year.
Results: Thirteen VAMCs were identified as serving a high proportion of Veterans living in rural areas and having an active Virtual Health Resource Center. Of those, seven VAMCs (54%) agreed to participate in the project and have letters sent to eligible Veterans (n=4,903). Letters were mailed to Veterans from May through December 2024. Seventy-two Veterans (1.7%) used their their unique code to activate and access the Insomnia Coach mobile app. At each of the seven sites, Veterans accessing the Insomnia Coach app ranged from 1% to 3%.
Conclusion: A mail-based approach to inform Veterans with insomnia and comorbid disorders and with potentially inequitable access to care resulted in minimal use of Insomnia Coach, an evidence-based CBT-I mobile app. However, still to be determined is the potential impact of our approach resulting in Veterans seeking other care options, including provider-delivered CBT-I. While Insomnia Coach use was low, this project will help inform future pragmatic approaches to inform Veterans about insomnia-related care and improve engagement.

AWAKENING THE SLEEPING GIANT: A PROCESS-BASED MODEL FOR SLEEP CARE COORDINATION AT A PEDIATRIC HEALTHCARE SYSTEM

Ariana Calloway[1], Maninder Kalra[2], Mattina Davenport[1]

[1] Nationwide Children's Hospital, [2] Division of Pulmonary and Sleep Medicine, Nationwide Children's Hospital

Introduction: With growing pediatric sleep inequities, it is essential that pediatric healthcare systems optimize sleep care through a system-wide, collaborative, and integrated approach across various programs and departments. Our commUNITY SLEEP Initiative (CSI) aimed to asset map the sleep care continuum – encompassing awareness, screening, referral, and management- to better understand how community-based programs and healthcare clinics intersect system-wide and identify opportunities for quality improvement.
Methods: CSI is designed to foster greater awareness of roles and responsibilities, close existing sleep care gaps, and develop a comprehensive process-based model for sleep care coordination (SCC) that ensures cohesive patient-centered care delivery. Information was gathered through unstructured interviews with clinic and program leadership knowledgeable about how sleep currently fits into their routine practice. An email was sent to departments to identify the appropriate contacts. During unstructured interviews, notes were taken on clinic activities.
Results: During unstructured interviews, notes were taken on clinic activities: sleep documentation in EPIC, screening tools, and clinic specific steps for managing identified patients' sleep problems and disordered sleep (e.g. referrals, provision of sleep resources or brief education, and direct intervention). Unstructured interviews identified key barriers and opportunities for enhancing SCC across the spectrum of clinics (e.g., specialty clinics; inpatient; primary care settings) and community-based programs (e.g., community well; school-based health). Discussions helped assess each department's role within the sleep care continuum and revealed system-wide quality improvement opportunities for SCC. There is a need for Targeted Universalism framework to apply both universal (e.g., universal dissemination of family sleep health awareness content; interprofessional education on sleep health) and targeted (e.g., culturally responsive and trauma informed adaptations; target sleep care navigation support to underserved patient populations). Following review and approval by the Sleep Center Director, a system-wide visual summary of the sleep care continuum and relevant SCC resources (e.g., sleep care navigators; inpatient sleep consultant) were shared with departmental leaders.
Conclusion: Addressing these barriers and opportunities through a more integrated, system-wide approach to SCC can enhance patient outcomes. Improving screening, referrals, and management of sleep problems and disordered sleep, and leveraging interdisciplinary resources will improve the accessibility, quality, and impact of SCC across departments.

EXPEDITING CARE FOR NONSURGICAL PEDIATRIC PATIENTS IN A LARGE HEALTHCARE SYSTEM: A QUALITY IMPROVEMENT PROJECT

Lacie Petitto[1], Anna Messner[1], Ramanveer Virk[1], Jinae Spear[1], DeLise Rhea[1], Jessica Ginn[1], Binal Kancherla[1], Kristin Becker[1], Susan Thomas[1]

[1] Texas Children's Hospital

Introduction: Sleep services are increasing in demand resulting in expansion of pediatric sleep programs. With the decline in number of board-certified sleep physicians, programs are utilizing advanced practice providers (APPs) to bridge this gap. Conducting more diagnostic polysomnography has led to more

children being identified with obstructive sleep apnea (OSA). Otolaryngology surgical intervention is the first line of therapy; however, if surgery is not indicated or if those children have postoperative residual OSA, positive airway pressure (PAP) therapy is warranted. Timely care with PAP therapy is essential to prevent negative clinical consequences. Currently, there is no literature describing workflow initiatives to promote access to PAP therapy initiation while utilizing APPs in the pediatric population. Objectives: 1. Report access challenges to sleep appointments for initiation of PAP therapy; 2. Describe workflow processes to increase access for referring otolaryngologists; 3: Summarize access outcomes and patient satisfaction rates
Methods: Narrative review of the workflow processes. Retrospective review of sleep clinic referrals, third next available appointment (TNAA) data, and clinician Press Ganey scores.
Results: Our pediatric sleep center conducts 23 sleep studies per night and the healthcare provider team consists of 11 physicians and 5 APPs. From 2022 to 2023, otolaryngologists submitted 247 sleep clinic referrals (~ 5/week) for management of OSA after it was determined that surgery was not indicated. Average wait time from referral to scheduled visit was 72 days in April 2024. In October, 1 appointment per week was reserved with each APP for otolaryngologists to schedule patients who need PAP initiation. Preliminary results conclude that wait times for PAP initiation decreased from 72 to 16 days (-56 days). Press Ganey overall APP provider top box scores were 88 with a high likelihood of recommending care (top box: 92). No safety concerns related to APP care delivery have been identified during performance evaluations.
Conclusion: We identify strategies using scheduling metrics and APPs to meet the demand and expedite care for children with OSA needing PAP. APPs additionally provide safe and high-quality care. Institutions facing barriers to access should consider restructuring clinic schedules while utilizing APPS to ensure timely treatment of OSA in pediatric patients.

HARNESSING AI TO BETTER UNDERSTAND PATIENT PERSPECTIVES ON THE ROLE OF THE HEALTHCARE PROVIDER IN PAP THERAPY

Shuying Yu[1], Vy Vuong[1], Meredith Barrett[1], Kimberly Sterling[1], Leanne Kaye[1]
[1] ResMed Science Center

Introduction: In obstructive sleep apnea (OSA), adherence to positive airway pressure (PAP) therapy is influenced by many factors, including the relationship between patients and their healthcare provider (HCP). Exploring patient perspectives on the facilitators and barriers to initiating and persisting with PAP therapy may help inform PAP promotion strategies.
Methods: Adult PAP therapy users (aged 18+; ResMed, San Diego) living with OSA were invited to participate in a one-time survey regarding their therapy experience and behaviors. Two open-ended questions asked about the user's pathway to diagnosis, and opportunities to improve the PAP therapy experience. Guided by an inductive-deductive thematic approach, de-identified qualitative responses were analyzed using a large language model (Enterprise ChatGPT) to better understand PAP users' interactions and experience with their HCPs. Prompt engineering was employed to optimize classification performance. All task outputs (theme identification) were reviewed by two researchers to ensure contextual relevance and accuracy. Redundant subthemes were collapsed into appropriate parent themes, and irrelevant content removed.
Results: Responses from 2,145 PAP therapy users were considered for analyses, with 98 respondents (4.6%) commenting on the HCP experience (mean (SD) age: 63 (12) years, 62% male). Fourteen sub-themes emerged which were then grouped into three main categories: 1) deepening HCP knowledge of OSA presentation, 2) addressing gaps in care, and 3) patient-centric needs. Respondents sought greater OSA awareness among their HCPs, articulated in responses around early identification of OSA signs and symptoms in order to shorten prolonged diagnostic pathways, sometimes spanning years. Responses also highlighted the need to better understand gender-specific differences in symptom presentation. Gaps in care highlighted user desire for better care coordination between specialists and primary care providers, improved follow-up after formal diagnosis and initiation of therapy, and more resources on therapy options. Finally, patient-centric needs included patient-first information on early symptom identification, and greater HCP empathy related to therapy challenges following diagnosis.
Conclusion: Building awareness around OSA symptoms (including gender-specific symptoms), care coordination, and patient-centered support, may help streamline OSA diagnosis, improve therapy outcomes, and enhance patient experiences. Leveraging AI-informed models to better understand user experience may further refine PAP promotion strategies.

IMPLEMENTATION OF BSM ORIENTATION GROUP AND CONTINUED CLINIC EFFICIENCY

Jessica Calgav[1], Sarah Kate McGowan[2], Austin Grinberg[2], Jennifer Martin[3], Monica Kelly[4]
[1] VA Greater Los Angeles HealthCare System, [2] Department of Mental Health, VA Greater Los Angeles, [3] VA Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare System, [4] VA Geriatric Research, Education and Clinical Center, VA Greater Los Angeles Healthcare System

Introduction: High rates of sleep disorders in Veterans increases demand for behavioral sleep medicine (BSM) services and clinical efficiency is essential to improving access to care. An ongoing quality improvement project assessing the utility of a clinic orientation group reduced intake no-show rates within a large Department of Veterans Affairs (VA) BSM clinic and revealed that some Veterans declined services after learning more about the treatment offerings. The goal of this analysis was to see if time from consult placed to time of formal diagnostic assessment (wait time) has decreased since implementing the orientation group.
Methods: Data were collected using electronic medical record review and included demographic information about Veterans seeking BSM services, dates of consults placed, and dates consults were completed. A t-test was conducted to compare wait times from one year prior to the orientation group versus during the 2nd year of group implementation (September 2023-September 2024).
Results: A one-tailed t-test revealed no statistical difference between wait times prior to the implementation of the orientation group (mean = 186 days) and during year 2 of the

orientation group (mean = 182 days; t(704)= -0.32, p= 1.65). However, time from consult to first contact with a BSM provider was faster during year 2 of the orientation group (mean = 72 days). Interestingly, 27% of less Veterans opted out of to participating in BSM services after attending the orientation group.
Conclusion: Although implementation of a BSM orientation group did not reduce overall wait time from consult to clinic intake, inclusion of the orientation group as part of the clinic referral process did reduce time to first contact with a BSM provider. This may improve overall engagement with BSM services and continue to improve clinic efficiency. The orientation group also continues to successfully identify Veterans who are most likely to engage in BSM services as over one quarter of Veterans referred to a BSM orientation group declined BSM services after learning more about services offered. Future projects should examine if reduced time to contact increases treatment adherence as well as if no show rates have continued to improve clinic efficiency.

ONE MAN'S TRASH, ANOTHER WOMAN'S RESEARCH: THE STUDY AND REDUCTION OF WASTE IN SLEEP MEDICINE

Laura Donahue[1]
[1] McGaw Medical Center at Northwestern University

Introduction: Healthcare practices in the US contribute to the climate crisis and plastic pollution through greenhouse gas emissions and reliance on single-use plastic materials. The healthcare sector is responsible for 8.5% of US emissions and produces two million tons of solid waste per year (Eckelman et al, PLOS One 2016; Practice Greenhealth). There is limited current literature examining the contribution of sleep medicine practices to US healthcare emissions and waste production. The purpose of this study was to quantify and categorize the waste generated by laboratory-based sleep studies and to identify targetable areas for waste reduction.
Methods: A comprehensive waste audit was conducted over a three-day period in an urban academic sleep laboratory. Each piece of waste generated by patient care during this time was collected, weighed and separated by individual study. The weight of waste attributed to all home sleep apnea tests (HSATs) completed during this period was estimated by weighing sample test components available in the lab. In addition to calculation of total waste produced, sub-analyses were conducted to determine average waste produced by study type and expected reductions in waste output based on different proposed practices.
Results: The 24 in-lab sleep studies (6 diagnostic PSGs, 11 split night PSGs, 6 titration studies, 1 inpatient NOMAD split night study) completed during the three-day period generated 24.18 kg of solid waste. The 75 WatchPAT HSATs and one home NOMAD test generated an estimated 9.97 kg of solid waste. On average, diagnostic PSGs produced 381.33 g of waste, split night PSGs 708.8 g of waste, and titration studies 752.6 g of waste. When applied to the total studies conducted during 2023, we estimate 885.77 kg of waste produced by in-lab studies annually (1596 kg if including HSATs).
Conclusion: Sleep medicine testing, including laboratory-based sleep studies and HSATs, produce a significant amount of waste. An important factor in reducing waste produced by sleep studies is by minimizing the use of single use items when feasible. Based on our lab's practices, waste can be reduced by switching to reusable EEG leads, sanitizing and reusing PAP water reservoirs, and replacing individual soap/lotion containers with large volume dispensers.

EVALUATING PATIENT CHARACTERISTICS INFLUENCING THE PREDICTIVE ACCURACY OF SLEEP DISORDER QUESTIONNAIRES

Suin Lee[1]*, Olive Cawiding*[2]*, Hyeontae Jo*[3]*, Jae Kyoung Kim*[2]*, Eun Yeon Joo*[1]
[1] Samsung Medical Center, [2] Korea Advanced Institute of Science and Technology, [3] Korea University

Introduction: Previously machine-learning algorithm, SimpLe quEstionnairE Predicting Sleep disorders (SLEEPS) was developed to predict obstructive sleep apnea (OSA), combined insomnia and sleep apnea (COMISA), or INSOMNIA (chronic insomnia disorder) with a few information of demographics and questions. This study aimed to validate the algorithm and to discern the characteristics associated with correct and incorrect predictions for each sleep disorder.
Methods: Patient data were collected from two sleep clinics affiliated with a university hospital. Diagnoses of OSA, COMISA, and INSOMNIA were determined through medical examinations, demographic data, polysomnography, and various questionnaires. Using this information, SLEEPS algorithm calculated the probability of each condition—OSA, COMISA, and INSOMNIA. The diagnostic accuracy was evaluated using the area under the receiver operating characteristic (AUROC) curve. The characteristics of patients with correct and incorrect predictions were analyzed for each sleep disorder using cutoff probabilities.
Results: A total of 4,526 patients were analyzed, with the AUROC values reported as 0.976 for OSA, 0.909 for COMISA, and 0.922 for INSOMNIA. The algorithm accurately predicted diagnoses in 91.6% of OSA, 79.7% of COMISA, and 81.4% of INSOMNIA. In the OSA group with incorrect predictions, patients were predominantly female($p< 0.001$) and younger(median 44 vs. 54; $p< 0.001$). This group had higher ISI scores(median 13 vs. 8; $p< 0.001$), lower AHI scores(median 27.4 vs. 38.2; $p< 0.001$), and lower body indices($p< 0.001$). In the COMISA group with incorrect predictions, patients were predominantly female($p< 0.001$) and younger(median 49 vs. 58; $p< 0.001$). They exhibited lower body indices($p< 0.05$), lower AHI(median 28.6 vs. 33.5; $p< 0.05$) and ISI scores(median 16 vs. 18; $p< 0.001$). In contrast, the INSOMNIA group with incorrect predictions was predominantly male($p< 0.001$). These patients had lower ISI scores(median 16 vs. 19; $p< 0.001$) but higher body indices and total AHI scores compared to those with correct predictions($p< 0.001$).
Conclusion: This study confirmed that SLEEPS algorithm demonstrates high and consistent accuracy in predicting sleep disorders. The identified cutoff values for sleep disorders can help alert undiagnosed individuals who may not recognize symptoms of sleep disturbances. Understanding the characteristics of individuals with correct or incorrect predictions provides valuable insights into the diagnostic performance of the algorithm.

IMPACT OF THE DISTANCE FROM A SLEEP CENTER ON TELEHEALTH RATES AND COMPLIANCE WITH OSA THERAPY

Robert Young[1], Jesse Thompson[1], Anam Sabzwari[1], Edward Rojas[1], Robert Stansbury[2], Sunil Sharma[1]

[1] West Virginia University, [2] West Virginia University School of Medicine

Introduction: Compliance with therapy for obstructive sleep apnea (OSA) is critical for achieving optimal patient outcomes. Factors such as the distance from a sleep center and the mode of consultation (in-person vs. telehealth) may influence compliance rates, no-show rates, and patient preferences. With the growing adoption of telehealth, a better understanding of factors driving patient preferences and how they affect outcomes is vital to delivering optimal care. This study aims to explore how demographic and geographic factors shape patient behavior and adherence.
Methods: We retrospectively analyzed data from all patients presenting to our clinic over a three month period. Patients were categorized based on visit type (in-person, video, telephone) and selected based on a diagnosis of OSA. This cohort of 296 patients were then further categorized on visit status (completed vs no-show). Distance from the sleep center was calculated using patient zip codes and an online mapping tool. Compliance was defined as ≥4 hours of PAP use per night on ≥70% of nights and we accepted subjective reporting of patient compliance. Patients with a hypoglossal nerve stimulator (HNS) were excluded from compliance analysis. Additional demographic variables were gathered through chart review.
Results: The cohort had a mean age of 51.8 (±15.6) years, with a male predominance (52.4%) and a mean BMI of 37.3 (±11.0). The average pretreatment apnea-hypopnea index (AHI) was 28.8 (±26.1). No-show rates were lower for telehealth visits (18%, 23/126) compared to in-person visits (40%, 68/170). Patients utilizing telehealth lived farther from the sleep center (69.5 ± 54.6 miles) compared to in-person patients (36.6 ± 42.7 miles). Compliance rates were highest for in-person visits (51.0%, 52/102), followed by telephone (47.2%, 25/53) and video (40.0%, 20/50) visits.
Conclusion: Distance from the sleep center and telehealth availability impact patient behavior, including no-show rates and compliance with OSA therapy. Telehealth reduces barriers to care for patients living farther from sleep centers, but in-person visits are associated with higher compliance rates. This is particularly salient for patients that may otherwise be unable to seek treatment and highlights the need for targeted strategies to improve care delivery across all visit types.

SHARED MEDICAL APPOINTMENT, A NEW MODEL OF CARE IN A SLEEP MEDICINE CLINIC

Kristin Phipps[1], Lauren Toots[1], Maha Alattar[1], Michele Nelson[1], Charles Bae[2]

[1] Virginia Commonwealth University, [2] University of Pennsylvania

Introduction: There is shortage of sleep medicine specialists with a typical sleep clinic visit starts with one patient spending 60 minutes with a single provider (physician or APP). This traditional model of care limits access. One of the biggest hurdles in our sleep clinic is seeing patients for the required 31–90-day CPAP compliance visit, which is required by insurance carriers to keep their CPAP. Shared medical appointment (SMA) can increase access and still provide individualized care in group settings. After initial new patient visit with single provider, SMAs is used for CPAP compliance follow-ups. This pilot trial aims to improve access while maintaining patient satisfaction with a SMA for CPAP therapy through multi-disciplinary approach.
Methods: We initiated a SMA in our sleep medicine clinic. A single provider worked with a sleep technician and nurse familiar with a typical CPAP journey to provide individualized care for a group of patients. Each patient signed a consent form prior to the SMA. Each SMA included 6-8 patients with obstructive sleep apnea (OSA) in a 60-minute group session. We started with a PowerPoint presentation to provide education about OSA and included CPAP therapy with details about airflow, mask issues, and oropharyngeal dryness. We reviewed each patient's data download and adjusted CPAP settings as needed. We encouraged patients to interact with each other and with providers.
Results: In 2023 (N=12), the average follow up time for a CPAP compliance visit was 104 days. After the recent implementation of the SMA in 2024 (N=13), the average follow- up time dropped to 68 days. Patient feedback about the SMA has been extremely positive.
Conclusion: Based on preliminary data, the SMA model is an innovative way to improve patient access by opening up more slots for new patients while accommodating follow up visits for CPAP compliance.

OPTIMIZING POST-HOSPITALIZATION CARE: A RETROSPECTIVE ANALYSIS OF PAP THERAPY FOLLOW-UP IN DISCHARGED PATIENTS

Deandra Kuruppu[1], Christopher Lau[1], Jayen Sum[1], Joyce Lee-Iannotti[1]

[1] University of Arizona- Phoenix

Introduction: Patients with hypoventilation syndrome often experience frequent hospitalizations due to delayed initiation of positive airway pressure (PAP) therapy. These same patients also often experience frequent readmissions due to suboptimal management of their underlying condition. While PAP therapy is effective in reducing complications, the role of timely outpatient follow-up in preventing readmissions remains insufficiently understood.
Methods: This retrospective study analyzed patients who were newly started and discharged with PAP therapy from a large tertiary care center between December 2022 and December 2024. Hospital records were reviewed for demographics, prior hospitalization history, outpatient follow-up within one month, and readmissions within six months. The primary outcome was the association between early outpatient follow-up and 180-day readmission rates. Differences were assessed using independent t- tests.
Results: Of 56 patients discharged with PAP therapy, 43% (n = 24) had at least one prior hospitalization in the preceding year, with a median of 2 admissions and average of 2.5 admissions. Only 38% (n = 21) completed outpatient follow-up within one month of hospital discharge. Patients without 1 month follow-up were significantly more likely to experience readmission within six months (34% versus 18%, P value = 0.049). Further analysis revealed an odds ratio of 2.35, thus patients without follow up

were approximately 2.35 times more likely to be readmitted compared to those that had follow up.
Conclusion: A significant proportion of patients discharged with positive airway pressure (PAP) therapy for hypoventilation syndrome do not receive timely outpatient follow-up, a gap in care that is strongly associated with an elevated risk of early hospital readmissions. This observation underscores the critical importance of implementing structured and comprehensive discharge planning protocols, as well as enhancing post-hospitalization care pathways. By prioritizing timely follow-up appointments and coordinated support, healthcare systems can better address this vulnerable population's needs, potentially reducing preventable readmissions and improving overall patient outcomes.

THE CRITICAL IMPORTANCE OF QUALITY AND PURITY MANAGEMENT IN MELATONIN SUPPLEMENT MANUFACTURING

Nobuhiro Kawai[1], Yoshiki Kida[2]
[1] Nobelpharma Co., Ltd, [2] Nobelpharma Co., Ltd.

Introduction: Melatonin supplements are widely used in the United States to manage sleep disorders. However, concerns have been raised regarding the accuracy of labeled dosages and the presence of impurities in these over-the-counter products. In the U.S., melatonin is regulated as a dietary supplement, which means it is not subject to the stringent quality control standards applied to pharmaceutical products. This regulatory gap can lead to significant variability in product quality, potentially impacting consumer safety and therapeutic efficacy.
Methods: We evaluated ten commercially available melatonin supplements in the U.S. Each sample was prepared by dissolving a quantity equivalent to approximately 6 mg of melatonin in 10 mL of water, followed by sonication to ensure complete dissolution. Subsequently, 300 mL of a methanol/water mixture (7:3) was added, and the solution was sonicated for 20 minutes and vigorously shaken for an additional 20 minutes. The final volume was adjusted to 500 mL with the methanol/water mixture, filtered through a 0.45-micron membrane, discarding the initial 4 mL, and the filtrate was analyzed. Quantitative analysis and impurity profiling were conducted using high-performance liquid chromatography (HPLC) methods adapted from our quality assurance standards.
Results: Among the ten products analyzed, four exhibited melatonin content deviating beyond the acceptable range of 90–110% of the labeled amount, indicating substantial discrepancies. Impurity testing revealed that, while all products met the specific impurity thresholds for known related substances (e.g., 5-methoxytryptamine ≤0.5%), several products contained higher overall levels of unidentified impurities, with some approaching 1% of the total content.
Conclusion: The findings highlight significant quality control issues in commercially available melatonin supplements in the U.S., with 40% of products failing to meet acceptable content standards and several exhibiting elevated impurity levels. These inconsistencies may compromise therapeutic efficacy and pose safety risks to consumers. There is an urgent need for enhanced regulatory oversight and stringent quality assurance protocols in the manufacturing of melatonin supplements to ensure product consistency, efficacy, and consumer safety. Healthcare providers should be aware of these quality variations when recommending melatonin and consider advocating for products that have undergone rigorous third-party testing.

SLEEP APNEA AND DRIVING: CURRENT LEGAL ISSUES IN SWITZERLAND

Cristian Palmiere[1]
[1] CURML

Introduction: Severe obstructive sleep apnea is considered a risk factor for possible road accidents. In switzerland, all license holders have to fulfill medical minimum requirements by law. Medical conditions conflicting with them may lead the authotities to temporarily revoke the driving license based on the results of the fitness-to-drive medical assessment. According to the current Swiss guidelines, not all drivers who have caused a presumed sleep accident have to undergo a full fitness-to-drive medical assessment. This is mandatory, for instance, in all situatione where it is not possible to determine whether the accident was truly caused by falling asleep or a transient loss of consciousness. The objective of this study was therefore to retrospectively investigate the cases observed in our facility during a period of four years (January 2021 - December 2024), for which the cause of the road accident was probably traced back to the presence of an undiagnosed or inadequately treated severe obstructive sleep apnea.
Methods: We reviewed all the cases that underwent a fitness-to-drive medical assessment in our facility during the period January 2021 - December 2024 following a road accident for the dynamics of which a possible temporary and inexplicable loss of consciousness (and therefore an obstructive sleep apnea problem) could not be ruled out.
Results: 44 cases of transient loss of consciousness, of undetermined origin, were taken into consideration (36 men, 8 women, aged between 24 and 69 years). All cases underwent a complete fitness-to-drive medical assessment, including ophthalmological, diabetological, cardiological, neurological, and pneumological evaluation. In 6 cases, a previously undiagnosed, untreated, or inadequately treated severe obstructive sleep apnea was considered the only factor potentially able to explain the dynamics of the road accident.
Conclusion: The systematic search for severe obstructive sleep apnea as a possible cause of a transient loss of consciousness and sometimes of a road accident must remain a priority in the medical assessment of fitness-to-drive. An important role must be played by general practitioners, who must direct patients at risk to sleep medicine centers, so that the diagnoses and adequate treatments can be implemented promptly, in order to prevent possible risks for road traffic

LEVERAGING ARTIFICIAL INTELLIGENCE ENHANCED PATIENT EDUCATION TO OPTIMIZE PAP TREATMENT ADHERENCE

Noman Baig[1], Deepthi Jaligama[1], Jin Tao[1], Momena Sohail[1], Pranshu Adavadkar[1], Ashima Sahni[1], Muhammad Najjar[1], Ashesha Mechineni[1], Bharati Prasad[1]
[1] University of Illinois at Chicago

Introduction: Artificial intelligence (AI) will inevitably be used in healthcare settings, and it has a significant impact on patient education. We aim to study how to leverage existing AI platforms and improve patient efficacy in treating obstructive sleep apnea (OSA) patients starting with positive airway pressure (PAP) therapy.
Methods: Nine sleep physicians employed ChatGPT and Gemini to acquire responses to a specific set of questions. Two introductory inputs (patient primer and physician primer) were supplied to prepare the AI platforms for analyzing patient and physician perspectives. Three categories of questions were presented concerning masks and pressure, equipment maintenance, and clinical outcomes during the commencement of PAP therapy. The readability of the outcomes was assessed using Flesch-Kincaid (FK) score. The raters used visual analog scales to score from 1-10 the accuracy and relevance of responses in each model.
Results: Primer 1 (patient role) answers: there was no significant difference between platforms in FK scores. The average FK scores for ChatGPT (57.15) and Gemini (55.58) are rated at a 10th-12th school grade reading level indicating difficult to read. The ChatGPT answers had significantly higher accuracy ratings for group 1 (8.36 vs 7.14) and group 3 (8.46 vs 6.98) questions. The ChatGPT answers had significantly higher relevance ratings for group 1 questions (8.81 vs 7.51). Primer 2 (physician role) answers: There was no significant difference between platforms' accuracy and relevance ratings. ChatGPT had an accuracy of 8.11 and a relevance of 8.49 to Gemini's 7.32 and 7.77. The validity and relevance ratings of the supporting evidence were all very low (≤2.1) because the platforms either cited unverifiable sources or did not cite.
Conclusion: Both platforms' answers to patient questions were objectively difficult to read. ChatGPT provided more accurate and relevant answers to patient questions in selective question groups and remained equivocal to Gemini otherwise. These pilot projects will help guide us in designing patient education materials which is the next step in utilizing these results.

ASSESSING THE FEASIBILITY OF A MULTIMODAL SLEEP INTERVENTION FOR COMMUNITY-DWELLING DYADS OF PEOPLE LIVING WITH DEMENTIA AND THEIR CARE PARTNERS

Melinda Jackson[1], Sumedha Verma[1], Prerna Varma[1], Aimee Brown[1], Rosemary Gibson[2], Jingling Huang[1], Ly Nguyen[3], Bei Bei[1], Tom Valenta[4], Ann Pietsch[4], Marina Cavuoto[5], Michael Woodward[6], Susan McCurry[7]

[1] Monash University, [2] Massey University, [3] Swinburne, [4] Independent researcher, [5] National Ageing Research Institute, [6] Austin Health, [7] University of Washington

Introduction: People living with dementia frequently experience sleep disturbances, and their informal care partners are also at high risk of poor sleep. Few sleep interventions consider the unique sleep interplay and challenges within caregiver-care-recipient dyads. This study evaluated the feasibility and preliminary efficacy of co-designed multimodal intervention to address sleep disturbances in dyads of people living with dementia and their care partners in Australia and New Zealand.
Methods: Dyads of people living with dementia and their care partner were recruited from the community via social media and Dementia Support services. Eligible dyads completed the Dementia, Sleep and Wellbeing Program, a co-designed, six-week online sleep intervention. The program included a mix of group-based and personalised sessions, which combined Cognitive Behavioural Therapy for Insomnia, mindfulness, activity, and light delivered by registered psychologists. Feasibility was evaluated by attrition, attendance, and satisfaction. Sleep was assessed using the Pittsburgh Sleep Quality Index, the Insomnia Severity Index, and the Sleep Disturbance Inventory. Psychological wellbeing was assessed via the Depression Anxiety Stress Scale-2. Feasibility outcomes were summarised using descriptive statistics, and sleep/mood outcomes were analysed using linear mixed models.
Results: Twenty-three dyads were assessed for the study. Four dyads withdrew before the intervention, and one dyad withdrew during intervention, resulting in 18 dyads who completed the study (Mage=67.34 years, SDage=10.76). Attendance rates were high, with seven care partners attending all sessions. Both people living with dementia and care partners reported high satisfaction with the intervention. For care partners, significant reductions were observed in insomnia severity (p=.006) and improvements in sleep quality (p=.042). Significant improvements in insomnia severity (p=.006), depression (p=.002) and stress symptoms (p=.006) were observed for people living with dementia.
Conclusion: These findings provide support for a multimodal, dyadic approach to reducing sleep disturbances among community-dwelling people with dementia and their carer, demonstrating high engagement and satisfaction, and early indications of improved subjective sleep and wellbeing. These results highlight the potential efficacy of online interventions to address sleep issues in this population.

AMERICAN ACADEMY OF SLEEP MEDICINE ADVOCACY: ANALYSIS OF GOALS AND ACHIEVEMENTS IN 2024

Sally Ibrahim[1], Joyce Lee-Iannotti[2], Alison Kole[3], Joanna Fong-Isariyawongse[4], Lindsay McCullough[5], K. Vohra[6], Eric Albrecht[7], Vidya Krishnan[8]

[1] University Hospitals Cleveland Medical Center and Case Western Reserve University, [2] University of Arizona- Phoenix, [3] Atlantic Health System, Morristown Medical Center, [4] University of Pittsburgh, [5] Division of Pulmonary, Critical Care, and Sleep Medicine, Rush University Medical Center, [6] Sleep Center at Ascension Heart Center, [7] American Academy of Sleep Medicine, [8] The MetroHealth System

Introduction: The American Academy of Sleep Medicine (AASM) Advocacy committee provides nonpartisan guidance and support for ASSM policy implementation. The committee develops strategies to engage efforts from members at the local and national levels, advancing these initiatives with elected officials and federal agencies. The committee meets regularly to discuss strategies on a wide variety of sleep health initiatives with seven key goals, including: 1)building legislative relationships to strengthen grassroot efforts; 2)reviewing and proposing AASM

resources/communications; 3)collaborating with the AASM Executive Board on setting advocacy priorities; 4)preparation and participation in Hill day- a visit to Capitol Hill for in-person advocacy efforts with national Congress representatives; 5) recruiting additional AASM member/stakeholders; 6)working with staff and lobbyists to identify speakers for Congressional Sleep Health Caucus; and 7)collaborating with other organizations to amplify our voice. These goals ensure policy support for sleep health. This analysis reviews how advocacy work achieved these goals in 2024.
Methods: A descriptive analysis of all activities in the prior year as they related to each of the seven advocacy committee goals, objectives and action items was performed. Committee members participated in reviewing of prior work of the committee and brainstorming new ideas annually. Analyses included information of activities in 2024, using historical information from committee monthly agendas, electronic and social communications, publications and other public activities. Each activity was evaluated and categorized to assess the success of achieving stated goals.
Results: The committee addressed numerous initiatives across nine key themes: telehealth, permanent standard time, physician payment, health equity, school start time, sleep research, the Sleep Health Caucus, current sleep-related events(e.g. CPAP recall), and AASM-advocacy collaboration both within and outside the organization. Within these themes, all 28 identified activities aligned 100% with the AASM-Advocacy Committee goals. The majority(64%) met ≥3 committee goals. Four total publications were published, including an AASM position statement on telehealth permanency; and formal letters to address relevant initiatives.
Conclusion: The AASM advocacy committee achieved all major goals in 2024. Activities addressed multiple committee priorities and successfully aligned with advocacy efforts. Future directions include increasing advocacy efforts and expanding collaboration with multidisciplinary organizations to advance sleep health.

SIMPLIFIED ML MODELS FOR AUTO-SCORING SLEEP STAGES AND EVENT-BASED DETECTION OF AROUSALS AND RESPIRATORY EVENTS: EVALUATION WITH EXPERT CONSENSUS

Michiru Kaneda[1], Sho Ogaki[1], Tomoyuki Nohara[1], Syuhei Fujita[1], Naoshi Osako[1], Tomoko Yagi[2], Takanori Ogata[1]
[1] ACCELStars Inc., [2] Kurume University

Introduction: Accurate scoring of sleep stages, arousal responses, and respiratory events is critical for diagnosing sleep disorders but remains labor-intensive and variable across experts. Simplified machine learning approaches offer efficient and interpretable alternatives to complex models. This study evaluates a machine learning model by comparing its predictions to consensus data created by experts.
Methods: Polysomnographic (PSG) data from healthy participants and patients with sleep apnea syndrome (SAS) were analyzed. After data quality assessment, 473 nights of healthy data and 244 nights of SAS data were used for sleep classification, 412 nights of healthy data and 179 nights of SAS data for arousal detection, and 179 nights of SAS data for respiratory event detection. Features for sleep classification were generated for 30-second epochs using data from surrounding intervals. Arousal and respiratory event detection relied on features generated for each second. Post-processing merged closely spaced events and removed brief events. Experts conducted discussions to resolve ambiguities and establish consistent criteria, improving annotation quality. Following this, they divided the dataset for annotation. A subset of data was annotated by all experts simultaneously to create consensus data, enabling comparisons between inter-expert agreement and model performance.
Results: The model achieved an accuracy of 0.86 and a Cohen's Kappa of 0.81 for sleep stage classification, with F1 scores of 0.89, 0.66, 0.87, 0.87, and 0.91 for Wake, N1, N2, N3, and REM. For arousal detection, recall and precision were 0.81 and 0.77, and for respiratory event detection, recall and precision were 0.88 and 0.83. For sleep classification, 27 nights annotated by four experts showed an average accuracy and Cohen's Kappa of 0.91 and 0.87 when compared to consensus annotations. The model achieved an accuracy of 0.90 and a Cohen's Kappa of 0.86, demonstrating comparable performance to the experts. Similarly, for arousal and respiratory events, the model matched inter-expert agreement, supporting its reliability.
Conclusion: Simplified machine learning models demonstrated expert-level performance in auto-scoring sleep stages and detecting arousal and respiratory events. These results highlight their potential for efficient, reliable sleep assessment solutions.

THE EFFECT OF ICU DIARY ON CAREGIVER STRESS, SLEEP DISTURBANCES AND FATIGUE: AN ONGOING STUDY

Pei-Yu Chang[1], Pei-Yu Chang[1], Huan-Ting Shen[1], I-Shiang Tzeng[2], Chia-Chun Tang[3], Shao-Yu Tsai[4]
[1] Taichung Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, [2] Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, [3] National Taiwan University, [4] School of Nursing, College of Medicine, National Taiwan University

Introduction: Family caregivers of patients admitted to the intensive care unit (ICU) often experience high stress, sleep disturbances, and fatigue. This study aimed to examine the impact of an ICU diary on reducing stress, improving sleep, and alleviating fatigue among primary family caregivers in the ICU.
Methods: This ongoing pilot experimental study was conducted in four adult ICUs at a teaching hospital in central Taiwan, using 1:1 randomization. The experimental group used an ICU diary comprising closed-ended sections for documenting essential medical information and open-ended sections for emotional support from physicians, nurses, patients, and caregivers. The diary was used for up to one week or until the day before ICU discharge. Both the experimental group and control groups received a stress management and sleep hygiene booklet. Eligible participants were (1) unpaid primary family caregivers (2) family members of ICU patients on mechanical ventilation for over 48 hours. The participants completed the Impact of Event Scale-Revised (IES-R), the General Sleep Disturbance Scale (GSDS), and the Lee's Fatigue Scale (LFS) at the time of recruitment and again either one week later or before the patient's discharge from the ICU.
Results: Sixty-two primary family caregivers were randomized to the experimental (n=30) or the control group (n=32). The ICU diary intervention showed no statistically significant effects

on stress, sleep disturbances, or fatigue (all p >.05). However, fatigue severity increased significantly in the control group over the study period (3.79±1.9 to 4.33±2.1, p <.05). The ICU diary had a 66.8% completion rate, primarily documenting patient updates (95.8%), with nurses more frequently offering caregiver encouragement (57.1%) than physicians or nurse practitioners (16.0%).

Conclusion: This study found that the ICU diary intervention did not significantly reduce stress, sleep disturbances, or fatigue among family caregivers. These findings may be due to the preliminary nature of the data. Future research should explore strategies to improve ICU diary completion rates and investigate caregiver satisfaction with communication and their perceived support from the diary.

ENHANCING CULTURAL AND LINGUISTIC RELEVANCE OF A PAP TELEMANAGEMENT INTERVENTION

Alexa Watach[1], Bruno Saconi[1], Jaime Perales-Puchalt[2], Christina Baker[2], Diego Mazzotti[2], Jorge Mora[1], Belen Esparis[3], Maria Pulgar[4], Brenda Borrega[2], Matthew Klimper[5], Jessica Jara[5], Dennis Hwang[6], Amy Sawyer[7], Mariana Ramirez[2]

[1] University of Pennsylvania, [2] University of Kansas Medical Center, [3] Malcom Randall Veterans Affairs Medical Center, [4] Lee. hey y Harrison de Venezuela/remote, [5] Kaiser Permanente, [6] Kaiser Permanente Southern California, [7] University of Pennsylvania School of Nursing

Introduction: Hispanic adults experience lower positive airway pressure (PAP) usage and higher rates of obstructive sleep apnea (OSA)-related comorbidities. This study linguistically and culturally adapted a tele-delivered self-management support intervention (TeleSMS) for Spanish-speaking Hispanic adults with OSA. TeleSMS is comprised of a text messaging library and health-literacy aligned animated videos.

Methods: Adaptations followed the 11-step Participatory and Iterative Process Framework for Language Adaptation (PIPFLA), including translations, review panels, and harmonization. Panels consisted of 12, 60-minute meetings with Hispanic, Spanish-fluent adults with positive airway pressure (PAP) treated OSA and 12 sessions with providers experienced in caring for Hispanic patients with OSA. Literacy demand assessments of the message library preceded adaptation.

Results: The original library's median readability was 9.7 (9.3 [min]-13.4[max]) (goal: grade <= 8) and complex language score was 23.2% (18.9-29.5) (goal: < 20%). After literacy editing, these improved to 8 (7.7-10.7) and 12.5% (7.5-17.2). Forward and back translation was completed by three individuals with iterative review by panel participants (N=12) originally from Mexico (33.3%), US (33.3%), or other Latin American countries (33.3%). Separate panels included 7 patients (71.4% female; 71.4% <= post-secondary education; 85.7% Spanish preferred language) and 5 providers (60% sleep physician; 40% staff; 60% English preferred language). Across 24 sessions, priority adaptations pertained to: (1) 'content' (e.g., simplified messages [defining concepts, breaking down long messages into shorter/simpler ones]; adding PAP parts/features photos; (2) 'culture' (adjusting terms/images [e.g., "rumble of a thunderstorm" to "relaxing nature sounds", "partner" to be more inclusive of additional household members "personas a su alrededor- people around you", add Hispanic emoticons); (3) 'wording' (e.g., too long/not catchy post-translation; incompatible translation "empujoncito" [nudge in English] considered odd; "white noise" not common in Spanish, instead "musica suave" [i.e., soft music] or "ruido blanco o de fondo" [i.e., white or background noise]; PAP parts, supplies and settings should be presented in English and Spanish due to internet searches and English language setting on machines).

Conclusion: Adapting a Spanish language intervention in collaboration with Latino stakeholders can enhance acceptability and appropriateness of TeleSMS to potentially enhance usability and adoption among Latinos.

ASSESSING THE DIAGNOSTIC ACCURACY OF LLM (CHATGPT-4) IN SLEEP MEDICINE CASES

Joseph Cheung[1], Anshum Patel[1], Estefany Garces Delgado[1]

[1] Mayo Clinic Jacksonville

Introduction: Large language models (LLMs), such as ChatGPT-4, have demonstrated promising potential as diagnostic tools across various medical disciplines. In sleep medicine, artificial intelligence tools are already used to analyze physiological sleep data and are being studied for their potential in phenotyping, endotyping, and predicting treatment responses. However, the effectiveness of LLMs in accurately diagnosing sleep disorders based on clinical history has not yet been studied. This study evaluates ChatGPT-4's diagnostic performance using clinical vignettes.

Methods: Nineteen clinical cases were selected from the Case Book of Sleep Medicine, Third Edition (AASM, 2019). Each case included patient history, examination findings, and test results. The vignettes were input into ChatGPT-4 using the following standardized prompt: "Based on the provided case details, generate the top 5 differential diagnoses and identify the most likely final diagnosis: (copy and paste clinical vignette)." The model was tasked with generating both differential diagnoses and a final diagnosis for each case. The AI's results were compared to reference diagnoses from the case book. Differential diagnoses were measured as the number of matches, and accuracy was reported as a percentage. Final diagnoses were scored as 0 (no match), 1 (partial match), or 2 (full match).

Results: The mean number of AI-generated differential diagnoses matching the AASM case differential diagnoses was 2.79 ± 0.71 (95% CI: 2.45–3.13). The mean accuracy percentage for differential diagnoses was 63.27% ± 15.61% (95% CI: 55.75%–70.79%), with scores ranging from 33.33% to 100%. For final diagnoses, ChatGPT-4 scored a total of 30 out of a possible 38, with a mean score was 1.58 ± 0.61 (95% CI: 1.29–1.87) out of 2, with 74% of cases achieving a full match. Performance was higher in cases with fewer differential diagnoses, whereas accuracy decreased in more complex cases.

Conclusion: ChatGPT-4 showed moderate to high accuracy in generating both differential and final diagnoses for sleep disorders. These findings suggest that AI could become a valuable clinical decision-support tool in sleep medicine. However, its

inconsistent performance in complex cases highlights the need for further refinement and clinical testing.

CONTEXTUAL PREDICTORS OF SLEEP COACHING PROGRAM ACCEPTABILITY AMONG FIRE SERVICE WORKERS

Matthew Lujan[1], Siyuan Huang[2], Hannah Miller[2], Dana Epstein[3], Matthew Buman[3], Daniel Taylor[4], Michael Grandner[5], Edward Bedrick[6], David Glickenstein[7], Patricia Haynes[4]
[1] Mel and Enid Zuckerman College of Public Health, University of Arizona, [2] Department of Health Promotion Sciences, University of Arizona, [3] College of Health Solutions, Arizona State University, [4] University of Arizona, [5] University of Arizona College of Medicine, [6] Department of Epidemiology and Biostatistics, University of Arizona, [7] Department of Mathematics, University of Arizona

Introduction: Sleep disorders are common in the fire service, yet few agencies have adopted evidence-based sleep health workplace wellness programs to address them. As part of the pre-implementation formative assessment, this project aimed to identify theoretically informed contextual factors that predict the acceptability of a new sleep health coaching wellness program among workers in approximately 20 Arizona fire agencies.
Methods: Cross-sectional survey data were analyzed from non-manager fire service personnel (n=145). Program acceptability was measured via the Acceptability of Intervention Measure. Contextual factors were measured using the Organizational Readiness for Change Assessment (ORCA) subscales, which include culture among captains, culture among senior leadership, leadership, measurement, readiness for change among opinion leaders, and resources. The ORCA instrument aligns with the integrated Promoting Action on Research Implementation in Health Services (i-PARIHS) framework for implementation. Linear regression was used to examine which contextual factors predicted intervention acceptability.
Results: A total of 145 firefighters and paramedics participated in the survey (M age = 38.89 years, SD = 9.35 years); the average time worked at the current place of employment was 10.17 years (SD = 9.35). Findings indicated that higher readiness for change among opinion leaders was significantly associated with greater program acceptability ratings (β= 0.05, SE = 0.02, $p < 0.001$). Leadership contextual factors generally did not predict program acceptability, except for culture among senior leadership. Worse evaluations of culture among senior leadership were associated with higher ratings of program acceptability (β = -0.06, SE = 0.03, $p < 0.05$).
Conclusion: Opinion leaders, including union members, are key champions for promoting the adoption of sleep health coaching in the fire service. There was no relationship between intervention acceptability and resources or other leadership variables, except for the negative culture of senior leadership. These findings highlight the importance of using measures, such as ORCA, that align with theory-informed implementation frameworks like i-PARIHS, to identify key facilitators and potential barriers to successful implementation in occupational settings.

SWEET DREAMS OR SLEEPLESS NIGHTS? COMPARING PATIENT SATISFACTION IN INTEGRATED VS. TRADITIONAL SLEEP CARE MODELS

Rebecca Hankla[1], Jason Ong[1], Samantha Edington[1], Frances Thorndike[1], Wendy Cerenzia[2], Brandon Coleman[2], Greg Salinas[2], Heidi Riney[1]
[1] Nox Health, [2] CE Outcomes, LLC

Introduction: Advances in telehealth and technology have created opportunities for a more comprehensive care approach for patients with OSA. However, it is unclear if these comprehensive care models translate to improved treatment adherence and patient satisfaction compared to their traditional sleep clinic counterparts. This study aims to evaluate self-reported patient experience and treatment outcome data between a traditional sleep care approach and a clinically integrated, comprehensive sleep care program.
Methods: To better understand the patient experience within these models of care, this study compares outcomes between a traditional sleep care approach and a clinically integrated, comprehensive sleep care program. The study analyzed survey responses from 206 patients with sleep apnea (n=102, traditional care model and n=104, comprehensive care model) with items evaluating patient satisfaction, CPAP adoption and adherence, and quality of life, with descriptive statistics, chi-square analyses, and t-tests conducted to compare outcomes between the two groups.
Results: A significantly higher proportion of patients ($p<.05$) in the comprehensive model (85%) were satisfied at all measured points along the patient's journey compared to the traditional care model (51%). Notably, significantly more patients in the comprehensive model were very satisfied with the ease of navigating the testing process (83% vs. 38%, $p<.05$), time between diagnosis and CPAP adoption (91% vs. 49%, $p<.05$), and availability and level of ongoing CPAP support (79% vs. 39%, $p<.05$). Comprehensive care patients experienced significantly fewer work disruptions due to sleep apnea, with 7% missing work in the past 3 months compared to 58% in the traditional model ($p<.05$).
Conclusion: The findings underscore the advantages of a comprehensive care model that improves patient satisfaction, streamlines the sleep apnea treatment journey, and enhances quality of life. These results, paired with prior evidence from the same model, highlight the benefits of removing obstacles to care, which increases patient satisfaction, improves adherence to therapy, and reduces overall healthcare costs, warranting further investigation into these relationships.

IMPACT OF COMORBID OBSTRUCTIVE SLEEP APNEA ON PHARMACOLOGICAL TREATMENT SELECTION FOR TYPE 2 DIABETES MELLITUS

Chien-Yu Tseng[1], Atul Malhotra[2], Adam Spira[3], Emerson Wickwire[4], Jennifer Albrecht[4], Halima Amjad[5], Alden Gross[3], Christopher Kaufmann[1], Earl Morris[1]

[1] University of Florida, [2] University of California, San Diego, [3] Johns Hopkins Bloomberg School of Public Health, [4] University of Maryland Baltimore, [5] Johns Hopkins University School of Medicine

Introduction: Obstructive sleep apnea (OSA) is highly comorbid with type-2 diabetes mellitus (T2DM). Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) and sodium-glucose cotransporter 2 inhibitors (SGLT2is) are both considered first-line options (usually together with metformin) for T2DM, especially in patients with chronic kidney disease (CKD) or cardiovascular disease. While both classes show benefits in OSA, the evidence base for GLP-1 RA's role in reducing OSA severity is more robust to date. We hypothesized comorbid OSA is associated with preferential treatment with GLP-1 RAs vs SGLT2is (as add-on therapy to metformin) in Medicare beneficiaries with T2DM.
Methods: We used a random 15% national sample of Medicare administrative claims data (10/1/2016-12/31/2020). We identified individuals aged ≥65 years with T2DM (≥2 outpatient or ≥1 inpatient claim with ICD-10-CM for T2DM) who newly initiated a GLP-1 RA or SGLT2i. Index date was first date prescribed GLP-1 RA or SGLT2i. Patients were required to have ≥1 year of continuous enrollment and ≥1 metformin prescription within 90 days before index date. OSA was defined as ≥2 outpatient or ≥1 inpatient OSA claims. We excluded patients with CKD stage 4/5 or end-stage renal disease in 1-year baseline period. We constructed logistic regression models to estimate odds of being prescribed GLP-1 RA vs. SGLT2i, comparing those with and without OSA. In adjusted models, we controlled for age, race, sex, acute myocardial infarction, stroke, heart failure, obesity, CKD, insulin use, and index year (to account for changing prescribing patterns).
Results: Of 60,548 patients with T2DM treated with metformin (mean age=72.6 [±5.33] years, 47.5% female), 45.2% were GLP-1 RA new users and 54.8% SGLT2i new users. Compared to those without OSA, patients with OSA had 27% increased odds of being prescribed GLP-1 RA vs. SGLT2i (OR=1.27, 95% CI=1.21-1.32). After adjustment, OSA remained a significant predictor of GLP-1 RA vs. SGLT2i prescribing (aOR=1.17, 95% CI=1.11-1.22).
Conclusion: Patients with comorbid T2DM and OSA were preferentially prescribed GLP-1 RAs vs. SGLT2is as add-on to metformin. Given the potential of GLP-1 RAs in reducing OSA severity, future research should incorporate clinicians' perspectives and prescribing experiences when investigating the long-term effectiveness and safety of these agents.

EXPLORATORY ANALYSIS OF PATIENT OPINIONS, PREFERENCES, AND EXPERIENCES WITH INSOMNIA TREATMENT

Mark Seewald[1], Joseph Teel[1], Matthew Kearney[1], Alexandria Muench[1], Richard Schwab[1], Brendan Keenan[1], Knashawn Morales[1], Michael Perlis[2]

[1] University of Pennsylvania, [2] Department of Psychiatry, University of Pennsylvania

Introduction: Little is known about patient beliefs and preferences regarding treatment approaches for insomnia. Understanding of such inclinations will allow clinicians to better address these perspectives, and in so doing improve treatment adherence. In the present study, patient beliefs about the relevance of evidence-based treatment and preferences for and experiences with over-the-counter (OTCs), prescriptive medications (RXs), and behavioral treatments (BTs), were surveyed.
Methods: Four items were added to the Penn Behavioral Sleep Medicine online screener (sleeplessinphilly.com), which profiles sleep and general health of individuals seeking to participate in research. Two questions asked about the importance of safety and effectiveness information for OTCs and RXs (on a 0-5 scale, 0=not important, 5=very important). One question asked respondents to rank which of the treatment approaches (OTCs, RXs, BTs) were most and least preferable. One question asked respondents to indicate which of these treatments they had tried, and in what order. Examples were given for each treatment (e.g., BT was parenthetically defined as "4-10 week cognitive behavioral therapy for insomnia").
Results: 181 patients completed the survey (82.3% female, mean±SD age of 48.2±12.2 years). The mean Insomnia Severity Index (ISI) for the group was 16.8±5.1. Roughly 80% of respondents scored evidence and safety information as important (responses of 4 or 5) for both OTCs (82.3%, 4.3±1.2) and RXs (80.7%, 4.3±1.2). The most frequently preferred first, second, and third choices were BTs (45.9%), OTCs (43.6%), and RXs (50.3%), respectively. Despite this stated preference, 71.8% of respondents tried OTCs first, 33.7% tried RXs second and 8.3% tried BTs third. Overall, just 8.8% tried BTs first, and 25.4% ever tried BTs.
Conclusion: Survey findings highlight that patients consider information on safety and effectiveness of insomnia treatment as important (equally so for Rx and OTC treatments), that they prefer behavioral and OTC care as compared to prescriptive medications. Interestingly, although the most patients stated a preference for behavioral therapies first, most reported trying OTCs first and only 8.8% had tried BTs first. This likely reflects the limited availability of BTs, particularly compared to the ease at which patients can access OTC therapies.

EXPLORATORY ANALYSIS OF PRIMARY CARE CLINICIANS' ATTITUDES, PREFERENCES, AND PRACTICE PATTERNS REGARDING THE TREATMENT OF INSOMNIA IN PRIMARY CARE

Mark Seewald[1], Joseph Teel[1], Matthew Kearney[1], Alexandria Muench[1], Richard Schwab[1], Brendan Keenan[1], Knashawn Morales[1], Michael Perlis[2]

[1] University of Pennsylvania, [2] Department of Psychiatry, University of Pennsylvania

Introduction: Little is known about primary care providers' (PCPs') attitudes, preferences, and practice regarding the management of insomnia. More information on how PCP's manage insomnia patients may enhance the implementation of evidence-based practice. This study surveyed PCPs with respect to their insomnia treatment preferences and practices.
Methods: An 8-item survey on managing insomnia in primary care was completed by 64 PCPs in the University of Pennsylvania Health System. The survey asked: "How important is it to address insomnia in primary care?"; "How important is it to limit this care to primary insomnia?"; "How important

is it to know which medications (over-the-counter [OTCs] and prescription [RX]) are safest/most effective?" (each on a 0-5 scale, 0=not important, 5=very important); and two additional questions regarding preferences and practice for three treatment options (OTCs, RXs, and behavioral treatments [BTs]).
Results: Over 90% of respondents indicated that managing insomnia in primary care is important (90.6% responded 4 or 5, mean±SD score of 4.5±0.7), and 25% rated the importance of limiting such care to "primary insomnia" as important (2.4±1.7). Most rated effectiveness/safety information as important for OTCs (87.5%, 4.6 + 0.7) and RXs (95.3%, 4.8 + 0.5). Most PCPs preferred BTs as first-line treatment (68.8%), followed by OTCs (28.1%), and RXs (3.1%), although the most common category prescribed/referred for first was OTCs (46.9%), followed by BTs (39.1%) and RXs (15.6%). Among those prescribing OTCs, Melatonin was most common (92.2% [73.4% IR; 18.8% XR]), followed by doxylamine (4.7%) and diphenhydramine (3.1%). Among those prescribing RXs, trazodone was most common (75%), followed by doxepin and zolpidem IR (both 10.9%).
Conclusion: The PCPs in this survey indicated that addressing insomnia in primary care is important, as is knowing which OTCs and RXs are safest/most effective. The most preferred treatment category was BTs, followed by OTCs, then RXs. The unexpected preference for recommending OTCs over RXs underscores the need for comparative effectiveness research on OTCs. The discordance between preference and practice is also noteworthy; despite preferring BTs, OTCs appear to be the go-to therapy. This may reflect both the lower availability of BTs and patient preferences influencing practice.

TYPES OF NONCONFORMANCE IN THE ACCREDITATION OF HOME SLEEP APNEA TESTING IN BRITISH COLUMBIA, CANADA

Aleksei Markin[1], Nav Rakhra[1], Sharan Manship[1]
[1] College of Physicians and Surgeons of British Columbia

Introduction: British Columbia is one of only two provinces in Canada that mandate accreditation for HSAT facilities. After achieving provisional accreditation by passing a desktop audit, 151 facilities became eligible to obtain full accreditation. This study examines the types of nonconformance identified during the full on-site assessment process.
Methods: Between 2022 and 2024, 95 facilities (62.9%) underwent on-site visits, which involved formal interviews with management and staff, evidence review, patient set-up observation, evaluation of ten clinical cases (final report packages), assessments of physical space, safety measures, and scoring quality. The process followed a standardized protocol based on 329 standards published in 2021 (1). The assessment results identified areas of nonconformance that facilities needed to address to achieve full accreditation.
Results: By December 2024, 95 out of 151 facilities in British Columbia (62.9%) had completed the accreditation process, with a total of 916 nonconformance issues identified during on-site assessments. These nonconformance issues were categorized as follows: procedural and documentation areas: 219 (23.8%); human resources standards: 139 (15.2%); medical director's duties: 114 (12.5%); ethical standards: 76 (8.3%); HSAT equipment evaluation and maintenance: 66 (7.2%); reporting standards: 54 (5.9%); scoring and Interpretation: 46 (5.0%); client complaints and; feedback requirements: 45 (4.9%); safety and privacy: 38 (4.2%); patient communication: 32 (3.5%); technical HSAT Issues: 26 (2.8%); test appropriateness, infection prevention, and information management: 61 (6.7%) combined. This analysis shows that procedural and documentation issues were the most common area of nonconformance, followed by human resources standards and the medical director's duties. We found that 10 out of 95 HSAT facilities (10.5%) fully met the current HSAT accreditation standards without any outstanding requirements.
Conclusion: Independent HSAT facilities are still essential in delivering diagnostic sleep services in British Columbia. These facilities have continuously embraced the accreditation process to enhance patient care and safety. This study, which presents the initial experience with the HSAT accreditation process, aims to pave the way for future research into the positive impact of accreditation programs on public health outcomes.

SLEEP HEALTH AMONG CIVILIANS IN THE GAZA STRIP DURING ONGOING ARMED CONFLICT

Bilal Irfan[1], Mohammed Al-Hasan[2], Abdulwhhab Abu Alamrain[3], Majd Abualnour[4], Abdallah Abu Shammala[5], Izzeddin Lulu[6], Nour Alshaer[7], Hrayr Attarian[8]
[1] Harvard Medical School, [2] Princess Alexandra Hospital NHS Trust, [3] Al-Aqsa Martyrs Hospital, [4] Horizons Academy, [5] Gaza European Hospital, [6] Al-Shifa Hospital, [7] Mohammed Yousef El-Najar Hospital, [8] Northwestern University Feinberg School of Medicine

Introduction: Sleep disturbances are common during periods of armed conflict, yet limited data exist on the sleep health of civilians living in conflict zones. Previous investigations in other regional populations such as Ukraine, and of Israeli adults amid the ongoing conflict, suggest that exposure to violence and uncertainty can adversely affect sleep. To address this gap, this pilot study examined self-reported sleep quality among Palestinians in the Gaza Strip during the current conflict.
Methods: A cross-sectional survey was conducted in multiple governorates of the Gaza Strip during the current hostilities at the beginning of December 2024. Participants completed the Pittsburgh Sleep Quality Index (PSQI), which yields a global sleep quality score. Demographic data, including gender, educational attainment, and geographic location, was collected. Mean PSQI scores were compared between men and women, between university and non-university graduates, and between northern (North Gaza and Gaza) and southern governorates (Deir Al-Balah, Khan Yunis, and Rafah). Statistical comparisons were conducted using t-tests; a p-value < 0.05 was considered significant.
Results: A total of 183 individuals participated (47 men, 136 women; 108 non-university graduates, 75 university graduates; 63 from the north, 120 from the south). The overall mean PSQI score was 11.05 (SD=4.11), and 92% (168/183) had scores >6, indicating poor sleep quality. Mean PSQI scores were similar for men (10.77±3.64) and women (11.15±4.26, p=0.58),

and for non-university (10.71±4.28) and university graduates (11.55±3.81, p=0.18). Northern residents reported significantly poorer sleep (11.95±4.19) than southern residents (10.58±4.00, p=0.03).
Conclusion: High levels of poor sleep quality were observed among civilians in the Gaza Strip, with minimal differences by gender or educational attainment. These findings show an increase from 52.8% reported poor sleep quality in 2022, highlighting the importance of targeted interventions to improve sleep health in populations amid armed conflict. Individuals in the north of Gaza, where attacks and hostilities have been more frequent and intense in the preceding few weeks, experienced significantly worse sleep quality compared to those in the south.

ASSOCIATIONS BETWEEN SLEEP DURATION AND RECEIPT OF MENTAL HEALTH CARE BEFORE AND AFTER THE COVID-19 PANDEMIC IN THE US: NHANES DATA (2017-2023)

Amanda Banaag[1], Mariana Szklo-Coxe[1]
[1] Old Dominion University

Introduction: Short and long sleep duration (SD) have been associated with mental health risks. During the COVID-19 pandemic, US adolescents and adults experienced changes in SD and an increased mental health burden. Due to pandemic-related social isolation measures, many experienced barriers to accessing healthcare services. This study aimed to determine the associations of SD to mental health care utilization and changes in utilization pre and post COVID-19.
Methods: This study utilized NHANES pre- and post-pandemic questionnaire data, 2017-March 2020 and August 2021-August 2023 from a nationally-representative sample of adolescents (ages 13-18) and adults (≥19 years) reporting SD weekdays or workdays, categorized as short, long, and recommended, using AASM's age-specific recommended hours nightly: 8-10 hours for adolescents 13-18; 7-9 hours for adults. Mental health care utilization was defined as receiving care from a mental health provider (last 12 months). Weighted chi-square and multiple logistic regressions assessed mental health care utilization odds by SD. Regressions for adolescent and adult populations adjusted for age, gender, race/ethnicity, health insurance status, and depression symptom presence (defined as PHQ-9 score of ≥4, with 'trouble sleeping' excluded from score calculations).
Results: This study utilized NHANES pre- and post-pandemic questionnaire data, 2017-March 2020 and August 2021-August 2023 from a nationally-representative sample of adolescents (ages 13-18) and adults (≥19 years) reporting SD weekdays or workdays, categorized as short, long, and recommended, using AASM's age-specific recommended hours nightly: 8-10 hours for adolescents 13-18; 7-9 hours for adults. Mental health care utilization was defined as receiving care from a mental health provider in the last 12 months. Weighted chi-square and multiple logistic regressions assessed mental health care utilization odds by SD. Regressions for adolescent and adult populations adjusted for age, gender, race/ethnicity, health insurance status, and depression symptom presence (defined as PHQ-9 score of ≥4, with 'trouble sleeping' excluded from score calculations).
Conclusion: In adults, reporting long sleep was associated with a 1.7-fold significantly higher odds of receiving mental health care during pre-and post-pandemic periods. Findings regarding long sleep's relationship to increased mental health utilization extend the literature on adverse outcomes associated with long sleep to the health services utilization domain and warrant further investigation.

RELATIONSHIPS OF OSA SYMPTOMS AND PRESCRIPTION MEDICATION USE FOR INSOMNIA TO HEALTHCARE UTILIZATION AMONG US ADULTS, NHANES 2017–MARCH 2020

Amanda Banaag[1], Mariana Szklo-Coxe[1]
[1] Old Dominion University

Introduction: Obstructive sleep apnea (OSA) and insomnia are two of the most prevalent sleep disorders in US adults and have been linked to increased healthcare utilization (e.g., emergency care visits, hospitalizations, outpatient visits) in various population subgroups (e.g., older adults, veterans, those with cardiovascular disease). This study aimed to assess relationships between OSA symptoms or prescription medications commonly used for insomnia (MCUFI) and healthcare utilization among a nationally representative sample of US adults.
Methods: Cross-sectional study of US adults (≥18 years) reporting OSA symptoms or MCUFI from NHANES pre-pandemic data (2017-March 2020). Adults with OSA were identified using Zhou et al.'s (2024) methodology and adults with MCUFI were identified using the prescription list methodology in Bertisch et al. (2014), excluding trazodone, doxepin, or quetiapine which were used as adjustment factors. Outcomes were overnight hospitalization and above-average (≥3) outpatient visits reported (past 12 months). Weighted multiple logistic regressions estimated odds for hospitalization and above-average outpatient visits by OSA and MCUFI, adjusted for age, gender, race/ethnicity, marital status, health insurance, education level, comorbidity status (arthritis, heart disease, COPD, diabetes, cancer, kidney disease, depressive symptoms).
Results: 8,005 adults were identified for inclusion, of whom 3,958 reported OSA symptoms, 202 reported MCUFI, 917 reported overnight hospitalization, and 2,824 reported above-average outpatient visits. Higher odds for overnight hospitalization was observed in those reporting OSA symptoms (OR=1.35, 95% CI=1.08-1.69) versus not, and no significant difference in those reporting MCUFI versus not. Higher odds for above-average outpatient visits were observed in those reporting MCUFI (OR=3.20, 95% CI=1.61-6.38) versus not, and no significant difference in those reporting OSA symptoms versus not. A significant interaction between OSA symptoms and health insurance status was found for overnight hospitalization. Hospitalization odds were increased for OSA without (OR=1.40 95% CI=1.10-1.79) versus with (OR= 0.94, 95% CI=0.55-1.60) health insurance.
Conclusion: Using a nationally representative US data set, higher odds of overnight hospitalization were found in adults reporting OSA symptoms and higher odds of above-average visits were found in adults reporting MCUFI. Further research is needed to understand the etiology of increased hospitalizations and outpatient visits among adults reporting OSA symptoms or MCUFI, respectively.

SLEEP QUALITY AMONG WEST BANK CIVILIANS DURING THE ONGOING ISRAEL-GAZA CONFLICT

Bilal Irfan[1], Mohammed Al-Hasan[2], Abdulwhhab Abu Alamrain[3], Majd Abualnour[4], Abdallah Abu Shammala[5], Izzeddin Lulu[6], Nour Alshaer[7], Hrayr Attarian[8]

[1] Harvard Medical School, [2] Princess Alexandra Hospital NHS Trust, [3] Al-Aqsa Martyrs Hospital, [4] Horizons Academy, [5] Gaza European Hospital, [6] Al-Shifa Hospital, [7] Mohammed Yousef El-Najar Hospital, [8] Northwestern University Feinberg School of Medicine

Introduction: Armed conflict is associated with significant sleep disturbances among civilian populations. Limited data exist on sleep health in Palestinians living under the conditions of the current Israel-Gaza War, particularly in the West Bank where armed violence is commonplace, but to a lesser extent than in the Gaza Strip. A study on Israeli adults with data up till January 2024 found that 61% experienced poor sleep quality (PSQI > 5). Understanding the extent of sleep disruptions during active hostilities is crucial to guiding interventions that may mitigate long-term health consequences.
Methods: A cross-sectional survey was administered to individuals residing in the West Bank during ongoing hostilities in December 2024. Participants completed the Pittsburgh Sleep Quality Index (PSQI), which yields a global sleep quality score. Demographic data, including gender, education, and residential area classification (Area A vs. Area B, C, and East Jerusalem), was collected. Statistical analyses included t-tests to compare mean PSQI scores across groups, with $p < 0.05$ considered significant.
Results: A total of 207 participants (43 men, 164 women; 113 non-university graduates, 94 university graduates; 123 from Area A, 84 from other areas) were surveyed. The overall mean PSQI score was 9.13 (SD=3.64), and 84% (174/207) had scores >5, indicating poor sleep quality. University graduates reported significantly higher mean PSQI scores (9.99±3.68) than non-university graduates (8.42±3.46, p=0.0018). Women reported significantly higher scores (9.45±3.52) than men (7.93±3.86, p=0.0147). No significant difference was found between Area A residents (8.80±3.51) and those living elsewhere (9.61±3.78, p=0.12).
Conclusion: West Bank civilians experienced poor sleep quality during the current conflict. Women and individuals with higher educational attainment reported significantly greater sleep disruptions. No significant difference was found among participants living in different legal & administrative enclaves of the West Bank, indicating that the impact of the conflict may be an overarching factor.

A SYSTEMATIC TRANSITION FOR COMPLEX PEDIATRIC SLEEP PATIENTS TO ADULT SERVICES

Susan Telencoe[1], Sachin Pendharkar[1], Adetayo Adeleye[1]

[1] University of Calgary

Introduction: Patients in pediatric sleep clinics can be medically complex, making the transition from pediatric to adult sleep medicine daunting for both patients and health care providers. In Calgary, Canada, a transition clinic was established to facilitate the transfer to new providers while mitigating disruption in care and poor outcomes. The purpose of this study was to describe the model's key structures and processes.
Methods: We conducted a retrospective chart review of all patients attending the transition sleep clinic. Data sources included electronic medical records and paper charting. We used Donabedian's structure-process-outcome framework to describe core elements of the transition clinic model.
Results: From 2017 to 2024, 30 patients (14 female) participated in the clinic. The most common diagnoses were obstructive sleep apnea (n=23, 77%), and narcolepsy (n=4, 13%). Patients with narcolepsy were included until 2022 when pediatric and adult patients were transferred to a sleep neurologist. The mean age at the first pediatric sleep encounter was 8.4 years, and mean age at transition was 17.8 years. 26 patients used NIV with 18/26 using BPAP, 6/26 using CPAP and 2/26 using AVAPS. Prior to transition, mean diagnostic AHI was 39 events/hour and mean oxygen saturation of 91.6%. The average number of comorbidities at transition was 5. Structure: Transition clinics were held at the pediatric sleep center in Alberta Children's Hospital. Health care providers (HCPs) included the pediatric sleep physician, adult sleep physician, and NIV coordinators from both centers. Process:. A pre- and post-clinic discussion was conducted for each patient amongst the HCPs. Transition summaries were prepared by the pediatric team for the EMR. Within each summary, a discussion between the HCPs was documented in 90% of visits, and a discussion with the patient about transition was documented in 87% of visits.
Conclusion: Preliminary findings suggest that a strong foundation of structures and processes can enable safe and effective transition from pediatric to adult sleep care. Further analysis of outcomes can support the rationale for establishing similar transition clinics in other jurisdictions.
Support (if any): This study is unfunded.

FEASIBILITY AND QUALITY EVALUATION OF A WEB-BASED PSYCHOMOTOR VIGILANCE TEST (PVT) SYSTEM FOR SLEEP DISORDER PATIENTS: A PILOT STUDY

Charles Bae[1], Allison Schwab[1], Michael Perlis[1], Anunay Raj[2], Mathias Basner[3]

[1] University of Pennsylvania, [2] NeuroUX, [3] University of Pennsylvania Perelman School of Medicine

Introduction: The Psychomotor Vigilance Test (PVT) is an established tool for assessing sleep deprivation or sleep loss related impairments in daytime function (i.e., fluctuations in attention and concentration that allow for inferences about sleepiness). With the wide adoption of mobile devices, text messaging and smart phone apps have emerged as a potential medium for delivering cognitive and human function tasks. A smart phone accessible, web-based PVT was developed (compatible with Apple and Android devices) to test the utility of PVT assessments as part of routine clinical care. Specifically, we will evaluate the feasibility of deploying a digital PVT via text messages and will monitor completion rates and solicit feedback about the experience. The study is ongoing.
Methods: Ten participants have been enrolled in the ongoing pilot study. Protocol: Send invitations (text messages) to complete a 3-minute PVT along with the Karolinska Sleepiness Scale (single

item) for a period of three months. The PVT and KSS are completed once a week during the first month and monthly for two months. As a feasibility study, the key metrics include completion rates, number of reminders administered per assessment day, and participant feedback on usability, clarity, and satisfaction.
Results: While the study is ongoing, during the first 2 weeks, all participants completed the PVT. Week 1: 80% completed the PVT after the first text message, 20% completed the PVT after the second text message. Week 2: 70% completed the PVT after the first text message, 20% completed the PVT after the second text message.
Conclusion: This pilot study will provide insights into the feasibility and potential challenges of using a text message-based PVT and KSS assessments in a clinical setting. Results will inform future implementation strategies for integrating PVT into clinical workflows. By providing a scalable and easily accessible PVT and KSS assessment tool, this system has the potential to improve patient monitoring, enhance clinical decision-making, and support personalized care for individuals with sleep disorders.

SLEEP APNEA IN HOSPITALIZED PATIENTS IN A RURAL COHORT: A 5 YEAR EXPERIENCE (SAHARA STUDY)

Kassandra Olgers[1], Mayuri Mudgal[2], Asif Rahman[3], Scott Knollinger[4], Vishal Deepak[5], Edward Rojas[6], Robert Stansbury[7], Sunil Sharma[6]
[1] West Virginia University Hospital, [2] Camden Clark Medical Center, [3] WVU Research Corporation, [4] WVU Medicine, [5] WVU, [6] West Virginia University, [7] West Virginia University School of Medicine

Introduction: Introduction Hospital sleep medicine is a novel and growing field. At our tertiary care center, patients are screened by a dedicated respiratory therapist with STOP BANG if BMI > 30 and admitted to internal medicine or cardiology services. All admitting services within the hospital may also request sleep screening studies. Patients are evaluated by a multi-disciplinary team.
Methods: Methods All patients seen by the inpatient sleep medicine consult service who undergo sleep screening testing are retrospectively added to a secure database (REDCAP). Patients who screen positive undergo a level III unattended polysomnography (PSG). PSG results are recorded in the database along with demographics, comorbidities, mortality, 30 day readmissions, discharge medications, and health care literacy scores.
Results: Results The database includes 2,728 patients of which 1449 underwent level III PSG. 530 patients had AHI < 5 whereas 387 had AHI > 5 but < 14. Next, 582 (40%) had suggested moderate – severe sleep apnea with AHI >15. The mean AHI was 16 with a standard deviation of 18.23. The mean age of the cohort was 59 years, of which 56.5% were males (n= 819), with mean BMI of 38.4. Most common comorbidities were congestive heart failure (48%), chronic obstructive pulmonary disease or asthma (36.5%), hypertension (79.7%), diabetes mellitus (46.4%) and atrial fibrillation (29.9%).
Conclusion: Conclusion Sleep apnea poses a significant burden among rural hospitalized patients. Screening for this condition is valuable as it aids in identifying clinically relevant cases and helps address healthcare disparities.

THE CLEVELAND CLINIC HYPERSOMNIA CAREPATH: PRELIMINARY RESULTS OF ADHERENCE AND SAFETY MONITORING

Catherine Di Lisio[1], Jinu Johnson[1], Matheus Lima Diniz Araujo[2], Nancy Foldvary-Schaefer[2]
[1] Cleveland Clinic Foundation, [2] Sleep Disorders Center, Neurological Institute, Cleveland Clinic, Cleveland, OH

Introduction: Patients with CNS disorders of hypersomnolence (CDH) are at increased risk of cardiovascular and other health comorbidities that require frequent monitoring, particularly in the setting of controlled substance use. A 2019-2021 market analysis of patients treated for CDH at Cleveland Clinic found only 27% of patient encounters were clinic visits; others, phone calls or electronic refill requests. Follow-up and safety assessments were not standardized. We piloted a Hypersomnia CarePath that standardizes access and quality and safety monitoring for a growing CDH population aligned with organizational and state regulations. Here, we report pilot phase results of adherence and safety assessments.
Methods: CDH patients on stable pharmacotherapy were enrolled in a follow-up CarePath based on pharmacotherapy type (3-month visits for traditional stimulants; 6-month visits for all other medications). All required one in-person and one physician visit (vs. midlevel provider) per year. Visit compliance was defined as the percent of required visits completed. Annual EKG and UTOX were performed in the 3-month pathway and by physician request for others.
Results: A total of 121 patients were enrolled since July 2022, mean age 42.8 (SD 15.3) yr, 79.3% female, 78.3% Caucasian, 8.3% Black, 5.0% Asian, 8.3% Other. Of these, 81 (67%) were in Q3 and 40 (33%) in Q6 pathways. Age, gender, and race were similar between groups. Visit compliance was 91% overall, 97% for Q3 and 74% Q6. A total of 67 EKGs and 40 UTOX assessments were completed. Abnormal and unexpected UTOX results were found in 4 (10%) cases. Abnormal EKGs were observed in 24 (35.8%) cases including 6 (46.1%) males and 18 (33.3%) females. Patient and caregiver acceptance and satisfaction were highly favorable.
Conclusion: Our novel Hypersomnia CarePath for CDH established standardized follow-up and safety assessments with high visit adherence and patient and caregiver satisfaction. Over one third of EKGs at enrollment (males more than females) and 10% of UTOX studies at the time of enrollment were abnormal. These findings support the need for routine quality and safety monitoring given the known risk of cardiovascular and psychiatric comorbidities in CDH.

UTILIZATION OF ELECTRONIC CONSULTS TO REDUCE WAIT TIMES FOR AN ACADEMIC SLEEP MEDICINE PROGRAM AND IMPROVE TIMELY DIAGNOSIS OF OBSTRUCTIVE SLEEP APNEA

Alexa Lyon[1], Chris Chou[2], Akram Khan[3], Asha Singh[4]
[1] Oregon Health & Science University Hospital, [2] EvergreenHealth Sleep Disorders, [3] Oregon Health & Science University, [4] Oregon Health and Science University

Introduction: Approximately 29.4 million adults in the United States have obstructive sleep apnea (OSA) and prevalence continues to rise. At Oregon Health & Science University (OHSU), access to sleep medicine is limited and clinic wait times are long, often upwards of 90 days, creating significant barriers to timely diagnosis and treatment. This necessitates innovation in the diagnostic process. The electronic consult (eConsult) program at OHSU allows primary care providers to request an asynchronous chart review from a specialist to receive preliminary recommendations without a traditional in-person consultation. We aim to evaluate utilization of the eConsult program and its role in reducing wait times and increasing access to sleep medicine services at OHSU.
Methods: A retrospective review of the electronic health record was conducted on eConsult referrals made to the OHSU sleep medicine clinic for undiagnosed sleep apnea from January 1, 2017 through September 1, 2024. We reviewed data regarding latency between eConsult requests to sleep provider response.
Results: There were 3,631 eConsults for undiagnosed sleep apnea. We found that undiagnosed sleep apnea is the primary reason for eConsults, making up 57% of eConsults placed to sleep medicine. There was a 521% increase in eConsults for undiagnosed sleep apnea when comparing 2017 to 2024 and an average annual increase in eConsult volume of 450% per year. On average, 80% of eConsults received a response from a sleep provider within 72 hours (mean response latency = 1.7 days).
Conclusion: The volume of eConsult referrals for undiagnosed sleep apnea submitted to the OHSU sleep medicine clinic has increased steadily since its inception in 2017. This mirrors the increasing prevalence and awareness of OSA in the general population. eConsults drastically reduce latency between initial referral and sleep provider response, with the majority of recommendations provided within 72 hours. With actionable recommendations more quickly accessible, diagnostic testing can be more expeditiously ordered. This streamlined process enables more efficient triage of straightforward patients with strong suspicion for undiagnosed OSA, which can improve access to treatment and overall health outcomes.

THE ROLE OF AGE, GENDER, AND DAYTIME SLEEPINESS IN PREDICTING CPAP ADHERENCE FOLLOWING BARIATRIC SURGERY

Claire Belevender[1], Serene Ozeir[1], Seif Bugazia[2], Ankita Badhwar[1], Dania Shakaroun[2], Arthur Carlin[2], Timothy Roehrs[2], Virginia Skiba[2]
[1] Henry Ford Hospital, [2] Henry Ford Health

Introduction: Obstructive sleep apnea (OSA) is a common comorbidity in bariatric surgery patients, with continuous positive airway pressure (CPAP) serving as a primary treatment. While bariatric surgery often results in significant weight loss and improvement in apnea severity, the roles of age, gender, and baseline daytime sleepiness—measured by the Epworth Sleepiness Scale (ESS)—in predicting CPAP adherence remain unclear.
Methods: This retrospective chart study reviewed 140 patients evaluated at the Henry Ford Bariatric Clinic and referred to the Henry Ford Sleep Disorders and Research Center for preoperative sleep testing between April and August 2023. CPAP adherence, defined as any reported usage, was analyzed in relation to ESS scores, age, and gender.
Results: Preliminary analyses revealed positive correlation between ESS scores and CPAP adherence, suggesting patients with higher daytime sleepiness are more likely to adhere to CPAP therapy. Older patients demonstrated higher adherence rates. Significant differences in adherence were also observed between genders, with male patients showing consistently higher adherence across all follow-up points.
Conclusion: Age, gender, and baseline ESS appear to play significant roles in predicting CPAP adherence following bariatric surgery. These findings highlight the importance of tailoring postoperative CPAP management to demographic factors, with particular attention to younger and female patients who may benefit from additional adherence support.

PREDICTORS OF PAP ADHERENCE FOLLOWING BARIATRIC SURGERY IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Serene Ozeir[1], Claire Belevender[2], Seif Bugazia[1], Ankita Badhwar[1], Dania Shakaroun[1], Arthur Carlin[1], Timothy Roehrs[1], Virginia Skiba[1]
[1] Henry Ford Health, [2] Henry Ford Hospital

Introduction: Obstructive sleep apnea (OSA) frequently coexists with obesity, and positive airway pressure (PAP) therapy remains the gold standard for its treatment. Bariatric surgery is an effective intervention for significant weight loss, which can alter OSA severity and PAP adherence. This study investigates predictors of PAP adherence post-surgery, focusing on pre- and post-surgery sleep clinic visits, apnea-hypopnea index (AHI), and referral source.
Methods: A retrospective chart review was conducted on 140 patients evaluated at the Henry Ford Bariatric Clinic and referred to the Henry Ford Sleep Disorders and Research Center for sleep testing from April 2023 to August 2023. Data analysis included pre- and post-surgery PAP usage, number of sleep clinic visits, AHI, and referral source. Statistical methods, including ANOVA and correlation analysis, assessed the relationship between these factors and PAP adherence across 3, 6, 9, and 12 months post-operatively.
Results: Significant predictors of PAP adherence included the number of post-operative sleep clinic visits and referral source. Patients with higher baseline AHI were more likely to adhere to PAP therapy at month 12. In addition, more frequent sleep medicine clinic showed evidence of increased PAP therapy adherence. Referral source significantly influenced adherence patterns, with patients referred directly from bariatric clinics exhibiting greater compliance compared to referrals from primary care providers or other sources.
Conclusion: Post-operative sleep clinic visits, referral source, and AHI are significant predictors of PAP adherence following bariatric surgery. These findings underscore the importance of structured follow-up care and referral pathways in promoting PAP adherence and improving long-term outcomes in OSA management.

SUCCESS RATE OF OBSTRUCTIVE SLEEP APNEA DIAGNOSIS IN A DIRECT REFERRAL PROGRAM VERSUS STANDARD CARE

Claire Belevender[1], Serene Ozeir[1], Pranay Korpole[2], Miriam Jaziri[2], Anthony Reffi[3], Beth Mclellan[2], Luisa Bazan[2]

[1] Henry Ford Hospital, [2] Henry Ford Health, [3] Henry Ford Health System

Introduction: Henry Ford Health implemented a Direct Referral program in 2015 to streamline access to sleep testing for obstructive sleep apnea (OSA). This study evaluates the success rate of establishing an OSA diagnosis in the Direct Referral program compared to standard care.

Methods: A retrospective chart review was conducted for patients referred for diagnostic sleep studies between September and December 2022 via a direct referral pathway versus the standard care pathway. Patients aged 18 years or older were included. Exclusion criteria included patients younger than 18 years and those participating in both pathways. Success was defined as completing all required sleep testing to confirm or exclude an OSA diagnosis.

Results: A total of 342 patients in the Direct Referral cohort and 509 in the standard care cohort were reviewed, with 250 and 500 patients completing workup to exclude or confirm OSA diagnosis respectively. The success rate for OSA diagnosis was 60.4% (151/250) in the Direct Referral cohort and 77.4% (387/500) in the standard care cohort (p <.001). Among those completing evaluation, OSA was diagnosed in 141 patients in the Direct Referral cohort and 365 patients in the standard care cohort.

Conclusion: The success rate for OSA diagnosis was significantly higher in the standard care cohort compared to the Direct Referral cohort. Enhanced counseling from sleep specialists in the standard care pathway may contribute to this difference. Efforts to improve compliance within the Direct Referral program are necessary to optimize its effectiveness.

COMPARISON OF TIME INTERVAL TO OBSTRUCTIVE SLEEP APNEA DIAGNOSIS IN A DIRECT REFERRAL PROGRAM VERSUS STANDARD CARE

Serene Ozeir[1], Claire Belevender[2], Pranay Korpole[1], Miriam Jaziri[1], Beth Mclellan[1], Anthony Reffi[3], Luisa Bazan[1]

[1] Henry Ford Health, [2] Henry Ford Hospital, [3] HENRY FORD HEALTH SYSTEM

Introduction: A Direct Referral program was initiated at Henry Ford Health in 2015 to facilitate easier access and expedite sleep testing. The effectiveness of the Direct Referral program in comparison to standard care is unclear in terms of time interval to establish Obstructive Sleep Apnea (OSA) diagnosis.

Methods: A retrospective chart review was conducted for patients referred for diagnostic sleep studies between September and December 2022 via the Direct Referral pathway versus a standard sleep clinic consult. Patients aged 18 years or older were included. Exclusion criteria included patients younger than 18 years and those participating in both pathways.

Results: A total of 342 patients were evaluated for inclusion in the Direct Referral cohort, and 509 patients were assessed for the standard care cohort. Ultimately, 147 patients were included in the Direct Referral cohort, while 268 patients were included in the standard care cohort for final analysis. The mean time to confirm or rule out an OSA diagnosis was significantly shorter in the Direct Referral group compared to the standard care group (51 days vs. 105.6 days; p <.001).

Conclusion: Time to inclusion or exclusion of OSA diagnosis was significantly shorter in the Direct Referral cohort compared to the standard care cohort.

SLEEP QUALITY IN MEDICAL STUDENTS AT A UNIVERSITY IN VENEZUELA AND ITS RELATIONSHIP WITH ACADEMIC PERFORMANCE

OSCAR MEDINA[1], Rosa Peña[2], Angel Perez[2], Edynel Medina[2], Maria Arenales[2], Nora Sanchez[2], Eduardo Torres[3], Manuel Riaño[3], Nora Medina[4]

[1] Universidad Simon Bolivar, [2] Universidad de Los Andes, [3] Universidad Simón Bolívar, [4] Colegio Metropolitano

Introduction: The demands of a medical career can affect the quality of sleep of students, which could affect their academic performance, but also, those who dedicate more time to their studies and sleep less, could have better grades. The aim of this study was to determine the sleep quality of medical students at a university in Venezuela and its relationship with academic performance.
Methods: Observational, descriptive, cross-sectional study. All first, second and fourth year medical students of the Universidad de Los Andes in San Cristóbal, Venezuela were invited to participate. After signing the informed consent, the Pittsburgh Sleep Quality Index was applied and related to their academic performance. Statistical analysis was performed with SPSS 22 and significance was considered less than 0.05. Chi-square was used for categorical variables and Pearson correlation for numerical variables. The study was approved by the Ethics Committee of the Universidad de Los Andes.
Results: Ninety students were included. The mean age was 23.70 years (SD: 3.17; min: 20 and max: 35), 57.8% were female. The mean grade point average was 15.75 out of 20 (SD: 2.20; min: 10 and max: 20). The mean PSQI was 8.46 (SD: 3.47; min: 2 and max: 17), (23.3% good, 56.7% moderate and 20% poor). Sleep latency was 21.94 minutes (SD: 17.21; min: 1 and max: 90) and hours of sleep 5.23 (SD: 1.04; min: 2 and max: 8). Students with better academic performance had higher PSQI scores (Pearson 0.027; P=NS). 0% of students with excellent academic performance reported good sleep quality and 26.7% poor, compared to students with fair academic performance, with 33.3% good and 20% poor sleep quality (P=NS). No significance was found in any of the other study variables.
Conclusion: The sleep quality of medical students tends to be poor. Those with better academic performance present worse sleep quality, probably because they dedicate more study hours at the expense of their sleep hours.

LET'S TALK ABOUT SLEEP!

Crystal Cassimere[1], Rupini Alla[2], Anna Wani[1]

[1] UT Southwestern, [2] Stanford University

Introduction: Exposure to sleep medicine education in ACGME accredited parent specialties of sleep medicine is scarce and varied. Literature states sleep-related didactics average 4.75 hours per year; less than 10% of programs have graduates pursuing sleep medicine fellowship. In the last five y ears at University of Kentucky's Family and Community Medicine residency (UK FM), only 4 of 1200 hours of didactics (less than 1%) have been dedicated to sleep. Lack of sleep education during residency leads to patient care gaps, and deficiency of exposure to this field dissuades trainees from pursuing sleep fellowship. To understand UK FM residents' opinions of sleep medicine, a survey was distributed before and after a formal lecture series.
Methods: Google surveys were disseminated via text message to residents. Submissions remained anonymous. The pre- and post-lecture surveys had congruent questions about sleep education, sleep disorder management, and tested knowledge about sleep disorders. The lecture series had three one-hour lectures during didactics. One week after the last lecture, the post-survey was disseminated. Results were then compared.
Results: The current cohort is comprised of 17 residents. Response rate was 94% for the pre-survey and 76% for the post-survey. After lectures, 46% agreed they had adequate education and understanding of sleep medicine compared to 0% before. Regarding managing specific disorders, more residents answered they had higher comfort after the lectures. Majority of the residents (>50%) answered 2/3 knowledge questions correctly after the lecture series. Overall trends indicated increased confidence and knowledge after the lectures.
Conclusion: By simply increasing sleep education didactics by 3 hours through this project, the total percentage of sleep didactics in resident education was tripled. This increased confidence and competency of resident s in sleep education. Our study highlights the current gaps in resident education related to sleep, the need to increase sleep didactics in sleep medicine feeder residencies, and ultimately how this education increases resident confidence and competency in sleep management.

EPIC MYCHART SLEEP CARE PLAN' TO IMPROVE CONTINUOUS POSITIVE AIRWAY PRESSURE ADHERENCE IN PATIENTS WITH NEWLY DIAGNOSED OBSTRUCTIVE SLEEP APNEA

Hnin Hnin Oo[1], Lakshmi Polisetty[1], Jyoti Lenka[2], Adrian Salmon[1]

[1] University of Connecticut, [2] VA Southern Nevada Healthcare System

Introduction: CPAP therapy is the gold-standard therapy for treatment of OSA. Adherence rates at UConn Health in the past 7 years range from 70 – 81%. Patients on CPAP require support and education to ensure ongoing adherence. A major limitation in the care of patients with OSA requiring CPAP is the lack of novel educational resources. This quality improvement (QI) project aims to improve this via an innovative tool delivered to patients via the Electronic Medical Records (EMR) portal.
Methods: The EMR tool, entitled "MyChart Sleep Care Plan" was designed by the authors with technical support from EMR staff. Briefly, the tool allows newly diagnosed patients with OSA requiring CPAP to enroll and choose their specific device and mask model and type. Our aim is to enroll fifty patients who has familiarity with EPIC MyChart. Patients are provided information on CPAP set up, maintenance, troubleshooting and mask fitting via brief audio/video formats. Sleep hygiene education, reminders and monthly sleep quality questionnaires are also included. The plan is accessible for the first 90 days of CPAP usage, targeting early adherence. Efforts to increase enrollment included emails to CPAP prescribing providers and in-person announcements. The data was analyzed to determine feasibility and further improvements in the tool.

Results: Sixteen patients were enrolled within 7 months with adherence data available for 15 patients to date. The median age was 48 years; 63% were female. 69% of patients had body mass index (BMI) > 30kg/m2. Regarding racial distribution, 44% white, 13% black, 38% Asian, 5% unknown with majority (88%) non-Hispanic in ethnicity. 60% of patients met adherence criteria as defined by US Centers for Medicare and Medicaid Services (CMS). Average 30-day adherence rate was 68%. Average engagement with assigned tasks was 45%. The tasks which were least engaged by patients were reminders for CPAP tubing/ mask cleaning (0-33%) and sleep questionnaires (25-50%).
Conclusion: "MyChart Sleep Care Plan" is a novel tool designed to improve CPAP adherence and provide effective patient education. While the tool is feasible, changes need to be made on an ongoing basis to improve the design and increase patient engagement.

LONGITUDINAL EFFECTS OF SLEEP EDUCATION ON UNDERGRADUATES AND GRADUATES STUDENTS: INSIGHTS FROM STANFORD UNIVERSITY'S DEMENT'S SLEEP AND DREAMS

Rafael Pelayo[1], Bruna de Freitas Dias[2], Giorgio Camillo Ricciardiello Mejia[3], Sara Lomba[4], Aubrey Danielle Lemer[2], Sharon Keenan[5], Cheri D. Mah[2], Emmanuel Mignot[2]
[1] Sleep Medicine Division, Stanford University School of Medicine, [2] Stanford University, [3] Mignot Laboratory, [4] Stanford School of Medicine, [5] The School of Sleep Medicine, Inc.

Introduction: Sleep disorders have become a significant concern among university students. The demanding nature of higher education, coupled with lifestyle factors such as stress, irregular sleep schedules, and academic pressures, exacerbates sleep disturbances and contributes to a range of psychological and physical health problems, including depression, anxiety, and impaired cognitive function. This study aimed to assess the impact of sleep education on university students' sleep-related symptoms.
Methods: Students enrolled in Stanford University's Dement's Sleep and Dreams course were completed the Alliance Sleep Questionnaire (ASQ), a validated tool for measuring sleep quality and disturbances, at the start and end of the course. This college level-course, provides comprehensive education on sleep health and science. The ASQ assesses various self-reported sleep-related issues, including insomnia, daytime sleepiness, circadian rhythm disorders, and the impact of sleep problems on mental health, with scales such as the Epworth Sleepiness Scale (ESS) and the Patient Health Questionnaire (PHQ-9) for depression.
Results: A total of 914 students completed the ASQ from 2016-2024. Students reported significant improvements in sleep-related symptoms over the 10-week course, including reductions in difficulty falling asleep, staying asleep, and waking up too early. Additionally, there was a marked decrease in daytime sleepiness and fatigue, as well as improvements in memory and concentration.
Conclusion: These findings show that a college level course can improve the sleep of students. This study highlights the potential benefits of sleep science courses as a valuable tool for promoting sleep health and well-being.

PREDICTORS OF SLEEP IMPROVEMENTS FROM THE SLEEP EDUCATION FOR EVERYONE PROGRAM (SLEEP)

Alyssa Tisdale[1], Robin Tucker[1], Liz Williams[1], Nahyun Kim[1]
[1] Michigan State University

Introduction: Poor sleep is prevalent among older adults. Sleep issues can lead to reduced quality of life and increased risk of developing chronic diseases. Behavioral interventions have been shown to improve sleep quality and duration. Predictors of success were explored in the SLeep Education for Everyone Program (SLEEP).
Methods: 131 adults participated. The Pittsburg Sleep Quality Index (PSQI) assessed sleep quality and duration; the Sleep Hygiene Index (SHI) measured undesirable sleep behaviors. Median income data based on zip code was obtained from the 2022 American Community Survey 5-Year estimates. BMI was calculated from self-reported height and weight and categorized into lean, overweight, and obese. A linear regression model determined predictors. Group differences were assessed utilizing one-way ANOVA.
Results: Participants were 64.9□13.4 years with an average BMI of 30.0□7.8 kg/m2. Older adults demonstrated greater improvement in SHI scores; less improvement was observed with worse initial SHI scores (adjusted R2=0.30, df=122, F=27.28, p< 0.001). Better sleep quality and greater sleep duration at baseline predicted more improvement in sleep quality (adjusted R2=0.32, df=118, F=57.36, p< 0.001) and duration (adjusted R2=0.43, df=113, F=84.81, p< 0.001) post-program. SHI scores for participants with lean BMI were better at baseline and post-program than overweight and obese BMI (p=0.005, p=0.010 and p=0.031, p=0.042, respectively). PSQI scores at baseline were better for lean participants compared to participants with obesity (p=0.033). Group differences were absent post-program, suggesting participants with obesity improved more (p=0.148). While no differences were present at baseline (p=0.695), sleep duration increased post-program in lean BMI participants compared to those with obesity (p=0.012). Race, education, employment, number of chronic conditions, and income did not predict post-intervention outcomes.
Conclusion: Older age and more favorable initial sleep scores were the best predictors for improvement after completing SLEEP. Individuals with obesity experienced greater gains in sleep quality than those who were lean but less improvement in sleep duration.

ENHANCING PRIMARY CARE PROVIDERS' COMPETENCE IN IDENTIFYING AND MANAGING BEHAVIORAL SLEEP DISORDERS

Ivy Chen[1], Katharine Simon[1], Kamilah McGuire[1], Annamarie Stehli[1], Jane Gagliardi[2], Robert McCarron[1], Ariel Neikrug[1]
[1] University of California, Irvine, [2] Duke University

Introduction: Sleep complaints are common in primary care in both adult and pediatric populations, yet provider training in identifying sleep disorders is limited. The UCI Train New Trainers (TNT) Fellowship addresses this gap by delivering sleep-specific content at their annual conference, designed to improve awareness and diagnostic accuracy of considering sleep disorders such as insomnia and circadian rhythm disorders while formulating differential diagnoses of cases with vague or multiple clinical symptoms.
Methods: Vague case vignettes including symptoms of depression, poor motivation, difficulty with concentration along with sleep concerns were presented several hours prior to (pre-) and one day after the delivery of sleep-specific content (post-) to the fellows from the General (n=172, Myears since degree=10.5±9.0, 66.9% females) and the Child and Adolescent Psychiatry (CAP; n=79, Myears since degree=12.0±9.6, 82.3% females) tracks at the in-person TNT Fellowship's Mid-Year Conference. Cases were specific to each track, with balanced case genders presented at pre- and post-assessment (gender changes, but symptoms remained consistent). Paired t-tests were conducted to analyze pre- to post-lecture differences, with effect sizes calculated using Cohen's h.
Results: Fellows demonstrated significant improvements in their competence in identifying sleep disorders as a possible diagnosis. In the General track, the inclusion of insomnia disorder in differential diagnoses increased from 55.6% at baseline to 85.3% post-lecture (p=0.0019, Cohen's h=0.67). In the CAP track, recognition of circadian rhythm disorders improved from 17.0% to 35.3% (p=0.033, Cohen's h=0.42).
Conclusion: The sleep lecture significantly improved PCPs' diagnostic accuracy in identifying sleep disorders such as insomnia in the General track and circadian rhythm disorders in the CAP track, consistent with the appropriate track-specific content that were covered. Continued training in structured assessments and behavioral sleep interventions is recommended to build on these gains.

SCHOOL-BASED SLEEP EDUCATION AND SCREENING PROGRAM AS PREVENTION TOOL AGAINST SLEEP WAKE DISORDERS

Kristina Blessing[1], Erin Van Enkevort[1], Denise Liscum[2], Nicole Lee[1], Anne Morse[3]
[1] Geisinger, [2] Montgomery Area School District, [3] Geisinger Commonwealth School of Medicine Geisinger Medical Center Janet Weis Children's Hospital,

Introduction: The World Health Organization (WHO) outlines characteristics of conditions that should be screened in schools: the conditions should be prevalent, screenable and actionable. In Pennsylvania, vision, hearing, scoliosis, and growth screenings are required at certain grade levels. In children and adolescents under 18 years of age approximately 6.8% have a diagnosed eye and vision condition, 15-20% with hearing loss, and 2-4% with scoliosis. The 2021 Youth Risk Behavior Survey found 71% - 84% of high school students get less than the recommended 8-10 hours of sleep per, with female students (80%), 12th grade students (84%) and black students (84%) being particularly sleep-deprived.
Methods: A school-based sleep education and screening program was initiated in a rural Pennsylvania school (7th – 12th grades) in December 2020. Sleep education resources were available to students, staff and families throughout the year. Students completed the Epworth Sleepiness Scale - Children and Adolescents and Childhood Sleep Habits Questionnaire during school hours twice per year (fall and spring). Students received immediate feedback on their sleep (healthy or room for improvement). More extensive assessment is offered to families of students with likely sleep pathology, providing information which can be shared with the student's health care provider.
Results: Over 4.5 years, a significant decrease in the percentage of students with sleep pathology based on screening scores has been observed (-30.2%) while participation rates remain consistent. A previously identified trend of 10th – 12th grades reporting significantly less weekday sleep hours than 7th – 9th grades is no longer apparent, with the most recent data showing the average reported weekday sleep hours for every grade within the recommended range for adolescents and an overall mean = 8.4 hours/night, N = 396. Students reporting less than 8 hours of sleep per weeknight decreased from 45.5% in 2020 to 28% in Fall 2024 (-17.5%).
Conclusion: School-based sleep education and screening is a feasible, cost-effective way to promote sleep hygiene and prevent sleep wake disorders among secondary students and is in line with WHO recommendations for school-based screenings.

REST, RESILIENCE, AND RESULTS: THE IMPACT OF SLEEP ON MEDICAL STUDENT HAPPINESS AND ACADEMIC PERFORMANCE

Zane Kaiser[1], Alex Requarth[1], Matthew Garr[1], Kurt Gilliland[1]
[1] University of North Carolina Chapel Hill School of Medicine

Introduction: Medical students face intense demands that often compromise sleep. Adequate sleep has been shown to improve cognitive functioning and emotional regulation, yet its impact on medical student happiness and performance remains underexplored. This study aimed to evaluate the relationship between sleep duration, academic performance, and happiness to identify opportunities for improving student wellness.
Methods: This IRB-approved prospective study enrolled 49 second-year medical students at UNC Chapel Hill from October to December 2023. Participants tracked daily sleep duration and logged self-reported happiness ratings (scale 1-100). Academic performance data were collected via midterms, finals, and USMLE Step 1 practice test scores. Descriptive statistics and correlation analyses were performed using SAS software.
Results: Analysis revealed significant positive correlation between hours of nightly sleep and happiness ($\beta = 0.5286$, $p = 0.0061$). Average weekly sleep duration in top performers (scores of 90%-99%) was 53.48 hours SD 3.70 vs 44.33 hours SD 26.39 in lowest performers (60%-69%). Performance did not differ in students sleeping < 5 hours (83.54) vs ≥5 hours (84.98) the night before exams ($p = 0.72$). Average sleep duration the night before tests vs

all other nights was 6.53±1.98 and 6.66 SD 1.76 hours (p = 0.41), respectively. Sub analysis of sleep before midterms (6.10 SD 2.65) and finals (6.38 SD 1.87) showed no difference compared to non-test days (p = 0.09, p = 0.15). Average nightly sleep time in test weeks vs non-test weeks was 6.65 SD 1.78 vs 6.63 SD 1.78 (p = 0.83).
Conclusion: This study highlights the positive relationship between sleep and happiness while suggesting that high performers sleep more on average with less cohort variability compared to lower performing peers. This suggests institutional interventions like educational workshops or flexible scheduling promoting healthy sleep habits could potentially improve academic performance. Confounding variables potentially impacting performance include differing study routines or baseline fund of knowledge. Further study is warranted to better characterize how sleep habits impact happiness and academic performance.

IMPLEMENTING SLEEP MEDICINE EDUCATION IN MEDICAL SCHOOL CURRICULUM; CHALLENGES AND TRIUMPHS

Madhu Varma[1]
[1] California University of Medical Sciences

Introduction: Sleep medicine education is poorly incorporated in existing medical school curriculum with average education ranging between 0-2 hours in a 4–6-year medical school curriculum. Students are sleep deprived, and ignorant about the importance of sleep medicine and sleep related breathing disorders impacting both their own and their future. Improving knowledge among medical students about sleep related disorders through asynchronous learning was planned and implemented for medical students over one year and impact evaluated.
Methods: 13 medical students M2 and M3 were enrolled in a hybrid sleep medicine education program. 20 hours of Inhouse lectures as well as curated lectures from AASM website were shared with students for online learning and 14 hours of in person lectures were provided. 30 hours of practicum in form of working with sleep physician were added. Students completed a survey on impact of the program on knowledge measures of sleep medicine. Data expressed as percentage.
Results: Improve understanding of fundamental concepts of sleep and the effect of sleep on health- 100% Improved understanding of Sleep Apnea- 100% Understand pertinent history questions and examination for diagnosing and evaluating sleep related disorders- 100% Developed a more informed view of health concerns related to sleep- 100% Improved understanding of Insomnia and its management- 100% Usefulness of the program to your future field of practice- 100% Usefulness of the program to your future field of practice- 100% Quality and effectiveness of teaching- 100%
Conclusion: Sleep medicine knowledge is important for future physicians and our results showed that even though our program was done as co curricular activity, based on over 34 hours exposure in medical knowledge and 30 hour exposure in practicum, overall impact of the program was significant. Sleep medicine should be integrated in medical school curriculum in some form, curricular or co curricular activity are both impactful

UNDERSTANDING KNOWLEDGE, ATTITUDES, AND SKILLS OF HOSPITALISTS' CARE OF THE PATIENT WITH OSA

Nancy Stewart[1], *Anya Koza*[2], *Kaitlin Barnes*[3], *Rhea Mahesh*[1], *Valerie Press*[4], *Mario Castro*[1]
[1] University of Kansas Medical Center, [2] Advocate Aurora Hospital, [3] KCU, [4] University of Chicago

Introduction: An estimated 24 million people in the United States (U.S.) have undiagnosed obstructive sleep apnea (OSA). Untreated OSA is associated with an increased risk of multiple health conditions including atrial fibrillation, hypertension, and stroke. These common disorders often require hospitalization. Research in primary care physicians demonstrates lack of knowledge regarding OSA and risk stratification. Although educational interventions for health care workers (HCWs) demonstrate improved outcomes for patients with OSA, the application of these materials on the in-patient setting is unknown. No study to date has investigated knowledge, attitudes, and skills of caring for sleep disorders, namely OSA by the in-hospital care team.
Methods: A self-selection survey for hospitalists was distributed to ten institutions across the United States via email. Following survey completion, participants were able to register for several incentive drawings. The online survey consisted of 65 questions about knowledge, attitudes, and skills, and took approximately 8 minutes to complete.
Results: Ninety hospitalists at academic and community hospitals responded to the survey. Of respondents, most (88%, n=80) practiced at academic hospitals. While almost half of respondents (42%, n=38) were in the Midwest, nearly a quarter of respondents represented the Northeast (23%, n=21) and the West 32% (n=29), while few (2%, n=2) represented the South. Nearly all (92%, n=83) of the hospitalists knew the gold standard for diagnosing OSA was polysomnogram; however, only one-third (36%, n=32) felt confident in their ability to discuss treatment options for OSA. One quarter (29%, n=26) of the hospitalists knew the purpose of the STOP-BANG Questionnaire in predicting risk of OSA. Less than half (42%, n=38) of hospitalists felt confident in their ability to administer the STOP-BANG for risk stratification.
Conclusion: Our study is the first study to evaluate hospitalists across the nation and their knowledge, attitudes, and skills in obstructive sleep apnea care. This study provides general insight into the current state of some U.S. hospitalists regarding important topics in Sleep Medicine. Additionally, this study identifies specific areas to target future education on OSA for hospitalists.

FINDING THE RIGHT MATCH: THE MORE THE MERRIER?

Victor Chun[1], *Varun Badami*[2], *Armand Ryden*[3], *Michelle Zeidler*[4]
[1] Department of Pulmonary, Critical Care, and Sleep Medicine, University of California, San Diego, [2] Division of Pulmonary and Critical Care, Johns Hopkins University School of Medicine, [3] Division of Pulmonary, Critical Care, and Sleep Medicine,

Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, [4] UCLA Healthcare

Introduction: The Sleep Fellowship application process has undergone several major changes, including a shift to virtual interviews since the 2020 interview season and alignment of the sleep fellowship match date with the American Medical Board Specialties match for the 2021 interview season. Our study evaluates their effects on applicants and match success.
Methods: We collected and analyzed aggregate deidentified sleep applicant rank list and match data from the National Resident Matching Program (NRMP) for the sleep match for academic years from 2012 to 2025. Data tracked over this period included applicant numbers, preferred and alternative specialties and positions offered.
Results: The number of applicants have increased since the implementation of these changes to the sleep match from 187 applicants in 2021 to 227 applicants in 2024. The ratio of applicants to positions increased over 1.0 for the first time in 2021 and has remained over 1.0 since then. For the first two years after the unification of match dates (2022 and 2023), the rise in applicants was entirely driven by those who ranked sleep as their non-preferred specialty (constituting 9% and 18% of total applicants, respectively). From the 2022 - 2025 appointment dates, those who matched into sleep as their non-preferred specialty was 5%, 6%, 3% and 2%.
Conclusion: The advent of virtual interviews has allowed applicants to apply to more programs. The alignment of the sleep fellowship match further increased the number of applicants. Initially, more physicians ranked and matched sleep as their non-preferred specialty. However, this trend reversed in the last two application cycles with improving match success for those who ranked sleep as a preferred specialty.

MULTI-NIGHT VALIDATION OF A SMART BED FOR APNEA DETECTION AND AHI ESTIMATION

Farzad Siyahjani[1], Kostiantyn Kalenyk[1], Saeed Babaeizadeh[1], Gary Garcia Molina[2]

[1] Sleep Number Labs, [2] Sleep Number

Introduction: Traditional sleep apnea diagnosis typically relies on single-night assessments, which may overlook night-to-night variations in respiratory events. Accurate estimation of the apnea-hypopnea index (AHI) requires multi-night monitoring, preferably leveraging unobtrusive monitoring methods. This study validates the Sleep Number smart bed's apnea detection algorithm against CerebraTM level 3 In-home Sleep Apnea Testing (HSAT) device for single-night monitoring and introduces and extends its application to multi-night K-AHI estimation. Instead of using smoothing or filtering methods on single night AHIs which generally overlook AHI weights for different nights, we propose the K-AHI index: count of all detected apneic events divided by total sleep hours in K sessions. We also examine the number of nights (K) necessary for reliable AHI assessment, using the HSAT device as a reference. The study received Institutional Review Board (IRB) approval (#P20220412, Allendale IRB), with all team members properly certified.
Methods: Data were collected for 93 nights using both the HSAT device and Sleep Number beds and 990 nights with only Sleep Number bed's ballistocardiograph (BCG) sensor from 11 participants (Age: mean 46.3 ± 6.5 years, Male/Female ratio 7/4, AHI mean 17.86 ± 12.1). Only six nights with missing or short sleep data were excluded from the analysis. Apnea episodes were detected every second by a BCG-processing deep neural network, marking an episode as apneic if it lasted at least 10 seconds. The K-AHI was then calculated for K = 1,..., 31. The HSAT device showed an average nightly AHI standard deviation of 5.8 across participants.
Results: The smart bed's ability to detect AHI > 10 showed a sensitivity of 88% and specificity of 67% and Receiver Operating Characteristic Area Under the Curve (ROC-AUC) of.80 across the 87 nights when compared to the HSAT device on single night. Aggregating data over 14 nights, the smart bed achieved the highest (ROC-AUC) of 0.85 for detecting AHI > 10, with sensitivity and specificity of 94% and 73% respectively.
Conclusion: The smart bed's apnea detection and KAHI metric show promising potential for seamless apnea risk monitoring, serving as an effective early indicator for undiagnosed individuals and enhancing early detection and intervention.

EFFECTS OF REAL-TIME MATTRESS TEMPERATURE ADJUSTMENT BASED ON SLEEP STAGES ON SLEEP QUALITY DURING THE SUMMER SEASON

Sungjin Heo[1], Jaehyun Bae[1], Joonki Hong[1], Dongheon Lee[1], Dojin Hyun[2], Gyrim Lee[3], Taewon Yun[3], Ki-Young Jung[4], Jeong-Whun Kim[5], In-Young Yoon[5]

[1] Asleep, [2] GNG Hospital Sleep Clinic, [3] KyungDong Navien, [4] Seoul National University, [5] Seoul National University Bundang Hospital

Introduction: There is a wealth of research showing that tropical nights during the summer season can negatively affect sleep quality. As a result, many people resort to sleeping with the air conditioner on throughout the night. Studies have shown that a person's body temperature gradually decreases after falling asleep, reaching its lowest point during deep sleep. Based on this, we aimed to investigate how providing an ideal mattress temperature during the summer affects sleep quality. Specifically, we proposed adjusting the mattress temperature in real-time—raising it during detected deep sleep and lowering it during other sleep stages.
Methods: Over a 10-day period, 30 participants underwent three polysomnography sessions (IRB No.P01-202408-01-035): one for natural sleep, one for constant temperature control (CTC), and another for real-time temperature adjustment (RTA). For both CTC and RTA, the default temperature was set to 28°C, Korea's preferred cooling mat temperature. During deep sleep (N3), RTA raised the temperature to 30°C in real time to prevent awakening caused by body temperature drops. For other sleep stages, including Light (N1, N2), and REM, the temperature returned to 28°C. Meanwhile, CTC consistently maintained 28°C as a control condition to compare the effects of static versus adaptive temperature control on sleep structure.
Results: Our results show significant changes in sleep architecture between Nature, CTC and RTA. Total sleep time (TST) increased from 6h41min, 6h44min to 7h13min (p<. 015, 023) and sleep efficiency (SE) from 83.35%, 83.83% to 89.77% (p<.019,.025). Wake after sleep onset (WASO) decreased from 79min, 78min to 49 minutes (p<.019,.024), REM Sleep extended from 87min, 93min to 106 minutes (p<.015, 018), and Duration of Deep sleep showed a significant difference only in the Nature between RTA. 41min to 56min (p<.047).
Conclusion: The results showed that, compared to the Nature sleep condition, CTC and RTA led to statistically significant improvements in objective indicators of polysomnography: increased TST, SE, increased REM sleep time and deep sleep time, and higher proportions of REM and deep sleep stage. This study confirmed that providing mattress temperature adjustments based on sleep stages during summer can improve sleep quality.

USE OF A HYBRID MATTRESS IMPROVES PERCEIVED SLEEP BUT NOT OBJECTIVE SLEEP

Duvia Lara Ledesma[1], Sharon Danoff-Burg[1], Holly Rus[1], Aislinn Beam[1], Morgan Weaver[1], Kiara Carmon[2], Sophia Markowitz[1]

[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Previous research has shown that comfort, including comfort of the mattress, is essential to sleep quality. In addition to comfort, temperature regulation plays an important role in sleep quality. This study compared sleep on a mattress designed to help the sleeper feel cool to participants' prior sleep on their original mattress.
Methods: Healthy adults (56% female; ages 22-73, mean age=44) who reported sleeping hot, hot flashes, or night sweats, as well as difficulties with frequent awakenings or time spent awake at night, participated in a 10-week field study, using a pre-post

intervention design. During the 4-week baseline period, participants used their regular mattress at home. During the 4-week intervention period, which occurred following a 2-week adjustment period, participants slept on a Serta iSeries Hybrid 2.0 mattress. Sleep was measured objectively using a PSG-validated, non-contact biomotion device, SleepScore Max, every night and by daily and pre-post self-report. Multilevel regression and paired t-tests were used to test for statistical significance.
Results: There were 1,420 nights of tracked sleep across 36 participants. Compared to baseline, objective sleep measurements did not show significant sleep improvement or sleep disruption. Self-report measures revealed improvements in perceived coolness, comfort, support, pressure relief, sleep quality, amount of tossing and turning, sleep satisfaction, and feeling well-rested in the morning (all ps<.001).
Conclusion: Participants reported better sleep quality in numerous ways, when using the mattress being tested compared to baseline, although no objective improvements were seen.

ADJUSTABLE BASE IMPROVES PERCEIVED SLEEP AND PERCEIVED BACK PAIN

Aislinn Beam[1], Sharon Danoff-Burg[1], Holly Rus[1], Morgan Weaver[1], Kiara Carmon[2], Duvia Lara Ledesma[1], Sophia Markowitz[1]
[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Previous research has shown that comfort is important for sleep quality. Adjustment of sleep positions to alleviate pressure can potentially lead to better sleep and less discomfort, including back pain. The current study examined an adjustable base with changeable positions compared to sleeping flat, in a general sample and a subsample with back pain.
Methods: Adults without sleep disorders (M age=47, 72% female) participated in a 6-week pre-post intervention field study. For a three-week baseline period, participants slept flat on their usual bed. For the next three weeks, participants slept on their own mattress using Sleepy's Signature Adjustable Base with adjustable settings (head/feet inclined). Sleep was measured using a PSG-validated, non-contact biomotion device, SleepScore Max, and daily questionnaires. A subset of participants reporting back pain at baseline was also examined. Multilevel regression was used to test for statistical significance.
Results: In the full sample (n=1298 nights; n=42 participants), there were no changes in objective sleep when switching from sleeping flat to using the adjustable base. However, participants reported having better perceived sleep quality (+15%, p<.001), feeling more well-rested in the morning (+18%, p<.001), and less back pain (-28%, p<.001). In the back pain subsample (n=938 nights; n=30 participants), there were no changes in objective sleep, but participants reported better perceived sleep quality (+16%, p<.001), feeling more well-rested in the morning (+20%, p<.001), and less back pain (-27%, p<.001), when using the adjustable base compared to sleeping flat.
Conclusion: When using the adjustable base, objective sleep did not change but perceived sleep and back pain improved, in both a general sample and a subsample reporting back pain.

EFFECTS OF USING AN ADAPTIVE MATTRESS ON OBJECTIVELY MEASURED SLEEP AND SELF-REPORTED SLEEP

Kiara Carmon[1], Sharon Danoff-Burg[2], Holly Rus[2], Aislinn Beam[2], Morgan Weaver[2], Devanshi Upadhyaya[2], Duvia Lara Ledesma[2]
[1] SleepScore Labs LLC, [2] SleepScore Labs

Introduction: Previous research has shown that comfort, including comfort of the sleep surface, is essential to sleep quality. In addition to comfort, temperature regulation plays an important role in sleep quality. This study compared sleep on a mattress designed to adapt to the body and help the sleeper feel cool to participants' prior sleep on their original mattress.
Methods: Healthy adults (53% female; M age=48) who reported difficulties with frequent awakenings or time spent awake at night, and sleeping hot or night sweats, participated in a 10-week field study, using a pre-post intervention design. During the 4-week baseline period, participants used their regular mattress at home. During the 4-week intervention period, which occurred following a 2-week adjustment period, participants slept on a TEMPUR-Adapt Hybrid mattress. Sleep was measured objectively using a PSG-validated, non-contact biomotion device, SleepScore Max, every night and by pre-post self-report. Multilevel regression and paired t-tests were used to test for statistical significance.
Results: There were 1,412 nights of tracked sleep across 35 participants. Compared to baseline, objective sleep showed no statistically significant improvements nor disruptions when using the adaptive mattress compared to the original mattress. Self-report measures revealed increases in perceived comfort (+62%), coolness (+103%), pressure relief (+120%), and support (+68%). Increases were also seen in perceived sleep quality (+69%), sleep satisfaction (+70%), and feeling well-rested upon waking (+85%) (all ps<.001).
Conclusion: Participants perceived many improvements in their comfort and sleep when using the adaptive mattress compared to baseline sleep on their original mattress; however, no changes in objectively measured sleep were observed.

USE OF A COOL TOUCH MATTRESS IMPROVES OBJECTIVE SLEEP AND PERCEIVED SLEEP

Duvia Lara Ledesma[1], Sharon Danoff-Burg[1], Holly Rus[1], Aislinn Beam[1], Morgan Weaver[1], Kiara Carmon[2], Sophia Markowitz[1]
[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Previous research has shown that comfort, including comfort of the sleep surface, is essential to sleep quality. In addition to comfort, temperature regulation plays an important role in sleep quality. This study compared sleep on a mattress designed to help the sleeper feel cool to participants' prior sleep on their original mattress.
Methods: Healthy adults (60% female; ages 24-67, mean age=42) who reported sleeping hot or night sweats, as well as difficulties with frequent awakenings or time spent awake at night,

participated in a 10-week field study, using a pre-post intervention design. During the 4-week baseline period, participants used their regular mattress at home. During the 4-week intervention period, which occurred following a 2-week adjustment period, participants slept on a Purple Restore Cool Touch mattress. Sleep was measured objectively using a PSG-validated, non-contact biomotion device, SleepScore Max, every night and by daily and pre-post self-report. Multilevel regression and paired t-tests were used to test for statistical significance.
Results: There were 1,347 nights of tracked sleep across 34 participants. Compared to baseline, objective sleep measurements showed increases in time spent in bed (+19 minutes, p< 0.001), total sleep time (+21 minutes, p< 0.001) and deep sleep (+5%, p=.025). Significant improvements were seen in SleepScore, an overall sleep quality metric (+4%, p< 0.001) BodyScore (+2%, p=.016) and MindScore (+3%, p=.035). Self-report measures revealed improvements in perceived coolness, comfort, pressure relief, sleep quality, and feeling well-rested in the morning (all ps<.001).
Conclusion: Participants experienced improved sleep quality, sleep duration, and more deep sleep when using the mattress being tested compared to baseline. In turn, they spent more time in bed and slept longer. Additional improvements were seen in self-reported outcomes such as feeling cool, comfortable, more satisfied with sleep, and feeling more well-rested in the morning.

MULTI-FEATURE ADJUSTABLE BASE IMPROVES OBJECTIVE SLEEP, PERCEIVED SLEEP, AND PERCEIVED BACK PAIN

Aislinn Beam[1], Sharon Danoff-Burg[1], Holly Rus[1], Morgan Weaver[1], Kiara Carmon[2], Duvia Lara Ledesma[1], Sophia Markowitz[1]
[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Research has shown that comfort is essential to sleep quality. Adjustment of sleep positions to alleviate pressure can potentially lead to better sleep and less discomfort, including back pain. The current study examined a multi-feature adjustable base compared to sleeping flat, in a general sample and a subsample with back pain.
Methods: Healthy adults (M age=45, 64% female) participated in a 6-week field study using a pre-post intervention design. For a three-week baseline period, participants slept flat on their usual bed. For the next three weeks, participants slept on their own mattress using Sleepy's Elite Adjustable Base with adjustable settings (head/feet inclined, lumbar support, massage, pillow tilt). Sleep was measured using a PSG-validated, non-contact biomotion device, SleepScore Max, and daily questionnaires. A subset of participants reporting back pain at baseline was also examined. Multilevel regression was used to test for statistical significance.
Results: In the full sample (n=1267 nights; n=44 participants), objective sleep improved when using the base, compared to baseline. Participants spent more time in bed (+8 minutes, +2%, p =.027) and scored higher on SleepScore, a sleep quality metric (+2%, p=.011). Participants reported increased perceived sleep quality (+26%, p<.001), less back pain (-45%, p <.001), and feeling more well-rested upon waking (+29%, p<.001). In the back pain subsample (n=536 nights; n=20 participants), participants spent more time in bed (+14 minutes, +3%, p=.025), slept longer (+15 minutes, +4%; p=.027), and spent more time in light sleep (+5.5%; p=.012). Subsample participants also reported increased perceived sleep quality (+31%, p<.001), less back pain (-45%, p <.001), and feeling more well-rested in the morning (+34%, p<.001).
Conclusion: When using a multi-feature adjustable bed base, participants in both a general sample and subsample reporting back pain showed improvements in objective sleep, perceived sleep, and perceived back pain.

INVESTIGATIONAL SLEEP PAD DEVICE INCREASES DEEP SLEEP OF MIDLIFE ADULTS WITH INSOMNIA SYMPTOMS: A RANDOMIZED CLINICAL TRIAL

Margeaux Schade[1], Victor Frolenko[1], David Reichenberger[2], Alexia Torres-Negron[3], Christa-Maria Ngam[4], Anne-Marie Chang[1]
[1] The Pennsylvania State University, [2] Oregon Health & Science University, [3] Harvard Medical School, [4] The University of Pennsylvania

Introduction: Insomnia is a prevalent sleep disorder affecting millions of adults in the U.S. There is a need for nonpharmacologic, accessible insomnia treatments. This pilot clinical trial (NCT05908344) evaluated a consumer-grade emerging technology for its effects on sleep and insomnia symptoms.
Methods: Eligible adults (40-65yrs) with Insomnia Severity Index (ISI) ≥8 completed an 8-week at-home, randomized, double-blind, cross-over intervention study with an investigational 'sleep pad' device. After Week 1 (Baseline), participants were randomized to sleep at home atop either a Sham or Active sleep pad for 3 continuous weeks. When Active, the sleep pad emitted a low-intensity radiofrequency gradient. After Washout (1-4.5 weeks), participants used a sleep pad with the alternate settings (Active or Sham). Sleep data were collected using polysomnography (PSG; staged with AASM criteria) and daily diaries. ISI was collected at the end of Baseline, first intervention period, Washout, and second intervention period. Linear Mixed Effects Models with random intercepts estimated differences between Active and Sham interventions, accounting for randomization order and measurement period. One night of PSG from each intervention period was compared. For self-reported sleep onset latency and ISI, changes from Baseline to the first intervention period were compared with changes from Washout to the second intervention period.
Results: Ten participants completed the protocol (55.2 ±6.0yrs; 8F; 90% Non-Hispanic White). Compared to Sham, NREM3 duration (+5.6 ±2.0mins, p=.025) and proportion (+1.4 ±0.5%, p=.029) were greater with the Active pad. The density of interruptions during NREM3 was lower (-4.1 ±1.6/hr, p=.036) with the Active pad than with Sham. Other PSG sleep stages, sleep duration, and sleep efficiency did not change (p>.05). Neither self-reported sleep onset latency nor ISI (n=8) differed (p>.05).
Conclusion: Sleep pad use deepened and consolidated sleep but did not ameliorate insomnia symptoms. NREM3 improvement may have implications for cognitive, cardiovascular, and immune health in aging. Future research should evaluate the underlying mechanisms and downstream effects of improving sleep with the radiofrequency gradient.

TEMPERATURE PROGRAMS TO ENHANCE SLEEP QUALITY IN WOMEN EXPERIENCING MENOPAUSE SYMPTOMS

Gary Garcia Molina[1], Vidhya Chellamuthu[2], Megha Rajam Rao[2], Leah McGhee[3], Trevor Winger[3], Nikhil Makaram[2], Pavlo Chernega[4], Yehor Shcherbakov[5], Erwin Veneros[6], Raj Mills[3]
[1] Sleep Number, [2] Sleep Number Labs, [3] Sleep Number Corporation, [4] GlobalLogic, [5] GlobalLogic Spain, [6] Nanami

Introduction: Frequent awakenings from sleep increase as women transition through menopause. Vasomotor symptoms (VMS) cause about 30 percent of objective wake-after-sleep-onset. Prior research indicates that inducing cooling sensations may alleviate VMS and improve sleep. Leveraging the ability of a smart bed platform to control the temperature of the in-bed microclimate, this study aimed at identifying temperature settings that enhance sleep quality in women experiencing menopause symptoms. Temperature settings include heating or cooling at three different intensities (low, medium, high). The platform includes validated ballistocardiography-based algorithms to quantify movement and cardiorespiratory metrics during sleep. Using these, a compounded metric (sleep score from 1 to 100) was derived which quantifies sleep quality. The score significantly correlates (positively) with total sleep time, REM and slow wave sleep duration; and (negatively) with sleep latency and wake-after-sleep-onset duration.
Methods: An IRB approved survey was presented to a cohort of Sleep Number customers. The survey included questions about menopause symptoms, severity, and onset date. Out of 483 women reporting menopause symptoms, 62 (mean age 51.8 [SD: 5.2] years-old) owned temperature-controllable smart beds. This analysis considered 183'318 sleep sessions (mean duration 8.3 [SD: 2.3] hours) recorded between October-2022 and October-2024. Each sleep session was subdivided into four 2-hour-long segments starting from 30 minutes before sleep onset. The sequence of temperature settings for each of these segments defines a temperature program. Linear mixed effect models (LMEM) having the sleep quality score as dependent variable, the temperature setting in each segment as fixed factors, and the user identifier as random factor, were fitted to the data.
Results: LMEM results suggest that sleep quality in this population significantly improves by a temperature program consisting in starting with cooling at high intensity, followed by heating at high intensity, and then cooling at low intensity. Sleep quality ~ 71.9 + 6.98×High cooling + 1.83× High heating + 1.00 × Low Cooling + Off All coefficients are significant ($p < 0.05$) and the largest improvement (~10%) is associated with the first setting.
Conclusion: Sleep quality in women experiencing menopause symptoms, may be enhanced through temperature programs. This hypothesis will be tested in an interventional study.

TEMPERATURE PROGRAMS TO ENHANCE SLEEP QUALITY: GENDER DEPENDENCY CONSIDERATIONS

Gary Garcia Molina[1], Megha Rajam Rao[2], Vidhya Chellamuthu[2], Leah McGhee[3], Trevor Winger[3], Nikhil Makaram[2], Pavlo Chernega[4], Yehor Shcherbakov[5], Erwin Veneros[6], Raj Mills[3]
[1] Sleep Number, [2] Sleep Number Labs, [3] Sleep Number Corporation, [4] GlobalLogic, [5] GlobalLogic Spain, [6] Nanami

Introduction: The ability of a smart bed platform to control the temperature of the in-bed microclimate was leveraged to identify temperature programs that enhance sleep quality. A temperature program consists of four 2-hour segments, each with a specific temperature setting (heating or cooling) at three possible intensity levels (low, medium, high), starting about 30 minutes before sleep onset. Heating (cooling) results from pushing (pulling) warm air into (from) the in-bed microclimate. The smart bed includes validated ballistocardiography-based algorithms to quantify movement and cardiorespiratory metrics during sleep. Using these, a compounded metric (sleep score from 1 to 100) was derived which quantifies sleep quality. The sleep score significantly correlates (positively) with total sleep time, REM and slow wave sleep duration; and (negatively) with sleep latency and wake-after-sleep-onset duration.
Methods: Thirty-one participants (12F/19M, mean age 48.6 (SD: 11.2) years-old), recruited among smart bed owners, enrolled in a controlled study within their homes. Each participant experienced 4 OFF only sessions and 10 sessions with temperature programs including balanced heating/cooling conditions at different intensities. Additionally, the data from 2.2 million sleep sessions from 33'814 Sleep Number customers (17482 F/16332 M; mean age 48.8 (SD: 7.0) years-old) that experienced self-applied temperature settings were used to refine the temperature program recommendations. Linear mixed models were used to determine the optimal temperature program (i.e. temperature setting for each segment) to enhance sleep quality.
Results: Controlled study For women and men, heating in the first segment followed by cooling in the second segment significantly increased sleep quality by 13.2 and 7.2 percent respectively. Field data The large amount of data allowed us to identify the temperature setting and intensity for each segment. Sleep quality (women) ~ 65.3 + 6.2×Low Heating + 1.9×Medium Cooling + 1.2×Low Cooling + Off Sleep quality (men) ~ 64.3 + 5.6×Low Heating + 2.2×Low Cooling + 0.92×Medium Cooling + 0.43×Low Cooling The optimal temperature program increases sleep quality by 14% in both women and men.
Conclusion: The results using the controlled study and field data are consistent and suggest that starting with low heating and following with colder settings can enhance sleep quality.

IMPACT OF SMART BED TEMPERATURE PROGRAMS ON FALLING ASLEEP PROCESS: AN EEG-BASED DELTA-BETA RATIO ANALYSIS

Gary Garcia Molina[1], Vidhya Chellamuthu[2], Megha Rajam Rao[2], Yehor Shcherbakov[3], Leah McGhee[4], Trevor Winger[4], Nikhil Makaram[2], Pavlo Chernega[5], Erwin Veneros[6], Raj Mills[4], Kathryn Reid[7], Phyllis Zee[7]
[1] Sleep Number, [2] Sleep Number Labs, [3] GlobalLogic Spain, [4] Sleep Number Corporation, [5] GlobalLogic, [6] Nanami, [7] Northwestern University Feinberg School of Medicine

Introduction: The transition from wakefulness to sleep occurs when the core body temperature decreases. The latter is facilitated by an increase in the cutaneous blood flow, which dissipates internal heat into the micro-environment surrounding the sleeper's body. We leveraged the ability of a smart bed platform to

change the temperature of the in-bed microclimate to assess its effect on the process of falling asleep. The smart bed can either heat-up or cool-down the microclimate by respectively pushing warm air into the bed microclimate or pulling air from it.
Methods: Eighteen participants (9F/9M, mean age 44.5 (SD: 6.7) years-old), spent two nights in the sleep lab. In balanced order, they were exposed to six possible bed temperature settings: cooling at high, medium and low intensity, off, and heating at low and medium intensity. Each setting was applied for three hours starting at the time of lights-off. Polysomnography (PSG), skin temperature, and smart bed logs were recorded each night. PSG data were manually staged into 30-second epochs according to AASM rules. For each sleep epoch, EEG spectra were calculated. As a correlate of sleep depth, the ratio of the power in the delta band (0.5 to 4 Hz) over power in the beta band (15 to 30 Hz) was calculated (DBR) and averaged over 10-min windows starting at sleep onset.
Results: Microclimate temperature settings did not significantly affect the duration of sleep stages. For the DBR analyses, we combined all heating and all cooling conditions to gain statistical power. Heating is significantly associated with deeper sleep compared to cooling in the time intervals [0 to 70] and [120 to 180] minutes. Heating is significantly associated with deeper sleep compared to Off for [0 to 10[, [40 to 60], and [140 to 180] minutes. DBR curves for cooling and Off were not significantly different.
Conclusion: Earlier sleep deepening and deeper sleep are associated with a warmer in-bed microclimate during the first 3 hours after lights-off.

USE OF COOLING BEDDING SET IMPROVES PERCEIVED SLEEP

Kiara Carmon[1], Aislinn Beam[2], Duvia Lara Ledesma[2], Holly Rus[2], Morgan Weaver[2], Sophia Markowitz[2], Sharon Danoff-Burg[2]
[1] SleepScore Labs LLC, [2] SleepScore Labs

Introduction: Research has shown that comfort and temperature regulation are essential to sleep quality. This study investigated whether use of a cooling bedding set would improve sleep in women experiencing temperature-related sleep difficulties. More empirical studies are needed to establish the impact of sleep products, including bedding, on both objective and self-reported measures of sleep quality.
Methods: Healthy adult women ages 40-60 (M=50) who reported difficulty falling asleep or staying asleep, and experiencing disrupted sleep due to sleeping hot, night sweats, or hot flashes, participated in a 6-week field study using a within-subjects, pre-post intervention design. For a 3-week baseline period, participants slept with their usual, non-cooling bedding. For the next 3 weeks, participants slept using Rest bedding (comforter, flat sheet, and two pillowcases). Sleep was measured objectively using a PSG-validated, non-contact biomotion device, SleepScore Max, and perceived sleep was measured with pre-post questionnaires. Multilevel regression and paired t-tests were used to test for statistical significance.
Results: There were 924 nights of tracked sleep across 30 participants. While objectively measured sleep did not change, pre-post analysis revealed increases when using the cooling bedding, compared to baseline, in self-reported sleep quality (+74%; p<.001), satisfaction with sleep (+80%; p<.001), and feeling well rested in the morning (+91%; p<.001). Perceived comfort in bed increased (+87%; p<.001), as did the feeling that the bedding temperature was cooler (+185%; p<.001). Also, the perceived intensity of sleeping hot (-51%; p<.001) and night sweats (-61%; p<.001) were reduced when using the cooling bedding.
Conclusion: No objective sleep improvements or disruptions were observed; however, numerous aspects of perceived sleep improved when sleeping with the cooling bedding, likely because the intervention was perceived as feeling cooler and more comfortable compared to participants' original bedding.

EFFECTS OF A VIBRATING SLEEP MASK ON OBJECTIVELY MEASURED SLEEP: A CONTROLLED, AT-HOME STUDY

Sharon Danoff-Burg[1], Holly Rus[1], Aislinn Beam[1], Morgan Weaver[1], Kiara Carmon[2], Sophia Markowitz[1], Duvia Lara Ledesma[1]
[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Previous research has shown that vibration can increase relaxation, induce drowsiness, and support sleep. The current study examined the effects of gentle vibration delivered via a light-blocking mask on objectively measured sleep outcomes compared to a non-vibrating, light-blocking mask.
Methods: Healthy adults with subclinical threshold sleep problems (M age = 45, 69% female) participated in a 6-week field study comparing Therabody® SleepMask to a non-vibrating control mask. For the first two weeks (baseline), participants tracked their sleep at home as usual, wearing no mask. For the next two weeks, the first group put on the vibrating mask when going to sleep, and the mask vibrated for 15 minutes with gradually decreasing intensity, while the second group wore the non-vibrating control mask to sleep. For the last two weeks, the groups crossed over to wear the other mask. Sleep was measured objectively using a PSG-validated non-contact biomotion device, SleepScore Max. Multilevel regression analyses compared nights when using the vibrating sleep mask to nights when using the control mask, controlling for baseline sleep.
Results: Objective sleep analyses included 2851 nights across 91 participants. Results showed that using the vibrating sleep mask was associated with improvements in objective sleep compared to when using the control mask: more time in bed (+12 minutes, 3% difference, p =.024) and increased sleep duration (+11 minutes, 3% difference, p =.032); lower proportion of light sleep during the night (2% relative difference, p =.035); more time in deep sleep (+3 minutes, 4% difference, p =.007); and higher BodyScore (1% difference, p =.048).
Conclusion: When comparing a gently vibrating, light-blocking mask to a non-vibrating, light-blocking mask, the vibrating mask showed better objective sleep outcomes.

EFFECTS OF A BLUE LIGHT PHONE SCREEN PROTECTOR ON OBJECTIVE SLEEP AND PERCEIVED SLEEP, EYE STRAIN, AND PRODUCTIVITY

Sharon Danoff-Burg[1], Holly Rus[1], Aislinn Beam[1], Morgan Weaver[1], Kiara Carmon[2], Sophia Markowitz[1], Duvia Lara Ledesma[1]
[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: A growing body of research has shown associations between exposure to light at night and negative impacts on health, in part due to suppressing the release of melatonin. People who use electronic devices before bed may increase their exposure to blue light, carrying consequences such as increasing the likelihood of poorer sleep. This study examined effects of a blue light filtering screen protector on sleep.
Methods: Healthy adults (79% female, M age = 39) reporting eye strain and regular light exposure after sunset from their iPhone for greater than 1 hour participated in a 9-week study (baseline sleep measurement at home with no screen protector, followed by using either Eyesafe CPF70 blue light filtering screen protector or a comparison screen protector, followed by crossing over to the other screen protector). Objective sleep was measured using a PSG-validated, non-contact biomotion device, SleepScore Max, and perceived sleep, eye strain, and productivity were measured using questionnaires. Multilevel regression and paired t-tests tested for statistical significance.
Results: There were 1088 nights of data across 36 participants. This abstract reports results of analyses comparing sleep after using the blue light filtering screen protector to sleep after using no screen protector. Compared to baseline, using the blue light screen protector was associated with improved SleepScore, an age- and gender-normalized measure of overall sleep quality (3% increase; p=.026) and improved BodyScore, an age- and gender-normalized measure of deep sleep (2% increase; p=.010). Self-report results showed that participants perceived less severe eye strain, felt productive more days per week, were more satisfied with their sleep, and woke feeling more well-rested (all ps<.05).
Conclusion: Objectively measured sleep quality improved when using a blue light filtering phone screen protector compared to baseline. In addition, participants reported improvements in perceived sleep, eye strain, and productivity.

EFFECTS OF A SUPPLEMENT SYSTEM ON OBJECTIVELY MEASURED SLEEP: A SINGLE-BLIND, RANDOMIZED CONTROLLED STUDY

Holly Rus[1], Sharon Danoff-Burg[1], Aislinn Beam[1], Duvia Lara Ledesma[1], Morgan Weaver[1], Kiara Carmon[2], Sophia Markowitz[1]
[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Supplements have been shown to improve sleep, specifically supplements including melatonin, zinc, and vitamin D. The aim of this study was to evaluate a supplement system on objective sleep outcomes in adults without sleep disorders.
Methods: Adults (55% female, mean age=51) who reported being in good health and screened for physical and lifestyle factors that could affect sleep, participated in a controlled 12-week field study. During the 4-week baseline period, participants slept at home in their usual environment without use of a supplement. For the next four weeks, participants were randomly assigned to use either a supplement or control product. Then they crossed over to use the other product (either supplement or control) for four weeks. The supplement period used Rebalance Health Anxiety System, a three-part supplement system that contains multiple vitamins and dietary nutrients with enhanced absorption. The control was also taken three times a day, and only contained vitamin B2 as an active ingredient. Sleep was measured objectively using a PSG-validated, non-contact biomotion device, SleepScore Max, every night. Multilevel regression was used to test for statistical significance.
Results: There were 1987 nights of data across 35 participants. Compared to control, controlling for baseline sleep, using Rebalance resulted in multiple objective sleep improvements including: decreased sleep onset latency (-4 minutes; 18% difference; p=.003), decreased number of awakenings (6% difference; p=.044), less time awake after sleep onset (13% difference; p=.001), a smaller proportion of the night spent awake after initially falling asleep (p<.001), improved sleep efficiency (p<.001), and improved sleep maintenance (p<.001).
Conclusion: Compared to a control, the supplement system was associated with falling asleep faster, waking up less often, spending less time awake during the night, and better sleep efficiency and sleep maintenance.
Support (if any): Rebalance

SMALL SPACE AIR TREATMENT SYSTEM IMPROVES OBJECTIVE AND PERCEIVED SLEEP OUTCOMES

Morgan Weaver[1], Sharon Danoff-Burg[1], Holly Rus[1], Aislinn Beam[1], Kiara Carmon[2], Sophia Markowitz[1], Duvia Lara Ledesma[1]
[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Previous research has shown that air quality can negatively affect sleep, specifically through irritating nasal passages and affecting allergies. This study examined the effect of an air purifier designed for rooms up to 200 square feet on objective and perceived sleep outcomes.
Methods: Healthy adults living in the US (69% female, M age = 48), who reported sleeping in a bedroom up to 200 square feet participated in an 8-week field study using a pre-post study design. For a four-week baseline period, participants slept as usual, tracking objective and perceived sleep. For the next four weeks, participants were instructed to use Amway Atmosphere Mini ™ Air Treatment System in their bedroom starting 20 minutes before bedtime and running throughout the night. Objective sleep was measured using a PSG-validated, non-contact biomotion device, SleepScore Max, and perceived sleep was measured using daily questionnaires. Multilevel regression was used to test for statistical significance.
Results: There were 1187 nights of data across 28 participants. Compared to baseline, nights using the air purifier showed multiple improvements on objective sleep including: more deep sleep (+3 minutes, 4% increase; p =.020), more REM sleep (+4 minutes, 6% increase; p =.010), higher proportion of REM sleep during the night (6% relative increase; p =.031), higher SleepScore (1% increase; p =.049), higher BodyScore (2% increase; p =.010), and higher MindScore (2% increase; p =.018). When using the air purifier, participants also reported higher perceived sleep quality (p <.001; 17% increase), and feeling more well-rested in the morning (p <.001; 16% increase) compared to baseline.
Conclusion: Objectively measured sleep and perceived sleep improved when using an air purifier in bedrooms up to 200 square feet before and during sleep compared to baseline.

EFFECTS OF AN AIR PURIFIER ON OBJECTIVE SLEEP, PERCEIVED SLEEP, AND PERCEIVED ALLERGY SYMPTOMS

Sophia Markowitz[1], Sharon Danoff-Burg[1], Holly Rus[1], Aislinn Beam[1], Morgan Weaver[1], Kiara Carmon[2], Duvia Lara Ledesma[1]

[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Allergy symptoms can negatively impact sleep quality and quality of life. Exposure to allergens at night can make breathing more difficult by irritating the nasal passages and worsening nasal congestion. This study examined the effectiveness of an air purifier in the bedroom environment to alleviate allergy symptoms during sleep.
Methods: Healthy adults (55% female, M age = 53) reporting difficulty falling or staying asleep, and allergy symptoms that disrupt sleep, participated in a 6-week study (3-week baseline sleep measurement at home with no air purifier, followed by using PuroAir 240 in the bedroom for 3 weeks). Objective sleep was measured using a PSG-validated, non-contact biomotion device, SleepScore Max, and perceived sleep and perceived allergy severity were measured using questionnaires. Multilevel regression and paired t-tests tested for statistical significance.
Results: There were 878 nights of data across 35 participants. Compared to baseline, using the air purifier was associated with increases in minutes of deep sleep (6% increase; p=.036), deep sleep as a proportion of the night (6% relative increase; p=.015), and BodyScore, an age- and gender-normalized measure of deep sleep (2% increase; p=.026). Also, participants experienced fewer awakenings (8% decrease; p=.013). Self-report results showed that participants perceived less severe allergy severity during the night, felt they had better overall sleep quality, were more satisfied with their sleep, and woke feeling more well-rested (all ps<.05).
Conclusion: Objectively measured sleep showed improvement in deep sleep metrics and reduced nighttime awakenings improved when using the air purifier compared to baseline sleep. In addition, participants reported improvements in perceived sleep and allergy symptoms.

LARGE SPACE AIR TREATMENT SYSTEM IMPROVES OBJECTIVE AND PERCEIVED SLEEP OUTCOMES

Holly Rus[1], Sharon Danoff-Burg[1], Aislinn Beam[1], Morgan Weaver[1], Kiara Carmon[2], Sophia Markowitz[1], Duvia Lara Ledesma[1]

[1] SleepScore Labs, [2] SleepScore Labs LLC

Introduction: Previous research has shown that air quality can negatively affect sleep, specifically through irritating nasal passages and affecting allergies. This study examined the effect of an air purifier designed for rooms up to 465 square feet on objective and perceived sleep outcomes.
Methods: Healthy adults living in the U.S. (68% female, M age = 50), who reported sleeping in a bedroom up to 465 square feet participated in an 8-week field study using a pre-post study design. For a four-week baseline period, participants slept as usual, tracking objective and perceived sleep. For the next four weeks, participants were instructed to use Amway Atmosphere Sky™ Air Treatment System in their bedroom starting 20 minutes before bedtime and running throughout the night. Objective sleep was measured using a PSG-validated, non-contact biomotion device, SleepScore Max, and perceived sleep was measured using daily questionnaires. Multilevel regression was used to test for statistical significance.
Results: There were 1284 nights of data across 31 participants. Results indicated that nights using the air purifier showed multiple improvements compared to baseline: longer sleep duration per night on average (+6 minutes; 2% increase; p =.043), better sleep efficiency (1% relative increase; p =.022), more deep sleep in minutes per night (+6 minutes; 7% increase; p <.001), more deep sleep as a proportion of the night (6% relative increase; p =.009), higher SleepScore (1% increase; p =.048), and higher BodyScore (3% increase; p <.001). Participants also reported higher perceived sleep quality (11% increase; p <.001), and feeling more well-rested in the morning (11% increase; p <.001) on nights using the air purifier compared to baseline.
Conclusion: Objectively measured sleep and perceived sleep improved when using an air purifier in bedrooms up to 465 square feet before and during sleep compared to baseline.

SENSITIVITY OF OVERNIGHT HEART RATE VARIABILITY TO DAILY BEHAVIORS AND EXPERIENCES IN A LARGE, REAL-WORLD SAMPLE

Sasha Milton[1], Andrew Cotton-Clay[2], Susan Baron[2], Laura Fava[2], Venkat Easwar[2], Arthur Kinsolving[2], Philippe Kahn[2], Jennifer Zitser[3], Clete Kushida[4], Yue Leng[1]

[1] Department of Psychiatry and Behavioral Sciences, University of California, San Francisco, [2] Fullpower Technologies, Inc., [3] Tel Aviv Sourasky Medical Center, [4] Stanford University School of Medicine

Introduction: Heart rate variability (HRV) is a marker of autonomic function. It is unclear, particularly in real-world settings, whether overnight HRV is sensitive to daily activities and experiences.
Methods: From 9/1/2023-9/30/2024, we measured HRV (SDNN [overall HRV] and RMSSD [parasympathetic activity]) using a commercially available, noninvasive, at-home device (Sleeptracker-AI Monitor, Fullpower Technologies Inc., California, USA) that monitors overnight HRV continuously using under-mattress piezo-electric sensors. Participants answered daily questions addressing alcohol use, caffeine use, smoking, stress, exercise, eating, and sleep quality. We compared HRV across responses using mixed linear models (with participant as a random effect), calculated estimated marginal means (EMMs), and performed pairwise comparisons. Further analyses included age/gender adjustment and exclusion of participants who answered questions the same way every time (completely within-subjects).
Results: Sample size differed by analysis (largest [SDNN by exercise]: 73,009 participants, 1,177,699 nights; smallest [RMSSD by smoking]: 1,145 participants, 2,519 nights; mean of all analyses: 30,906.8 participants, 484,500.6 nights), as did sample characteristics (overall mean age=47.9±12.9 years; 47.4% female). SDNN and RMSSD were lower (p< 0.001 for

all pairwise comparisons) on nights after which individuals reported alcohol use (SDNN/RMSSD EMM=37.3/28.6 ms) vs. non-use (SDNN/RMSSD EMM=40.6/31.9 ms), caffeine non-use (SDNN/RMSSD EMM=39.3/31.0 ms) vs. use (SDNN/RMSSD EMM=39.7/31.4 ms), smoking (SDNN/RMSSD EMM=38.1/32.1 ms) vs. not (SDNN/RMSSD EMM=41.4/34.7 ms), having a stressful (SDNN/RMSSD EMM=39.4/31.1 ms) vs. normal (SDNN/RMSSD EMM=39.8/31.5 ms) vs. stress-free day (SDNN/RMSSD EMM=40.0/31.7 ms), exercising at high intensity (SDNN/RMSSD EMM=39.1/30.8 ms) vs. leisurely (SDNN/RMSSD EMM=39.6/31.4 ms) vs. not exercising (SDNN/RMSSD EMM=40.0/31.6 ms), eating a meal (SDNN/RMSSD EMM=38.7/30.5 ms) vs. a snack (SDNN/RMSSD EMM=39.6/31.3 ms) vs. not eating within two hours of bedtime (SDNN/RMSSD EMM=40.2/31.9 ms), and sleeping not well (SDNN/RMSSD EMM=38.8/30.6 ms) vs. normally (SDNN/RMSSD EMM=39.1/31.0 ms) vs. well (SDNN/RMSSD EMM=39.5/31.2 ms). All comparisons remained significant with similar effect sizes after age/gender adjustment and after exclusion of participants who answered only one way.
Conclusion: In a large, real-world sample, alcohol use, caffeine non-use, smoking, stress, exercise, eating before bedtime, and self-reported poor sleep were associated with decreased overnight HRV. Innovative sleep technologies may help elucidate the link between daily behaviors and experiences and overnight autonomic function.
Support (if any): Fullpower Technologies.

MONTHLY CHANGES IN SLEEP PATTERNS IN KOREANS: A MOBILE SLEEP TRACKING DATA ANALYSIS

Hyuntak Hong[1], Seunghun Kim[1], Sungeun Moon[1], Sooyeon Kim[1], Joonki Hong[1], Dongheon Lee[1], In-Young Yoon[2], Jeong-Whun Kim[2], Ki-Young Jung[3]
[1] Asleep, [2] Seoul National University Bundang Hospital, [3] Seoul National University

Introduction: Korea experiences significant seasonal variations in sunlight, temperature, and humidity, which are expected to influence sleep patterns. However, studies on the effects of these changes on sleep patterns in the Korean population are limited. This preliminary study uses consumer sleep trackers to observe monthly changes in sleep patterns by analyzing data collected from active users of Sleep Routine, a mobile, contactless sleep tracking service.
Methods: Data were collected from December 1, 2023, to November 30, 2024, from users in Korea who used the sleep tracker at least once per month. This service requires users to manually start and stop measurement. Using this data, the following metrics were calculated: measurement time (time in bed), total sleep time, sleep onset time, wake time, sleep onset latency, and wakeup latency. These metrics were observed on a monthly basis to examine changes across different seasons.
Results: A total of 237,190 sessions from 1,067 users were analyzed, with an average of 19,765.8 sessions per month (ranging from 17,321 in December to 21,544 in March). The average number of measurements per user was 222.3 (SD = 74.21, range: 24-358). The average time in bed was 424.7 minutes, and the average total sleep time was 364.9 minutes, with the longest time in December (369.7 minutes) and the shortest in June (358.8 minutes) ($p < 0.001$). Average sleep onset occurred at 12:42 AM, and wake time at 6:39 AM, with the earliest wake time in June (6:34 AM) and the latest in October (6:43 AM). The average sleep latency was 17.85 minutes, and wakeup latency was 7.64 minutes, with the longest latency in August (9.03 minutes) and the shortest in December (6.38 minutes).
Conclusion: Monthly changes in sleep patterns were observed on a significant scale, with notable fluctuations. Specifically, wake time appears to be more influenced by seasonal changes. A limitation of this study is the accuracy of the sleep tracking service, which is expected to improve with ongoing advancements in AI models and further validation studies.

SOCIODEMOGRAPHICS AND MOTIVATIONS PREDICT WEARABLE DATA SHARING WITH HEALTHCARE PROVIDERS

Shuying Yu[1], Meredith Barrett[1], Ann Cameron[1], Graywyn Bareno[1], Xueling Zhu[1], Ross Deas[1], Leanne Kaye[1]
[1] ResMed Science Center

Introduction: Consumer wearables provide personalized insights into health behaviors that can be used to enhance care management for many chronic conditions including sleep health. However, sharing these unique data insights with healthcare providers (HCPs) varies widely. This study investigates predictors of data-sharing among wearable device users.
Methods: Employees of a multinational corporation participated in an e-survey on wearable device usage and behavior between July and August 2024. A weighted logistic regression model assessed the likelihood of a user sharing wearable data with their HCP. Predictors included: sociodemographic factors (age, gender, global region, race, ethnicity, perceived financial security, and self-reported OSA status), data confidence, and sleep tracking motivation. Odds ratios (OR [95% confidence interval]) are reported.
Results: Responses from 1,589 people were assessed (mean (SD) age: 42 (10) years, 46% female), with most respondents reporting current use of a wearable device (64%) and having high confidence in device data accuracy (85%). Users with high data confidence (vs. low confidence) were 2.4 times more likely to share data with their HCPs (2.44 [1.54, 3.96]; $p < 0.001$), and those motivated by sleep tracking (vs. not) were twice as likely to share their data with HCPs (2.01 [1.61, 2.51]; $p < 0.001$). Compared to North American users, users from Europe (0.25 [0.18, 0.34]; $p < 0.001$), Australia & New Zealand (0.54 [0.40, 0.71]; $p < 0.001$), and Asia (0.40 [0.24, 0.65]; $p < 0.001$) were significantly less likely to share their data with HCPs. Hispanic (vs. non-Hispanic) users were 50% less likely to share their data with HCPs (0.51 [0.26, 0.98]; $p < 0.05$). Finally, users who indicated some financial security (vs. no financial security) were significantly less likely to share their data (slightly secure: 0.41, [0.17, 0.97], $p < 0.05$; mostly secure: 0.43, [0.19, 0.94], $p < 0.05$).
Conclusion: Greater data confidence, being motivated by sleep tracking, residing in North America, identifying as non-Hispanic, and lower perceived financial security were important predictors of data sharing with HCPs. Tailoring interventions on sociodemographic factors and user behaviors may help promote

data sharing with HCPs, which may further support chronic disease management.

RELIABILITY OF BRIEF ACCELEROMETER-BASED SLEEP MEASUREMENTS FOR CAPTURING LONG-TERM SLEEP DURATION AND VARIABILITY

Tianyi Huang[1], Sina Kianersi[2], May Beydoun[1], Kaitlin Potts[2], Heming Wang[3], Lenore Launer[1], Susan Redline[4]
[1] National Institute on Aging, [2] Brigham and Women's Hospital, [3] Brigham and Women's Hospital, [4] Department of Medicine, Brigham and Women's Hospital, Harvard Medical School

Introduction: Existing epidemiologic studies examining the associations of sleep quantity and/or variability with incident chronic disease using accelerometers have predominantly focused on short-term measurements, typically spanning several days to one week. Quantitative evidence is lacking on whether these brief sleep assessments accurately reflect longer-term sleep patterns.
Methods: Our study included 6,320 participants (mean age: 52.4 years) from the All of Us Research Program who had a main sleep period recorded by Fitbit on ≥300 days within a calendar year. To simulate sleep studies in real-world settings, we randomly selected one week of data for each participant and calculated the mean and standard deviation (SD) of their sleep duration for that week. We then extended these calculations to the corresponding month and year from which the week was sampled, as well as across all days contributed by the participants (median: 1,368 days; range: 308–3,836). Pearson correlations were calculated among weekly, monthly, yearly and all-available sleep measures. Multiple linear regression was used to examine the associations of mean and SD of sleep duration with sociodemographic factors, evaluating whether these associations differed by the duration of sleep monitoring.
Results: The sample average of mean sleep duration was 412.7, 412.8, 411.7 and 410.5 minutes for the weekly, monthly, yearly and all-available timeframes, respectively. The corresponding average for sleep duration SD was 61.8, 64.6, 68.1, and 72.3 minutes, respectively. The weekly sleep duration means had a correlation of 0.89 with monthly means, 0.83 with yearly means, and 0.77 with all-available means. The corresponding correlation for sleep duration SD was 0.70, 0.60, and 0.54, respectively. Older age, being male, and employment were associated with shorter and less variable sleep duration, whereas racial minority status was associated with shorter and more variable sleep duration. Higher education, being married/partnered, and higher income were only associated with less variable sleep duration. These associations were generally consistent across measures based on different monitoring periods.
Conclusion: One-week accelerometer-based sleep assessment reliably captures longer-term average sleep duration, but accurately characterizing sleep variability may require a longer monitoring period. Our findings provide important evidence that could inform the study design and interpretation in future research.

SLEEP QUALITY IMPROVES AFTER EXERCISE FOR CHRONIC OROFACIAL PAIN: A 4-WEEK ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Salim Muhammed[1], Eric Duan[1], Rachel L. Cundiff O'Sullivan[2], Ana Duarte[1], Yang Wang[1], Luana Colloca[1]
[1] Department of Pain and Translational Symptom Science, University of Maryland School of Nursing, [2] Program in Neuroscience, Graduate Program in Life Sciences, University of Maryland

Introduction: Sleep plays a vital role in human health, with its functions linked to immunity, metabolism, mood, attention, and memory consolidation. Recent research has elucidated a bidirectional relationship between sleep and chronic pain, in that pain often impairs sleep quality which further exacerbates pain. There is a critical need for studies using objective measurements to validate sleep data as they are not subject to limitations inherent in subjective methods (i.e. recall bias). This study incorporated an Ecological Momentary Assessment (EMA) approach to examine the effect of exercise on chronic pain-related outcomes compared to non-exercise standard-of-care in 40 temporomandibular disorder (TMD) patients.
Methods: 40 TMD participants were randomly assigned to an exercise or control group for 30 days. The exercise intervention consisted of daily oral facial muscle movements and general muscle stretching, while the control group continued their standard care. Participants also completed sleep and activity monitoring using a wrist actigraphy watch (CamNTech). Linear mixed models were used to compare exercise and control groups in physical activity and sleep quality.
Results: Of 40 patients, 31 completed the study—16 in exercise, 15 in control—with both groups showing similar baseline chronic pain intensity ((t29=-9,82, p=.421) and pain-related interference (t29=-9,82, p=.421). The exercise group demonstrated significant improvement compared to their non-exercise counterparts in higher sleep efficiency (F1,222.65=187.08; p<.001), lower sleep fragmentation (F1,444.72=4.73; p=.03), longer actual sleep time (F 1,442.65=144.61; p<.001), and reduced sleep latency (F1,606.60=32.52; p<.001). Moreover, actigraphy data confirmed that the exercise group performed longer continuous vigorous activity and shorter sedentary activity than the control group.
Conclusion: These findings highlight the significant role of exercise in enhancing sleep quality among chronic pain patients, particularly by improving sleep duration, efficiency, fragmentation, and latency. However, larger cohorts are warranted to further explore exercise's potential therapeutic role as a mediator to improve pain outcomes through sleep.

REAL-WORLD SLEEP PATTERNS SURROUNDING THE SPRING DAYLIGHT SAVING TIME CLOCK CHANGE IN A LARGE LONGITUDINAL COHORT

Matt Bianchi[1], Balaji Goparaju[2], Yen Oyang[2], Nader Bagherzadeh[2]
[1] Apple Inc., [2] Apple Inc

Introduction: Daylight saving time is a roughly 8 month period framed by one-hour changes in clock time, forward in the spring, and backward in the fall. Although the spring clock change is often described as "losing an hour" of sleep, objective changes in sleep duration and related metrics remain incompletely understood.
Methods: We analyzed objective sleep tracking data from a validated wrist-based sleep tracking feature in over 14,000 adult participants who provided informed consent and opted in to share health and sleep data as part of the IRB-approved Apple Heart and Movement Study.
Results: The average change in sleep duration on the night of the spring shift ("forward") was 22.8 minutes (SD 75.9 minutes) lower compared to the trailing month of weekend sleep. At the individual level, n=3,885 participants (27.5%) lost at least 60 minutes compared to their trailing weekends, while n=4,783 participants (33.9%) were within 30 minutes of their trailing weekends. Comparing those who lost at least one hour of sleep duration to the most consistent group (within 15 minutes of their trailing average), the average age was within 2 years, and the male/female proportions were within 5%. The sub-group means for sleep duration, sleep start time, and nightly variability (SD) of sleep duration were similar (within 10 minutes in each case). Of note, N=1,652 participants (11.9% of the cohort) gained at least 60 minutes on the night of the spring shift. These individuals showed earlier sleep start times than their baseline by a mean of 29.7 minutes.
Conclusion: While the population average showed 23 minutes lower sleep duration on the night of the spring shift, the within-participant sleep changes showed a broad distribution, ranging from >=1 hour loss to >=1 hour gain. This heterogeneity may reflect a combination of vulnerability to clock changes and/or compensatory sleep behaviors, e.g., the earlier sleep start time among those with relatively preserved sleep duration on the night of spring clock change.

ANALYZING SLEEP TIPS ACROSS FOUR MAJOR SOCIAL MEDIA PLATFORMS

Sudha Tallavajhula[1], Lauren Carlisle[2], Luca Costea[3], Ephraim Binu Varghese[4], Netra Tallavajhula[5]
[1] University of Texas Health Sciences Center, [2] Texas A&M University, [3] Glenda Dawson High school, [4] Cypress Ranch High School, [5] Clements High School

Introduction: The undisputed power of social media facilitates the dissemination of all information, factual or otherwise. Sleep tips are no exception. This is especially true because of the high prevalence of sleep disorders and poor access to specialists, magnifying public demand for solutions. Our study aims to analyze sleep 'hacks' on four popular social media platforms. We characterized them by categories [scheduling tips, consumables, environmental aids, and relaxation techniques] and supportive literature.
Methods: Data was collected from four social media platforms: YouTube, TikTok, Instagram, and X (formerly known as Twitter), including 200 videos posted on each platform [except-100 on TikTok] over 2022-24. Variables extracted included user demographic, how many likes the post had, the number of shares (except for YouTube; does not show shares), the number of comments, the number of views (except where not specified; likes were used in this case), content, and research evidence.
Results: 7.6, 3.5, 12.5, and 7.3% tips across X, YouTube, Instagram, and TikTok pertained to sleep scheduling. 40, 59, 13.5, and 33.6% of videos across the four respective platforms related to consumables like food and supplements. Again, across the platforms above, 18, 3.5, 10, and 15.5% of the videos advised environmental solutions. 34, 27, 34, and 41% across the four platforms alluded to habitual relaxation techniques. 30% of Instagram videos incorporated multiple categories of advice. Overall, 59% of videos on X, 26% on YouTube, 20% on Instagram, and 35% on TikTok had evidentiary support in literature.
Conclusion: Consistent sleep scheduling, supported extensively by scientific literature in treating insomnia, receives very little attention on social media platforms. The more popular trends circulate around consumables like food and supplements to help sleep. Relaxation techniques also seem to be popular across these platforms, although there is very little uniformity in the type of relaxation advised. Of concern, only a fraction of "sleep hacks" advertised had any supportive evidence. While it is nearly impossible to analyze every single sleep tip circulating in the media, our research is intended to convince the lay public to seek reliable care and inform providers of the measures their patients are likely to experiment with.

SOUND-BASED AI MODEL FOR ESTIMATING APNEA-HYPOPNEA INDEX IN SLEEP APNEA DETECTION

Seunghun Kim[1], EunSung Cho[1], Hankyeol Kyung[1], Joonki Hong[1], Dongheon Lee[1], Ki-Young Jung[2], In-Young Yoon[3], Jeong-Whun Kim[3]
[1] Asleep, [2] Seoul National University, [3] Seoul National University Bundang Hospital

Introduction: Obstructive sleep apnea (OSA) is a common sleep disorder associated with numerous health outcomes. Accurate diagnosis and severity assessment typically rely on the Apnea-Hypopnea Index (AHI), a standard metric obtained from polysomnography (PSG). However, PSG is costly and impractical for multi-night monitoring. This study validates a sound-based AI model to estimate AHI, exploring its potential as a convenient, contactless monitoring tool for long-term OSA management.
Methods: The AI model simultaneously predicts OSA events, sleep stages and snoring events. Performance was enhanced by improving data quality, extending the attention range, and augmenting Mel spectrogram data. The training dataset included 2,973 nights of sleep recordings collected between 2013 and 2024, using either PSG microphones or smartphone microphones. All recordings were annotated with PSG for both OSA and sleep stages. The model predicts apnea or hypopnea events in 6-second intervals and uses a simple linear regression on their

distribution across the predicted sleep stages to estimate the AHI. Performance was assessed by comparing the estimated AHI with the manually scored AHI from PSG.
Results: On a separate test set of 1,492 nights, the model's estimated AHI strongly correlated with the PSG reference (r=0.97) and showed a mean estimation error of -0.74 events/hour (95% CI: -0.74 ± 11.02). As a screening tool at different AHI thresholds (≥5, ≥15, and ≥30), the model achieved accuracies of 92%, 93%, and 94%; sensitivities of 0.94, 0.94, and 0.93; specificities of 0.88, 0.91, and 0.95; and ROC AUCs of 0.97, 0.98, and 0.98, respectively. When classifying OSA severity into four categories (AHI 0 to < 5, 5 to < 15, 15 to < 30 and ≥ 30), it attained 81% accuracy and a macro F1 score of 0.80.
Conclusion: This sound-based AI model accurately estimates AHI using only audio data, providing a low-cost and contactless approach to OSA screening and management. Its ability to enable home-based, long-term monitoring can greatly improve patient access to diagnosis and care. Future research will focus on enhancing robustness across diverse sleep environments and varying noise conditions.

BRINGING MEDICINE EXPERTISE TO YOUR SCREEN: A NEW FRONTIER IN CURBSIDE SLEEP CONSULTATION LEVERAGING LARGE LANGUAGE MODELS?

Nina Kuei[1], Nhi Lam[2], Kamal Gandotra[3], Pai-Lien Chen[4], Ambrose Chiang[3]
[1] University Hospitals, [2] Cleveland VA Medical Center, [3] Louis Stokes Cleveland VA Medical Center, [4] FHI 360

Introduction: Advances in large language models (LLMs) have opened new avenues for healthcare applications. Recently, ChatGPT-4 successfully achieved the pass mark >80% in 5 of 10 sleep medicine examination domains, indicating a strong foundational knowledge of sleep medicine. However, the ability to answer USMLE-type multiple-choice questions may not equate to the capacity to offer accurate and comprehensive answers to clinical queries or real-world case scenarios. Current literature exhibits a significant gap in validation research examining the clinical utility of LLMs in evidence-based medicine practice. This investigation aims to evaluate the potential usefulness and reliability of LLMs as adjunctive clinical decision-support tools (namely, "curbside consultants") in sleep medicine.
Methods: Six clinical sleep queries and six case scenarios were presented to 6 LLMs including 3 general-purpose LLMs (ChatGPT-4o, Gemini-1.5-Pro, and Llama-3.1-405B) and 3 medical-specialized LLMs (OpenEvidence, Clara AI, and MediGPT). Performance assessment was conducted independently utilizing two independently developed 5-point Likert scales evaluating two primary domains: answer content (accuracy, relevance, comprehensiveness/depth, clarity/coherence, and unique insightfulness) and reference quality (accuracy, relevance, currentness, comprehensiveness/depth, and searchability). Benchmark answers were established through consensus among four sleep medicine specialists. Analysis of variance was used to compare the performance of the LLMs.
Results: The medical LLMs demonstrated superior overall performance compared to the general LLMs (P< 0.001). The primary distinction was observed in reference quality metrics, where medical LLMs significantly outperformed general LLMs across all parameters: accuracy, relevance, and searchability (p< 0.001), currentness (p=0.001), and comprehensiveness/depth (p=0.010). Notably, Open Evidence achieved the highest reference quality (p< 0.001). In contrast, the answer content analysis revealed no significant overall differences between medical and general LLMs (p=0.659). Most answer content-related metrics, including accuracy, relevance, or unique insightfulness, did not differ significantly (p>0.050). An exception was clarify/coherence, where medical LLMs were superior to general LLMs (p=0.030). Furthermore, MediGPT and ChatGPT-4o displayed better content comprehensiveness/depth relative to other LLMs (p< 0.001). These two LLMs exhibited comparable performance in overall metrics (p=0.615), answer contents (p=0.922), and reference quality (p=0.621).
Conclusion: Both medical-specialized and general-purpose LLMs show promise as adjunctive decision-support tools in clinical practice. However, substantial improvements in reference quality are critically needed across most LLM platforms.

EXPLORING THE POTENTIAL OF WAKE PROBABILITY IN HYPNODENSITY FROM A SOUND-BASED AI MODEL AS A MEASURE OF SLEEP DEPTH

Seunghun Kim[1], Sungwoo Park[1], Namhee Kim[1], Jiwon Lee[1], Joonki Hong[1], Dongheon Lee[1], Jeong-Whun Kim[2], Ki-Young Jung[3], In-Young Yoon[2]
[1] Asleep, [2] Seoul National University Bundang Hospital, [3] Seoul National University

Introduction: Conventional sleep staging classifies every 30-second epoch into discrete states, often missing ambiguous states. Hypnodensity, which provides probabilistic estimates of all stages, has shown potential in addressing these ambiguities. In this study, we focused on the wake probability (WP) component of hypnodensity to evaluate its potential as a continuous index of sleep depth, analogous to the Odds Ratio Product (ORP) derived from EEG signals. By integrating WP into a sound-based AI model that uses only audio recordings, we aimed to offer a novel metric for assessing sleep depth without polysomnography (PSG).
Methods: A sound-based AI model was trained on a dataset including 2,973 nights of sleep recordings collected from 2013 to 2024, using PSG or smartphone microphones. Each recording was annotated with PSG for sleep stages. WP was derived by applying a softmax function to the wake-class logit for each 30-second epoch, generating values between 0 and 1. This study evaluated whether WP reflects sleep depth by analyzing its correlation with sleep stages, arousability (likelihood of arousal or awakening), and transitions within individual sleep cycles.
Results: On a separate test set of 1,492 nights, WP effectively predicted sleep/wake states, with a WP < 0.1 and > 0.9 achieving 97% and 93% accuracy for sleep and wake states, respectively. WP values progressively decrease with deeper sleep stages, reflecting increased sleep depth, as mean WP values (±SD) for PSG-defined stages were: W (0.72 ± 0.16), N1 (0.18 ± 0.13), N2 (0.04 ± 0.05), N3 (0.01 ± 0.03), and REM (0.03 ± 0.06). Binning epochs by WP into 20 intervals revealed a strong linear correlation (r = 0.96) with arousability in the subsequent 30-second epoch. In individual sessions, higher WP values consistently matched wake epochs, while small peaks or nonzero WP values frequently coincided with arousals.

Conclusion: WP derived from hypnodensity in a sound-based AI model could offer insights into sleep depth and transitions, complementing conventional sleep staging. Future work will seek additional evidence to support the use of WP as a continuous measure of sleep depth.

THE EFFECT OF EXTENDING TOTAL BEDTIME ON VIDEO GAME PERFORMANCE IN HIGH SCHOOL STUDENTS

Sarah Yaekoub[1], Jack Zarrouf[1], Mark Zarrouf[2]
[1] T. L. Hanna, [2] Glenview School for Engineering

Introduction: The effect of video games (VG) on school performance has been studied thoroughly. The majority of researchers concluded that video games have a negative effect on cognition. Yet we were unable to find a study evaluating the effect of improved sleep and extended bedtime on VG performance and cognition in teenagers during school days. This study investigates the effects of sleep extension on VG performance and cognition, as well as daytime sleepiness in teenagers during school days.
Methods: Using an open label prospective approach, the pilot study investigated students' VG performance, cognitive test (ZZTest), sleep activity tracker findings and daytime sleepiness with daily sleep extension. 30 healthy teenage students (grade 8-12) were asked to participate. They maintained their habitual sleep-wake schedule for a one-week baseline period followed by a one-week sleep extension period. Parental consents were obtained prior to participation in the study.
Results: 26 participants had available data at the end of the study. 9 (35%) females and 17 (65%) males. During the first week, the Mean (SD) bedtime for the participants was 22:40 (0.83), mean wake up time was 6:40 (0.89). Mean wake up time on non-school days was 8:40. During the second week (intervention) the students improved their mean bedtime to 19:10 (8.2) P=0.01. mean wake up time during the second week was not significantly different 7:00 Performance on the subway server game improved significantly between the first week and second of the study (total mean time of ability to stay in the game improved significantly from 151/113 to 478/125 during the second week P=0.001). Further analysis of cognitive test ZZTest is underway.
Conclusion: Improving sleep time and bedtime in teenage students significantly improved their performance on video games. This is the first study to evaluate the effect of improved sleep on video games, rather than the effect of video games on sleep in teenagers.

EXAMINING THE RELATIONSHIP BETWEEN SLEEP AND COVID-19 STATUS IN A US NATIONAL SAMPLE

Ali Aalam[1], Xiaobei Chen[2], Hannah Jury[2], Muhammad Ali Syed[2], Catalina Quintero[2]

[1] Universiy of Florida, [2] University of Florida

Introduction: Despite increasing awareness of COVID-19's long-term effects, its specific impact on sleep remains unclear. This study investigates the relationship between COVID-19 status and sleep quality and duration using a nationally representative dataset.

Methods: Data from 26,260 adults surveyed in the 2022 National Health Interview Survey were analyzed to assess the relationship between sleep duration and quality and COVID-19 status. Sleep duration was assessed by asking participants "On average, how many hours of sleep do you get in 24 hours?" Sleep quality was evaluated based on four indicators of the frequency (4-point scale from never to every day) of sleep disturbances in the past 30 days, including (1) need for medication to help sleep, (2) experiencing trouble falling asleep, (3) experiencing trouble staying asleep, and (4) not feeling well rested. A composite variable was recorded by summing the frequency scores of each indicator, with the highest values indicating poorer sleep quality. Linear regression models were conducted to assess the associations between each sleep outcome and COVID status (1. long COVID or COVID-19-related symptoms lasting 3 months or longer, 2. positive COVID-19 test, 3. no COVID-19), while holding constant the effect of potential confounders (e.g., age, sex, race-ethnicity, education, anxiety in the past two weeks). Analyses accounted for the complex sample design.

Results: Approximately 7% of the sample reported experiencing long COVID, 32% had COVID-19 confirmed by a positive test, and 61% had no history of COVID-19. Compared to those without COVID-19, individuals with long COVID-19 slept approximately 0.3 hours less per night on average (β = -0.27, 95% C.I. = -0.36 to -0.19, $p < 0.001$). Similarly, individuals reporting long COVID demonstrated an approximate 0.4-point increase in poor sleep quality scores compared to those without COVID (β = 0.44, 95% C.I. = 0.31 to 0.58, $p < 0.001$). No significant differences in sleep patterns or quality were observed between individuals with and without COVID (excluding long COVID).

Conclusion: Long COVID was associated with shorter sleep and poor sleep quality. These findings highlight the need to examine the mechanisms involved in sleep disturbances and the role of sleep as a prognostic factor.

SEX, AGE, RACE: MODERATORS OF THE ASSOCIATION BETWEEN SLEEP HEALTH AND MENTAL HEALTH DURING THE COVID-19 PANDEMIC

David Wilton[1]

[1] Loyola University Maryland

Introduction: The COVID-19 pandemic created unprecedented disruptions to daily life, altering health behaviors, including sleep. Sleep health plays a critical role in emotional well-being, with disturbances linked to increased anxiety, depression, stress. COVID-19 offered a unique opportunity to examine how sleep health changes impacted mental health and whether these effects varied across sex, age, race. Understanding these dynamics can inform interventions to mitigate sleep and mental health challenges during global crises.

Methods: These data were drawn from a study examining associations among COVID-related stress, health behaviors, and mental health in May 2020 (Coiro et al., 2021). Participants self-reported 10 changes in sleep health pre- to post-lockdown, including sleep duration, quality, difficulty waking. The 21-item DASS-21 questionnaire (Lovibond & Lovibond, 1995) was used to measure mental health symptoms. Bivariate analyses explored the association between sleep health changes and DASS-21 scores, while moderation analyses examined the influence of sex, age, race on these associations.

Results: Participants (n = 567) were diverse in age (M = 35.7 years, SD = 12.4), sex (54% female), race (35% non-White). Sleep health declines were significantly correlated with higher DASS-21 scores ($r = .51$, $p < .01$). Males reported significantly more mental health symptoms (M = 17.3, SD = 8.4) vs. females (M = 15.6, SD = 7.9); however, females exhibited a stronger association between sleep health declines and mental health vs. males. Non-White individuals and younger adults reported significantly more mental health symptoms than their counterparts, though race and age didn't moderate the association among sleep health declines and DASS-21.

Conclusion: Although women reported stronger associations between sleep health declines and mental health symptoms, men reported worse overall mental health. This suggests that women may be uniquely impaired by disrupted sleep, potentially reflecting differences in gender roles, stress processing, or symptom presentation. Although Non-Whites and younger adults reported greater sleep disruptions, race and age didn't moderate the association between sleep declines and DASS-21. Public health strategies should prioritize accessible sleep health interventions to mitigate mental health risks and build resilience across diverse populations during global crises.

PREDICTORS OF POST-COVID CLINICAL AND COGNITIVE CONSEQUENCES: AN UPDATE

Danny Greig[1], Chandra Miryala[2], Ruchi Rastogi[2], Lariab Imtiaz[2], Bradley Axelrod[2], M. Safwan Badr[3], Lili Zhao[2], Susmita Chowdhuri[2]

[1] John D. Dingell VAMC, [2] JDDVAMC, [3] Wayne State University School of Medicine

Introduction: "Post-acute sequelae of SARS-COV-2 infection (PASC)" is a condition with a wide range of physical and mental health consequences that are present four or more weeks after SARS-COV-2 infection. Fatigue is one of the common post-COVID conditions, but whether sleep disturbances due to COVID-19 infection influence the chronic physical and mental health consequences are unknown. The goal of this pilot study is to assess if sleep disturbances and sleep apnea severity contribute to PASC.

Methods: We prospectively collected sleep, quality of life (QoL) and neurocognitive data in patients with PASC and control participants with OSA but without past COVID-19 infection. Questionnaires were administered at baseline and after 3 months to evaluate sleepiness, fatigue, sleep disturbance, and QoL.

Cognitive testing included Trail Making Test (TMT) A and B, Paced Auditory Serial Addition Test (PASAT), Stroop Task, Digit Coding, Hopkins Verbal Learning Test-R (HVLT-R), Weschler Abbreviated Scale Intelligence II (WASI), Weschler Memory Scale IV (WMS), and Psychomotor Vigilance Test (PVT), respectively. COVID-infection related data was also collected.

Results: We have enrolled 104 total participants thus far; 47 patients with PASC (39 males, 8 females; age: 60.0±12.9 years, BMI: 31.6±5.6 kg/m2, AHI: 36.6±27.8 events/hr, Education: 14.5±2.1 years) and 57 controls (48 males, 9 females; age: 64.6±11.9 years, BMI: 32.1±8.5 kg/m2, AHI: 41.4±27.5 events/hr, Education: 14.3±2.6 years). Baseline data in PASC vs. controls are given as: FSS Total Score: 39.0±13.4 vs. 33.4±14.9.4(p=0.06), ESS: 10.4±4.6 vs.9.0±5.5, PROMISE Sleep Impairment Score: 22.6±9.3 vs.18.7±8.3 (p< 0.05), 6-Minute Walk Test Total Distance Walked: 467.7±102.5 vs. 420.4±84.4 meters, FOSQ Total Score: 16.1±3.0 vs. 15.8±3.9, TMT-A 93.6±16.5 vs. 105.0±14.8 (p< 0.01), TMT-B: 92.9±21.1 vs. 101.6±17.8 (p=0.07), HVLTR Total Recall: 82.8±17.3 vs. 86.6±15.7, WMSIV Visual Reproduction Delayed Recall: 99.0±18.2 vs. 103.8±18.7, Stroop Color-Word Score: 92.0±15.5 vs. 94.8±13.2, WASI-II FISQ4 Score: 93.9±14.9 vs. 94.5±14.8, PASAT Rate 2 Correct: 31.8±24.1% vs. 34.4±14.8%, PVT Mean Reaction Time: 392.9±376.4 vs. 346.7±245.9 ms, PVT lapses 9.5±26.7 vs 1.5±3.2.

Conclusion: Sleep impairment, reduced attention span and increased lapses in vigilance were noted in patients with PASC vs controls. Additional analyses will delineate the associations between post-COVID symptoms, sleep disturbances and cognitive consequences following SARS-CoV-2 infection.

LONG COVID SLEEP DISTURBANCES: PHENOTYPES AND RISK FACTORS FROM A SAFETY-NET HOSPITAL STUDY

Angela Sohng[1], Ariana Rauch[1], Neoreet Braha[1], Shruti Misra[1], Andrew Tsao[1], Ta'kiya Moore[1], Michael Alosco[1], Jai Marathe[1], Sanford Auerbach[1]

[1] Boston University Chobanian & Avedisian School of Medicine

Introduction: Millions globally suffer from long-term functional and cognitive impairment from post-acute-SARS-CoV-2 infection (PASC), or "Long COVID." Sleep disturbances (SDs), either new or exacerbated, are common but under-researched in this population despite their impact on immune function, chronic organ illness, and quality of life.

Methods: Retrospective chart review of patients seen at Boston Medical Center's Long COVID Clinic (01/2022-12/2023). SDs experienced during PASC were classified into four phenotypes: insomnia, hypersomnia, mixed, and other. Binomial and multinomial regression identified predictors, with no SD as the reference and Area Deprivation Index (ADI) as the covariate. P-values were adjusted for multiplicity using the Benjamini-Hochberg method.

Results: Among 452 PASC patients (median age 47, 70.4% Female, 46% White), 28.1% had no SD, while 34.7% reported insomnia, 9.3% hypersomnia, 20.8% mixed insomnia/hypersomnia, and 6.9% other SDs. ADI was the only significant demographic predictor of SD (p=.016); vaccination status, number of infections, and hospitalizations were not predictive. Comorbidities strongly linked to SD-Insomnia included pre-existing insomnia (OR=3.97, p<.01), chronic pain (OR=2.75, p<.01), anxiety (OR=2.24, p<.01), and depression (OR=1.98, p=.024). These also predicted SD-Mixed insomnia/hypersomnia. Additionally, chronic heart disease (OR=5.02, p=.024), OSA (OR=3.16, p=.022), and chronic pulmonary disease (OR=2.76, p<.01) were specifically associated with SD-Mixed. No comorbidities predicted hypersomnia. PASC symptom predictors (all p<.01) included fatigue, post-exertional malaise (PEM), brain fog, anxiety, depression, and POTS/dysautonomia. SD-Hypersomnia was notably associated with PEM (OR=10.39, p<.01), gait instability (OR=9.12, p=.012), and POTS/dysautonomia (OR=8.09, p<.01). SD-Mixed was especially defined by fatigue (OR=18.5, p<.01) and PEM (OR=10.93, p<.01). Notable medication risk factors for SD-Insomnia included benzodiazepines (OR=3.53, p<.01) and PPIs (OR=2.22, p=.033). Beta-blockers (OR=3.46, p=.024) and albuterol (OR=3.40, p<.01) were stronger predictors of SD-Mixed but also significant for SD-Insomnia.

Conclusion: SD-Insomnia and SD-Mixed were strongly linked to pre-existing comorbidities, PASC symptoms, and medications, while SD-Hypersomnia was primarily driven by PASC-related symptoms. Treatment strategies should be tailored based on SD phenotypes: addressing comorbidities and minimizing iatrogenic effects for SD-Insomnia and SD-Mixed, while targeting PASC symptoms of autonomic dysfunction, PEM, and gait instability for SD-Hypersomnia. Recognizing these distinct patterns may improve personalized management of sleep disturbances in PASC.

ASSESSMENTS OF SLEEP AND HOME SLEEP TESTING REFERRALS FROM A LONG COVID CLINIC IN NORTHEAST OHIO

Kingman Strohl[1], Isabelle Carter[2], Anna May[3], Isabella Hsieh[4], Juliane Torer[5], David Rosenberg[5]

[1] University Hospitals Cleveland Medical Center, [2] Rutgers University Robert Wood Johnson Medical School, [3] VA Northeast Ohio Healthcare System, [4] Hawken Academy, [5] UH Ahuja Medical Center

Introduction: In September 2021, one Northeast Ohio hospital system created a Long Haul COVID referral clinic for primary care providers to refer adults with any new or worsening health problems 3 or more months following an acute COVID 19 infection (99.3% PCR documented; 25% post-hospital). A standardized face-to-face clinical evaluation also included current symptoms of fatigue and sleep health, and a prior pre-COVID clinical history, and intake patient-based questionnaires for new or chronic insomnia, excessive daytime sleepiness, regular loud snoring, choking, or a suspicion of sleep apnea.

Methods: Of the initial 287 patients to April 2022, 277 (96.5%) had complete data (61% women, 54 yrs: range 18-90 yrs) Presenting 10 months (range 3-20) after the acute infection. The clinical history and presenting questionnaire data on those with a primary or co-primary complaint of fatigue.

Results: 209 patients (64% women) presented with fatigue as a primary symptom. 109/209 (52%) had one or more sleep symptoms with new-onset insomnia (63/109 or 58%), excessive

sleepiness (44%), heavy snoring and/or suspected sleep apnea (32%), and sleep choking (8%). No demographics nor sleep satisfaction explained this. 87/109 (80%) completed home monitoring with an AHI 4% 10±11/hr (M±SD), heart rate of 68±12 bpm, baseline saturation 95±2%, and percent time < 90% 11±2%. Of these 14/87 (16%) individuals had an AHI >15 (range 15-57/hr), and 36/87 (41%) had an AHI 4% < 5/hr. A higher BMI was associated with an AHI >15/hr (p< 0.001). Neither AHI findings nor symptoms differentiated those with or without fatigue.
Conclusion: Sleep complaints were not unique to fatigue. Those with fatigue accepting home sleep testing could have moderate or severe OSA, but many did not. As recently reviewed (Ely et al 2024), post-COVID fatigue is a collection of frustrating neurocognitive and non-specific traits, but no specific sleep endotypes.

EXERCISE MODALITY AND SLEEP-RELATED INTERFERENCE OF DAILY FUNCTIONING IN COVID-19: COMPARATIVE EFFECTS OF CARDIO AND STRENGTH TRAINING

Nekabari Yakpogoro[1], Alisa Huskey[1], Kathryn Kennedy[1], Michael Grandner[2], Sarah Green[3], William Killgore[1]
[1] The University of Arizona, [2] University of Arizona College of Medicine, [3] University of Arizona

Introduction: Individuals with COVID-19 commonly experience mild to severe sleep disturbances, and impaired sleep can worsen daytime functioning. Cardiovascular exercise can improve immune health and thus, we explored the relationship between self-reported exercise and daytime dysfunction, examining the effects of cardiovascular exercise and strength training. We hypothesized that cardiovascular exercise would have a greater impact on daytime dysfunction than strength training in individuals with COVID-19.
Methods: A total of 13,313 adults completed online surveys between April 2020 and April 2021. We collected data using online surveys during the first thirteen months of the pandemic. Sleep-related interference of daily functioning was measured using a subscale of the Pittsburgh Sleep Quality Index with higher scores indicating greater sleep disturbance. Additionally, participants indicated the number of hours of physical exercise completed each week and to indicate what percent of exercise devoted to cardiovascular training, strength training, or light exercise/stretching. From the larger sample, 743 individuals endorsed that they had been diagnosed with a case of COVID-19. Of these, 725 had usable data on all variables of interest. The final sample include 339 were males (M age=34.17, SD= 9.48), 383 females (M age=35.12, SD=10.59) and 3 did not report sex. A multiple linear regression with simultaneous entry was conducted to determine which exercise modality predicted sleep-related interference with daily functioning in the context of the others.
Results: The combination of exercises accounted for 1.8% of the variance in sleep-related daytime dysfunction (R^2=0.018,F(3,721)=4.45). There was a significant negative association between cardiovascular exercise and the interference of sleep problems with daily functioning (β=-0.175, p< 0.031), and a positive association between light exercise and sleep-related daytime dysfunction (β=0.225, p< 0.002). There was no statistically significant correlation between strength training and the interference of sleep problems with daily functioning (β=0.051, p=0.358).
Conclusion: Individuals diagnosed with COVID-19 and who performed more cardiovascular exercise, and less stretching/light exercise reported fewer problems with daily functioning due to sleep issues. This underscores the need for cardiovascular exercise-related interventions in the treatment of COVID-19 and potentially other respiratory infections.

EFFECT OF CPAP ON COGNITIVE FOG IN POST COVID PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Venkatesh Krishnamurthy[1], Kristine Wilckens[2], Pinar Garbioglu[1], Stuti Vaidya[1], Steven Swanger[1], Alexis Whitehead[1], Sanjay Patel[1]
[1] University of Pittsburgh, [2] University of Pittsburgh School of Medicine

Introduction: Cognitive fog is a frequent complaint among patients suffering from post-COVID Condition, reported in up to 60% of patients. Obstructive sleep apnea (OSA) commonly co-occurs in post-COVID Condition and may exacerbate symptoms. We sought to evaluate if treatment of OSA with continuous positive airway pressure (CPAP)decreases cognitive fog in post-COVID patients with OSA.
Methods: Patients with post COVID Condition, as per World Health Organization criteria, with self-reported symptoms of cognitive fog and diagnosed with OSA were recruited. They underwent neuropsychological testing to evaluate processing speed with Trail-Making Task A and Digit Symbol Substitution; executive function with the Stroop, Trail Making Task B, and digit span; semantic and categorical fluency; spatial memory assessed with the Benson complex figure task; and global cognition assessed with the Montreal Cognitive Assessment (MoCA) at baseline and 4±2 weeks after starting CPAP.
Results: Among 14 patients who completed the study, the mean age was 48.5 ±14.5 yrs, 57% were women, 14% were Black, median AHI was 12 (12;27), mean BMI was 34.3±10.1, and the mean nightly CPAP use was 5.8±2.6 hours. Cognitive function improved with CPAP on the following tests: Digit Symbol Substitution (post CPAP 60.9±2.7 vs baseline 53.6±2.9, p=0.01), Stroop color test (75.2±3.6 vs 66.9±2.1, p< 0.01), Stroop color-word test (46.9±3.3 vs 41.6±3.0, p< 0.01), Benson complex figure-delayed (13.9±0.6 vs 12.3±0.5, p=0.047). In addition, patients reported improvements on PROMIS cognitive function (26.7±2.1 vs 17±1.6, p< 0.01), Epworth Sleepiness Scale (ESS) (5.9±1.2 vs 10.5±1.1, p< 0.01), Insomnia Severity Index (ISI) (12.4±1.5 vs 18.9±1.2, p< 0.01), and the stress (12.6±2.3 vs 18.3±3.1, p< 0.01) and depression (10.3±1.9 vs 14.7±1.9, p=0.01) subscales of the Depression and Anxiety Stress Scale-21. Changes in PROMIS cognitive score (r=0.63, p=0.02) and Trial Making test A (r=-0.58, p=0.048) were correlated to the duration of nightly CPAP use.
Conclusion: Our findings suggest screening and treating comorbid OSA among patients with post-COVID Condition can improve cognitive fog.

PRAZOSIN INDUCED PARESTHESIA: A REFRACTORY RESTLESS LEGS MIMICKER

Katherine Seibert[1],[2], Aaron Thomas[2], Abigail Maller[1],[2]

[1] University of California Los Angeles, [2] Veterans Affairs, Greater Los Angeles Healthcare System

Introduction: Restless Legs Syndrome (RLS) is a clinical syndrome characterized by an urge to move the legs while at rest that occurs primarily at nighttime and improves with movement. RLS is a clinical diagnosis as no objective testing is available to confirm the diagnosis. Other conditions may impact patients' extremities during sleep, potentially leading to a misdiagnosis of RLS. We describe the case of a patient who had prazosin induced paresthesia that was mistakenly diagnosed as refractory RLS.
Report of case: A 32-year-old man with post-traumatic stress disorder and a body mass index of 49 kg/m2 presented in 2014 with snoring. He was diagnosed with severe obstructive sleep apnea (OSA) on a home sleep apnea test, respiratory event index of 36.4 events/hour. He started auto-adjusting positive airway pressure (APAP) therapy. He presented for follow up at four and eight months after starting APAP without any lower extremity symptoms. However, he did report nightmares and was started on prazosin 2 mg nightly. At his follow up visit 5 months later, he noted partial improvement of his nightmares on prazosin, but new onset of lower extremity discomfort at nighttime. He was diagnosed with RLS and started on gabapentin. His ferritin level was 429 ng/mL and transferrin saturation was 32%. Over the ensuing follow up visits, his prazosin was titrated to 12 mg nightly with only partial improvement in his nightmares. Meanwhile, his lower extremity symptoms proved to be severe and refractory to high doses of gabapentin, ropinirole, pregabalin and acetaminophen with codeine. In 2023, his diagnosis of RLS was called into question given his atypical symptoms of sharp, 'pins and needles' lower extremity pain and refractoriness to treatment. After chart review revealed a temporal correlation between symptom onset and prazosin initiation, prazosin induced paresthesia was considered. His lower extremity symptoms resolved shortly after prazosin discontinuation.
Conclusion: RLS is a common sleep disorder, however many conditions present with nighttime lower extremity symptoms creating a diagnostic challenge for clinicians. Clinicians must carefully consider whether a patient's symptoms are consistent with RLS or a mimicker. Our case highlights a rare RLS mimicker of prazosin induced paresthesia.

AN "EYE-CLOSING" EXPERIENCE: A RARE CASE OF POST-COVID HYPERSOMNIA

Mariam Mirza[1], Efeose Airewele[2], Hrayr Attarian[3]

[1] Northwestern Memorial Hospital, [2] Northwestern University, [3] Northwestern University Feinberg School of Medicine

Introduction: Idiopathic hypersomnia (IH) is a central disorder of hypersomnolence characterized by excessive daytime sleepiness, long unrefreshing naps and morning inertia. Some triggers may include abrupt shifts in sleep-wake cycles, viral illnesses, anesthesia, and head trauma. Age of onset is usually 15 to 30 years. We report a case of post-COVID late onset IH.
Report of case: An otherwise healthy 54-year-old male presents with daytime sleepiness for two years. He had no sleep complaints prior to that. In 2022 he noticed his productivity decline and fell asleep behind the wheel. He reported cognitive difficulties including trouble with word finding, remembering names, and loss of fluency since 2020, after he had COVID. He had no vaccines except for the shingrex vaccine three months before the onset of sleepiness. Epworth sleepiness score was 20 and he reported long unrefreshing naps. Neurological exam and testing including blood work, neuropsychological testing, MRI Brain, and PET brain scan were all normal. He had a normal polysomnogram and the MSLT the next day showed a MSL of 2.5 minutes with no SOREMPs.
Conclusion: There have been four cases of primary hypersomnias reported following COVID-19 infections, three IH, and one narcolepsy type 2. All three cases of IH were below age 35. The narcolepsy type 2 case was a 54-year-old male with a history of hypertension and OSA who reportedly had improvement 20 months after the infection (Morelli-Zaher et al 2024). Biologically active agents, including vaccines, may cause hypersomnia in vulnerable individuals. A sudden increase in the incidence of narcolepsy was reported in several European countries following the influenza A (H1N1) vaccination campaign with Pandemrix (Mignot 2020). In addition, prior studies have noted up to 62.5% cases of sleepiness after the administration of COVID-19 vaccines (Sakinah et al 2021). There has also been a case report of hypersomnia relapse, possibly due to COVID-19 vaccination (Wu 2021). There have been no reported cases of hypersomnia following shingrex vaccine. Our case may represent a manifestation of long-COVID, or a rare reaction to shingrex.

SUCCESSFUL TREATMENT OF BIOT'S CENTRAL SLEEP APNEA WITH PHRENIC NERVE STIMULATOR IN A PATIENT WITH RHEUMATOID ARTHRITIS AND CHRONIC OPIOID USE

Huda Khan[1], Uriet Dewan[2], Abigail Boudreaux[1], Alexandria M. Fornerette-Harris[3], Tara Thomas[3], Antara Mallampalli[1], Supriya Singh[1]

[1] Baylor College of Medicine, [2] St. George's University, [3] Michael E. Bakey VA Medical Center

Introduction: Central sleep apnea (CSA) is characterized by recurrent episodes of apnea due to a lack of respiratory effort, often associated with heart failure. This case discusses an instance of Biot's central sleep apnea exacerbated by chronic opioid use secondary to rheumatoid arthritis (RA), highlighting the successful use of a phrenic nerve stimulator (PNS) as a treatment modality in this patient.
Report of case: A 52-year-old male with RA presented to our sleep center with complaints of excessive daytime sleepiness, frequent nocturnal arousals, and snoring. The patient had been on chronic opioids for pain management. Given these symptoms, a polysomnography (PSG) study was conducted. The AHI (Apnea-Hypopnea Index) was 37 events per hour, with a total of 164 respiratory events consisting of 137 central apneas (Biot's central apneas), 7 obstructive apneas, and 20 hypopneas. The oxygen saturation nadir was 85%. The arousal index consisted of

50 events per hour, and the patient exhibited mild snoring during the study. These polysomnography findings indicated severe CSA likely exacerbated by opioid use. An attempt was made to taper opioid use to improve central event burden; however, this led to inadequate pain control, profoundly impacting the patient's activities of daily living (ADLs). The patient could not tolerate bilevel positive airway pressure (BPAP) therapy due to claustrophobia and hand deformities from rheumatoid arthritis, which hindered independent mask usage. Considering the challenges of traditional therapies in this patient and the severe nature of his CSA, a phrenic nerve stimulator was recommended. The device successfully implanted and was activated six weeks post-implantation. At 12-week follow-up, a repeat PSG was performed, demonstrating an AHI of 7 events per hour, consisting primarily of hypopneas. The patient reported enhanced sleep quality and increased daytime alertness.
Conclusion: Currently, PNS is employed primarily for CSA due to heart failure. However, this case expands its application to opioid-induced CSA, demonstrating PNS to be an effective treatment that leads to significant improvements in both sleep quality and daytime functioning. This case underscores the importance of individualized treatment strategies in complex sleep disorders and highlights the need for further research into the applications of PNS in diverse patient populations.

TIRZEPATIDE TREATMENT OF OBESITY HYPOVENTILATION SYNDROME

Patrick Holman[1,2], Hollyann Loui[2,3], Michelle Zeidler[1,2], Kevin Eng[4],
[1] UCLA Healthcare, [2] West Los Angeles VA, Department of Medicine, Division of Pulmonary, Critical Care & Sleep Medicine, [3] UCLA, [4] UCLA David Geffen School of Medicine

Introduction: Individuals with an elevated body-mass-index (BMI) are at higher risk for obstructive sleep apnea (OSA), and those with a BMI above 30 may develop obesity hypoventilation syndrome (OHS). Mechanisms of hypoventilation include increased respiratory workload, decreased diaphragmatic excursion, and changes in respiratory drive and lung compliance. New classes of medications such as glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1) agents have been approved for diabetes and weight loss. More recently, in the SURMOUNT-OSA trial, Tirzepatide was shown to treat moderate to severe sleep apnea in obese patients1. There is a paucity of data on using these medications in patients with OHS.
Report of case: A 68-year-old female with obesity (BMI 38) was diagnosed with OSA with an apnea-hypopnea index (AHI) of 23. She was started on automatic positive airway pressure (APAP) with excellent compliance but persistent elevation in serum bicarbonate. Arterial blood gas showed paCO2 of 49, with a normal pH. A polysomnogram titration to CPAP of 13 resolved respiratory events, but TcCO2 levels were 53-56 with borderline low oxygen levels. Pulmonary function testing showed mild restriction. Chest imaging excluded underlying lung disease. She was started on intelligent volume-assured pressure support (iVAPs) but experienced pressure intolerance and transitioned to spontaneous bilevel positive airway pressure with normalization of her paCO2. She was started on Tirzepatide for weight loss and achieved significant reduction of BMI to 27. Given her difficulty tolerating BPAP, a repeat PSG was done which showed AHI of 12 without hypoventilation. She transitioned back to APAP with improvement in tolerance and symptoms.
Conclusion: Obese patients with sleep apnea and elevated serum bicarbonate should be evaluated for OHS. For patients with OHS, weight loss is a vital part of management. Our case demonstrates successful treatment of OHS through weight loss assisted by a GLP-1 medication.

WHEN NORMAL IS NOT PERMANENT: LATE-ONSET CONGENITAL CENTRAL HYPOVENTILATION SYNDROME IN A CHILD WITH PHOX2B NPARM MUTATION

Tamanna Mahesh Kumar Chandak[1], Katharina Graw-Panzer[2]
[1] New York-Presbyterian - Weill Cornell Medicine, [2] Weill Cornell Medicine

Introduction: Congenital Central Hypoventilation Syndrome (CCHS) is a rare disorder caused by mutations in the PHOX2B gene, leading to impaired autonomic control of respiration. Non-polyalanine repeat expansion mutations (NPARM) account for approximately 10% of CCHS cases and are often associated with neural crest tumors. Classic CCHS symptoms typically present at birth with alveolar hypoventilation during sleep. Here, we present a rare case of a pediatric patient with a PHOX2B NPARM mutation who developed central hypoventilation at 6 years of age.
Report of case: An 18-month-old male with a PHOX2B: c.234_240del (p.Tyr78)* NPARM mutation was referred for respiratory evaluation. He had a history of stage IV neuroblastoma at 9 months of age, which was in remission after treatment with chemotherapy and surgical resection. No respiratory insufficiency was noted at birth, during anesthesia, or with respiratory infections. Initial polysomnography at 19 months of age showed severe obstructive sleep apnea (OSA) with an Apnea-Hypopnea Index (AHI) of 14/hr, no central apneas, and no hypoxemia. The end-tidal CO_2 ($EtCO_2$) maximum was 59 torr, with 53% of total sleep time (TST) spent >50 torr. An ENT evaluation revealed no airway obstruction. A CPAP titration study effectively eliminated all hypopneas at 7 cmH_2O while maintaining a transcutaneous CO_2 ($TcCO_2$) maximum < 50 torr. Subsequent CPAP titration studies at 3 and 4 years of age demonstrated effective resolution of hypopneas at CPAP 9 cmH_2O. The $TcCO_2$ maximum values were 49 torr and 51 torr, respectively. At 6 years of age, a split-night polysomnography was performed to reassess his baseline respiratory status. The diagnostic portion of the study showed resolution of OSA (AHI 0/hr) but revealed significant hypoventilation with $EtCO_2$ maximum 56 torr and 60% of TST spent >50 torr. Thus, the patient was diagnosed with late-onset CCHS. BPAP 15/7 cmH_2O with a backup rate effectively maintained CO_2 < 50 torr.
Conclusion: This case highlights the importance of serial polysomnography in children with PHOX2B mutations as delayed onset of hypoventilation can occur in childhood or adulthood. Early detection and timely escalation of therapy to support ventilation are crucial in preventing long-term complications, including cognitive and developmental impairments resulting from prolonged hypoxia and hypercapnia.

MICRONIZED PROGESTERONE INDUCED SLEEP PARASOMNIAS: A RARE ASSOCIATION

Anam A. Sabwari[1], Edward Rojas[2], Robert Stansbury[3], Robert Young[1], Stephen Coutras[1], Sunil Sharma[2], Mouhannad Azzouz[1]

[1] West Virginia University Dept. of Sleep Medicine, [2] West Virginia University, [3] West Virginia University School of Medicine

Introduction: Progesterone-induced sleep parasomnia is a rare neuropsychological condition that can manifest as somnambulism and sleep-related eating disorder (SRED) in women. The precise mechanism underlying this phenomenon remains unclear. Discontinuing the offending agent, micronized progesterone, is typically the treatment of choice.
Report of case: A 48-year-old female presents to the sleep clinic with complaints of hypersomnia, sleep walking and nocturnal eating episodes.. She described episodes occurring a few hours after falling asleep, during which she would leave her bed, walk around, and eat from the refrigerator, with no recall of the events upon waking. Medications on presentation included Prometrium (micronized progesterone), Singulair, Albuterol, and Ferrex. Both EEG and brain imaging were unremarkable, and a previous polysomnogram (performed 10 years ago) had been negative for sleep-disordered breathing. Initially, the treatment plan involved watchful waiting, and a repeat polysomnogram was considered. At a follow-up visit four months later, the patient reported undergoing an elective hysterectomy, after which Prometrium was discontinued. Following the discontinuation of micronized progesterone, the parasomnia episodes resolved.
Conclusion: In this case, micronized progesterone was identified as the likely cause of sleep parasomnias. No better explanation could be identified, as the episodes ceased after discontinuation of the medication. While progesterone analogs may enhance overall sleep quality and reduce sleep movements through positive allosteric modulation of the GABA type A receptor, and also help in increasing NREM sleep, a direct relationship with progesterone and sleep parasomnias remains unclear. Further research is needed to determine a definitive connection between progesterone and sleep parasomnias.

WORSENING OF SLEEP APNEA WITH HYPOGLOSSAL NERVE STIMULATION OVER-TITRATION

John A. Das[1], Stephanie Stahl[2]

[1] Western Reserve Hospital, [2] Indiana University School of Medicine

Introduction: Hypoglossal nerve stimulation (HGNS) is a treatment for obstructive sleep apnea. Through stimulation of the hypoglossal nerve, genioglossus activation causes the tongue to protrude and subsequent airway enlargement. After implant and a period of self-adjustment, a HGNS titration polysomnogram is typically performed to determine optimal settings. We describe a case of over-titration, leading to worsening sleep-disordered breathing (SDB).
Report of case: A 67-year-old woman with snoring and witnessed apneas initially underwent a baseline home sleep study with a respiratory event index of 45.5/h. She was unable to tolerate positive airway pressure and subsequently underwent HGNS implant. At her HGNS activation visit, she was sent home on an outgoing setting of 0.8V (functional threshold), patient control range 0.6-1.6V, + - + electrode configuration, 90/33 pulse width/rate. At her follow up, she was on 1.5V, had good usage at an average of 7.9 hours/night, and reported improved snoring and resolution of witnessed apneas. A HGNS titration study was then performed on electrode configuration + - +, 90/33 pulse width/rate, and amplitudes 1.3-1.9V. Her SDB was well controlled in the lateral position in NREM sleep on 1.3 and 1.4V with an apnea-hypopnea index (AHI) < 10/h; however, frequent events were seen in the supine position. On settings 1.7V and higher, increasing events were seen in the lateral position with an AHI >30/h and sleep became more disrupted. A trial of lowering to 1.3 or 1.4V with positional therapy was recommended.
Conclusion: This case demonstrates that over-titration of HGNS can lead to worsening of SDB. Limited data is currently available on HGNS over-titration. The mechanism for this worsening is not well understood. Possible causes include increased sleep disruption with higher stimulation and subsequent respiratory instability. Another postulated cause is that higher voltages could activate muscles that not only cause tongue protrusion, but also those that cause tongue retraction. An alternative explanation suggests that high voltages increase fatiguability of the genioglossus muscle. With the rising use of HGNS, providers should be aware of this potential adverse effect. When SDB continues to worsen with advancing amplitudes, lower voltages should be considered.

DRUG-INDUCED SLEEP ENDOSCOPY FOR EVALUATION OF HYPOGLOSSAL NERVE STIMULATOR EFFICACY: A CASE REPORT

Abdullah Arjomand[1], Katie Tribuls[1,2], Kevin Patel[3]

[1] University of South Florida, [2] Tampa General Hospital, [3] James A. Haley Veterans Affairs Medical Center

Introduction: Drug-induced sleep endoscopy (DISE) is a crucial step for determining hypoglossal nerve stimulator (HNS) therapy candidacy in the treatment of obstructive sleep apnea (OSA). Currently, DISE is not routinely used to evaluate efficacy of therapy following HNS implantation. We present the case of a patient with OSA who underwent DISE for evaluation of HNS therapy following implantation and titration.
Report of case: A 54 year old man with a prior medical history including class I obesity and systemic hypertension was seen in follow-up of longstanding OSA. He initially trialed positive airway pressure (PAP) therapy, of which he was intolerant, and subsequently underwent HNS implantation and titration. Home sleep apnea test with HNS therapy demonstrated residual severe OSA. He then attempted to resume use of PAP in addition to HNS, however he remained unable to adhere to PAP. He was then fitted for a mandibular advancement device (MAD) to use in conjunction with HNS. Subsequently, he had difficulty tolerating MAD due to headaches. At that point, the decision was made to perform a drug-induced sleep endoscopy (DISE) with use of both HNS and MAD to visually evaluate the residual obstructive respiratory events and assess for possible alternative treatment options. During DISE, complete velopharyngeal collapse was observed with and without use of optimally-titrated HNS and concurrent MAD. Additionally, near-continuous obstructive apneas were observed with both therapies in use, with prolonged,

severe oxygen desaturations. The procedure was terminated, and treatment options were discussed with the patient with recommendation for tracheostomy if still unable to tolerate PAP therapy, with consideration of possible upper airway surgeries.
Conclusion: DISE currently has a clearly defined role in the evaluation of candidacy for HNS for OSA. The above case illustrates a possible additional role for DISE in the evaluation of HNS treatment efficacy.

OVERCOMING TREATMENT-EMERGENT CENTRAL SLEEP APNEA: A CASE OF DUAL NEUROMODULATION WITH HYPOGLOSSAL AND PHRENIC NERVE STIMULATOR

Arashdeep Rupal[1], Kevin Patel[2], W. McDowell Anderson[3]
[1] University of South Florida, [2] James A. Haley Veterans Affairs Medical Center, [3] University of South Florida Morsani College of Medicine

Introduction: Central and obstructive sleep apnea (CSA/OSA) are typically managed with positive airway pressure (PAP) therapy. For patients unable to tolerate PAP, novel implantable devices, such as hypoglossal nerve stimulation (HNS) for OSA and phrenic nerve stimulation (PNS) for CSA, provide alternative treatment options. While treatment-emergent central sleep apnea (TeCSA) is a recognized phenomenon in OSA patients transitioning to a central apnea pattern under PAP therapy, recent studies have also anecdotally associated persistent TeCSA with HNS. TeCSA presents a significant challenge, as PAP intolerance impacts both CSA and OSA patients in a similar manner. This case report describes the successful management of TeCSA following HNS implantation for OSA, leading to the resolution of CSA with the use of PNS.
Report of case: A 57-year-old male with class I obesity (BMI: 32 kg/m^2) presented with excessive daytime sleepiness (ESS 16). Polysomnography (PSG) demonstrated severe OSA with an Apnea-Hypopnea Index (AHI) of 35, without significant central events. The patient was unable to tolerate Continuous Positive Airway Pressure trial due to claustrophobia and frequent mask leaks. A drug-induced sleep endoscopy revealed >75% tongue-related obstruction and absence of complete concentric collapse at the velum, confirming the patient as an appropriate candidate for HNS. The patient underwent HNS implantation, followed by PSG titrations and sleep endoscopies with adjustment in voltage settings. At lower voltages, persistent OSA was observed, while at higher voltages, the patient developed TeCSA. A PSG conducted at the higher voltage setting revealed an AHI of 38 with central apnea index (CAI) of 34. Echocardiography ruled out heart failure as a contributing factor. Due to persistent symptoms (ESS 17), a PNS was implanted and after appropriate titration of HNS and PNS systems, the patient experienced significant improvement in his symptoms and severity of sleep apnea with resolution of CSA (AHI 16, CAI 1).
Conclusion: As HNS use for treating OSA in patients with PAP intolerance becomes more prevalent, TeCSA may emerge as a significant therapeutic challenge due to the limitations of using NIV for its treatment. In carefully selected patients, neuromodulation with PNS may offer a safe and effective alternative for managing persistent TeCSA.

BUPRENORPHINE-NALOXONE FOR THE TREATMENT OF MEDICALLY REFRACTORY RESTLESS LEGS SYNDROME: A CASE SERIES

Emma Sherfinski[1], Hira Chaudhary[1], Yasemin S. Tashman[1]
[1] Mayo Clinic Arizona

Introduction: Restless Legs Syndrome (RLS) affects up to 3% of the adult population in the United States, with approximately one-third of these individuals experiencing medically refractory disease. Historically, treatments for RLS have included iron replacement, dopamine agonists, and alpha-2-delta ligands. However, dopamine agonists are often associated with augmentation, a phenomenon in which RLS symptoms worsen. This includes increased severity, earlier onset, spread of symptoms to other parts of the body, and the need for higher doses of medications. Over the past decade, the use of opioid therapy for refractory RLS has become more widely accepted. Buprenorphine-naloxone, a combination medication, includes buprenorphine, a partial agonist at the mu-opioid receptor, which is less likely to cause respiratory depression, overdose, or euphoria compared to full agonists. Naloxone, an opioid antagonist, is included to deter misuse. Here, we share the treatment responses of three patients with refractory RLS who were treated with buprenorphine-naloxone.
Report of case: Pre- and post-treatment IRLS were compared in three Sleep Medicine patients (two females, aged 70, and one male, aged 72) on therapeutic doses of buprenorphine-naloxone. Patient charts were reviewed for medication side effects. Previous treatments included dopamine agonists, alpha-2-delta ligands, iron supplementation, benzodiazepines, methadone, and melatonin. Pre-treatment IRLS scores were 13, 13, and 24, classified as moderate to severe. The formulations used included buprenorphine-naloxone 2-0.5 mg sublingual tablets and buprenorphine-naloxone 2-0.5 mg 1/8 films. Therapeutic daily doses of buprenorphine-naloxone ranged from 7.5 to 60 morphine milligram equivalents (MME) per day. Post-treatment IRLS scores were 0, 2, and 3, representing an average reduction of over 15 points on the IRLS. Average time between pre- and post-treatment IRLS was 29 months. Side effects were reported by one patient, including fatigue, depressive symptoms, and reflux, but none of the patients experienced side effects that limited the use of the medication.
Conclusion: In this case series, we demonstrate the positive impact of buprenorphine-naloxone in managing refractory RLS, as evidenced by substantial reductions in IRLS scores from moderate to severe levels. We hope to encourage clinicians to consider buprenorphine-naloxone as an effective and well-tolerated treatment option for patients with refractory RLS.

EARLY-ONSET RESTLESS LEG SYNDROME WITH RAPID PROGRESSION AND GABAPENTIN-INDUCED AUGMENTATION: A CASE OF COMPLEX MANAGEMENT IN A PEDIATRIC PATIENT

William Rosales[1], Malvika Sagar[1]
[1] Baylor College of Medicine

Introduction: Restless leg syndrome (RLS) is a neurological disorder linked to various medical, psychiatric, and sleep conditions, including mood disorders and Attention Deficit Hyperactivity Disorder (ADHD). Early-onset RLS occurs before age 35, usually with gradual symptom progression. Iron deficiency plays a key role in its pathophysiology. First-line treatments include alpha2-delta calcium channel ligands like gabapentin, while dopamine agonists (DA) are second-line. This report discusses a case of rapid symptom progression and response to combination therapy with gabapentin and pramipexole.
Report of case: An 11-year-old male with a history of Anxiety, and ADHD who had been experiencing RLS for two years. Symptoms started as an urge to move his legs while in bed at night and significant bilateral leg paresthesia, relieved by leg movement; the sensation progressed to his abdomen and chest over time. At the time of the initial diagnosis, Ferritin levels were within normal limits, and a polysomnogram (PSG) was done with no evidence of sleep-disordered breathing or periodic limb movement disorder. He was started on Gabapentin 100 mg at night at the time of the initial diagnosis and the dose was increased over time as he experienced symptom recurrence and worsening despite initial improvement. Currently, he is on Gabapentin 700 mg, and Guanfacine 1 mg, which was also added during previous visits for ADHD management. Pramipexole 0.125 mg was started 18 months after the initial diagnosis, with adequate control of symptoms. Irritability and behavioral issues were noted shortly after, which the mother attributed to the combination of Guanfacine and Pramipexole, with discontinuation of Guanfacine and recurrence of mild RLS symptoms, with the patient having approximately 4 episodes per week at the moment.
Conclusion: Augmentation, a dose-related iatrogenic worsening of RLS symptoms, is commonly associated with long-term use of DA. This report depicts a rare case of possible RLS augmentation from alpha2-delta calcium channel ligand use, and interval improvement of symptoms when combination therapy was started. Behavioral changes were noted shortly after the initiation of Pramipexole. Impulse control disorder and Irritability have been reported as common adverse effects of DA use, which highlights the importance of adequately tailoring therapy according to each patient's comorbidities.

HIGH-DOSE RIVASTIGMINE IN REM BEHAVIOR DISORDER - A THERAPEUTIC COINCIDENCE OR STROKE OF LUCK?

Sundua Imran[1], Cynthia Bodkin[2], Shalini Manchanda[1]
[1] Division of Pulmonary, Critical Care, Sleep, and Occupational Medicine, Indiana University School of Medicine, [2] Department of Neurology, Indiana University School of Medicine

Introduction: Stiff Person Syndrome (SPS) is an autoimmune neurological disorder associated with anti-GAD65 antibodies where stiffness and spasms of axial and limb muscles are the common manifestations. Other atypical features now being recognized are cranial neuropathies, sensory ataxia, and REM sleep behavior disorder (RBD).
Report of case: A 62-year-old woman with seronegative rheumatoid arthritis and positive GAD65 antibody presented with gait instability in 2015 and was given the diagnosis of SPS. Her diseased progressed to include cranial neuropathies (dysarthria, dysphagia, diplopia), sensory ataxia, torso stiffness, autonomic instability (syncope, nausea, sweating), and REM sleep behavior disorder. Immunosuppressive treatments rituximab, methotrexate and hydroxychloroquine showed some improvement in symptoms. Rituximab was stopped in 2020 because of the pandemic and regarding immune suppression. Her stiffness, and RBD worsened. In 2024 the patient received IVIG therapy every 3 weeks and noticed improvement in some symptoms but continued to have bothersome RBD. However, the RBD improved after being placed on rivastigmine. This case demonstrates how SPS with atypical multi-system symptoms can be difficult to manage. Cranial neuropathies, RBD, autonomic symptoms and sensory ataxia are not common but have been described more frequently in SPS and might be associated with neuroinflammation. IVIG was effective in reducing muscle spasticity and, improving the quality of sleep and minimizing the number of medications currently being administered. Its action might be explained by the regulation of neuroinflammation and the immune response. However, cranial neuropathies, autonomic symptoms and RBD remained challenging the patient, suggesting the non-reversible damage which is not uncommon with autonomic dysfunction.
Conclusion: This case shows the complexity of treating symptoms associated with SPS. Further studies are required to determine the treatment's effectiveness overall and to define its role in the management of cranial and autonomic symptoms. Multiple disciplines must be involved in managing SPS patients with atypical features to ensure the best outcome.

JOLTING AWAKE: EXPLORING THE IMPACT OF SLEEP-RELATED NECK MYOCLONUS

Rudra Ramanathan[1], Kammi Grayson[2], Alcibiades J. Rodriguez[2], Rebecca Lalchan[1], R. Nisha Aurora[1], Mandana Mahmoudi[3]
[1] NYU Grossman School of Medicine, [2] NYU Langone Medical Center, [3] NYU Langone Grossman School of Medicine

Introduction: Sleep-related neck myoclonus (SRNM) consists of brief motor events that primarily occur during REM sleep. Although typically considered physiological, SRNM can significantly impair sleep quality. We retrospectively reviewed three cases of SRNM presenting with non-restorative sleep.
Report of case: Case 1: A 26-year-old female with bruxism and temporomandibular joint dysfunction presented with chronic daytime fatigue. Her initial Epworth Sleepiness Score (ESS) was 17. Polysomnography (PSG) excluded obstructive sleep apnea (OSA) but revealed frequent neck myoclonus during REM sleep (SRNM-Index 34.64/hour). Treatment with a single dose of Clonazepam 0.5 mg was discontinued due to headaches. Botulinum-toxin-type-A (20 Units total) was injected into the masseter and splenius capitis muscles. The patient reported reduced head-neck tension, fewer nighttime awakenings, and the ESS improved to 8. Case 2: A 24-year-old female with fibromyalgia and POTS presented with non-restorative sleep. Her initial ESS was 17. PSG revealed mild OSA (AHI 8.9/hour, REM-AHI 21.7/hour) and frequent neck myoclonus during REM sleep (SRNM-index 30.3/hour), some triggered by airflow obstruction. Auto-PAP therapy improved sleep, reducing ESS to 8. Clonazepam 0.5 mg at bedtime further enhanced sleep, but she discontinued it due to dependence concerns. Botulinum-toxin-type-A (10 Units total) was injected into the

splenius capitis muscle, resulting in significantly improved sleep quality, and further reduction of the ESS to 4. She was able to discontinue Modafinil, which she previously took for disabling daytime fatigue. Case 3: A 42-year-old male presented with non-restorative sleep. He was diagnosed with severe OSA (AHI 35/hour, REM-AHI 57/hour) and frequent neck myoclonus during REM sleep (SRNM-index 62/hour). Auto-PAP therapy was initiated, leading to improved sleep. Treatment with Gabapentin 300-600 mg or Gabapentin ER 300-600 mg at bedtime partially improved sleep. Clonazepam 0.125 mg at bedtime further enhanced sleep, but he discontinued it due to concerns about dependence. Botulinum-toxin-type-A (20 Units total) was injected into the splenius capitis muscle, reducing head-neck tension and improving sleep quality. The patient's ESS ranged from 2 to 5 at baseline and follow-up visits.
Conclusion: From this case series, we can deduce that targeted therapy with Botulinum-toxin can be beneficial in cases of SRNM with non-restorative sleep.

EPAP EMERGENT CENTRAL SLEEP APNEA: INSIGHTS FROM A NOVEL PRESSURE TRANSDUCER FLOW CANNULA

Kate Young[1], Kingman Strohl[2], Ambrose Chiang[3]
[1] University Hospitals Cleveland Medical Center, Case Western Reserve University, [2] Case Western Reserve University / University Hospitals, [3] Louis Stokes Cleveland VA Medical Center

Introduction: Nasal Expiratory positive airway pressure (EPAP) therapy represents a therapeutic alternative to continuous positive airway pressure therapy (CPAP) in managing obstructive sleep apnea (OSA). Established OSA interventions, including CPAP therapy, mandibular advancement devices, tracheostomy, and hypoglossal nerve stimulation, have demonstrated the potential to induce or unmask central sleep apnea (CSA). A systematic literature review identified a single documented case of EPAP-emergent CSA associated with the Provent device (discontinued 2020). Contemporary FDA-cleared EPAP devices, specifically Bongo Rx and ULTepap, have had no reported cases of treatment-emergent CSA in the literature. We present a case of ULTepap-emergent CSA, confirmed by using a novel "clip-on" pressure transducer flow cannula (BRIGGS Medical, Avon, Ohio) for quantitative measurement of nasal airflow dynamics.
Report of case: A seventy-six-year-old male veteran with a history of heart failure with preserved ejection fraction, status post coronary artery bypass graft, mild chronic obstructive pulmonary disease, moderate obstructive sleep apnea presented for CPAP troubleshooting. Prior therapeutic interventions with CPAP and bilevel PAP were unsuccessful. A titration study demonstrated severe CSA with Cheyne-Stokes breathing with a therapeutic AHI of 4.1 on CPAP of 13 cmH2O. Despite therapeutic CPAP efficacy, the subject demonstrated poor CPAP adherence and failed to tolerate Bongo Rx devices across available sizes. Following a successful trial of ULTepap, a split night study with ULTepap was conducted using the novel ULTepap pressure transducer flow cannula. The diagnostic portion revealed obstructive hypopneas with flow limitation, while the therapeutic portion demonstrated paradoxical deterioration, with AHI increasing from 46 to 62 events/h, predominantly comprising CSA.
Conclusion: We present the first documented instance of ULTepap-emergent CSA, validated through measurements obtained with an innovative flow cannula specifically engineered for ULTepap application. The historically low detection rate of EPAP-emergent CSA may be attributed to technical limitations in measuring flow during EPAP. While treatment-emergent CSA typically resolves within a few months of therapy initiation, this newly developed cannula enables follow-up monitoring of CSA emergence and resolution after the ULTepap implementation. This case illustrates both a rather paradoxical therapeutic response and offers a methodological advancement to measuring flow during ULTepap therapy.

REFRACTORY HYPERSOMNIA IN IDIOPATHIC HYPERSOMNIA FOLLOWING COVID-19 - THERAPEUTIC INTERVENTION WITH SODIUM OXYBATE

Talha Memon[1], Binh Pham[1], Powen Hsueh[1], Arianna Gaytan[1], Zaara Said[1]
[1] Sleep Medicine Department, Southwest Healthcare Medical Education Consortium, Temecula Valley Hospital

Introduction: This case highlights the link between viral infections, particularly COVID-19, and the development of neurological disorders like narcolepsy. Initially diagnosed with idiopathic hypersomnia, the patient's symptoms worsened after COVID-19, leading to narcolepsy type 1 with cataplexy. This progression shows how viral infections can trigger or worsen sleep disorders. Narcolepsy type 1 involves autoimmune mechanisms, where the immune system targets hypocretin-producing neurons essential for wakefulness. COVID-19 may trigger this response in genetically predisposed individuals. The patient's transition from idiopathic hypersomnia to narcolepsy shows how viral infections can exacerbate neurological conditions. This case also highlights challenges in distinguishing idiopathic hypersomnia from narcolepsy. Despite not meeting typical criteria for two sleep-onset REM periods (SOREM) on the Multiple Sleep Latency Test (MSLT), excessive daytime sleepiness and cataplexy supported the diagnosis.
Report of case: A 17 year old female with GAD and allergic rhinitis presented for severe daytime sleepiness. Patient was a Division 1 NCAA athlete. Initial PSG and MSLT PSG - AHI: 3 MSLT -SOL- 4 minutes SOREM- 0/5 (IHS) She was started on Modafinil 100 with improvement in sleepiness and quality of life. In February 2023, the patient had COVID-19 and developed her first cataplexy episode while at a cheer competition. Her cataplexy episode was described as her knees buckling as her excitement built up prior to her cheering competitions. Overall sleepiness was no longer controlled on Modafinil after COVID. Multiple cataplexy episodes were noted during Cheering competitions. Lexapro was initiated and Modafinil dosage was titrated with minimal benefit in sleepiness or cataplexy. PSG and MSLT (post COVID) PSG - AHI: 2.8; MSLT – SOL- 5 mins SOREM- 1/5 After testing she was transitioned to Xywav with reported improvement in daytime sleepiness with complete resolution of cataplexy symptoms.
Conclusion: In conclusion, this case study underscores the importance of considering viral infections as potential triggers for narcolepsy and other neurological disorders. Ongoing research into the mechanisms linking viral infections and neurological diseases is crucial for improving understanding and

developing targeted interventions. Understanding the interplay between genetic susceptibility, immune regulation, and environmental triggers is key to advancing diagnostic and therapeutic approaches for narcolepsy and other neuroimmune disorders.

AWAKE AGAINST THE ODDS: A NARCOLEPSY PATIENT'S JOURNEY TO BECOME A PHYSICIAN

Deandra Kuruppu[1], Joyce Lee-Iannotti[1]
[1] University of Arizona - Phoenix

Introduction: Excessive sleepiness is widespread across the United States. Specifically, severe excessive daytime sleepiness is higher in women compared to men (13% vs 8.6%) in the general population. In the medical field, daytime sleepiness is often overlooked as a byproduct of our grueling schedules. However, in this case, our patient did not realize until her third year of fellowship that her overwhelming drowsiness and cataplexy were symptoms of narcolepsy.
Report of case: A 35-year-old female with a history of depression, currently in a highly demanding subspecialty fellowship, realized during her sleep medicine rotation that she needed to seek evaluation as a sleep medicine patient. She had experienced hypersomnia for 25 years, requiring at least 10 hours of sleep to function. She struggled with drowsiness throughout her fellowship, especially in the afternoons, after meals, and after 6 PM. She recalled childhood cataplexy (which resolved with escitalopram) and frequent sleep paralysis. Her Epworth Sleepiness Scale score was 18, and she relied on two to five caffeinated drinks daily. Polysomnography showed mild periodic leg movements and an MSLT revealed a mean sleep latency of 7.68 minutes and two sleep-onset REM periods, diagnosing her with narcolepsy type 1. She initially began treatment with modafinil 100 mg but continued to experience daytime sleepiness, likely exacerbated by her demanding schedule. The dosage was subsequently increased to 200 mg, which enabled her to function effectively and successfully complete her fellowship.
Conclusion: It's essential to recognize that, as medical professionals, we too can be diagnosed with the same conditions as our patients. While the demanding schedules of college, medical school, residency, and fellowship can cause daytime somnolence, it's crucial to identify when symptoms deviate from normal exhaustion. This patient's perseverance through years of hypersomnolence is truly remarkable, managing to overcome significant challenges while still becoming a successful physician. She developed coping mechanisms and maintained her resilience despite her symptoms. She initially chose to pursue a career in a demanding field because its active nature helped her remain alert throughout the day. We must remember to look after ourselves as patients too—narcolepsy is something that can affect us just as much.

SPONTANEOUS RESOLUTION OF CENTRAL SLEEP APNEA DUE TO CHIARI ONE MALFORMATION IN A CHILD

Tingrui Wang[1], Daniel Combs[2]
[1] Department of Sleep Medicine, University of Arizona, [2] Department of Pediatrics, University of Arizona

Introduction: Chiari malformation (CM) type I can cause obstructive sleep apnea (OSA) and central sleep apnea (CSA) as a result of brainstem compression affecting control of breathing and airway muscle tone. Surgical decompression may improve both OSA and CSA. We report a child with CSA due to CM type I resolve without surgical decompression.
Report of case: A 5-year-old boy presented to sleep medicine clinic with known CM type 1 witnessed silent pauses in breathing, excessive daytime sleepiness and unusual movements during sleep. Polysomnography demonstrated severe CSA (central apnea hypopnea index [AHI] 29.7), and REM sleep without atonia. The patient was initiated on Bilevel Positive Airway Pressure therapy Spontaneous Timed mode (BPAP-ST) as well as a trial of acetazolamide 250 mg nightly which was subsequently discontinued as patient was adherent to BPAP-ST. He was compliant with BPAP-ST therapy nightly with residual AHI < 5 and greatly improved daytime sleepiness. Brain magnetic resonance imaging showed low lying and elongated cerebellar tonsils with adequate cerebral spinal fluid (CSF) flow. No surgical intervention beyond monitoring was performed due to adequate CSF flow. Five years later, repeat polysomnography after holding BPAP-ST showed complete resolution of CSA and no evidence of REM sleep without atonia. Based on study results, BPAP-ST was discontinued. Six months after discontinuation of BPAP-ST, patient reports doing well without excessive daytime sleepiness or other sleep-related symptoms.
Conclusion: CM is a known cause of both CSA and OSA (as well as REM sleep without atonia) in children and adults which can be effectively managed by positive airway pressure therapy or surgical decompression. In adults, resolution of CM type 1 is exceedingly rare. However, children have been reported to have spontaneous resolution of CM type 1. This is believed to occur due to increased posterior fossa volume with growth allowing for ascent of the cerebellar tonsils. Given this, use of positive airway pressure therapy for sleep apnea and watchful waiting rather than surgical decompression may be an appropriate treatment option in selected cases.

LESS IS MORE: REDUCING VOLTAGE TO MANAGE A CASE OF PERSISTENT TECSA IN INSPIRE

Jay Thetford[1], Susie Fong[2], Melisa R. Chang[3]
[1] UCLA David Geffen School of Medicine, [2] UCLA Health, [3] Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles and VA Greater Los Angeles Healthcare

Introduction: Treatment emergent central sleep apnea (TECSA) is a rare event when managing obstructive sleep apnea (OSA) with non-PAP therapies including hypoglossal nerve stimulation (HNS), occurring < 4% of cases. The proposed mechanism for TECSA in HNS therapy is thought to be due to increased airway patency which unmasks high chemosensitivity and leads to a "loop gain" phenomenon. While case reports of TECSA in HNS are reported, the optimal treatment strategy for this remains unknown. We present a case in which awake endoscopy was used to optimize voltage settings, leading to symptomatic improvement in a patient with persistent TECSA in HSN therapy.
Report of case: A 58 year-old female with severe OSA (REI 40/h on HST) and PAP intolerance presented to sleep clinic for

management of Inspire following implantation. Initial PSG titration showed a significant reduction in AHI to 3/h at 2.4V. After slow outpatient titration to 2.4V, the patient experienced mild improvement in daytime sleepiness but was found to have continued nocturnal desaturations on oximetry testing, spending 49 minutes < 88% SpO2. Repeat HST showed an REI of 35/h on therapy and a subsequent PSG titration demonstrated high baseline CAI of 60/h, with best results at 2.3V (AHI 13/h; 4 central apneas, 5 obstructive hypopneas) when titrated between 2.2-2.6V. Higher voltages had more events. TTE and MRI brain were unremarkable, and patient denied any opioid use. Due to continued sleep fragmentation, daytime sleepiness, and persistent nocturnal hypoxia, the patient was referred to ENT to evaluate device efficacy. ENT performed an awake endoscopy and found that 1.9V on +-+ configuration had good opening with less inspiratory effort compared to voltages of 2.1V and above. The patient has since experienced significant improvement in sleep quality and daytime sleepiness at 1.9V, currently pending a repeat PSG titration study to ensure efficacy.

Conclusion: While TECSA in HNS therapy has been described, its true prevalence and pathophysiology remains incompletely understood. Some proposed mechanisms include increased airway patency leading to loop gain phenomenon and overstimulation resulting in arousal-induced excessive ventilation. One hypothesized treatment strategy includes a reduction in stimulator voltage, which resulted in symptomatic improvement in this case.

ASSESSING THE NEURODEGENERATIVE PROGRESSION OF REM BEHAVIOR DISORDER AND TRAUMA ASSOCIATED SLEEP DISORDER WITH CUTANEOUS ALPHA-SYNUCLEIN TESTING

Rupini Alla[1], *Mitchell Miglis*[1]
[1] Stanford University

Introduction: Isolated rapid-eye-movement sleep behavior disorder (iRBD) is one of the earliest and most specific prodromal signs of α-synuclein driven neurodegenerative disease including Parkinson's disease, dementia with Lewy bodies, and multiple system atrophy. Trauma Associated Sleep Disorder (TASD) overlaps significantly with iRBD, with features of both dream enactment and REM without atonia; however, it remains unclear if TASD also represents a prodromal neurodegenerative disease. Cutaneous phosphorylated alpha-synuclein (P-Syn) is a sensitive and specific biomarker of α-synuclein; however, rates of P-Syn positive in TSAD are unknown.

Report of case: A 35-year-old man with medical history of major depressive disorder and post-traumatic stress disorder was referred for the evaluation of sleep violence and dream enactment. He reported weekly nightmares with dream enactment that have been persistent for a few years. Most of these actions were typically in response to nightmares related to his time in Afghanistan. He denied other prodromal symptoms including hyposmia, cognitive impairment, or autonomic dysfunction. Video polysomnogram confirmed the presence of REM without atonia. Autonomic testing including measures of sudomotor, cardiovagal, and sympathetic adrenergic function was normal. Skin biopsy was performed at the C7 paraspinal area, proximal and distal leg and processed for immunohistochemical analysis of P-Syn. All sites were normal without denervation of P-syn deposition.

Conclusion: A diagnosis of RBD or TASD can be distressing for patients due to the risk of progression to a debilitating neurocognitive disorder. This case illustrates the utility of synuclein testing in further distinguishing RBD and TASD. Skin biopsies are usually well-tolerated by patients and can offer an objective approach to characterizing disease severity and progression. Further studies are needed in larger cohorts to confirm absence of P-Syn in TASD.

RECURRENT EARLY-MORNING SYNCOPE: A CASE OF VASOVAGAL SLEEP SYNCOPE WITH TEMPORAL SLEEP-WAKE DEPENDENCY

Alon Y. Avidan[1], *Dana Awad*[1]
[1] UCLA

Introduction: Vasovagal sleep syncope (VVSS) is a rare condition characterized by transient loss of consciousness (LOC) shortly after awakening, often while supine or during early morning hours. We present a case of a woman with recurrent early-morning syncopal episodes emerging during early-morning wake times in the setting of sleep restriction and forced awakening.

Report of case: A 22-year-old female presented with an 8-year history of recurrent LOC emerging exclusively during early-morning awakening in association with early AM awakenings for a new job. These paroxysmal episodes are consistently preceded by prodromal symptoms of dizziness, nausea, pallor, diaphoresis, and an impending sense of doom lasting up to 2 minutes. There was no history of convulsions, tongue biting, or incontinence. Coinciding with these spells, the patient reports sleep inertia and a "drunken-like" state without any residual neurologic sequelae. Previous electroencephalograms and neuroimaging were normal. Tilt table and orthostatic testing did not reveal orthostatic changes. Diagnostic polysomnography with forced awakening during early AM slow-wave sleep depicted tachycardia up to 110 beats per minute with mild bradycardia down to 50 beats per minute upon standing, indicative of vasovagal reflex cascade. Episodes discontinued upon resumption of normal sleep-wake patters.

Conclusion: This case illustrates the important inclusion of VVSS in the differential diagnosis of complex nocturnal behaviors emerging in the early AM during SWS. Early recognition and tailored interventions to avoid sleep restriction are essential to improving quality of life and functional outcomes.

ELEVATED CENTRAL VENOUS PRESSURES MAY INCREASE RISK FOR UPPER AIRWAY RESISTANCE SYNDROMES IN PATIENTS WITH CARDIAC SINGLE VENTRICLE PHYSIOLOGY

Patricia A. Martin-Hoyt[1], *Andrew Ligsay*[1]
[1] Ann & Robert H. Lurie Children's Hospital of Chicago

Introduction: Patients with cardiac single ventricle physiology undergo multi-staged palliative surgeries culminating in

the Fontan procedure. These patients are at increased risk for obstructive sleep apnea, but the etiology of this is not well understood. Here, we highlight a case showing how increased central venous pressures may contribute to upper airway resistance, therefore increasing the risk for obstructive sleep-disordered breathing.
Report of case: The patient was a female child with cardiac single ventricle physiology consisting of a double outlet right ventricle with mitral valve atresia. She underwent initial palliative surgery within her first month of life followed by a bidirectional Glenn at nine months of age. Her oxygen saturations after this surgery were appropriately in the 80s-90s in room air. She was followed by the sleep medicine service and underwent two polysomnograms 19 months apart due to gasping at night and restlessness. Both showed average oxygen saturations in the 80s-90s. The obstructive apnea hypopnea indices (AHI) were 0.2-2.6/hour. Snore indices were 15.8-17.7/hour. Echocardiograms and cardiac catheterizations within six months of each study showed mildly depressed systemic ventricular function, no evidence of pulmonary hypertension (PH), and stable superior vena cava (SVC) pressures of 12 mmHg. The patient underwent Fontan completion at 5 years of age. A cardiac catheterization shortly after her procedure which showed an increase in SVC pressure to 18 mmHg. There was still no evidence of PH. Echocardiograms before and after her cardiac catheterization, as well as two months following surgical intervention showed mild-moderately depressed right ventricular function. A repeat polysomnography five months post-Fontan procedure showed a stable AHI (1.6/hour), but snoring index was increased to 51.0/hour suggesting increased upper airway resistance.
Conclusion: This is the first case report highlighting serial changes in central venous pressures evaluated by cardiac catheterization with associated changes in polysomnography findings. A mechanism of elevated central venous pressures leading to tonsillar and/or adenoid edema could increase the risk for upper airway resistance syndromes in this population.

A CASE OF BREAKTHROUGH SLEEPINESS ON SODIUM OXYBATE WITH EXCESSIVE SLOW WAVE SLEEP

Brian A. Soto[1], Katie Tribuls[2], Rakesh Shah[2]
[1] University of South Florida, [2] University of South Florida College of Medicine

Introduction: Sodium oxybate is commonly used in disorders of hypersomnia to decrease excessive daytime sleepiness and decrease disrupted sleep. The medication acts by increasing slow wave sleep through agonizing GABA-B receptors. Dosage optimization is done incrementally and based on subjective improvement in excessive sleepiness.
Report of case: Here we present a 48 year old female with a history of obstructive sleep apnea on PAP therapy and Narcolepsy Type II-Idiopathic hypersomnia spectrum. She presents with breakthrough sleepiness with an ESS of 12 after initially improving with Sodium Oxybate. She was titrated to the maximal total dose of 9 mg without improvement. Repeat polysomnogram with the sodium oxybate showed adequate treatment with PAP therapy with a residual AHI of 2.8. Her study revealed appropriate sleep efficiency, however she had a significant increase of N3 sleep of 62% without REM sleep. She had 425 minutes of sleep time and sleep efficiency of 91%. MSLT demonstrated decreased MSL of 7.6 minutes with no SOREMs which was now most consistent with Idiopathic hypersomnia. For further evaluation a MWT was performed which showed MSL of 36 minutes without evidence of SOREMs. Her UDS was negative. Other medical causes for hypersomnia ruled out and no other medications suggest alternative reasons for breakthrough sleepiness. Patient is planned to be counseled on starting therapy with a wake promoting agent pitosant therapy during her follow up visit.
Conclusion: The optimal treatment of idiopathic hypersomnia is still unclear and current guidelines are based on studies for narcolepsy. While sodium oxybate can be used as a first line agent in narcolepsy, it only has a conditional recommendation for idiopathic hypersomnia and is usually used when there is treatment failure with wake promoting agents. Although there is known increased N3 with sodium oxybate, there is little evidence regarding the optimal amount of stage 3 sleep to improve excessive sleepiness. Additionally, could there be a threshold where an excessive amount of slow wave sleep contributes to worsening sleepiness, possibly by increasing sleep inertia. Titration guided by polysomnogram could give further insight to optimal doses of sodium oxybate and slow wave sleep.

PARADOXICAL INSOMNIA, VISUAL SNOW SYNDROME, AND OZONE TOXICITY: HOW ARE THEY CONNECTED?

Janey Dudley[1], Daniel Rongo[1,2], Likhita Shaik[1,2], Michael Ibarra[1]
[1] UT Southwestern Medical Center, [2] North Texas VA Medical Center

Introduction: Paradoxical insomnia is insomnia disproportional to the presence of objective sleep disturbance or daytime impairment. Hypervigilance occurs while patient is trying to sleep, suggesting paradoxical insomnia has a hyperarousal component, and there may be physiological or perceptual deficits that affect sleep/wake discrimination causing sleep time underestimation. Visual snow is a recently identified neurologic condition consisting of a constant visual disturbance described as multiple dots over the entire visual field. Visual snow syndrome occurs when, in addition to visual static, patients also report palinopsia, entoptic phenomena, photophobia, and nyctalopia. With pollutant ozone toxicity, well-established evidence has been produced for short-term effects, especially on respiratory and cardiovascular systems. Unfortunately, ozone therapy has mostly been studied in the setting of environmental exposures, less so in alternative medicine settings.
Report of case: 41 year old female with history of anxiety, depression, visual snow syndrome, and recent ozone toxicity presented to hospital for pain, vision changes, weakness, and insomnia. Two months before presentation, patient was receiving IV ozone therapy repeatedly that led to suspected ozone toxicity. Days later, patient was diagnosed with visual snow syndrome by neuro-optometrist. Lack of sleep for the following two months prompted hospital presentation. Patient described inability to sleep, but explained entering a "twilight state" where she dreamed, but could hear her surroundings. 24 hour EEG confirmed patient was sleeping and ruled out nocturnal seizures. Free radical damage from ozone toxicity could lead to thalamic injury, but none was seen on functional MRI. With normal testing/imaging and based on descriptions of this "twilight" state, her symptoms were consistent

with paradoxical insomnia, so she was discharged from hospital on Valium 5mg TID, Ambien 20mg nightly, and Lyrica 125mg nightly – despite these medications, she reported she was still unable to sleep. In outpatient follow up, she had a normal polysomnogram and actigraphy consistent with paradoxical insomnia. Over the next few months, medications were weaned, and patient was treated for paradoxical insomnia.
Conclusion: This case portrays multiple rare diagnoses in one patient with a relatively common sleep diagnosis. It also highlights the role polypharmacy plays in treatment for neurological and psychiatric complaints.

AVOIDING THE 2 FOR 1: CHALLENGES IN RISK-ASSESSMENT OF POST-PROCEDURE EXTUBATION FAILURE IN NEUROMUSCULAR DISORDERS

Navneet Ramesh[1], Peter Nguyen[2], Janine Vintch[1]
[1] Harbor-UCLA, [2] Rancho Los Amigos National Rehabilitation Center

Introduction: Patients with neuromuscular disorders who require mechanical ventilation support for elective procedures face numerous barriers to ventilator liberation, particularly for patients already on non-invasive ventilation (NiV). Preoperative risk stratification is additionally challenging for providers given the absence of perioperative guidelines, thus leading to wide variability in procedural approaches and outcomes.
Report of case: A 53-year-old man with amyotrophic lateral sclerosis (ALS) presented with worsened dysphagia and orthopnea. Due to discomfort, he had been inconsistently using his full-face mask NiV device. His significant secretion burden was managed with nebulizer treatments and a chest wall oscillation vest. His pulmonary function tests showed a FEV1 2.06L (60% predicted), FVC 2.54L (58% predicted), and total lung capacity 3.46L (53% predicted). Given his worsening dysphagia and following multidisciplinary discussions involving pulmonology, neurology, and gastroenterology, he elected for percutaneous endoscopic gastronomy (PEG) placement. There were no intraoperative complications. However, copious secretions and profound muscular weakness prevented ventilator liberation, leading to tracheostomy placement. He subsequently developed pneumonia which further limited ventilator weaning. Given his previously expressed wishes to avoid long-term ventilator dependence, he elected to transition to comfort-focused measures.
Conclusion: Although less than 10% of patients with ALS receive tracheostomies, PEG placement is more common. Preoperative assessment and optimization is therefore crucial, particularly in assessing the likelihood of post-procedural extubation when intubation and sedation is necessary. Current ALS guidelines recommend PEG placement when the FVC is greater than 50%. Despite this patient meeting this threshold, he was unsuccessfully weaned from mechanical ventilatory support. Additional patient characteristics such as secretion burden, nutritional status, and comorbid conditions are likely important considerations, but difficult to quantify. There is emerging evidence for PEG placement in ALS patients under moderate sedation while continuing NiV. However, given the lack of consensus guidelines for preoperative risk stratification for this patient cohort, it is unknown which patients would benefit from these advanced approaches. This is of particular relevance to our safety-net hospital system where such procedures are not widely available. Therefore, additional metrics are undoubtedly warranted to improve preoperative optimization such that patients can make well-informed decisions, since tracheostomies have significant impacts on quality of life and caregiver burden.

DEVICE MALFUNCTION IN HYPOGLOSSAL NERVE STIMULATION (HGNS) FOR SEVERE OBSTRUCTIVE SLEEP APNEA (OSA)

Ariel Park[1], Rajesh Zacharias[1], Aarti Grover[1], Wei He[1], Greg Schumaker[1], Joel Oster[1], Lyndsay Hayden[2], Bobby Rosenthal[2]
[1] Tufts Medical Center, [2] Inspire

Introduction: HGNS is a well-established treatment for OSA in patients intolerant to CPAP therapy. However, device-related technical issues can hinder therapy efficacy. This case highlights challenges in managing severe OSA with a malfunctioning HGNS device.
Report of case: A 65-year-old male with severe OSA (home sleep test, AHI 92.6/h, entirely supine, O_2 nadir 75%) underwent HGNS implantation due to CPAP intolerance. Programming during activation identified 1.3V as tolerable, but the patient could not advance beyond this due to discomfort, resulting in minimal improvement in his symptoms. Awake endoscopy showed the initial configuration A(+/-/+) achieved excellent airway opening at 1.7V. Adjustments to pulse width and rate improved tolerance, allowing him to increase the amplitude to 1.9V. Despite these adjustments, HGNS titration study failed to identify a therapeutic amplitude. The expected device artifact was intermittently absent on PSG, and the patient reported no sensation of therapy while supine. Subsequent interrogation revealed abnormal impedance with concerns about signal transmission from implantable pulse generator (IPG) to center electrode. This issue, termed "connection issue" by the manufacturer, likely originated at the IPG level and caused intermittent functionality of the center electrode at the cuff. To address this, the electrode configuration was adjusted to C(-/o/-), turning off the center electrode. A follow-up PSG demonstrated consistent device artifact and patient reported feeling the device at all times. The study also revealed a significant positional component to his OSA which was not previously known and HGNS was effective only in the non-supine position. The patient was advised to use combination therapy with positional therapy and gradual device up-titration. If this approach fails, IPG replacement may be required to enable alternative configurations.
Conclusion: This case demonstrates how HGNS device malfunction can hinder therapy optimization and highlights the importance of identifying absent device artifacts on PSG. Although rare, device malfunction can result in poor outcomes and reduced tolerance. Comprehensive evaluations including close follow-up, awake endoscopy, and engineering diagnostics enabled bypass of the device malfunction. In case of persistent positional sleep apnea, combination therapy may be necessary. These findings underscore the value of individualized and multidisciplinary care in overcoming technical challenges in HGNS therapy.

TRAUMATIC BRAIN INJURY-INDUCED TRANSIENT REM SLEEP BEHAVIOR DISORDER IN A VETERAN WITH OBSTRUCTIVE SLEEP APNEA AND POST-TRAUMATIC STRESS DISORDER

Amanullah Siddiqui[1], Valeria E. Munguia Jovel[1], Alexandre Abreu[1], Kori B. Ascher[1], Monica A. Giraldo[1]

[1] University of Miami Miller School of Medicine

Introduction: REM behavior disorder (RBD) is a condition in which affected individuals have dream enactment behaviors. These behaviors are often associated with nightmares and can result in injury to self or bed partner. RBD is known to have an intricate association with other sleep disorders, psychiatric conditions, and neurodegenerative diseases.
Report of case: We describe a case of transient RBD following a traumatic brain injury (TBI) in a 31-year-old male veteran with a history of post-traumatic stress disorder (PTSD) and obstructive sleep apnea (OSA). He was initially diagnosed with OSA in 2014 but was unable to tolerate positive airway pressure (PAP) therapy at the time. Shortly after the patient sustained a TBI in early 2015 he began experiencing episodes of sleep-walking and dream enactment behaviors, consistent with RBD. These symptoms persisted for several months but resolved spontaneously within one year with no recurrence of symptoms to date. The patient presented to our sleep center to establish care in 2024 with complaints of worsening snoring, excessive daytime hypersomnia, and occasional nightmares. The re-evaluation revealed progression of his OSA in the setting of an increase in body mass and age. However, the progression of his OSA was not associated with a reemergence of the parasomnia behaviors that initially followed his TBI.
Conclusion: This case highlights the complex relationship between TBI, RBD, PTSD, and OSA. Although RBD is typically associated with neurodegenerative diseases, its transient presentation following TBI suggests a distinct etiology separate from idiopathic or neurodegenerative RBD. A multidisciplinary approach and close follow-up is needed in such cases, especially in the veteran population that faces a complex interplay of mental health conditions and sleep disorders. Additional research is needed to clarify the mechanisms linking TBI to transient-RBD and its interactions with PTSD and OSA. This case adds to growing evidence connecting TBI with sleep disturbances and psychiatric comorbidities, further reinforcing the importance of early diagnosis and holistic management for affected patients.

A CASE OF MERCURY POISONING AND SLEEP DISTURBANCES

Nhi Bui[1], Kevin Kaplan[1]

[1] Baylor College of Medicine

Introduction: A 16-year-old male with no chronic health issues presented with snoring, witnessed apnea, excessive daytime sleepiness, and nighttime leg discomfort. For seven months, he frequently fell asleep during the day but he was able to maintain energy for daily activities. He also felt an urge to move his legs at night for relief. His sleep schedule was from 8:30 PM to 5:30 AM in his own dark, quiet room. His mother noted episodes of sleep talking, screaming, and unusual hand movements during sleep, but denied signs of sleep paralysis, cataplexy, or hallucinations. The patient has never had a prior sleep study. Polysomnography revealed mild obstructive sleep apnea without recorded parasomnias.
Report of case: Additional symptoms included muscle weakness, sweating, watery diarrhea, a 30-pound weight loss, and a rash on his arms and abdomen. Two months after his symptoms began, his brother developed similar symptoms. Subsequent testing showed elevated serum and urine mercury levels. Further investigation revealed that nine months prior, the patient had received a plastic vial containing an unidentified metallic liquid from a classmate, which could have led to exposure through direct contact with spillage and aerosolization from carpet vacuuming. Following chelation therapy, their mercury levels decreased with improvement of daytime sleepiness and other symptoms.
Conclusion: Mercury is a neurotoxin that can affect sleep. Autopsy findings from workers exposed to elemental mercury show its accumulation in the pineal gland (Parmalee, 2017). In Thailand, adults in E-waste facilities with an average urinary mercury level of 19.0 µg/g reported more insomnia symptoms compared to unexposed workers (Derachat, 2018). Reports of high mercury exposure in adults and children through accidental poisoning or gold mining documented sleep complaints including fatigue, excessive sleepiness, and sleep disturbances (Bose-O'Reilly, 2016; Do, 2017; Kasznia-Kocot 2010). Mercury exists in elemental, inorganic, and organic forms, all of which can be toxic to the nervous system. Diagnosis is confirmed by measuring mercury levels in blood or 24-hour urine, with urine testing preferred for suspected chronic exposure. Those affected by mercury toxicity should be immediately removed from exposure sources, and most neurotoxic effects resolve after chelation therapy and cessation of exposure.

PARADOXICAL EPIGLOTTIC MOTION IN THE EVALUATION FOR HYPOGLOSSAL NERVE STIMULATION

Alaa Alabdul Razzaq[1], Abdullah Arjomand[1], Karel Calero[2]

[1] University of South Florida, [2] University of South Florida Morsani College of Medicine

Introduction: Hypoglossal nerve stimulation (HNS) has become an increasingly popular option for the treatment of select patients with obstructive sleep apnea (OSA) intolerant to positive airway pressure (PAP) therapy. Eligibility for HNS requires a thorough evaluation, including drug-induced sleep endoscopy (DISE), to determine the pattern of upper airway collapse. Epiglottic obstruction, especially paradoxical movement during tongue protrusion, poses a unique challenge when evaluating candidacy for HNS.
Report of case: A 69-year-old male with a history of hypertension, gastroesophageal reflux disease, interstitial lung disease, type 2 diabetes mellitus, and migraines presented with persistent OSA symptoms, including sleep fragmentation and morning headaches. Diagnosed with moderate OSA 9 years earlier, he was intolerant to PAP therapy and failed a mandibular advancement device (MAD) due to dentition issues. A repeat polysomnogram confirmed moderate OSA with an apnea-hypopnea index of 15 and oxygen saturation nadir of 78%. Considering alternatives to PAP, he underwent DISE to assess candidacy for HNS. DISE revealed no concentric velopharyngeal collapse but

demonstrated paradoxical epiglottic obstruction that worsened with tongue protrusion and partial jaw thrust. Improvement was noted only with maximal jaw thrust. Based on these findings, HNS was not recommended to the patient, who was advised to reattempt MAD therapy and consider hyoid suspension surgery.
Conclusion: This case highlights the importance of individualized assessment in OSA management. During DISE, attention should be paid to findings beyond pattern of velopharyngeal collapse. DISE findings of paradoxical epiglottic obstruction may reduce HNS efficacy, as suggested in prior literature.

OBSTRUCTIVE SLEEP APNEA AND ORTHOSTATIC HYPOTENSION: AN UNCONVENTIONAL ASSOCIATION

Ryan S. Cobb[1], Mildred Barnett[2], Kevin Patel[2]
[1] University of South Florida, [2] James A. Haley Veterans Affairs Medical Center

Introduction: Although Obstructive Sleep Apnea (OSA) has a commonly recognized association with hypertension, it is not often thought of as causing or exacerbating hypotension, specifically orthostatic hypotension. Here we present the unusual case of a patient with a long history of OSA and good compliance with Auto-PAP therapy, whom after temporarily going without PAP therapy due to parts malfunction, developed progressively worsening orthostatic symptoms ultimately necessitating inpatient admission and remedied after restoration of PAP therapy.
Report of case: 61yo M with PMHx known OSA, mild traumatic brain injury, Pulmonary embolism, Paroxysmal Atrial Fibrillation s/p ablation and hypothyroidism who presented to the Emergency Department at his primary care physician's recommendation due to progressively worsening BP at home with systolic blood pressures as low as 80s as well as dizziness upon standing. The symptoms started 3 weeks after he reported difficulty using his Auto-PAP due to improper fit of a new mask. He was given IV fluids in the Emergency Department which did not alleviate his symptoms. Adrenal insufficiency workup was also negative. Interestingly, once he was loaned an Auto-PAP, his symptoms improved, and he was discharged shortly thereafter. The appropriate adjustments were made to his home device, and his symptoms have not recurred since.
Conclusion: In this unique case, the patient developed symptoms consistent with orthostatic hypotension after discontinuing PAP therapy, and his symptoms resolved after restoration of appropriate PAP therapy. This uncommon observation raises an intriguing thought regarding our current understanding of blood pressure control and its relationship with untreated OSA. Although the mechanisms between OSA and hypertension are well established, we propose that the orthostatic hypotension observed in this case is due to baroreceptor dysregulation as well as increased Atrial Natriuretic Peptide (ANP) release causing a relative hypovolemia.

FRACTURED SLEEP: SERIOUS INJURY UNCOVERS A CHALLENGING CASE OF ABNORMAL MOVEMENTS IN SLEEP

Dominic J. Kiley[1], Subodh Arora[1]
[1] Walter Reed National Military Medical Center

Introduction: Disorders of arousal (DoA) and sleep-related hypermotor epilepsy (SHE) are difficult to distinguish. Both involve abnormal movements in sleep that may lead to serious harm to the patient or others. We present a case of abnormal movements in sleep leading to serious injury and discuss diagnostic features of SHE.
Report of case: The patient is a 48-year-old male with severe OSA on CPAP. He presented after multiple falls from bed. One fall resulted in a right tibial-fibular fracture requiring surgical fixation. He described five to ten episodes of nightly rhythmic limb movements leading to falls out of bed. The episodes occurred in the first half of the night. After an event, he would experience full awakening with preserved memory of rhythmic body movements leading to fall. Events were not dream related and devoid of sleepwalking, sex-related behavior, or sleep eating. Comprehensive physical and neurologic exam was only notable for ecchymoses on the right forearm. In-lab polysomnography on CPAP showed successful control of OSA and simultaneously captured eight episodes of abrupt onset stereotyped motor activity arising out of N3 sleep. These 30-90 second episodes included rhythmic arm flapping, head bobbing and synchronized leg movements. EEG during episodes was obscured by muscle artifact. EEG following episodes showed wake rhythm. There were no epileptiform discharges, hypersynchronous activity or build up to the episodes. The patient was treated with one milligram of oral clonazepam nightly and the episodes improved. He has had no falls out of bed or injuries since starting medication.
Conclusion: Distinguishing SHE from DoA is challenging. EEG abnormalities are not found in the majority of cases of SHE and more than half of patients are reported to have a normal scalp EEG. This patient had stereotyped movements captured on video with no epileptiform discharges on EEG. Unrecognized and untreated SHE may lead to serious injury. Diagnostic and confidence level criteria have been described by Tinipur et al. to support this important diagnosis in the absence of EEG-confirmed epileptiform activity. Video recording of episodes is a critical contributor to accurate diagnostic assessment of patients with abnormal movements in sleep.

SEVERE SLEEP ONSET CENTRAL APNEAS IN A YOUNG FEMALE WITH SEIZURE DISORDER AND ARNOLD CHIARI MALFORMATION POST-DECOMPRESSION

Daniel Rongo[1], Janey Dudley[1], Likhita Shaik[1,2], Michael Ibarra[1], Won Lee[1], Venjata Mukkavilli
[1] UT Southwestern Medical Center, [2] North Texas VA Medical Center

Introduction: This case highlights the challenges towards treating a patient with isolated sleep-onset central apnea. I present a challenging case of a young female with a sleep-onset central sleep apnea treated with a conservative management approach leading to significant improvement.
Report of case: A 30-year-old female with a medical history of cognitive delay, Lennox-Gastaut with intractable seizures, and Arnold Chiari malformation status post-decompression (10 years prior) was referred for evaluation due to episodes of apnea observed by her mother. She notably had her clonazepam discontinued a few months prior to this presentation. During these events, she experienced oxygen desaturations to the 60s lasting up

to 2–3 minutes. Labs suggest a chronic hypocapnic state at baseline. Polysomnography revealed isolated severe sleep-onset central apneas without significant sleep-disordered breathing during the rest of the night. Total apnea-hypopnea index (AHI) was minimal, but the severity of apneic-episodes during sleep onset warranted immediate attention. Continuous EEG was unremarkable. BiPAP ST and ASV were considered but given her developmental delay and risk of worsening apneic episodes this was deferred. The patient was started on low-dose clonazepam and empiric oxygen therapy at 2 liters/min, resulting in significant improvement of central sleep apnea events. No further apneas have occurred.
Conclusion: The onset of sleep causes ventilatory instability with transition from alpha to theta activity. During this transitory state, wakeful CO2 eupnea converges with the emerging CO2 apnea threshold of sleep which predisposes to apneic episodes. Although normal in healthy individuals, various predisposing factors such as a low CO_2 reserve, heightened chemoreceptor sensitivity, or increased loop gain can significantly increase the risk and magnitude of these central apneic events. The challenge in this case was in limiting excessive ventilation with the use of potentially deleterious non-invasive ventilation while maintaining her drive to breath. Our intervention targeted normalizing her baseline hypocapnia with pharmacotherapy and supplemental oxygen which improved her symptoms thereafter on follow-up visits, avoiding the need for intermittent non-invasive ventilation.

THE VALUE OF SMART SECURITY CAMERAS IN DIAGNOSTIC EVALUATION OF COMPLEX NOCTURNAL BEHAVIORS

Mohamadmostafa Jahansouz[1], Alon Y. Avidan[1]
[1] UCLA

Introduction: Sleep clinicians regularly encounter patients who present with complex nocturnal behaviors (CNB) where differentiating sleep-related epilepsy (SRE) from parasomnias is critical for management and prognosis. Sleep terrors (ST) arise from non-REM sleep and are generally self-limited, while SRE may require detailed neurologic workup and, in some cases, long-term antiepileptic treatment. We present a patient who presented with abnormal arousals at night, initially diagnosed as ST where video footage from a Smart Security Camera (SSC) prompted long-term video-electroencephalographic monitoring (LTVEM), which confirmed the presence of SRE.
Report of case: A 14-year-old male presented with abnormal nocturnal behaviors consisting of abrupt awakening in the first half of the night with screaming, agitated demeanor, followed by confusion and amnesia. Outpatient video electroencephalogram (EEG) during the day was normal. Nocturnal polysomnography utilizing expanded electromyographic montage did not support the presence of sleep apnea (AHI, RDI =0, SaO2 nadir =95%). Two nocturnal events were recorded, both emerging from NREM sleep with confusion, but the limited four-channel electroencephalogram (EEG) did not reveal any ictal activity. Sleep extension and scheduled awakening intervention were employed over the next month but did not resolve the episodes, which occurred nightly at a frequency of 3-4 episodes per night. The patient's parents resorted to placement of SSC over the child's bed. Video footage capturing five days of data revealed (1) abrupt awakenings with stereotyped agitation, screaming, and repetitive bicycling and (2) quiet confusion and searching behavior.. The unusual frequency and stereotyped semiology of the events raised suspicion for nocturnal seizures, and the patient was admitted for LTVEM. On the first day of admission, he presented with vigorous hyperkinetic spells, and the EEG captured interictal epileptiform discharge emerging from the mesial frontal lobe. Subsequent management with Levetiracetam resolved the episodes.
Conclusion: This case highlights the potential diagnostic value of SSC as the video footage was instrumental in corroborating the presence of frequent CMN with stereotypic semiology in a patient presumed to have ST, prompting LTVEM and confirming the SRE. Home SSC is a low-cost but high-value tool that may identify patients who may benefit from LTVE in the evaluation of CNB.

FROM PERITONEAL DIALYSIS TO TRANSPLANT: INSIGHTS INTO RESOLVING RESTLESS LEG SYNDROME IN END-STAGE RENAL DISEASE

Briana Makadia[1], David Rye[1]
[1] Emory University School of Medicine

Introduction: In end-stage renal disease (ESRD), the sensory symptoms and motor signs of restless legs syndrome (RLS), including periodic limb movements of sleep (PLMs), are twice as common, severely disabling, and often resistant to standard treatments like dopaminergics and gabapentinoids. While renal transplantation can lead to remission, significant morbidity often occurs due to delays inherent in the matching versus queue system, and the recognition and treatment of RLS/PLMs in ESRD remains challenging. We report a case of RLS/PLMs where worsening symptoms in ESRD caused substantial morbidity. This highlights the clinical need for enhanced recognition and treatments in the form of a non-traditional opioid – namely, buprenorphine, which exhibited remarkable efficacy, safety, and absence of tolerance.
Report of case: A 33-year-old man with familial RLS since his early twenties, presented in 2020 with severe RLS (IRLSSG rating scale of severity of 33/40; insomnia severity index of 28/28; and Epworth Sleepiness Scale of 18)), months after starting PD for ESRD due to IgA nephropathy. Five nights of ambulatory, triaxial accelerometry (PAM-RL) showed a PLM index of 49.9 events per hour, 70.4 minutes of time "up" nightly, and an estimated total sleep time of 5 hours and 55 minutes. After initiating buprenorphine, the PAM-RL index rose to 59.52 events per hour; however, his time "up" decreased to 3.8 minutes, total sleep time increased to 7 hours and 50 minutes, and his IRLSSG score improved to 20/40. Following a kidney transplant in 2022, his symptoms showed further improvement, enabling a reduction in his buprenorphine dosage to 0.5 mg per day.
Conclusion: Opioids are utilized for refractory RLS, but are often approached with caution. Buprenorphine, a DEA Schedule III partial μ-opioid receptor agonist, should be considered for use as it offers several advantages over Schedule II opioids for the treatment of RLS. These include: (a) a longer half-life, (b) liver-based rather than renal elimination, (c) a lower risk of respiratory depression, (d) reduced abuse potential—particularly relevant as the patient had a history of opioid misuse following a rugby injury—and (e) a minimal risk of tolerance (based on personal observations).

HIGH-ALTITUDE PERIODIC BREATHING: DIAGNOSTIC AND MANAGEMENT CHALLENGES

Tingrui Wang[1], Sabine Obagi[2], Karolina D. Perez[2], Misty Shah[1], Saif Mashaqi[1], Salma Patel[1]

[1] University of Arizona, [2] University of Arizona College of Medicine - Tucson

Introduction: High-altitude periodic breathing (HAPB) is characterized by alternating cycles of central apnea and hyperpnea driven by hypoxia and ventilatory instability at high altitudes. These fluctuations can fragment sleep, causing frequent nocturnal awakenings, excessive daytime fatigue, and impaired cognitive function. Moreover, hypoxia and oxygen desaturation associated with HAPB may exacerbate pre-existing medical conditions, such as cardiovascular or pulmonary diseases, posing further risks to a patient's health.

Report of case: A 55-year-old male with a history of interstitial lung disease, bilateral lung transplant, and obstructive sleep apnea (OSA) on continuous positive airway pressure (CPAP) therapy presented for follow-up evaluation of OSA. He reported location-dependent symptoms, including unrefreshing sleep and morning fatigue when visiting Pinetop, Arizona (7,000 ft elevation), compared to feeling well-rested in Tucson (2,400 ft elevation). A recent titration study conducted in Tucson in August 2023 demonstrated that CPAP therapy at a pressure of 15 cm H_2O effectively reduced his respiratory index to 3.4 events per hour. However, a review of his PAP data revealed residual apnea-hypopnea indices (AHIs) consistently exceeding 10 events per hour during stays in Pinetop, peaking at 42 events per hour, with most events classified as central apneas. By contrast, his AHI in Tucson consistently remained below 5 events per hour. The significant increase in AHI and symptoms at high altitude were attributed to HAPB. Without a detailed travel history, this diagnosis could have been overlooked since the overall AHI was 5. A titration polysomnography (PSG) at high altitude was recommended to reassess and tailor his management strategy.

Conclusion: This case underscores the need to recognize high-altitude periodic breathing (HAPB) as a potential cause of sleep-disordered breathing, particularly in patients with complex medical histories. The patient's dramatic differences in AHI and symptoms based on altitude highlight the importance of obtaining a thorough travel history to ensure accurate diagnosis and management. Treatment options for HAPB include descent to lower altitudes, supplemental oxygen, positive airway pressure therapy, and pharmacologic interventions such as acetazolamide. Among these, descent is the most effective, as it directly addresses the underlying hypoxia. Supplemental oxygen can also alleviate hypoxia and stabilize ventilatory patterns, improving sleep quality and reducing fatigue.

TREATMENT EMERGENT NIGHTMARES IN OBSTRUCTIVE SLEEP APNEA

Caitlin S. Yumori[1], Aaron Thomas[2], Melisa R. Chang[1,2]

[1] UCLA, [2] VA Greater Los Angeles Healthcare

Introduction: Nightmares have been well documented in untreated obstructive sleep apnea (OSA) since the 19th century. Early researchers found that blocking the nose and mouth with a cloth induced nightmares and hypothesized that recurrent oxygen desaturation prompted nightmares. Previous studies have demonstrated a reduction in nightmares with positive airway pressure (PAP) therapy. We present a case in which PAP therapy worsens nightmares.

Report of case: A 70 year old male veteran with severe OSA presents to establish care with the Veteran's Administration sleep clinic. He was previously prescribed auto-adjusting continuous positive airway pressure (APAP), but despite several attempts at desensitization he stopped using it. The patient states the primary barrier has been new onset severe nightmares with APAP therapy. He did not have consistent dream content themes, but reports that when he awakens he feels like he is suffocating. The patient did not have issues with any nightmares prior to APAP initiation. He has no previous diagnosis of post-traumatic stress disorder nor other psychologic comorbidities. On review of his APAP compliance data, the patient attempted to use APAP for over two months. He had high leak and residual apnea hypopnea index 17.6/hr with central index 1.3/hr, obstructive index 4.5/hr, and unknown index 11.1/hr. He is pending a repeat split polysomnogram with PAP titration.

Conclusion: This patient demonstrates an unexpected response to PAP therapy—new onset severe and recurrent nightmares. Previous studies have demonstrated improvement in nightmares with treatment of OSA, so his response is uncommon. The mechanism of this is unclear. Patients with higher AHI typically have lower nightmare recall than more mild forms of OSA, likely due to decreased REM sleep. We suspect that the patient has an unfortunate combination of partially treated OSA, where he has both increased REM sleep and ongoing frequent arousals due to high leak and high residual AHI. We will determine whether this patient continues to have this side effect when his PAP is optimized.

"STIMULATION ARTIFACT" AS A CLINICAL SURROGATE FOR HYPOGLOSSAL NERVE STIMULATOR ACTIVATION: A CASE REPORT

Amogh Nadkarni[1], Damien Stevens[1], Anne Bennett[2]

[1] The University of Kansas Medical Center, [2] The University of Kansas Health System

Introduction: Hypoglossal nerve stimulation (HGNS) is an effective second-line therapy for obstructive sleep apnea (OSA) in patients intolerant to continuous positive airway pressure (CPAP). Polysomnography (PSG) is a critical tool for titration and optimization of HGNS settings. However, there is limited understanding of the "stimulation artifact," visualized as a sinusoidal 33 Hz wave on the chin electromyography (EMG) lead, which is thought to correspond to electrical stimulation of the hypoglossal nerve. Our case outlines how this artifact can be used as a reliable surrogate for device activation and to guide clinical decision-making during titration.

Report of case: A 57-year-old male with a past medical history significant for anxiety, diabetes, and hypertension underwent HGNS implantation after intolerance to CPAP and mandibular

advancement therapy. Sleep history was notable for difficulties with sleep initiation and sleep maintenance, with low Epworth Sleepiness Scale scores. Despite consistent device usage, his follow-up revealed persistent insomnia and frequent nightly pauses on device downloads, however noted overall increased energy and reduction in snoring. He underwent an in-laboratory PSG for titration. PSG data demonstrated overall excellent apnea-hypopnea reduction barring a 30-minute window of supine N2 sleep, where frequent hypopnea and apnea episodes were noted. Hypnogram as reported demonstrated activation of HGNS for the entire sleep period. Review of polysomnography raw data identified the absence of stimulation artifact signals during this corresponding window, correlating with device deactivation, thought to be accidental, during this interval. The study was re-scored and evaluated based on the time of the sleep study spent with the HGNS device activated, as evidenced by the "stimulation artifact" signal, following which final treatment recommendations were provided and the patient was encouraged to use the device outpatient with close clinical follow-up.

Conclusion: This case highlights the clinical significance of the stimulation artifact as a real-time indicator of HGNS activation during PSG. Its visualization and reporting on the chin EMG lead not only verifies therapy delivery but also enables accurate titration of device settings. Long term implications include integration of this surrogate into reporting models for standard PSG interpretation and advancing awareness of this phenomenon amongst respiratory therapists and clinicians.

THE UNSEEN BURDEN OF UNTREATED OBSTRUCTIVE SLEEP APNEA (OSA): AORTIC COMPLICATIONS LEADING TO EMERGENCY SURGERY

Rajesh Zacharias[1], Ariel Park[1], Aarti Grover[1], Greg Schumaker[1], Joel Oster[1], Wei He[1]

[1] Tufts Medical Center

Introduction: OSA contributes to cardiovascular complications through intermittent hypoxia and intrathoracic pressure swings, leading to vascular wall stress. This case illustrates untreated severe OSA as a potential factor in acute aortic dissection requiring emergent intervention.

Report of case: A 69-year-old male with past medical history of hypertension, hyperlipidemia, and untreated severe OSA (AHI 58.5/h, O_2 nadir 70%, O_2 < 90% during 41.7% of total sleep time) initially presented to PCP's office for acute substernal chest pain. He was sent to an emergency room where they found rising troponin and elevated d-dimer. CT angiogram chest was ordered to evaluate for pulmonary embolism which showed mild ectasia of the ascending aorta measuring roughly 4 cm without dissection. He was then transferred to a tertiary hospital for ischemic evaluation. After the transfer, he subsequently described only pleuritic chest pain and fevers and was found to have new pericardial effusion, elevated CRP, and ST elevations consistent with pericarditis. Stress testing ruled out cardiac ischemia. He then developed a new atrial flutter and his repeat CT angiogram showed aortic intramural hematoma with pseudoaneurysm. The patient was evaluated by cardiothoracic surgery and was taken to the operating room for an emergent repair of aortic dissection with ascending aorta and hemiarch replacement.

Conclusion: Severe untreated OSA is increasingly recognized as a significant contributor to vascular complications, including aortic dissection and aneurysm progression. Friend et al. (2022) demonstrated that OSA might predispose individuals to larger aortic diameters at the time of acute dissection, suggesting a mechanistic link between repeated apnea-induced wall stress and vascular vulnerability. Similarly, Mason et al. (2012) identified OSA as a potential accelerant of aneurysm expansion due to episodic surges in intrathoracic pressure, oxidative stress, and vascular inflammation. In this patient with long-standing severe OSA, his aortic complication likely reflects chronic intermittent hypoxia and sympathetic overactivation inherent to his untreated OSA. These findings suggest the need for vigilant management of OSA in patients with vascular comorbidities, particularly those at risk of aortic pathologies. Further research is needed to assess whether treating OSA could mitigate the progression of aortic disease and improve patient outcomes.

UNMASKING SLEEP-DISORDERED BREATHING CHALLENGES: CARDIAC ARREST IN A PRADER-WILLI PATIENT WITH UNTREATED OSA AND SLEEP RELATED HYPOVENTILATION

Kirti Veeramachaneni[1], Patricia A. Dettenmeier[1], Rocio Zeballos-Chavez[1,2]

[1] Saint Louis University School of Medicine, [2] SSM Health Saint Louis University Hospital, 3 SSM Health Cardinal Glennon Children's Hospital

AQ5

Introduction: Prader-Willi Syndrome (PWS) is a genetic syndrome (incidence 1 in 25,000) characterized by hypotonia, psychomotor retardation, developmental delay, hyperphagia, obesity, etc. Over 80% of individuals with PWS have sleep-disordered breathing (SDB).

Report of case: A 13-year-old male with PWS (BMI 78.4, >99%), obstructive sleep apnea (OSA) and sleep-related hypoventilation (SRH) presented to outpatient MRI (with anesthesia) to rule out lower extremity osteomyelitis. During intubation attempts, he became hypoxic, bradycardic, and subsequently underwent brief cardiac arrest. After receiving 1mg epinephrine, 1mg atropine, and 1 minute CPR, he regained cardiac activity and was hospitalized in the PICU with laryngeal mask airway and, later, high flow nasal cannula. Recent PSG had shown OAHI/total AHI 81.3/SpO2 nadir 76% associated with SRH (81% TST with CO > 50mmHg). He had a history of PAP intolerance and non-adherence to follow up visits. During admission, he continued to have SRH with hypoxemia and BiPAP intolerance. Developmental status and aggression made adherence challenging. Throughout his hospitalization, interventions by the sleep team aimed to develop a positive relationship with him and the BIPAP therapy (including mask fitting, changing PAP settings, medication use (hydroxyzine), behavioral interventions (e.g., play therapy, positive reward systems), etc. BiPAP compliance improved to 90% and more than 4 hours with normal AHI.

Conclusion: PWS is a genetic syndrome associated with SDB and an abnormal hypercapnic ventilatory response with higher arousal thresholds leading to SRH. Individuals with PWS are at risk for OSA, but those with obesity are at higher risk. Obesity contributes to changes in anatomy, metabolic demand, cardiopulmonary reserve, ventilation, circulation, and pharmacokinetics that require special consideration. It is important to

pursue treatment of SDB, to avoid serious/fatal consequences if left untreated. PAP intolerance and inadequate compliance in PWS are challenging; medications, behavioral interventions, and desensitization are viable options for improvement.

A LEAD IN THE CASE OF A PATIENT WITH A MALFUNCTIONED HYPOGLOSSAL NERVE STIMULATOR

Drew Robinson[1], Patricia Patterson[1], Puneet Aulakh[1]
[1] University of Alabama at Birmingham

Introduction: Obstructive Sleep Apnea (OSA) is a disorder characterized by reduced airflow (hypopneas) or cessation of airflow (apneas) 10 seconds in duration or longer. Continuous Positive Airway Pressure (CPAP) is the mainstay of treatment for OSA, but its effectiveness is limited by patient adherence. Alternative treatments are limited by patient adherence, morbidity, and suboptimal efficacy. Hypoglossal Nerve Stimulator (HNS) is a surgically implanted device stimulating tongue protrusion and is an effective treatment for moderate to severe OSA in patients intolerant of CPAP. Complications are minimal with most being procedure and device-related discomfort as well as temporary tongue weakness.
Report of case: A 71 year male with history of obstructive sleep apnea (OSA) with apnea hypopnea index (AHI) of 26.9/hour with lowest oxygen saturation of 83% intolerant of CPAP underwent hypoglossal nerve stimulator implantation. He was lost to follow-up and returned to sleep clinic 28 months after initial presentation. At that visit, he reported a sensation of his tongue being pinched despite being set at the lowest level and was unable to use the device despite multiple attempts made at adjusting settings. The patient was later found to have a heterogenous thyroid mass ultimately requiring thyroidectomy following a nondiagnostic fine needle aspiration with pathology confirmed medullary thyroid carcinoma. Following surgery, he noted that the HNS remote control was unable to connect to his HNS device. The issue persisted despite resetting the HNS device using the programmer in the clinic. Chest radiography was obtained for further evaluation, which demonstrated a foreshortened stimulation lead terminating over the right hemithorax concerning for inadvertent device lead excision during the thyroidectomy. Histopathology confirmed presence of a wire device measuring 16 cm. The patient followed up with his ENT surgeon and requested HNS device explantation.
Conclusion: This case report illustrates a unique and potential complication that may be encountered in patients with HNS implantation undergoing head and neck surgical procedures. This case also highlights the need for special consideration to surgical approach and technique in patients with HNS implantation needing to undergo head and neck surgery.

TRAUMA-ASSOCIATED SLEEP DISORDER WITH DREAM ENACTMENT BEHAVIOR

Zachary Sherman[1], Albert Vacheron[1], Rabin Shrestha[1], Amado X. Freire[1]
[1] University of Tennessee Health Science Center

Introduction: Trauma-associated sleep disorder (TASD) is a proposed parasomnia that, while sharing criteria with REM-behavior disorder (RBD) remains under-recognized by clinicians. It is more common in the veteran population, and lacks clear guidelines on treatment, especially when accompanied by dream enactment behavior.
Report of case: A 67 year-old Gulf War veteran presented to sleep clinic with over 30 years of frequent dream enactment behavior (DEB). He has a concurrent history of insomnia, depression, and PTSD. Military service lasted 23 years, with active combat 1990-1991. DEB started then, as frequently as 5-7 times weekly. Behaviors include throwing nearby items, jumping out of bed, crawling on the floor, swinging, and yelling. The patient can only intermittently recall corresponding dreams. He has no tremor, shuffling gait, or change in handwriting. Neurological exam showed no cogwheel rigidity or resting tremor. He was diagnosed with trauma-associated sleep disorder and started on melatonin in 2017. Even with doses up to 15 mg there was no effect on parasomnia frequency or intensity, or any effect on sleep length or latency. He tried prazosin and doxazosin without improvement. These were stopped for side effects. Nighttime nausea and dizziness from other medication prevented starting clonazepam. He was later started on amitriptyline, which helped with sleep onset, but did not affect parasomnia. The patient is averse to group therapy because hearing others' trauma has previously made his nightmares worse. The planned treatment is 1-on-1 image rehearsal therapy.
Conclusion: TASD with DEB is a parasomnia not discussedin the ICSD-3-TR. Proposed mechanisms include hyperactivity in the locus coeruleus and peri-LC structures, as seen in PTSD, chronic stress, and psychiatric medications. TASD features nightmares that can occur in REM and NREM sleep and should be considered in any veteran with dream enactment. IRT is a non-pharmacologic treatment for PTSD-associated nightmares, but its effect on DEB is unclear, with only case reports. This patient has a decades-long history of DEB, but no signs of other neurological illnesses. The risk of evolution to true RBD and of developing alpha-synucleinopathies in these patients need to be clarified.

LONG-STANDING HALLUCINATIONS, A RARE PRESENTATION OF LEWY BODY DEMENTIA

Kanza Zahid[1], Alcibiades J. Rodriguez[1], Kammi Grayson[1]
[1] NYU Langone Medical Center

Introduction: Lewy Body Dementia (LBD) is a neurodegenerative disorder characterized by cognitive fluctuations, visual hallucinations, and parkinsonian features. While visual hallucinations are common in LBD, their early and prolonged presentation without significant cognitive decline is rare. This case report describes a patient with a 13-year history of visual hallucinations preceding the diagnosis of LBD, highlighting the importance of recognizing atypical presentations of this condition.
Report of case: A 79-year-old female presented with a 13-year history of complex, well-formed visual hallucinations with preserved insight. The hallucinations occurred during sleep transitions and when her eyes were closed, consisting of scary animals and recreated daily events. She experienced 4-5 episodes per week without auditory components or delusions. The patient's medical

history included autoimmune hemolytic anemia, giant cell arteritis, cardiovascular disease, sleep apnea, insomnia, and anxiety. Neurological examination revealed axial and upper limb rigidity, more pronounced on the right side, mild postural and action tremor in both upper extremities, and gait abnormalities. Cognitive assessment showed mild impairment (MoCA 23/30) with deficits in visuospatial/executive function, naming, attention, and delayed recall. Diagnostic workup included normal visual examination, polysomnography ruling out REM sleep behavior disorder, and normal EEG.Brain MRI showed mild chronic microvascular ischemic disease and a left sphenoid meningioma. FDG-PET revealed hypometabolism in bilateral temporal, lateral occipital, mesial frontal lobes, and cerebellar hemispheres, aligning with findings in DLB and supporting the diagnosis. DaT scan showed normal uptake. Autonomic testing demonstrated moderate abnormal sweating in hands and feet, decreased Valsalva ratio, and labile blood pressure. UPSIT score indicated moderate microsmia.
Conclusion: This case highlights the importance of considering LBD in patients with long-standing visual hallucinations, even in the absence of significant cognitive decline or typical parkinsonian features. The prolonged prodromal period with predominantly psychiatric symptoms underscores the need for comprehensive evaluation and long-term follow-up in elderly patients presenting with visual hallucinations. The combination of visual hallucinations, mild cognitive impairment, subtle parkinsonian signs, autonomic dysfunction, and specific FDG-PET findings supports the diagnosis of LBD. This case emphasizes the heterogeneity of LBD presentations and the potential for extended periods of isolated psychiatric symptoms before the emergence of more classical features.

RESOLUTION OF PULMONARY HYPERTENSION WITH PAP IN A PATIENT WITH ACHONDROPLASIA AND SEVERE OSA

Caroline Dooley[1], Sonal Malhotra[1]
[1] Baylor College of Medicine

Introduction: Achondroplasia is an autosomal dominant skeletal dysplasia that results in short stature, midface hypoplasia, and craniocervical junction constriction, resulting in sleep disordered breathing. Cases of pulmonary hypertension (PH) in patients with achondroplasia have been attributed to chronic hypoxemia in the setting of obstructive sleep apnea (OSA), central apnea caused by cervicocranial compression, as well as congenital lung hypoplasia. OSA can cause or worsen PH, presumably related to increased pulmonary vascular resistance from alveolar hypoxia. Management of OSA can lead to improvements in, or resolution of, PH. We present a case of PH in the setting of severe OSA in which vasodilators could be discontinued after successful control of OSA with PAP.
Report of case: A now 3 year old male with achondroplasia, severe OSA, and PH was referred to sleep medicine at 4 months of age for snoring and respiratory distress. Polysomnogram revealed severe OSA with an oAHI of 25.1/hour, CAI of 0/hr, SpO2 nadir of 77%, and TcCO2 max of 67 mmHg, successfully treated with supplemental oxygen. He was subsequently admitted for acute hypoxemic respiratory failure with evidence of right heart failure, and discharged on continuous positive airway pressure (CPAP). One month later he was admitted for bronchiolitis and started on sildenafil, given elevated right ventricular pressures on transthoracic echocardiogram (TTE) despite CPAP. Brain MRI showed severe osseous stenosis of the foramen magnum and cervical spinal canal at the C1 level for which he underwent surgical decompression. He was discharged on CPAP, however he was not able to tolerate PAP at home, thus a repeat PSG was obtained and BPAP was recommended. Following this he was admitted for RSV, and was transitioned to Average Volume Assured Pressure Support (AVAPS) with increased compliance. Repeat TTE showed no evidence of PH, and he was weaned off sildenafil, with no change in TTE.
Conclusion: Individuals with achondroplasia have an increased risk of central and obstructive sleep apnea, both of which are associated with PH. This case demonstrates resolution of PH after treatment of OSA with PAP, allowing discontinuation of vasodilator therapy, highlighting the importance of OSA management in preventing and improving long term sequelae.

AN UNEXPECTED SEVERE SIDE EFFECT FOLLOWING MODAFINIL USE

Andrea Margarita A. Saludes[1], Steven Holfinger[1], Gabriel Sraha[1]
[1] The Ohio State University Wexner Medical Center

Introduction: Modafinil is a widely prescribed wakefulness-promoting agent used to treat narcolepsy and other sleep disorders. It is generally well-tolerated. Common side effects include headache, nausea, and back pain. Rare but serious adverse effects, including Stevens-Johnson syndrome and multi-organ hypersensitivity reactions, have been reported. However, to our knowledge, severe neuropathic pain has not been reported as an adverse reaction to modafinil.
Report of case: A 25-year-old female with a recent diagnosis of narcolepsy type II was started on modafinil. An initial dose of 100 mg caused mild headache and appetite suppression. Increasing the dose to 200 mg adequately improved her daytime sleepiness and was continued. Three weeks after initiation, she developed severe, diffuse muscle and joint pain accompanied by a fever of 101.4°F, facial and eye redness, and a severe headache. She sought care at an urgent care facility, where no rash was noted. Flu and COVID-19 tests were negative, and modafinil was temporarily discontinued. One week later, she resumed 200 mg modafinil and experienced a recurrence of headaches and appetite loss. The following day, she had five syncopal episodes. The next morning, after taking 100 mg modafinil with coffee, she developed pins-and-needles sensations in her hands and feet, which gradually progressed proximally. This worsened into severe, deep, burning neuropathic pain and cramping muscle pain involving her back, buttocks, and arms. She presented to the emergency department, where examination revealed no rash, swelling, or erythema but showed 4/5 muscle strength in the lower extremities and normal sensation. Initial labs showed elevated white blood cell count and mild elevations in CK, ESR, and CRP. Iron deficiency was noted. Additional testing, including autoimmune myopathy and myositis panels, TSH, vitamin levels, and MRI of the brain and spine, was unremarkable. Oxycodone, gabapentin, and compression wraps provided significant relief. She was discharged on day 3, and her symptoms and labs normalized within a few days. Follow-up labs a week later showed further improvement.

Conclusion: Though modafinil is generally well-tolerated, this case highlights a severe reaction of neuropathic pain closely linked to modafinil administration. This emphasizes the need for clinicians to remain vigilant for delayed adverse reactions when using modafinil.

COMBINATION THERAPY: HYPOGLOSSAL NERVE IMPLANT AND CUSTOM MANDIBULAR ADVANCEMENT DEVICE

Aaron Glick[1], Adishi Ranjan[2], Uriet Dewan[3], Caroline Dooley[4], Sue Ellen Richardson[1], Supriya Singh[4]
[1] University of Texas Health Science Center Houston School of Dentistry, [2] University of Central Florida College of Medicine, [3] St. George's University, [4] Baylor College of Medicine

Introduction: Obstructive sleep apnea (OSA) is a sleep disorder characterized by recurrent episodes of airway obstruction during sleep. Hypoglossal nerve stimulation (HGNS) is an emerging treatment option for patients who are intolerant to continuous positive airway pressure (CPAP) therapy.
Report of case: A 62-year-old male with history of generalized anxiety disorder presented to the sleep clinic seeking alternative treatments for OSA. He reported daytime sleepiness, loud snoring, and bruxism. He had previously been intolerant to CPAP due to anxiety and discomfort. A drug-induced sleep endoscopy was performed, confirming the patient as a suitable candidate for HGNS. His initial polysomnography (PSG) revealed an AHI of 50 events per hour, indicating severe OSA. The patient underwent HGNS implantation. Following activation of the device, he reported a significant improvement in sleep quality and increased daytime alertness. A follow-up PSG indicated a reduction in AHI from 50/hr to 11/hr, demonstrating the substantial effectiveness of HGNS therapy. Despite the improvement in AHI, which was now in the mild range, the patient continued to experience persistent snoring and bruxism. An oral examination revealed considerable tooth attrition. The dental team was consulted, leading to the removal of all maxillary teeth. A plan was established to restore the edentulous maxilla with a complete denture. Given the anticipated delay in denture fabrication and persistent bruxism injuring the gums, a custom-fabricated mandibular advancement device (EVO) was created. This unusual approach involved anchoring the device to the maxillary arch, accommodating the patient's edentulous status. A home sleep apnea test was conducted with the hypoglossal nerve stimulator activated and the oral appliance in place. The result was a reduction in both AHI to 2/hr and bruxism therefore limiting the damage to the upper gums. The combination of HGNS therapy and the custom mandibular advancement device proved effective in managing the patient's OSA and bruxism.
Conclusion: HGNS was successfully used in this case to treat severe OSA in a patient who was intolerant to CPAP. The addition of a custom mandibular advancement device in an edentulous patient underscores the adaptability of treatment strategies. The combination therapy emphasizes the importance of personalized and multidisciplinary approaches to treating OSA.

INTERPRETING POLYSOMNOGRAM IN THE PRESENCE OF DEEP BRAIN STIMULATOR ARTIFACT

Elen Gusman[1], Aaron Thomas[1], William Zhong[2], Alon Y. Avidan[3]
[1] David Geffen School of Medicine at the University of California Los Angeles and VA Greater Los Angeles Healthcare System, [2] David Geffen School of Medicine at the University of California Los Angeles, [3] UCLA Sleep Disorders Center

Introduction: The application of polysomnography (PSG) for the evaluation of Obstructive Sleep Apnea (OSA) and REM sleep behavior disorder (RBD) presents a unique challenge in the setting of neurostimulation, such as Deep Brain Stimulation (DBS). DBS delivers high frequency pulse stimulation to the brain, which results in artifact that obscures sleep staging. We present a case that illustrates the presence of artifact in a patient with Parkinson's disease (PD) treated with DBS who presented for evaluation of OSA and dream enactment behavior (DEB).
Report of case: A 60-year-old male with PD status post bilateral subthalamic nucleus DBS presented for evaluation of OSA and DEB. The patient underwent PSG with extended EMG montage. He declined to turn off his DBS device. During the PSG, a 125 Hz artifact obscured the EEG, EOG, EKG, and chin EMG channels. The DBS artifact was characterized by a series of narrow-band components at the harmonic frequency of the DBS generator with a pulse width of 60 and 125 Hz. While the DBS artifact hindered our ability to stage sleep and evaluate the patient for REM sleep without atonia (RSWA) in the chin, it did not compromise our ability to score respiratory events and RSWA in the limbs. The PSG confirmed OSA with an AHI 8.7/hr and RBD based on an episode of shouting and abrupt movement during sleep as well as RSWA in the limb EMG.
Conclusion: This case demonstrates the unique challenges of PSG scoring and interpretation in the setting of DBS. When clinically indicated, PSG with expanded EMG montage provides a high diagnostic yield of OSA and RBD despite DBS artifact. Several interventions can be used to suppress DBS artifact on PSG, including using matched filtering and frequency-domain Hampel filtering to remove outliers. Turning off the DBS is an option as well, however this often results in the emergence of tremor artifact in patients with PD. With the increased use of neurostimulation among patients who are likely to be evaluated for sleep disorders, this case highlights the importance of recognizing DBS artifact on PSG.

IMPACT OF COMORBIDITIES ON PHRENIC NERVE STIMULATION THERAPY FOR CENTRAL SLEEP APNEA: TWO EXPLANTATION CASES

William Rosales[1], Adishi Ranjan[2], Supriya Singh[1], Antara Mallampalli[1], Velamuri Kanta[1]
[1] Baylor College of Medicine, [2] University of Central Florida College of Medicine

Introduction: Central sleep apnea (CSA) and Cheyne-Stokes respiration (CSR) frequently occur in patients with congestive heart failure (CHF), particularly those with reduced ejection fraction

(EF). This report details two cases of CHF patients with CSA who failed BiPAP therapy and were treated with phrenic nerve stimulator (PNS; the Remedē® system) but required eventual explantation. Both cases demonstrate how comorbidities influenced outcomes.

Report of case: Patient 1: CHF with Insomnia and CSA A 65-year-old male with CHF (EF 20%), CSA, hypertension, and anxiety experienced persistent insomnia despite BiPAP S/T (spontaneous/timed) therapy. A phrenic nerve stimulator was implanted, resulting in improvements in CSA episodes and maintenance insomnia. However, initiation insomnia persisted, aggravated by the patient sensing device activity during sleep. Cognitive Behavioral Therapy for Insomnia (CBTi) was attempted but provided no significant relief. The patient ultimately requested device explantation due to ongoing sleep disturbances. Patient 2: CHF with Severe COPD and CSA A 72-year-old male with CHF (EF 30%), CSA, and severe COPD who also failed PAP therapy for the sleep apnea. Following PNS implantation, the patient initially reported improvements in CSA symptoms. However, a COPD exacerbation led to severe cough, which persisted despite treatment with antibiotics and steroids, and resulted in device lead displacement. Given the risk of recurrent lead displacement, the decision was made to explant the device. These cases highlight the challenges in treating CSA in CHF patients, particularly when comorbid conditions like insomnia and COPD are present. Patient 1: While PNS improved CSA symptoms and maintenance insomnia, unresolved initiation insomnia pointed to the need for tailored insomnia management in CSA cases. Patient 2: Illustrates the impact of respiratory comorbidities like COPD on CSA therapy with PNS, complicating device efficacy.

Conclusion: Phrenic nerve stimulation offers a promising alternative for managing CSA in CHF patients, but success depends heavily on the presence of comorbid conditions. Insomnia and respiratory disorders can significantly hinder treatment outcomes, as illustrated by our cases. Optimizing care requires personalized, integrative approaches, including consideration of all comorbidities, to improve therapeutic success.

THE DOUBLE-EDGED PILL: PEDIATRIC AUGMENTATION OF RLS WITH GABAPENTIN

Andrea Nguyen[1], Andrew Valenzuela[2]

[1] University of Arizona – Phoenix, [2] Banner University Medical Group

Introduction: The American Academy of Sleep Medicine (AASM) updated its guidelines on restless leg syndrome (RLS), advising reduced use of dopamine agonists due to side effects like augmentation. While gabapentin shows low augmentation rates (~0.9%) in adults, limited data exist for pediatric cases. This report highlights treatment-resistant RLS in a 10-year-old male, potentially involving gabapentin-related augmentation.

Report of case: A 10-year-old with mild obstructive sleep apnea (OSA) and significant atopy presented with chronic nocturnal leg tingling relieved by movement. Family history included RLS in his father and pregnancy-related symptoms in mother. Labs were unremarkable, including ferritin at 85 ng/mL. X-rays ruled out lower extremity malignancy. Neurology consultation yielded no additional guidance. Oral iron therapy failed to improve symptoms. Gabapentin was initiated and titrated with resolution of symptoms. After one year, symptoms worsened despite gabapentin. The mother explored alternative therapies including transcutaneous electrical nerve stimulation unit, compression, massage, and magnesium, with minimal relief. Ferritin dropped to 47 ng/mL; oral iron was resumed. Symptoms escalated and occurred earlier in the day, raising concerns of gabapentin-induced augmentation. Gabapentin was weaned, and pregabalin was considered but declined due to parental concerns of side effects. Benzodiazepines were also avoided due to a family history of substance misuse. CPAP therapy for mild OSA was poorly tolerated despite multiple adjustments. Eventually, the mother agreed to trial IV ferric carboxymaltose with pending improvement.

Conclusion: This adolescent initially responded to gabapentin, requiring high doses to control RLS. Occurrence of symptoms earlier in the day with increasing severity suggested augmentation. Co-morbid uncontrolled OSA may have contributed, though pediatric adherence to CPAP can be challenging. This case highlights a fairly underreported phenomenon of gabapentin-induced augmentation in pediatric RLS. This highlights the complexities of managing restless leg syndrome in children and emphasizes the need for more research and treatment strategies in the pediatric population.

NON-24-HOUR SLEEP-WAKE CIRCADIAN RHYTHM DISORDER IN A 44-YEAR-OLD SIGHTED WOMAN

Francis Paul D. Battung[1], Claire L. Wendling[1]

[1] Dartmouth-Hitchcock Medical Center

Introduction: Non-24-hour sleep-wake rhythm disorder has typically been a diagnosis associated with blindness, in which the retino-hypothalamic tract does not convey a diurnal light signal to the suprachiasmatic nucleus. In this situation, sleep onset is not entrained with environmental cues to maintain a 24-hour pattern, and it naturally drifts away from the earth's light-dark cycles due to the underlying biological clock in humans, which has a day-length of 24.2 hours. Sighted individuals with this circadian disorder are rare and likely have a different etiology for their symptoms.

Report of case: Patient is a 40-year-old woman with past medical history of obesity and bipolar affective disorder seen at Dartmouth-Hitchcock Sleep Disorders Center due to long history of circadian disruption including daytime sleepiness and difficulty sleeping at night. She described a pattern of going to sleep approximately 1 hour later every night in a progressive fashion, leading to an inability to maintain a stable sleep schedule. She reported 2 prior sleep studies which were negative for sleep-disordered breathing. She stated that she was disabled and had no structured daytime activities, spending most of the day on the same couch where she slept at night. She also reported dozing briefly after eating on a regular basis. Regarding possible parasomnia symptoms, she had experienced sleep paralysis on venlafaxine but had no cataplexy symptoms. She had also experienced hallucinations while awake, but not while falling asleep or waking up. During most recent visit, HST and Actigraphy were ordered to further assess reported symptoms. Results of the HST showed an REI 4% of 3/hour, with a minimum SpO2 of 86% and a mean SpO2 of 94%. Results of the 4-week actigraphy

showed a progressive shift in bedtime over the 4-week period, associated with a progressively later wake time.
Conclusion: Although very rare, sighted individuals could present with a non-24-hour sleep-wake rhythm disorder and is likely to have a different etiology for their symptoms. This is an interesting case report about a sighted 40-year-old woman presenting with an actigraphy showing a pattern of sleep approximately 1 hour later every night in a progressive fashion.

THE GROWTH HORMONE DILEMMA IN PRADER-WILLI SYNDROME: BALANCING OBSTRUCTIVE SLEEP APNEA RISK WITH THE BENEFITS OF GROWTH HORMONE THERAPY

Prashant Kumar Singh[1], Jason Bronstein[1]
[1] Icahn School of Medicine at Mount Sinai

Introduction: Recombinant growth hormone therapy (rGHT) should be considered for patients with Prader-Willi syndrome (PWS). However, rGHT increases the risk of lymphoid hyperplasia (LH), potentially worsening obstructive sleep apnea (OSA). Case reports have linked rGHT and LH to sudden death during the initial treatment phase. Current guidelines recommend sleep oximetry, preferably completed by polysomnography (PSG), before starting rGHT in all patients, and repeating it and obtaining ENT assessment 3–6 months after initiation. We present a child with PWS who developed LH after starting rGHT, leading to rGHT discontinuation due to safety concerns, despite sleep apnea resolution. This case raises questions about whether rGHT should be withheld in patients with LH without significant sleep apnea, considering its long-term benefits.
Report of case: The patient was seen at age 7 weeks for hypotonia. Genetic testing confirmed PWS. Before starting rGHT, PSG revealed severe sleep apnea, primarily central. ENT evaluation showed no LH, and rGHT was initiated. Following therapy, tonsillar hypertrophy was identified, leading to discontinuation of rGHT. Repeat PSG was normal, but due to reports of sudden death in patients with LH, rGHT was withheld for over a year. Patient's BMI rapidly increased, muscle tone decreased, and subsequent sleep study revealed mild OSA.
Conclusion: Patients with PWS have high annual mortality (~3%), but there is no evidence to suggest rGHT increases this risk. Multiple studies found no increase in OSA-related mortality while receiving rGHT in PWS. More evidence-based guidelines are needed to clarify whether rGHT should be withheld in cases of LH without clear worsening of OSA. Withholding rGHT should carefully be considered on a case-by-case basis, as this can deprive patients from the benefits of rGHT.

PERSISTENT NOCTURNAL TACHYPNEA IN CENTRAL SLEEP APNEA: UNMASKING THE ROLE OF CARDIOGENIC OSCILLATIONS

Huzaifa Wasanwala[1], W. McDowell Anderson[1], Karel Calero[1]
[1] University of South Florida Morsani College of Medicine

Introduction: Nocturnal tachypnea is commonly linked to central sleep apnea (CSA) with Cheyne-Stokes breathing (CSB), a pattern of nocturnal tachypnea alternating with apneas. Persistent nocturnal tachypnea in the setting of CSA, however, is unusual and can result from cardiogenic oscillations (COs)—cyclic intrathoracic pressure changes during the cardiac cycle—which mimic inspiratory efforts and trigger bilevel positive airway pressure (PAP) devices, leading to inappropriate initiation of tachypnea.
Report of case: An 83-year-old man with a history of moderate obstructive sleep apnea (OSA), central sleep apnea, and heart failure with reduced ejection fraction (HFrEF), presented with complaints of nocturnal tachypnea observed by his wife. The patient had a 20-year history of OSA, initially managed with continuous positive airway pressure (CPAP). However, as his heart failure progressed, he developed CSA. He transitioned to adaptive servo-ventilation (ASV), which provided better control of his central apneic events. Following a myocardial infarction, his ejection fraction declined to 25%, prompting a switch from ASV to bilevel PAP with a backup rate, given the increased risk of cardiovascular mortality associated with ASV therapy in patients with reduced EF. While on bilevel PAP, the patient's wife noted persistent episodes of tachypnea during the night. A Nox T3 portable home sleep study demonstrated central apneas with fluctuating respiratory rates (14–56 breaths/min), resembling CSB. However, bilevel PAP compliance reports revealed persistently elevated tachypnea (95th percentile respiratory rate: 33 bpm). Given the discrepancy, inappropriate triggering by COs was suspected. The trigger sensitivity on the bilevel PAP device was reduced to a lower setting. Follow-up compliance data revealed significant improvement: the 95th percentile respiratory rate decreased to 22 bpm, and the triggered percentage for detected spontaneous breaths dropped from 93% to 42%. By lowering the sensitivity, the device became less prone to triggering from minor, non-respiratory airflow generated by cardiogenic oscillations. Two years of follow-up observations reveal continued resolution of nocturnal tachypnea.
Conclusion: Persistent nocturnal tachypnea in CSA patients with heart failure may result from an interplay between CSB and COs triggering bilevel PAP devices. Adjusting trigger sensitivity effectively reduced CO-induced over-triggering, allowing for an accurate assessment of the patient's respiratory pattern.

SLEEPING WITH THE ENEMY: CPAP THERAPY PARADOXICALLY WORSENS SLEEP APNEA

Aarti Duggal[1], Alka Bora[1], Jonathan C. Jun[2]
[1] Johns Hopkins University School of Medicine, [2] Johns Hopkins University

Introduction: Obstructive sleep apnea (OSA) is often treated with continuous positive airway pressure (CPAP) therapy. We present a case wherein CPAP therapy paradoxically worsened OSA.
Report of case: A 35-year-old man presented to Johns Hopkins Sleep Medicine Clinic endorsing excessive daytime sleepiness, with an Epworth Sleepiness Scale rating of 11. Several years prior, he had a home sleep apnea test that reportedly demonstrated severe OSA. He was treated briefly with CPAP but was unable to continue CPAP therapy after an insurance change. He also gained significant weight in the interim. We recommended a repeat sleep study, with findings of severe OSA as indicated by an apnea-hypopnea index (AHI) of 89.9 events per hour and an

oxygen nadir of 79%. Due to OSA severity, the patient's study was split to include CPAP titration. Surprisingly, CPAP induced even worse OSA, with pressures from 6 to 12 cm H2O demonstrating persistent inspiratory flow limitation. There was some improvement noted at a pressure of 14 cm H2O before the study ended. The patient preferred an oronasal mask interface during the study due to impaired nasal breathing. Ultimately, the patient was advised to wear CPAP at a pressure of 16 cm H2O with the oronasal mask interface tested. Thirty-day adherence data for CPAP use demonstrated appropriate adherence with a residual AHI of 2.1 events per hour. He reported an improvement in daytime sleepiness and expressed satisfaction with his treatment.
Conclusion: Our case demonstrates that CPAP therapy paradoxically worsened OSA during a titration study. We speculate that this phenomenon was caused by using an oronasal mask interface, which can cause posterior displacement of the tongue when air enters the mouth. We will continue to encourage the patient to switch to a nasal mask when he feels it tolerable, as we know several studies demonstrate that oronasal mask interfaces are often associated with lower CPAP tolerability, higher CPAP pressure requirements, and higher residual AHI scores.

WHAT A PICKLE. A CASE OF HYPOGLOSSAL NERVE STIMULATOR DISPLACEMENT

Christopher G. Simone[1], Dina Kianoury[1]
[1] Medstar Georgetown University Hospital

Introduction: Hypoglossal nerve stimulators (HNS) provide an alternative treatment for obstructive sleep apnea (OSA) in patients intolerant to CPAP machines. These devices are surgically placed, typically with the generator anchored above the pectoralis major muscle and under the fat pad on the right side of the chest. While complications are rare, displacement is the most common reason for revision surgery. We present a case of HNS generator dislodgment following exertion during a pickleball game.
Report of case: A 66-year-old female with severe OSA and CPAP intolerance had an HNS implanted in June 2022. In May 2023, she experienced neck pain and noticed a lump on her right chest while playing pickleball. She pressed the lump and continued playing. Over the next few days, her sleep quality declined, and her OSA symptoms reappeared. Suspecting device dislodgment, she visited her otolaryngologist, who confirmed the device had been dislodged and was mobile in the chest wall. She underwent successful revision surgery in June 2023, followed by significant improvement in her sleep apnea symptoms.
Conclusion: This case highlights the overlooked risks associated with implantable surgical devices. While detailed data on HNS complications are limited, the risks tied to implantable cardiac devices are well documented. Among the most common reasons for cardiac device dislodgment include intense physical exertions or trauma. Although pickleball is not the most intensive physical activity, the repetitive motion needed in the sport can potentially increase the risk of device dislodgment. The MAUDE database does not list device migration among the most common complications, but reported migrations have risen as more data has been collected. A literature review does not reveal any reported cases of HNS dislodgment following physical exertion in activities requiring arm swinging. Case reports on HNS device dislodgment suggest that obesity and abundant breast tissue are risk factors for device migration, with no mention of physical activity being a risk factor. This case identifies upper arm exertion as a potential risk factor for HNS device migration. Further research and incident reporting are necessary.

NARCOLEPSY TYPE 2 FOLLOWING MYCOPLASMA PNEUMONIA INFECTION

Nawaz Rupani[1], Ayesha Quadri[1], Jag Sunderram[2]
[1] Robert Wood Johnson Hospital - New Brunswick, [2] Rutgers Robert Wood Johnson Medical School

Introduction: Narcolepsy is an uncommon sleep disorder characterized by excessive daytime sleepiness, cataplexy, hypnagogic hallucinations, sleep paralysis, low levels of hypocretin-1 in the CSF, and a strong association with the HLA DQB1*0602 allele. Secondary narcolepsy has been associated with infections including Streptococcus Pyogenes, COVID-19, influenza H1N1 and the H1N1 vaccination. To date, there is one reported case of narcolepsy type 1 (NT1) associated with M. Pneumonia infection in a pediatric patient. We report a case of narcolepsy type 2 (NT2) following M. pneumonia infection in an adult.
Report of case: A 33-year-old female with a history of severe persistent asthma, obesity, depression and PTSD who presented to sleep clinic with excessive daytime sleepiness for the past 8 months. She was initially hospitalized for an asthma exacerbation and found to have positive mycoplasma pneumonia IgM antibodies. Two weeks after discharge, she reports increased sleep requirements of 20 hours per day, auditory hypnogogic hallucinations, and infrequent episodes of sleep paralysis. Two months before her clinic visit, she fell asleep while driving, causing a motor vehicle accident. She denied symptoms of cataplexy. Her ESS was 19. Given an unremarkable physical exam, cranial imaging was deferred. Overnight polysomnogram showed positional sleep apnea with an overall AHI of 7. The five naps MSLT showed mean sleep latency of 4.4 minutes, 2 SOREMs, and negative urine drug screen. HLA DQB1*0602 was positive but she declined CSF analysis for hypocretin levels. She was treated with Modafinil 200 mg twice daily. However, due to persistent sleepiness she is awaiting approval to start Pitolisant.
Conclusion: NT1 is believed to be autoimmune mediated given the strong genetic association with HLA DQB1*0602 which regulates T-cell immunity. Several articles have reported the development of NT1 following infections, especially streptococcal infections, influenza, and most recently, COVID-19. This case highlights the development of NT2 following mycoplasma pneumonia infection and suggests a similar pathophysiology mechanism resulting in a partial loss of hypocretin producing cells. The hypothesized mechanisms include cytokine storm, hyper-activation of the immune system and molecular mimicry.

KLEINE-LEVIN SYNDROME AND EMERGENT MANIC SYMPTOMS IN A YOUNG PATIENT AFTER RAMELTEON INITIATION: A CASE REPORT

Yoel Green[1], Emmanuel Mignot[1]
[1] Stanford University

Introduction: Kleine-Levin Syndrome (KLS) is a rare central disorder of hypersomnolence characterized by episodes of excessive sleep, altered behavior (e.g., hyperphagia, hypersexuality), and cognitive dysfunction. This case describes a young patient with KLS who developed emergent manic symptoms following the initiation of ramelteon, a melatonin receptor agonist.
Report of case: A 15-year-old male presented with recurrent KLS episodes, marked by hypersomnolence exceeding 18 hours per day, confusion, irritability, hypersexuality, and disorganized behavior, with full recovery between episodes. Ramelteon 8 mg was initiated to prevent recurrent KLS episodes. 36 days later, the patient developed manic symptoms, including decreased need for sleep, grandiosity, paranoia towards his parents, and disorganized behavior. Ramelteon was discontinued, and psychiatric consultation was obtained. Lithium was initiated and titrated to 300 mg twice daily to address the emergent manic symptoms and potentially reduce future KLS episodes. An atypical antipsychotic was prescribed for acute mania management. The patient demonstrated significant initial improvement and received further psychiatric involvement in his care for optimization.
Conclusion: This case highlights the complexity of managing KLS when emergent psychiatric symptoms occur. The temporal relationship between ramelteon initiation and the onset of mania raises the possibility of a paradoxical circadian reaction, potentially linked to shared vulnerabilities between KLS and bipolar disorder. The TRANK1 gene, associated with both conditions, may contribute to this connection. This underscores the importance of individualized treatment planning, considering potential genetic predispositions when prescribing circadian-targeted therapies. Multidisciplinary collaboration among sleep medicine, neurology, and psychiatry is essential for monitoring treatment responses and ensuring comprehensive care. Further research is needed to explore the nature of circadian dysfunction in KLS and its psychiatric comorbidities.

REFRACTORY OBSTRUCTIVE SLEEP APNEA IN CHILDREN WITH RUBINSTEIN-TAYBI SYNDROME

Jessica Ahn[1], Kiran Nandalike[2], Ambika G. Chidambaram[1]
[1] University of California, Davis, [2] UCD Health

Introduction: Rubinstein-Taybi Syndrome (RTS) is a rare genetic condition characterized by distinctive broad and/or angled fingers and toes, craniofacial dysmorphism, short stature, and global developmental delay. The studies in adults with RTS report higher prevalence of obstructive sleep apnea (OSA) but the data in children is limited.
Report of case: We follow five children with RTS at our pediatric sleep center, all with moderate to severe OSA (ages: 3-18 years, Apnea Hypopnea index (AHI): 7.5-90 events/hour). Two of them continued to have severe OSA following adenotonsillectomy (AT). Case A was diagnosed with severe OSA (AHI 12.2 events/hour, SpO2 nadir 70%) at 11 months of age and underwent AT. After AT, this patient's OSA symptoms improved but his AHI remained elevated at 8.5 events/hour with SpO2 nadir 76% and he needed oxygen therapy. A repeat sleep study at age three showed severe OSA (AHI 20.7 events/hour, SpO2 nadir 87%); hence, he underwent drug-induced sleep endoscopy, revision adenoidectomy, epiglottopexy and inferior turbinate reduction. A follow-up sleep study showed AHI of 9 events/hour with SpO2 nadir 78%. This patient is currently undergoing desensitization for high flow nasal cannula therapy. Case B was diagnosed with OSA at 2 years of age following an episode of bradycardic arrest during anesthesia for a urologic procedure. During that same hospital stay, he underwent AT with improvement of symptoms but was lost to follow-up. At 17 years old, he was diagnosed with very severe OSA (AHI 90 events/hour, SpO2 nadir 75%) and treated with non-invasive ventilatory (NIV) support. Later, he underwent revision adenoidectomy, lingual tonsillectomy and epiglottopexy. However, he continued to have symptoms that necessitated NIV support. For cases A and B, OSA recurrence coincided with an increase in body mass index.
Conclusion: The experience at our center shows moderate to severe OSA in children with RTS and OSA persistence despite airway revision surgeries in two children. Craniofacial anomalies, hypotonia, and obesity likely contribute to residual OSA. NIV treatment is often challenging given their cognitive impairment. This highlights the need for further studies to understand the natural history of OSA, evaluate causative factors, and analyze the effects of various treatment options in RTS.

SUSPECTED FRONTOTEMPORAL DEMENTIA-PSP VARIANT VS. ANTI-IGLON5 ENCEPHALITIS: CASE REPORT WITH SLEEP ALTERATIONS

Paola L. Zamora-Martínez[1], Jose Garza-Marichalar[2], Beatriz Chavez-Luevanos[3], Luis Arreola-Sanchez[3], Stefan Fernández-Zambrano[2]
[1] Departamento de Psiquiatría "Dr. José E. González" Universidad Autónoma de Nuevo León, [2] Psychiatry Service, "Dr. José E. González" Universidad Autónoma de Nuevo León, [3] Neurology Service, "Dr. José E. González" Universidad Autónoma de Nuevo León

Introduction: Sleep-wake disturbances are common in neurodegenerative diseases, especially in movement disorders, affecting quality of life. Progressive supranuclear palsy (PSP) is a tauopathy characterized by tau hyperphosphorylation, leading to degeneration of cortical and subcortical brain structures, particularly the midbrain. Sleep abnormalities in PSP include REM sleep behavior disorder (RBD), restless leg syndrome (RLS), periodic leg movement in sleep (PLMS), obstructive sleep apnea (OSA)/central sleep apnea (CSA), insomnia, and excessive daytime sleepiness (EDS). Anti-IgLON5 disease, first described in 2014, is a recently recognized neurological condition. Unlike other tauopathies like PSP and corticobasal syndrome (CBS), anti-IgLON5 features distinct tau deposition patterns. Polysomnography with synchronized audiovisual recording is crucial for diagnosis, showing characteristic sleep patterns like "undifferentiated-NREM (UN-NREM)" and "poorly-structured N2 (P-SN2)".
Report of case: We present a 62-year-old patient with symptoms starting in 2021, including hyperexplexia to sounds, rapid movements of the right upper limb, and delayed speech latency. In 2022, anxiety, restlessness, weight loss, and thoughts of doom emerged, along with a festinating gait and axial flexion posture. By 2023, the patient developed perseverative thoughts, compulsive guttural sounds, bilateral tremors, and sleep disturbances, including long daytime naps. Behavioral disinhibition,

topographic disorientation, and emotional lability were also noted. In mid-2024, the patient exhibited nighttime leg movements, gait instability, progressive dysphagia, increased irritability, and a suicide attempt, leading to admission in the psychiatric unit. Due to dysautonomia, the patient was transferred to neurology, where polysomnography was conducted. Polysomnography findings revealed severely disrupted sleep architecture: prolonged wakefulness (327.5 minutes), predominance of light sleep (Stage N1, 85.1%), and a significant reduction in Stage N2 (10.0%) and REM sleep (4.9%). These findings indicate profound sleep fragmentation and loss of restorative sleep stages.
Conclusion: Due to the lack of financial resources from both the patient and the hospital, as well as the absence of necessary supplies for cerebrospinal fluid measurements to detect anti-IgLON5 autoantibodies, a definitive diagnosis could not be established. The treatment was symptom-directed.

IDIOPATHIC HYPERSOMNIA DURING PREGNANCY
Doo Woong Choi[1], Lynn M. Trotti[2]
[1] Emory University, [2] Emory University School of Medicine

Introduction: Idiopathic hypersomnia (IH) is a central hypersomnia disorder that results in severe sleepiness, often accompanied by long sleep, pronounced sleep inertia, and cognitive symptoms. Because IH is often diagnosed in adolescence or early adulthood, women may already be diagnosed with and treated for IH when they enter their childbearing years. In healthy people, pregnancy commonly results in daytime sleepiness, particularly in the first trimester. In contrast, rare cases of resolution or temporary improvement of IH during pregnancy have been reported.
Report of case: A 39-year-old, G1P0 woman was diagnosed with IH >10 years prior to her pregnancy, with multiple sleep latency test showing mean sleep latency of 5.5 minutes and no sleep onset REM periods. Prior to pregnancy, her IH was treated with Solriamfetol 150 mg and flumazenil 12mg in the morning, 18mg at bedtime. Because of limited pregnancy safety data for Solriamfetol and flumazenil, she changed to methylphenidate for pregnancy. During pregnancy, she reported a dramatic benefit on her IH symptoms, despite taking very low doses of methylphenidate. Specifically, she noted "I'm feeling less sleepy than expected", staying awake during the day with less effort, and a reduction in her IH cognitive symptoms ("It's just easier to think"). Prior treatment with traditional stimulants pre-pregnancy had not resulted in similar improvements. Her on-treatment, pre-pregnancy Epworth was 19. In pregnancy weeks 12, 22, and 31, her Epworth scores were 16, 17, and 18, on methylphenidate daily doses (divided) of 7.5mg/day, 12.5mg/day, and 17.5mg/day, respectively. Despite this gradual increase in Epworth scores and methylphenidate dosing, at week 31 she reported her IH symptoms all remained noticeably less severe than pre-pregnancy, reporting "I wish I could just keep this [state of pregnancy]". She is considering whether to breastfeed while taking methylphenidate.
Conclusion: This case illuminates several considerations regarding medication decisions between patients and their healthcare providers in the pre-pregnancy, pregnancy, and post-partum periods. It also adds to rare cases in the literature describing improvement in IH symptoms during pregnancy. Further research is required to understand the typical course of IH symptoms during pregnancy and identify mechanisms underlying these changes.

A CASE OF RESTLESS LEGS SYNDROME AND HEREDITARY HEMOCHROMATOSIS
Michael T. Godar[1], Sharmeela Kuperan[1]
[1] Walter Reed National Military Medical Center

Introduction: Hereditary hemochromatosis (HH) is a genetic disorder characterized by iron overload due to increased GI tract iron absorption. Treatment often involves therapeutic phlebotomy with target ferritin of 50-150ng/mL. Restless legs syndrome (RLS) can be seen in HH, possibly due to low regional iron stores in the brain despite systemic iron overload. We present a rare case of RLS in a patient with HH whose clinical course was complicated by augmentation due to over-correction of serum ferritin and use of dopaminergic agents.
Report of case: A 46-year-old male with no medical history presented to primary care with bilateral leg discomfort and difficulty falling asleep. RLS diagnosis was made based on meeting all 2014 IRLSSG consensus criteria. Blood testing showed: elevated ferritin of 932.4ng/mL, elevated TSAT 67%, iron 182mcg/dL, TIBC 272. Genetic testing for HFE showed a homozygous C282Y mutation, confirming HH. Phlebotomy and nightly ropinirole 0.25mg was initiated. Ferritin levels stabilized between 100-200ng/mL for 3 years, though subsequently fell and remained below 75ng/mL. This coincided with onset of RLS symptoms earlier in the day as well as spreading to involve more proximal legs and hands. Ropinirole dose was gradually increased to 1.5mg/day for symptom management. He was subsequently referred to Sleep Clinic for frequent nighttime awakenings, daytime sleepiness, and snoring. Ferritin level was 35.8ng/mL and diagnostic polysomnogram showed an AHI 5.2/hr, PLMI 20/hr, PLMAI 3.2/hr. In collaboration with Hematology, target ferritin was increased to 200-300ng/mL. Augmentation was further managed with initiation of nightly gabapentin while beginning a slow taper off ropinirole.
Conclusion: This case highlights a rare combination of RLS symptoms and concomitant HH, which suggests localized CNS iron deficiency despite markedly elevated serum ferritin. Abnormalities in the iron transport system across the blood-brain barrier could explain this discrepancy. However, our patient's RLS symptoms did worsen with serum ferritin levels falling below 50-75ng/mL. Therefore, a multi-disciplinary approach with Hematology is needed in managing these patients to avoid exacerbation of RLS symptoms due to overcorrection of serum ferritin levels.

RARE GENES, RESTLESS NIGHTS: A CASE OF OBSTRUCTIVE SLEEP APNEA IN A PATIENT WITH CORNELIA DE LANGE
Andrea Nguyen[1], Andrew Valenzuela[2]
[1] University of Arizona - Phoenix, [2] Banner University Medical Group

Introduction: Cornelia de Lange syndrome (CdLS) is a rare genetic disorder affecting 1 in 10,000 newborns. It is characterized by growth restriction, developmental delays, and high rates of comorbid respiratory, cardiac, gastrointestinal, and neurologic conditions. Approximately 25% of individuals with CdLS experience epilepsy, for which vagal nerve stimulators (VNS) can be used as a treatment. However, VNS has been associated with obstructive sleep apnea (OSA) through various mechanisms including decreased airflow and change in respiratory effort. This report highlights a CdLS patient with OSA initially attributed to VNS implantation.
Report of case: A 13-year-old male with a history of CdLS, chronic epilepsy managed with VNS, and ahistory of adenotonsillectomy at a young age presented to the pediatric sleep clinic for OSA management. Two years post-VNS implantation, his epilepsy remained poorly controlled on EEG. Pediatrician noted hypersomnia and snoring, and a sleep study was ordered which revealed severe OSA (apnea-hypopnea index (AHI) of 14.8/h, central apnea index (CAI) of 0.4/h, and oxygen nadir of 81%). Initially, VNS-induced worsening of OSA was suspected, and nighttime VNS settings were adjusted. His mother reported continued restlessness during sleep, but no witnessed apnea. Patient underwent repeat adenoidectomy with ENT. Post-operative sleep study confirmed persistent severe OSA (AHI 18.1, RDI 46, oxygen nadir 74%). The patient began therapy with APAP 5–15 cm H_2O and excellent adherence. On APAP, his residual AHI improved to 1.3, indicating effective treatment of sleep disordered breathing.
Conclusion: This case underscores the complexity of managing OSA in patients with rare syndromes and various comorbidities. While VNS was initially suspected to exacerbate OSA, settings adjustment proved ineffective, highlighting the need for comprehensive evaluation. Despite repeat surgical interventions, PAP therapy ultimately proved to be the most efficacious treatment, demonstrating that even patients with syndromic conditions and complex medical histories can achieve effective treatment & adherence with appropriate interventions. Providers must remain informed about the unique needs of the complex pediatric population to deliver optimal care, including those with vagal nerve stimulators.

SLEEP-RELATED HYPOVENTILATION IN CYSTIC FIBROSIS: THE SILENT DANGER

Rupini Alla[1], *Pahnwat Tonya Taweesedt*[1]
[1] Stanford University

Introduction: Cystic fibrosis is a genetic disorder that affects multiple organs, particularly the lungs and pancreas. This progressive condition can compromise lung function through recurrent respiratory infections, bronchiectasis, and chronic inflammation with hypoxia. One area that warrants further research is the effect of cystic fibrosis on sleep. Individuals with cystic fibrosis can face challenges with sleep-related breathing disorders which can exacerbate fatigue and impair one's quality of life.
Report of case: A 39-year-old male with history of cystic fibrosis, diabetes mellitus, depression, chronic sinusitis, and pancreatic insufficiency presented for evaluation of daytime fatigue and excessive daytime sleepiness. Patient reported fatigue, snoring and unrefreshed sleep for several years. He had reports of sleepwalking as a child which resolved in adulthood, otherwise no other specific sleep complaints were reported. His vital signs were within normal limits and no desaturation on room air was noted during the clinic visit. Body mass index was 26.04 kg/m2. Upon reviewing his previous laboratory results, HCO3 levels were noted to be 29 mmol/L. Patient underwent an in-lab polysomnography with CO2 monitoring. The study revealed sleep-related hypoventilation with baseline TcCO2 at 39 Torr, increasing to a maximum of 73 Torr in the study and baseline oxygen level of 92% with a nadir of 84%. However, the AHI, according to AASM criteria overall was 2.7. The REM supine AHI was higher at 13.8. Desaturation was also noted to be in the low 90s and high 80s during wakefulness and during sleep, independent from respiratory events. Patient is to initiate Bilevel S/T for significant hypoventilation and to follow up in the clinic to assess response regarding symptoms of excessive daytime sleepiness and fatigue.
Conclusion: This case aims to emphasize the critical role of recognizing sleep-related hypoventilation as a significant contributor to daytime fatigue in patients with cystic fibrosis and to advocate for the use of non-invasive ventilation strategies, such as Bilevel S/T, to enhance respiratory function and improve quality of life. Moreover, it highlights the necessity of CO2 monitoring during polysomnography, challenging the traditional focus on obstructive sleep apnea alone as the sole explanation for excessive daytime somnolence in this patient population.

WHEN MACROGLOSSIA IS NOT BECKWITH-WIEDEMANN: A CASE OF AN INFANT WITH CONGENITAL CENTRAL HYPOVENTILATION SYNDROME

Samira Naime[1], *Shauna Michelle Vandoren*[1]
[1] Children's Mercy Kansas City

Introduction: Congenital central hypoventilation syndrome (CCHS) is a rare genetic disorder caused by the mutation of the paired-like homeobox 2B (PHOX2B) gene that leads to alveolar hypoventilation during sleep and at times while awake. The majority of patients with CCHS have polyalanine repeat mutations (PARM) whereas 10% have non-PARM (NPARM). Of those with NPARM, less than 1% are caused by whole gene deletion. NPARM is associated with more severe phenotypes; however, some may have variable penetrance causing variable presentation within families.
Report of case: Our patient is a 4-month-old infant born at 32 weeks in an outside hospital and transferred to our tertiary NICU at 10 weeks of age due to feeding difficulties, respiratory distress, hypoxemia, macroglossia and concern for Beckwith-Wiedemann syndrome. Upon transfer, she was on 2L of oxygen (FiO2: 0.3) via high flow nasal cannula. During her stay, she was noted to have hypoventilation which was thought to be secondary to upper airway obstruction. Upper airway evaluation by ENT revealed mild laryngomalacia for which supraglottoplasty was performed. Drug induced sleep endoscopy (DISE) revealed macroglossia with posterior displacement of the epiglottis causing obstruction. Due to concerns for obstruction and persistent hypoxemia, she was referred for a polysomnogram (PSG). The study was started on room air, but 1/4L of oxygen via low flow nasal cannula (LFNC) was initiated after 6 minutes due to persistent hypoxemia and hypoventilation. PSG showed an apnea hypopnea index (AHI)

of 18/hour, central apnea index (CAI) of 11/hour with persistent nocturnal hypoventilation based on ETCO2, transcutaneous CO2 monitor (TCM) and blood gas (ETCO2 > 50mmHg for 85% of total sleep time (TST), max ETCO2: 62mmHg, TCM>50mmHg for 96% TST, peak TCM: 70mmHg). Given these findings, recommendations were made to obtain PHOX2B gene testing and obtain neurologic workup. Exome sequencing showed deletion of the PHOX2B gene consistent with CCHS.
Conclusion: A high suspicion for CCHS should be present in patients with central apnea and hypoventilation. Many children with CCHS may be missed due to complex genetic testing and variation in clinical presentation.

A CASE OF PULSE RATE ARTIFACT DUE TO DEVICE AVERAGING TIME DURING ATRIAL FIBRILLATION ON HOME PORTABLE SLEEP STUDY

Ahmed S. Beydoun[1], B. Tucker Woodson[1]
[1] Medical College of Wisconsin

Introduction: Obstructive sleep apnea (OSA) is an established risk factor of atrial fibrillation (Afib). Home portable sleep studies composed of a nasal cannula, finger pulse oximeter and measures of ventilatory effort are being increasingly utilized to diagnose OSA due to convenience and decreased costs. The NOX system is, and device recorder secured around the chest using a belt. We report that the portable monitoring systems using 4 beat averaging time create a pulse artifact on recording that is consistent with atrial fibrillation.
Report of case: A 69-year-old male with history of atrial fibrillation with prior successful cardioversion underwent a two-night diagnostic home portable NOX sleep study. The first night of the study demonstrated a pulse rate artifact beginning abruptly around 0150. Prior to artifact, the average pulse rate was 45 beats per min with a very narrow range. In contrast the artifact demonstrated an increase of the average pulse rate 80 beats min and a wide pulse rate range (> +/- 20 beats/min). Subsequent smartwatch warning about an abnormal and irregular heart rhythm prompted the patient to visit the ED visit where EKG confirmed Afib followed by successful cardioversion. Subsequently, the second night of his study demonstrated no pulse rate artifact. Afib did not resolve despite appropriate OSA treatment and has been recommended ablation by Cardiologist.
Conclusion: Our case highlights the pulse rate variation produced by the averaging time during Afib on home portable sleep study. While not diagnostic, it is important to recognize this pattern and understand the role that sampling rate and averaging time play in generating the pattern seen.

PRECISION THERAPY IN TREATING SEVERE OSA

Joy Ayyoub[1], Krutika Patel[2], David Binder[2]
[1] Icahn School of Medicine at Mount Sinai, [2] Dental Sleep Apnea NY

Introduction: Continuous positive airway pressure (CPAP) is widely considered the gold standard treatment for severe obstructive sleep apnea (OSA). Adherence remains a significant barrier to therapy, with studies reporting non-adherence rates ranging from 28% to 83%. Oral appliance therapy (OAT) is considered effective when reducing the apnea-hypopnea index (AHI) by approximately 50% and is primarily recognized for the treatment of mild to moderate OSA. Its use in severe OSA remains less understood. This case highlights the role of combination therapy in select patients with severe OSA.
Report of case: An 81-year-old male with a history of heart failure with preserved ejection fraction presented with fragmented sleep and excessive daytime sleepiness. He underwent a home sleep apnea test (HSAT) which revealed severe OSA with a component of Cheyne-Stokes respiration (CSR) and significant central apnea events, showing a baseline AHI4% of 52.6 events per hour (62.6 supine, 9.8 non-supine), a central apnea/hypopnea index of 13.4, a CSR of 17%, with a nadir oxygen saturation (SpO2) of 59% and a cumulative time below 89% of 87 minutes. Given his aversion to CPAP, a repeat HSAT with the use of an OAT demonstrated an improvement in AHI4% to 26 events per hour, with persistent severe OSA supine (77.4 versus 11.7 events per hour), but no further evidence of CSR or central apnea events. Nocturnal hypoxemia persisted with a nadir SpO2 of 56% and a cumulative time below 89% of 52 minutes. With the addition of combination positional therapy and OAT, the AHI4% improved to 3.6 events per hour with no further hypoxemia.
Conclusion: Adherence to positive airway pressure (PAP) therapy represents an ongoing challenge, with mask discomfort and pressure intolerance frequently reported as the most common reasons for non-adherence. There continues to be a need for alternative treatment options, particularly in patients with severe OSA and high hypoxic burden, such as our patient. This case highlights the efficacy of OAT, particularly when combined with other treatment modalities, as a viable first-line therapeutic approach in select patients. Tailoring treatment to individual endotypes and phenotype can enhance outcomes and expand therapeutic possibilities beyond PAP, further emphasizing the importance of individualized care.

USING HIGH FLOW NASAL CANNULA FOR SEVERE OBSTRUCTIVE SLEEP APNEA IN AN 8-MONTH-OLD WITH COFFIN-SIRIS SYNDROME: A CASE REPORT

Mahrukh Riaz[1], Harshitha Mergey Devender[2], Anayansi Lasso-Pirot[3], Montserrat Diaz-Abad[4]
[1] University of Maryland Baltimore, [2] Baltimore VA Medical Center, [3] University of Maryland Department of Pediatrics, [4] University of Maryland School of Medicine

Introduction: Obstructive sleep apnea (OSA) prevalence rises from 1-5% in the general pediatric population to as high as 80% in children with complex comorbidities, as reported in published studies. Adenotonsillectomy (AT) is the primary treatment modality but has limited success in children with obesity or underlying medical conditions. Continuous positive airway pressure (CPAP) is the main treatment post-AT but suffers from low adherence. High flow nasal cannula (HFNC) is emerging as a more tolerable alternative, with evidence suggesting it achieves similar reductions in obstructive apnea-hypopnea index (oAHI) and other polysomnographic metrics as CPAP.
Report of case: An 8-month-old female with Coffin-Siris syndrome presented with severe OSA. Her medical history included

2q13 chromosomal deletion, congenital hypotonia, agenesis of the corpus callosum, gastroesophageal reflux requiring G-tube and Nissen fundoplication, optic nerve hypoplasia, and mild micrognathia. At birth, she experienced respiratory distress requiring CPAP, subsequently weaned to room air. However, she was later noted to have persistent stridor and oxygen desaturation episodes. A polysomnogram (PSG) showed an overall AHI of 42.2 without significant hypoxemia or hypercarbia. Initial management included supplemental oxygen. The patient was subsequently hospitalized for bronchiolitis, and started on scopolamine for excessive secretions, in addition to bronchodilators. At 8 months, she exhibited restless sleep with snoring, choking, mouth breathing, and apneas associated with bradycardia of < 60 beats per minute (BPM). Repeat PSG, revealed an oAHI of 20.2/hr with a nadir oxygen saturation of 79% and hypercapnia (ETCO2 >50 mmHg for 79% of sleep time). Per otolaryngology she was not a surgical candidate and nocturnal home HFNC oxygen at 8 L/min at 22% FiO2 was started. This resulted in improvement of her symptoms, oxygen saturation (96-100%) and resolution of heart rate variability. Follow-up at 24 months showed persistent symptom improvement with HFNC. Mother reported more restful sleep, improvement in oxygenation, airway clearance with reduced sessions of chest physiotherapy, and no hospitalizations.

Conclusion: HFNC is a viable alternative home therapy for pediatric OSA patients with complex medical comorbidities who are not surgical candidates. This case demonstrates sustained symptom improvement and better adherence with HFNC compared to traditional CPAP therapy.

BILEVEL PAP DATA IN THE SLEEP APNEA PATIENT WITH CO-MORBID INTERSTITIAL LUNG DISEASE

Tekle Didebulidze[1], Biana Lang[1]

[1] Dartmouth Hitchcock Medical Center, Section of Sleep Medicine

Introduction: Obstructive sleep apnea (OSA) is a common co-morbidity in patients with interstitial lung disease (ILD). Studies estimate that OSA prevalence among ILD patients ranges from 17-88%, compared with 2–4% in healthy adults, underscoring a strong association. ILD, characterized by progressive fibrosis and impaired gas exchange, can exacerbate hypoxemia during sleep, while OSA, marked by recurrent airway collapse, may worsen nocturnal oxygen desaturation and increase respiratory effort. Breathing pattern changes, such as altered respiratory rates, tidal volumes, minute ventilation and/or inspiratory to expiratory ratio (I:E Ratio) are frequently observed in ILD patients. These respiratory indices can be identified via bilevel positive airway pressure (BiPAP) therapy reports, providing valuable insights into patient's respiratory status. This case report highlights the utility of readily accessible data to gain deeper understanding of patient's clinical status.

Report of case: A patient with a 5-year history of OSA and CPAP (continuous positive airway pressure) intolerance established care for OSA on 01/2021. Following a PAP titration study, he restarted CPAP but struggled with therapy and was lost to follow-up. In June 2023, he was reevaluated while undergoing ILD workup. By 7/2023, he was diagnosed with fibrotic ILD (hypersensitivity pneumonitis vs. nonspecific interstitial pneumonitis) and underwent wedge lung resection. In August 2023, BiPAP was started, showing initial improvement with mild mask fit issues. In 2024, his condition deteriorated. More acutely in May 2024 developed bilateral pulmonary embolism and progressive respiratory failure. Ultimately, on 9/2024, he underwent bilateral lung transplantation. The data obtained from patients' bilevel PAP therapy report during this time offers a unique opportunity to review his pulmonary physiology as his clinical course deteriorated and after subsequent lung transplantation. Marked increases in respiratory rate, drops in tidal volume, increase in minute ventilation and increasing I:E ratio was seen. In stark comparison, with lung transplantation, all these values normalized.

Conclusion: Home BiPAP devices may provide easily accessible data on pulmonary physiologic parameters which can be followed longitudinally. Understanding normal parameters, recognizing abnormal patterns in pulmonary and other diseases, and monitoring this data over time may offer additional insights to enhance patient care.

CHALLENGES IN MANAGING SEVERE OBSTRUCTIVE SLEEP APNEA WITH HYPOGLOSSAL NERVE STIMULATION: A CASE REPORT

Pranav Mehta[1], Ashwini Bandi[1], Abigail Boudreaux[2], Antara Mallampalli[2], Supriya Singh[2]

[1] McGovern Medical School at UTHealth Houston, [2] Baylor College of Medicine

Introduction: Hypoglossal nerve stimulation (HGNS) is a second-line treatment for obstructive sleep apnea (OSA) in patients who cannot tolerate positive airway pressure (PAP) therapy. However, its efficacy as a standalone treatment in severe cases is limited. This case highlights the challenges of HGNS and supports a multimodal treatment strategy enhanced by drug-induced sleep endoscopy (DISE).

Report of case: We present a 57-year-old female with BMI 32 and severe OSA with an apnea-hypopnea index (AHI) of 92. She was intolerant to PAP due to mask discomfort, dry mouth, and claustrophobia. Following HGNS implantation, she experienced complications with device up-titration including persistent dry mouth and tongue discomfort. Her follow-up sleep study with an HGNS amplitude of 2.1 revealed an elevated AHI of 65, indicating persistent airway obstruction. Repeat DISE showed ongoing soft palate collapse with various HGNS electrode configurations, while moderately improving the base of tongue collapse. Additionally, a deviated nasal septum and collapsed lateral wall of the hypopharynx were noted. During DISE, a hyoid-suspension maneuver was manually performed by the physician, revealing improved patency, suggesting that a hyoid-suspension surgery would be beneficial. The patient was subsequently referred back to ENT and underwent hyoid suspension surgery and septoplasty, which improved the soft palate and hypopharyngeal opening. Six weeks later, repeat DISE and sleep studies with HGNS set at 2.1 amps demonstrated an open soft palate and base of tongue, with a significantly reduced AHI of 12 events per hour.

Conclusion: This case illustrates the limitations of HGNS as a monotherapy for severe OSA. Despite initial HGNS implantation, the patient's symptoms persisted, necessitating additional investigation and surgical interventions. By combining HGNS with hyoid suspension surgery and septoplasty, the patient faced significant improvements in airway patency with a notable

reduction in AHI. This illustrates the importance of a multimodal treatment approach and the benefits of repeat DISE in optimizing therapy for severe OSA.

OTALGIA POST-HNS ACTIVATION

Vivian W. Chan[1,2], Melisa R. Chang[1,2]
[1] Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, [2] VA Greater Los Angeles Healthcare, Los Angeles

Introduction: Hypoglossal nerve stimulation (HNS) is a surgical treatment for obstructive sleep apnea (OSA) for patients intolerant of positive airway pressure (PAP) therapy. This implanted medical device is used to stimulate the hypoglossal nerve leading to tongue protrusion and airway opening. The procedure and treatment are generally well tolerated. Common complications include post-op pain, infections, neuropraxia, and hematoma. We present a case of a patient developing otalgia post-HNS activation.
Report of case: A 54-year-old male with a history of severe OSA (respiratory event index 44.7/hour) with PAP intolerance underwent HNS implantation. He returned one month later to undergo HNS activation. During attempted activation, he reported right ear pain at 0.8 volt (V) stimulation, described as a "shock" sensation to the right eardrum that persisted only with stimulation. He denied associated hearing changes, dizziness, and pain elsewhere. He denied any other trigger for pain. HNS activation was deferred this visit to allow time for recovery. He returned two months later to re-trial activation. He did not experience recurrent right ear pain at 0.8 V or higher voltage up to 1.0 V. His HNS was set at an amplitude of 1.0 V. During subsequent visits, the voltage was gradually increased with improvement of OSA symptoms. He did not report recurrent ear pain.
Conclusion: Given the sensation of shock occurred only with stimulation of the nerve, the pain was attributed to nerve injury. Given the resolution of the pain after several months, the pain was suspected to be secondary to post-surgical inflammation leading to activation of nerves, and less likely to be from dissection of the nerves. Otalgia can result from impingement of several nerves and their branches including the trigeminal, facial, glossopharyngeal, and vagus nerves. Upon review of literature, we noted one case of exacerbated atypical trigeminal neuralgia that was suspected to be secondary to activation of muscles including genioglossus, geniohyoid, and potentially the palatoglossus during HNS stimulation, with symptoms only resolving after HNS explantation and medical treatment. While otalgia is not a common complication following HNS implantation, it is important to counsel patients on these risks.

A CASE OF UNEXPLAINED NOCTURNAL HYPOXIA

Rose Basnyat[1,2], Melisa R. Chang[1,2], Armand Ryden[1,2], Kevin Eng[1,2]
[1] Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, [2] VA Greater Los Angeles Healthcare, Los Angeles

Introduction: We present a patient with unexplained nocturnal hypoxia out of proportion to his severe obstructive sleep apnea (OSA) and detail the workup done to assess for causes of hypoxia.
Report of case: A 75 year-old male with a BMI of 30 kg/m2 and past medical history of cirrhosis and non-oxygen dependent chronic obstructive lung disease presented with snoring, nocturnal awakenings and excessive daytime sleepiness. A home sleep apnea test showed moderate OSA and prolonged desaturations without preceding apneas or hypopneas. Thereafter, a split-night polysomnogram with bilevel positive airway pressure (BPAP) titration showed severe OSA with a baseline AHI of 64/hr. The patient was titrated to BPAP pressures of 17/12 cm H2O with resolution of obstructive events but continued hypoxia requiring 3LPM oxygen supplementation. An awake arterial blood gas (ABG) did not show evidence of hypercapnia. There was mild hypoxemia with an A-a gradient of 37.5 mmHg. An ABG shunt study to determine responsiveness to supplemental oxygen is pending. Pulmonary function testing showed a mixed obstructive and restrictive pattern by GOLD criteria with hyperinflation and normal diffusing capacity. Computed tomography of the chest demonstrated right diaphragmatic elevation without parenchymal lung disease. Echocardiogram with bubble study was negative for shunting and did not reveal pulmonary hypertension. After a limited daytime positive airway pressure (PAP) nap study, auto-titrating continuous positive airway pressure (APAP) set at 10-16 cmh20 with 3LPM oxygen bleed in was recommended. On this, a 3-night oximetry test showed ongoing significant oxygen desaturations despite adequate treatment of OSA. Oxygen bleed-in was increased to 5LPM. A repeat 3-night oximetry is pending.
Conclusion: The nocturnal hypoxia is likely multifactorial secondary to obstructive and restrictive lung disease along with a possible shunt. Right diaphragmatic elevation seems unlikely to cause severe hypoxia. A phrenic nerve study and transcranial doppler are pending. Platypnea-orthodeoxia was absent and hypoxia did not resolve with oxygen therapy. It is possible that PAP, known to cause an increase in RV afterload due to elevated intrathoracic pressure, could potentially cause an unidentified shunt to become a right to left shunt thereby causing hypoxia.

DEVELOPMENT OF RESTLESS ARMS SYNDROME AFTER INITIATION OF DULOXETINE

John A. Das[1], Stephanie Stahl[2], Sachin Shah[3]
[1] Western Reserve Hospital, [2] Indiana University School of Medicine, [3] IU Health Physicians

Introduction: Restless arms syndrome (RAS) is a disorder in which affected individuals experience the urge to move their arms. These symptoms are particularly worse in the evening and improve with movement. RAS is rare, with very few cases being described. The etiology is suspected to be related to iron deficiency or dysfunction of iron utilization within the central nervous system.
Report of case: A 68-year-old woman with a medical history including anxiety, a mood disorder, and insomnia presented to the sleep clinic after developing an uncomfortable urge to move her arms around bedtime after increasing duloxetine. The patient was initially started on duloxetine 20 mg four months prior to her

visit. Her dose was then increased two months later to 60 mg. Her RAS symptoms started shortly after this increase. An iron panel and ferritin level were ordered to evaluate for additional contributors of RAS, which yielded values of 74 and 54.9, respectively. She was subsequently started on ferrous sulfate with repeat levels pending. The patient was counseled that antidepressants, with the exception of bupropion, can cause restless leg syndrome (RLS), and thus, were likely to be the cause of her RAS. Additionally, she was advised to refrain from alcohol, tobacco, and caffeine as these can be triggers of RAS. Relaxation techniques and the application of hot or cold packs were recommended as well.
Conclusion: The International RLS Study Group has established criteria used to diagnose RAS. Thus far, very few cases of RAS have been diagnosed using these criteria and RAS is likely underdiagnosed. While 22–50% of patients with RLS experience similar symptoms in the arms, restlessness rarely starts in the arms. This case supports evidence that reuptake inhibition of serotonin and norepinephrine may be implicated in the etiology behind RAS in addition to underlying iron deficiency.

RESTLESS SLEEP DISORDER IN A CHILD WITH AUTISM SPECTRUM DISORDER: RESPONSE TO INTRAVENOUS IRON THERAPY

Kate Young[1], Carolyn E. Ievers-Landis[1], Sally Ibrahim[1]
[1] University Hospitals Cleveland Medical Center, Case Western Reserve University

Introduction: Restless Sleep disorder (RSD) is a relatively new diagnosis with etiology similar to other sleep-related movement disorders. Polysomnography typically shows at least five or more large muscle movements per hour/sleep, positional changes, and normal sleep architecture. Lab workup includes low ferritin levels. Autism spectrum disorder (ASD) comorbidity in a younger pediatric patient with RSD presents a clinical challenge due to difficulty cooperating with diagnostic procedures and therapy. To date, RSD treatment recommendations have been based on studies with typically developing children ages 6-18 years.
Report of case: A 3-year-old male with a history of non-verbal ASD, lead exposure, and iron deficiency anemia (iron saturation of 14%, ferritin 8, TIBC 436, iron 84 ug/dL) was referred to Sleep Medicine for sleep onset and maintenance insomnia, insufficient sleep, and significant daytime behavior problems. Polysomnography was deferred due to erratic sleep patterns and sensory challenges. Oral iron supplementation failed due to restricted dietary preferences. Medication trials (melatonin, clonidine, hydroxyzine) were unsuccessful. Therapy for insomnia by a psychologist with expertise in behavioral sleep medicine yielded a modest response. Patient was referred to hematology and received three intravenous infusions of iron sucrose spaced two weeks apart. Parents and specialists in sleep psychology, occupational therapy, speech, and advanced behavioral analysis endorsed dramatic improvement in sleep duration (from 7 to 11 hours). Gains in the PROMIS sleep disturbance scales followed by cognition, social functioning, and developmental milestones occurred within a few months of iron level normalization (iron saturation of 37%, ferritin 124, TIBC 386, iron 141 ug/dL).
Conclusion: This case illustrates sleep improvement for a young child with severe ASD and RSD with intravenous iron treatment. Identifying and treating RSD in patients with ASD is challenging in the context of other co-occurring medical and psychological symptoms/disorders. The intravenous route may be an option in children with developmental/sensory differences who cannot tolerate oral iron therapy. The role of behavioral therapy in conjunction with intravenous iron treatment is an area for future clinical and research examination.

EVOLUTION OF OSA IN CROUZON'S SYNDROME

Malti Bhamrah[1], Nida Qadir[1], Harjinder Singh[1], Rupa Koothirezhi[1], Cesar Liendo[1], Oleg Chernyshev[1]
[1] Louisiana State University Shreveport

Introduction: Crouzon's syndrome is caused by fibroblast growth factor receptor 2 (FGFR2) gene mutation and is seen in 16 out of 1 million live births. It is characterized by the premature closing of calvarial and cranial base sutures as well as the orbit and maxillary complex resulting in exophthalmos, flattened forehead, midface hypoplasia, and hypoplastic maxilla. This deformity, this leads to a high prevalence of obstructive sleep apnea. Here we present a case of the progression of OSA in a patient with Crouzon's with subsequent medical and surgical interventions.
Report of case: At age 15 months, patient was evaluated by Pediatrician for loud snoring and witnessed apneas. Her I'M SLEEPY questionnaire was positive with score of 4 and physical exam was pertinent for +3 tonsillar hypertrophy. She was evaluated by ENT where evaluation of pathognomonic facies was initiated and found positive for Crouzon's due to FGFR2 gene variant - c.1018T>C, p.Tyr340His. At 2 years old, initial PSG showed AHI: 24.3, RDI: 24.3, Oxygen Nadir 93%. Underwent T&A with ENT and established care with Sleep Medicine for management. Found to have continued symptoms of loud snoring, apneas, unrefreshing sleep. Second PSG at 4 years old, showed AHI 8.8, RDI: 9.7, Oxygen Nadir 93%. Attempted usage of AutoPAP, unable to tolerate due mask intolerance and chronic rhinitis. Underwent anterior cranial vault reconstruction with midface advancement with OMFS and Neurosurgery. Third PSG at 6 years old, AHI 3.6. Compliance was difficult to implement due to mask intolerance. At 8 years old, underwent LeFort III surgery and corrective orbital surgery. Fourth PSG at 9 years old, AHI 4.1, RDI 16.5, Oxygen Nadir 97%. Recommendations to attempt AutoBiPAP and continued follow up with OMFS for surgical versus orthodontic interventions.
Conclusion: Crouzon's syndrome is characterized with anatomical deformities which leads to high prevalence of OSA of 68% but data is limited given the overall epidemiology of this syndrome. The predominant contributing factor for OSA is midface hypoplasia. Treatment options include T&A followed by PAP using nasal interface and definitive treatment is surgical midface advance like Le Fort III with distraction osteogenesis, monobloc advancement and facial bipartition.

NON-POLYALANINE REPEAT PHOX2B MUTATION PRESENTING AS SEVERE CENTRAL SLEEP APNEA AFTER DINUTUXIMAB

Nataly J. Sanchez Solano[1], Christopher Cielo[2], Nancy Y. Lin[2]
[1] University of Pennsylvania, [2] Children's Hospital of Philadelphia

Introduction: Congenital central hypoventilation syndrome(CCHS) is a rare disorder of autonomic nervous system dysregulation affecting control of breathing. Ten percent of cases result from non-polyalanine repeat expansion mutations(NPARM) of the paired-like homeobox 2B(PHOX2B) gene. NPARM are often associated with severe phenotypes, such as the need for invasive mechanical ventilation in the neonatal period, malignant neuroblastoma, and severe Hirschsprung's disease. Children with NPARM with mild ventilatory abnormalities are rare. We present a case of a 4-year-old child with metastatic neuroblastoma, later diagnosed with CCHS, following acute respiratory failure after dinutuximab.
Report of case: A four-year-old full-term male with past history of congenital bilateral ptosis and metastatic neuroblastoma status post surgical resection was admitted for dinutuximab immunotherapy. During pathologic analysis of neuroblastoma, it was found to have NPARM of PHOX2B (c.691_698dup). Following dinutuximab infusion, he developed fever, pain requiring opioid medications, acute hypercarbic respiratory failure, and mental status change, initially concerning for iatrogenic oversedation related to opioids or infusion side effects. Laboratory results showed mild hyponatremia(135 mmol/L), hypokalemia(3.6 mmol/L), elevated bicarbonate(28 mmol/L). Venous blood gas showed acute respiratory acidosis with severe hypercarbia(pH 7.2, pCO2 113 mmHg). He required intubation and mechanical ventilation. Brain imaging revealed microhemorrhages in dorsal pons and thalamocapsular regions, but clinical significance was unclear. Electroencephalogram was normal. Infectious work up was negative. After extubation, diagnostic polysomnography was performed to evaluate control of breathing and revealed severe central sleep apnea(CAHI=100.2 events/hour), obstructive sleep apnea (OAHI=5.2 events/hour), and non-apneic hypoxemia(SpO2< 90% for 107 minutes) with no significant hypoventilation (TCO2>50 mmHg for 13% total sleep time). After starting 0.25L/min supplemental oxygen, CAHI improved to 31.2 events/hour, OAHI to 0.4 events/hour. Unfortunately, hypoventilation was induced with application of supplemental oxygen(TCO2>50 mmHg for 48% total sleep time), limiting further titration. He was discharged on supplemental oxygen pending further evaluation.
Conclusion: NPARM in PHOX2B are rare and typically result in severe hypoventilation during the neonatal period. This unique presentation of an older child with NPARM in PHOX2B, severe central sleep apnea but without hypoventilation, discovered subsequent to neuroblastoma evaluation. This case highlights there may be a broader spectrum of late-onset presentations of CCHS in children with NPARM in PHOX2b.

BIOT'S BREATHING
Aditi Desai[1], Vishal K. Patel[1]
[1] Corewell William Beaumont University Hospital

Introduction: In 1875, Camille Biot oberserved an irregular breathing pattern—now called Biot's breathing—in a patient with tuberculous meningitis. This pattern is characterized by rapid, shallow breaths followed by periods of apnea or gasping. Unlike Cheyne-Stokes respiration, which involves crescendo-decrescendo pattern of breathing influenced by vasomotor changes (increased heart rate and decreased blood pressure during the apneic phase), Biot's breathing lacks such rhythmic fluctuations. Biot's breathing is typically associated with damage to the brainstem, particularly the medulla oblongata or pons, from conditions such as trauma, stroke, infection, opioid abuse, or tentorial herniation. Disruption of the pneumotaxic center and respiratory control mechanisms in the brainstem may lead to intermittent hypoventilation and cyclic hypoxemia. This pattern is seen in critically ill patients who require intubation or are on mechanical ventilation.
Report of case: A 76-year-old female was evaluated in the sleep clinic for snoring, witnessed apneas, gasping arousals, insomnia, and daytime fatigue. A home sleep apnea test diagnosed severe obstructive sleep apnea(OSA) with a Respiratory Event Index(REI) of 68.5. She was initially treated with autoCPAP(-continuous positive airway pressure) which showed elevated Apnea-hypopnea Index(AHI) prompting a need for a bilevel positive airway pressure(BiPAP) titration study. During the study, she was noted to have Biot's breathing pattern. Titration was started at 8/4cmH2O to final pressure of 25/20cmH2O. Significant findings of this study were as follows: reduced sleep efficiency of 67.13%, fragmented sleep and an elevated AHI despite titration. Further investigation revealed that two months prior, patient had a fall and likely traumatic brain injury. CT scan of the brain showed minimal periventricular hypoattenuation but no acute trauma. Patient also had hydrocodone on her medication list. She was eventually titrated to ASV which showed some improvement in her sleep apnea management.
Conclusion: Biot's breathing is a rare and underreported phenomenon with limited representation in literature. Although it is typically associated with conditions like meningitis, this case may represent a transient condition caused by inadequate ventilation during titration. While the patient had a recent fall and was using opioids, no traumatic injury or opioid overuse was confirmed. Further research is indicated to explore the relationship between Biot's breathing and complex sleep-disordered breathing.

A CASE OF MEDICATION-RELATED CENTRAL APNEA DURING WAKEFULNESS
Reid Eggleston[1], Kara Dupuy-McCauley[1]
[1] Mayo Clinic

Introduction: Tizanidine is an alpha-2 receptor adrenergic agonist employed for treatment of musculoskeletal pain and muscle spasticity. Drowsiness, xerostomia, and, less frequently, sleep disturbance are notable side effects. Central sleep apnea (CSA) occurs in patients taking other alpha-2 receptor agonists such as clonidine but the frequency of CSA among users of tizanidine is less well-known. Rarer still is the presence of central apneic episodes during wakefulness in patients without heart failure who have an intact brainstem and are not taking opioids or benzodiazepines. We report a case of a patient with central apneic episodes during wakefulness in the setting of tizanidine use.
Report of case: A 60-year-old white male was referred to our sleep center for sleep apnea. He was previously diagnosed with severe obstructive sleep apnea (apnea-hypopnea index of 104 events per hour) but was not adherent to continuous positive airway pressure (CPAP) due to a previous head injury which made use of CPAP straps intolerably painful. Thus, he had undergone

a modified uvulopalatopharyngoplasty 3 months prior to evaluation. Despite UPPP he continued to have excessive daytime sleepiness. A repeat polysomnogram revealed frequent central apneic episodes during periods of wakefulness that did not persist after sleep onset. The patient had taken his nightly tizanidine 8 mg prior to testing. Echocardiogram prior to testing showed mild diastolic dysfunction and brain magnetic resonance imaging was unremarkable. A polysomnogram was repeated 1 month later, this time with tizanidine held for 1 week prior to testing. Wake-onset central apneic episodes had resolved without any other changes in medication or health status.

Conclusion: Certain medications such as opioids, benzodiazepines, and baclofen are known to induce CSA. However, to the best of our knowledge this is the first case of a commonly prescribed alpha-2 agonist implicated in the development of wake-onset central apneic episodes. More study is needed to elucidate the impact of tizanidine on ventilatory function in the wake and sleep states and whether similar effects may occur among other centrally acting medications.

REVIVING THE SLEEP-WAKE CYCLE: INTEGRATED APPROACHES TO CIRCADIAN RHYTHM AND RLS MANAGEMENT IN A COMPLEX CASE

Likhita Shaik[1], Daniel Rongo[1,2], Janey Dudley[1], Anna Wani[1], Abha Patel[2]

[1] UT Southwestern Medical Center, [2] North Texas VA Medical Cen ter

Introduction: Circadian rhythm disorders, often misdiagnosed as primary insomnia, can be challenging to treat with medications alone. Effective management requires an integrated approach that combines behavioral therapy, circadian rhythm interventions, and lifestyle modifications[1,2]. This case details the treatment of a 59-year-old male with an irregular sleep-wake pattern, severe social anxiety, and restless legs syndrome (RLS). His treatment involved behavioral strategies and circadian rhythm interventions, resulting in significant improvements in his sleep and overall well-being.

Report of case: The patient presented with severe sleep disturbances, including spending up to 20 hours in bed per day, with a highly fragmented sleep schedule. His typical sleep pattern involved sleeping at 11:00 PM and waking at 3:15 AM, averaging 6–7 hours of broken sleep nightly, compounded by excessive daytime naps. Initial home sleep apnea testing revealed a total sleep time (TST) of 4 hours and 26 minutes, an apnea-hypopnea index (AHI) of 0.7/hr, and a minimum oxygen saturation of 91%. Follow up polysomnography showed a TST of 175.5 minutes, with a sleep efficiency of 56%, an AHI of 1.0/hr, and a periodic limb movement index of 83.4/hour. An integrated treatment plan was initiated, combining cognitive behavioral therapy for insomnia (CBT-i), sleep environment modifications, and lifestyle changes. The patient was encouraged to adhere to a consistent sleep-wake schedule and reduce time spent in bed during the day. Additionally, he started an exercise program to help manage his RLS symptoms and joined a senior center for increased social engagement. Several sedative medications, including melatonin, hydroxyzine, and trazodone were gradually discontinued. The patient now uses doxepin for insomnia and gabapentin a few times per week for RLS symptoms. Following these interventions, he was able to maintain consolidated nighttime sleep. His RLS symptoms also improved with regular physical activity.

Conclusion: This case illustrates the effectiveness of an integrated treatment approach combining behavioral therapy, circadian rhythm interventions, and lifestyle changes in managing complex sleep disorders like circadian rhythm dysfunction and RLS. The patient's use of CBT-i, exercise, and improved sleep hygiene led to a significant reduction in sleep fragmentation and a more regular sleep-wake cycle, as reflected in the improvement in patient's symptoms.

HYPOGLOSSAL NEUROPRAXIA FOLLOWING ELECTRICAL CARDIOVERSION FOR ATRIAL FIBRILLATION

Robert Young[1], Kassandra Olgers[1], Anam Sabzwari[1], Edward Rojas[1], J.D. Armstrong[1], Sandeep Arora[1], Robert Stansbury[1,2], Sunil Sharma[1]

[1] West Virginia University, [2] University of Pittsburgh

Introduction: Hypoglossal nerve stimulation (HNS) is an alternative therapy for moderate-to-severe obstructive sleep apnea (OSA). Atrial fibrillation (AF) frequently co-occurs with OSA due to their interrelationship.

Report of case: A 71-year-old male with AF and moderate OSA (AHI 26.9) intolerant to positive airway pressure (PAP) therapy underwent HNS implantation in 2021. He was admitted for dofetilide loading and electrical cardioversion (CV). CV was performed using a single 360 J shock with anterior-posterior pad placement. Following CV, the patient activated his HNS and immediately experienced a "shock-like" sensation on the right side of his tongue and buccal mucosa with concomitant worsening of right tongue deviation. Reducing HNS voltage did not did not alleviate symptoms; however, turning off the device resolved them. The voltage was well tolerated prior to admission. Chest and soft tissue neck x-rays demonstrated stable device and electrode positions. He was advised to defer HNS use for two weeks and re-attempt activation at the lowest voltage. At four-week follow up, he reported resuming HNS therapy without recurrence of symptoms, and tongue deviation had resolved. Device interrogation confirmed normal function.

Conclusion: Patients with OSA and HNS may require CV for AF. Newer generation HNS have less risk of device malfunction following CV. If neuropraxia occurs, it is typically self-limited and no treatment is required. Those managing care for AF and OSA patients should be cognizant of potential post CV issues with HNS and counsel patients accordingly. Current generation HNS may need additional design updates in the future to help prevent neuropraxia following CV.

COMPLEX CASE OF HYPOGLOSSAL NERVE STIMULATION (HGNS) IN OBSTRUCTIVE SLEEP APNEA (OSA) WITH CARDIAC COMORBIDITIES

Ariel Park[1], Aarti Grover[1], Rajesh Zacharias[1], Joel Oster[1], Wei He[1], Greg Schumaker[1]

[1] Tufts Medical Center

Introduction: HGNS is an effective treatment for OSA in patients who are intolerant to CPAP therapy. However, achieving optimal therapeutic settings can be particularly challenging in patients with significant comorbidities. This case highlights the complexities of managing severe OSA with HGNS in a patient with cardiovascular disease, emphasizing the need for repeated evaluations and interdisciplinary collaboration.
Report of case: A 73-year-old male with severe OSA (AHI 58.8/h, O_2 nadir 74%) and history of aortic valve replacement initially underwent HGNS implantation followed by uneventful activation. However, his post-implantation course was notable for HGNS titration study which failed to identify a therapeutic amplitude. During the study, the patient reported shortness of breath and chest discomfort along with audible wheezing. He also had hypoxia when awake and desaturations without clear flow limitations when asleep on night of the titration. His study revealed periodic breathing throughout the night which prompted an evaluation by his cardiologist. The patient was found to have critical bioprosthetic aortic stenosis, moderate aortic insufficiency, and mild to moderate mitral regurgitation on his transthoracic echocardiogram. The patient subsequently received transcatheter aortic valve replacement (TAVR) and following the surgery, he reported significantly improved sleep quality. Despite his subjective improvement, the home sleep test revealed a persistently elevated AHI of 46.1/h. Further adjustments of device settings following findings from awake endoscopy still failed to significantly reduce obstructive events. Advanced titration was then conducted to find the ideal electrode configuration and exhalation sensitivity, which finally led to reduction in his AHI to 1.1/h as well as improvement in his periodic breathing.
Conclusion: This case underscores the challenges of optimizing HGNS therapy in patients with severe OSA and complex comorbidities. Device titration was complicated by coexisting cardiac dysfunction, which initially masked the effectiveness of HGNS therapy. The identification and treatment of critical aortic stenosis through TAVR led to subjective improvement in sleep quality, underscoring the need to evaluate other potential contributors to persistent symptoms beyond sleep apnea and HGNS-related factors. Achieving optimal HGNS efficacy also required advanced titration and individualized adjustments, demonstrating the importance of comprehensive evaluations and multidisciplinary approach.

A SEVERE CASE OF PROPRIOSPINAL MYOCLONUS

Robert Young[1], Mouhannad Azzouz[2], Anam Sabzwari[1], Edward Rojas[1], Robert Stansbury[3,4], Sunil Sharma[1]
[1] West Virginia University, [2] West Virginia University Dept of Sleep Medicine, [3] West Virginia University School of Medicine, [4] University of Pittsburgh

Introduction: Propriospinal myoclonus (PSM) is a rare disorder characterized by axial muscle jerks originating in the thoracoabdominal region and spreading outward. These are often exacerbated in recumbent positions and preceded by an internal sensation. Spinal cord pathology is reported in 7–20% of cases, with greater prevalence in daytime symptoms. Cough has not been reported in association with PSM. This case describes a 51-year-old female with refractory chronic cough and myoclonic jerks, ultimately diagnosed with PSM requiring multiple medications for symptom control.
Report of case: A 51-year-old female presented with a persistent cough following refractory treatments for gastroesophageal reflux disease (GERD) and asthma. Gastroenterology evaluation revealed grade A esophagitis, but GERD therapy yielded minimal improvement. Pulmonary function testing was normal, and treatments with steroids, montelukast, and inhaled therapies had little effect. ENT evaluation ruled out vocal cord dysfunction. Speech therapy also failed to improve symptoms. One year after symptom onset, the patient developed myoclonic jerks predominantly in the lower extremities, worsening in the evenings, particularly when reclining. Neurology consultation revealed jerks preceded by an internal sensation originating in the thoracic spine and radiating outward along with unremarkable exam findings. Episodes occurred up to 30 times per hour. Gabapentin provided minimal relief for both cough and spasms. Clonazepam reduced jerking frequency by 70% when taken daily, though escalation was limited by sedation. Levetiracetam was trialed after a previous case reported success with dual therapy, but was discontinued due to fatigue. Lacosamide 100 mg twice daily reduced spasm frequency to 10–30 daily, primarily in the evenings. Interestingly, reductions in spasms correlated with improvements in cough. MRI of the brain revealed scattered subcortical T2 FLAIR hyperintensities without significant findings. Spine imaging is pending. Based on clinical presentation and treatment response, the patient was diagnosed with PSM, also suspected to be the underlying cause of her chronic cough.
Conclusion: There has not been a reported case requiring clonazepam and lacosamide for symptom control.The correlation between reduced spasms and improved chronic cough highlights the potential for PSM to manifest with atypical symptoms.

A DAYTIME SOLUTION TO A NIGHTTIME DILEMMA - PAP-NAP TO GUIDE THERAPY OF SLEEP-DISORDERED BREATHING

Zara Bashir[1], Kevin Eng[2,3], Armand Ryden[2,3], Michelle R. Zeidler[3,4]
[1] UCLA, [2] Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, [3] VA Greater Los Angeles Healthcare, Los Angeles, [4] Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles

Introduction: The PAP-NAP, a daytime abbreviated sleep study, is a tool designed to improve positive airway pressure (PAP) therapy use in patients with sleep-disordered breathing. We present a case where a PAP-NAP study was utilized to determine appropriate therapy in a complex sleep patient with persistent high residual apnea hypopnea index (AHI).
Report of case: A 54-year-old obese male with history of chronic pain and depression was diagnosed with severe obstructive sleep apnea (OSA) (AHI 90/h) in 2010 via a polysomnogram and titrated to CPAP 9 cm H2O with improvement in symptoms. He became noncompliant in 2014 and reinitiated therapy in 2018 with persistent snoring and fatigue. Repeat sleep study resulted in a CPAP prescription of 18 cm H2O with excellent compliance, minimal leak and residual AHI of 9/hr. The patient was diagnosed with tonsillar cancer in March 2024 requiring opioids for pain. Despite significant weight loss (BMI fell from baseline of

40 to 28), he required 11+ hours of sleep with high residual AHI of 17.2/hr and HCO3 of 31.5 (previously normal). CPAP was transitioned to APAP 16-20 cm H2O with 90th centile pressure of 19 cm H20 and high AHI. The patient underwent a bilevel titration study notable for minimal sleep and severe central and mixed sleep apnea. Given need for continued opioids, and patient resistance to repeat sleep study, decision was made to conduct a PAP-NAP in conjunction with arterial blood gas (ABG) to determine ideal therapy for patient - adaptive servo-ventilation (ASV) versus bilevel. ABG showed a metabolic alkalosis with normal paCO2. PAP-NAP showed excellent response to ASV-Auto with resolution of obstructive and central sleep apnea. At one month the patient demonstrated excellent compliance, with a residual AHI of 8/hr and improvement in daytime sleepiness.
Conclusion: Our patient was complex due to a history of severe OSA with emergence of severe central sleep apnea after weight loss and opioid use in the setting of new malignancy. He underwent several PSG titration studies, and declined an additional overnight study. PAP-NAP was the key to optimizing PAP therapy and improving his daytime symptoms.

COMPARISON OF A TWO DIFFERENT HOME SLEEP APNEA TESTS ON A SINGLE NIGHT

Matthew Mascioli[1], Stephanie Stahl[2]
[1] University of Indiana, [2] Indiana University School of Medicine

Introduction: The diagnosis of obstructive sleep apnea (OSA) has increasingly relied on home sleep apnea tests (HSATs) for their convenience and cost-effectiveness, making the comparative analysis of such devices critical. Flow-based and peripheral arterial tone (PAT) HSAT devices are available. This case study compared these two different HSAT devices used simultaneously on a single night. The WatchPAT HSAT (Zoll Itamar, Atlanta, GA) is a wrist-worn device with a chest sensor that uses PAT technology to detect respiratory events and reports sleep stages. The Alice NightOne HSAT (Philips Respironics, Murrysville, PA) measures nasal airflow and uses a single respiratory effort belt.
Report of case: A 31-year-old man with no significant medical history wore both a WatchPAT and Alice NightOne HSAT simultaneously on a single night. The PAT HSAT showed an overall the American Academy of Sleep Medicine (AASM) apnea-hypopnea index (AHI) (hypopneas defined as associated with a ≥3% oxygen desaturation or arousal) of 14.1/hr, Centers for Medicare & Medicaid Services (CMS) AHI (hypopneas defined as associated with ≥4% oxygen desaturation) 5.9/hr, and an AASM rapid eye movement sleep AHI of 47.1/hr. The flow-based HSAT showed a total AASM AHI of 7.4/hr, CMS 3.0/hr. Total recording time was 212 minutes for the PAT device and for the flow-based device. The PAT device reported a total sleep time of 349 minutes with a sleep latency of 56.5 minutes. Sleep parameters were not reported with the flow-based device. No cardiac findings were seen in either study. The patient preferred the PAT device due to comfortability and overall ease of the process.
Conclusion: Studies demonstrate that PAT HSATs may overestimate the AHI, while flow-based HSATs tend to underestimate the AHI. These differences may be attributed to differences in scoring algorithms and physiological metrics analyzed. A lack of a sleep time measure with most flow-based HSATs leads the AHI being reported over the total recording time, not sleep time, often leading to a lower AHI. These findings underscore the importance of selecting an HSAT based on the clinical context and diagnostic needs, highlighting the complementary strengths of both devices in managing OSA.

BENEFIT OF HYPNOSIS IN NREM AROUSAL PARASOMNIAS

Shubhangi Gupta[1], Enrique Tobias[2]
[1] University of North Dakota Family Medicine Residency Program, [2] Sanford Health

Introduction: Non-rapid eye movement (NREM) parasomnias include complex behaviors such as sleepwalking, sleep-related eating disorder and confusional arousals that emerge mainly during deep sleep. Adult lifetime prevalence varies widely (4–67%). Management typically focuses on education, safety measures, and addressing underlying triggers. When standard therapies prove insufficient, adjunctive techniques like hypnosis may offer additional benefit.
Report of case: A 59-year-old female with a long-standing history of intermittent sleepwalking and sleep-related eating sought care following a near-fatal sleep-driving incident. Her background included generalized anxiety, depression, PTSD, anorexia, and restless legs syndrome. Comprehensive evaluation ruled out nocturnal epileptiform activity, periodic limb movements, and obstructive sleep apnea. Polysomnography demonstrated confusional arousals from N2 sleep and increased phasic muscle tone in REM, without witnessed abnormal movements. Reduced arousals in the first half of the night suggested sedation from multiple psychotropic medications concerning for polypharmacy. Initial management involved psychiatry consultation to streamline her psychotropic regimen, alongside behavioral and environmental interventions to ensure safety. After excluding active organic or psychological factors perpetuating the episodes, one session of clinical hypnosis was performed and recorded. The patient listened to the recording daily, gradually reducing its use as episodes improved. Clonazepam was introduced and up titrated when potentially harmful episodes persisted. At follow-up, both the patient and her bed partner reported a notable reduction in frequency and severity of the episodes, with no further injurious events.
Conclusion: In a case of refractory NREM parasomnia, hypnosis—implemented after careful evaluation, medication adjustment, and safety measures—resulted in meaningful clinical improvement. This brief, time-efficient intervention may serve as a valuable adjunct to established therapies when conventional measures alone do not achieve adequate control.

RAPID RESOLUTION OF CPAP-INDUCED EAR DISCOMFORT IN OBSTRUCTIVE SLEEP APNEA: A CASE OF PRESSURE TITRATION

Monica A. Giraldo[1], Alexandre Abreu[1], Kori B. Ascher[1], Maria V. Suurna[1], Valeria E. Munguia Jovel[1], Hao Cheng[2], Douglas M. Wallace[3], Amanullah Siddiqui[1]
[1] University of Miami Miller School of Medicine, [2] Miami VA Medical Center, [3] University of Miami

Introduction: Continuous Positive Airway Pressure (CPAP) therapy is the cornerstone of treatment for obstructive sleep apnea (OSA). However, higher pressure settings can occasionally lead to unexpected complications. This case highlights the importance of careful pressure titration while treating OSA, particularly in patients experiencing ear-related symptoms.
Report of case: A 74-year-old male with a history of coronary artery disease and moderate OSA (REI 22.9/hour) presented with left ear discomfort exacerbated by CPAP use. Auto PAP was decreased from 4 to 20 cmH2O to 4 to 8 cmH2O to improve PAP tolerance, but due to persistent hypersomnia, he underwent PAP titration where the optimal therapeutic pressure was BPAP at 17/12 cmH2O. However, due to poor tolerance and left ear pressure sensation, the device was placed in automatic mode with a maximum IPAP of 10 cmH2O and pressure support (PS) of 4 cmH2O. Despite some initial improvement, the patient continued to experience left ear pressure sensation. A CT scan of the brain revealed fluid in the left ear. Neuroimaging with MRI of the internal auditory canal and temporal bone CT were normal. BPAP was set at 6/4 cmH2O with significant relief of the ear discomfort and subsequent improvement in PAP adherence.
Conclusion: This case highlights the potential for pressure-related complications during treatment with PAP, potentially linked to conditions such as temporal bone dehiscence or barotrauma. It emphasizes the importance of individualized pressure adjustment to reduce side effects related to PAP therapy so its utilization can be optimized in the treatment of OSA. Sleep specialists should be vigilant for unusual pressure-related symptoms and be prepared to adjust therapy as required, even if it means deviating from standard titration protocols.

SLEEP DISORDERS IN SPINOCEREBELLAR ATAXIA TYPE 2

Tri Nguyen[1], Megan Acho[1], Shelley Hershner[1]
[1] University of Michigan

Introduction: The most common sleep disorders associated with spinocerebellar ataxia type 2 (SCA2) are restless leg syndrome (RLS) (18%), periodic limb movements of sleep (PLMs) (38%), and obstructive sleep apnea (OSA) (50-70%). In rare cases, SCA2 can be associated with REM-sleep behavior disorder (RBD) (6.2%). Here, we present a rare spinocerebellar ataxia type 2 case, in which the patient demonstrates RBD, RLS, PLM, and OSA on their polysomnogram.
Report of case: A 33-year-old right-handed man with a history of RLS and SCA2 (diagnosed 10 years ago by genetic testing with 43 CAG repeats) presented for evaluation of sleep disturbance. He reported episodic catathrenia, intermittent apneas, nocturnal limb movements, and nightmares. Family history was significant for a grandfather with OSA. A baseline polysomnogram demonstrated frequent limb movements during non-REM sleep, and increased EMG tone during REM sleep, during which the patient had at least 4 episodes of semi-purposeful movements, which included hand movements and brief kicks and jerks of the lower extremities. A subsequent titration reproduced frequent semi-purposeful limb movements during REM sleep including leg jerks, arm flailing, head turning, and picking at his sheets. The PLM index ranged from 70-110 events/hour. RBD was not associated with untreated OSA. On follow-up, the patient recalled his ex-wife complaining about him hitting her during sleep.
Conclusion: SCA2 is characterized by the olivopontocerebellar atrophy accompanied by degeneration of the thalamus and substantia nigra. Increased CAG repeats are hypothesized to lead to loss of REM-sleep atonia and, subsequently, RBD2. Recognition of RBD in CAG repeat pathologies, such as spinal and bulbar muscular atrophy, Huntington's disease, dentatorubral pallidoluysian atrophy, and spinocerebellar ataxias types 1,2,3,6,7, and 17 can lead to early screening and treatment. PLMs may be caused by dysfunction of the dopaminergic system in the hypothalamus with descending pathways to the spinal cord and dysfunction in D2 receptor binding in the striatum. In contrast to RBD, there is no correlation between CAG repeats and PLMs. The development and subsequent severity of PLMs are closely associated with disease duration and ataxia. PLMs and RBD are underrecognized sleep disorders in SCA patients.

SENSOR LEAD BREACH IN HYPOGLOSSAL NERVE STIMULATION THERAPY

Gabriel Sraha[1], Andrea Margarita Saludes[1], Lawrence Chan[2]
[1] Ohio State University Wexner Medical Center, [2] The Ohio State University

Introduction: Targeted hypoglossal nerve stimulation (HNS) offers an alternative treatment approach by activating lingual muscles for patients with moderate to severe OSA who are intolerant of CPAP therapy.
Report of case: We present a case of a 71-year-old Male with severe obstructive sleep apnea, diagnosed in 2017. He developed CPAP intolerance after a short trial and subsequently underwent a Uvulopalatopharyngoplasty (UPPP) with re-emergence of OSA symptoms following the procedure. After the failure of another CPAP trial, the patient was implanted with HNS on 12/27/19. His device was activated; however, he was unable to complete his titration study due to the pandemic. He returned to clinic on 10/19/22 with the complaint of HNS intolerance. He reported the stimulation as uncomfortable, often turning on before he fell asleep. In-clinic interrogation showed no downward waveform deflections, good tongue movement and appropriate ratios on impedance check. His amplitude and start delay settings were adjusted. A follow up titration study at 3 months showed an ideal amplitude of 1.9V with well controlled apnea. At his follow-up visit on 3/15/23, the patient reported improved tolerance with usage averaging 45 hours per week. Interval HSAT showed respiratory event index of 14.2. At his 1-year follow-up, device interrogation revealed downward deflections and high frequency noise on sensor waveform. Findings were discussed with the device manufacturer and recommendation issued to stop treatment. Advanced testing showed persistent shark-fin waveform and high frequency noise indicative of respiratory sense lead breach. Patient was referred to ENT for revision of HNS. The surgeon noted a section of the respiratory lead that was discolored and fractured revealing the location of the sheath breach. He also noted a cracked sheath around the stimulation lead necessitating replacement of the entire HNS unit. Post surgery, the patient returned to clinic for successful activation and showed resolved abnormal waveform and no high frequency noise. Follow up sleep studies are pending.

Conclusion: This case illustrates an approach to trouble shooting sensor lead hardware compromise and demonstrates the importance of monitoring for abnormal waveforms.

CSA INDUCED BY EXCESS PRESSURE SUPPORT: A CASE REPORT

Poulomee Tripathi[1], Robert J. Murray[1]
[1] University of Kentucky

Introduction: Studies and cases have reported an association between the pathogenesis of OSA and CSA. There is also some increased propensity for CSA in OSA patients. A specific form of CSA, treatment emergent central sleep apnea (TECSA), mostly occurs with CPAP titrations. Additional risk factors for TECSA include bilevel PAP or high pressure support levels.
Report of case: Mr. C is a 37 year old male who originally was referred to the University of Kentucky sleep medicine clinic to establish care. He had already been diagnosed with OSA at an outside facility. His Epworth Sleepiness Scale score was 7. He was on BiPAP 18/10 cm H2O, with a pressure support of 8. His BiPAP download showed CSA, with a central index of 21 and AHI of 23 overall. He was not on any centrally acting medications, had no history of CVA, and his echocardiogram showed a normal LVEF. His therapy was changed to CPAP 10cm H2O. Within 14 days, his central index decreased to 8.6 and AHI was 10.8; most recently his AHI is now < 5. Clinically, he states he finally was able to obtain uninterrupted, deep sleep that was restorative in the mornings.
Conclusion: TECSA is an acknowledged complication of PAP therapy for OSA. However, this case demonstrates an event where high-pressure support via BiPAP induced CSA. 20-30% of patients with OSA are prescribed BiPAP for a variety of reasons. It is imperative to link the pathophysiology of CSA and OSA in patients with otherwise no clear etiology of CSA and acknowledge how elevated pressure support induced hypocapnia may correlate with the development of TECSA.

RESTLESS LEGS SYNDROME IN A PEDIATRIC PATIENT: A RARE COMPLICATION FOLLOWING GLOMERULONEPHRITIS

Likhita Shaik[1], Janey Dudley[1], Daniel Rongo[1,2], Anna Wani[1]
[1] UT Southwestern Medical Center, [2] North Texas VA Medical Center

Introduction: Restless Legs Syndrome (RLS) is a neurological disorder characterized by an irresistible urge to move the legs, often accompanied by uncomfortable sensations. In pediatric populations, RLS is less common, with studies suggesting a prevalence of 2-4%[1,2]. Although 12-35% of pediatric chronic kidney disease patients experience RLS symptoms, the incidence of RLS with glomerulonephritis is much lower, with only a few documented cases in the literature[3,4]. Therefore, the association of RLS in a child with glomerulonephritis is an unusual presentation, making this case particularly noteworthy.
Report of case: A 9-year-old male presented with difficulty falling asleep, maintaining sleep, and feeling fatigued despite adequate sleep hours since a year. These symptoms coincided with his recent diagnosis of glomerulonephritis following recurrent streptococcal infections. Despite undergoing tonsillectomy and adenoidectomy to treat these recurrent infections, the patient continued to experience significant daytime sleepiness, often falling asleep at school or in the car. The parents also reported frequent leg twitches, jerks, sleepwalking, and nocturnal eating episodes which cycled into restless and non-refreshing sleep. The patient's sleep study revealed no signs of sleep apnea, however showed reduced REM sleep (9.1%), low sleep efficiency (54%), increased sleep onset latency (190 minutes), and an arousal index of 7.5. These findings suggested significant sleep disruption, due to the patient's leg movements. Given the timing of his symptoms following the diagnosis of glomerulonephritis, RLS was suspected. Subsequent testing for ferritin level was found to be 56 ng/mL, which was slightly below optimal levels for his age. Treatment with a multivitamin containing iron and gabapentin led to significant improvements in his sleep quality and daytime symptoms. Parasomnias and leg twitches improved, and restorative sleep resulted.
Conclusion: This case highlights the rare occurrence of RLS following glomerulonephritis in a pediatric patient, underscoring the importance of considering neurological symptoms in children with kidney disease. Further research is needed to explore the potential link between renal conditions and RLS in pediatric populations.

NONCODING RNAS AND NEUROLOGICAL DISEASES: A NOVEL POLR3B MUTATION EXPANDING THE PHENOTYPIC SPECTRUM

Anna K. Kloster[1,2], Manuella Almada[2], Mariana Moyses-Oliveira[2], Sandra Doria Xavier[2], Gustavo Antonio Moreira[1,2], Sergio Tufik[2,3], Monica L. Andersen[2,3]
[1] Universidade Federal de São Paulo, [2] Sleep Institute, Associação Fundo de Incentivo à Pesquisa, [3] Departamento de Psicobiologia, Universidade Federal de São Paulo

Introduction: Charcot-Marie-Tooth disease (CMT) is a heterogeneous group of monogenetic peripheral neuropathies with a prevalence of 1:2,500. Patients with CMT significantly lower sleep quality and excessive daytime sleepiness. Recent studies have shown that missense variants in POLR3B are part of the genotyping spectrum of mutational mechanisms associated with CMT. A total of 10 patients with neurological conditions, including CMT, and POLR3B missense heterozygous de novo mutations have been previously reported; however, sleep disturbances in individuals with these mutations are uncharacterized.
Report of case: The 35-year-old female patient with Charcot-Marie-Tooth syndrome and a missense mutation in the POLR3B gene (c.1424A>G/p.Gln475Arg) had a normal term delivery without complications. She had a history of chronic obstructive pulmonary disease, systemic lupus erythematosus, arthralgia, and progressive bilateral hearing and vision loss, skin lesions, and mouth ulcers. At age 27 years, she developed abdominal spasms and cognitive impairment, which progressed to dysautonomia, requiring her to stop working as a psychologist. Magnetic resonance imaging findings at the age of 31 years include right paramedian disc protrusion with spinal cord compression and left temporal extra-axial expanding

lesion. Polysomnography type I carried out at the age of 35 years showed normal sleep architecture, apnea/hypopnea index (AHI=0.9) and oxygen saturation. In Pittsburg Sleep Quality Index (PSQI) and Epworth Sleepiness Scale (ESS), she achieved 5 and 9 scores, respectively. She scored 2 in each of the PSQI subdomains referring to "sleep disturbances" and "sleep medications". Her autoperception of sleep quality and sleepiness (PSQI and ESS scores) contrasted with the report of her main caregiver, which described major problems in initiating and maintaining sleep.
Conclusion: The description of this case highlights the need of clinically evaluation sleep disturbances in CMT cases. When clinical data from the 10 previous reported patients are contrasted with this current narrative, this specific case is the only to have a late on-set disease, expanding the putative prognosis of this clinical spectrum. Sleep disorders were not mentioned in other case reports. To expand the genotype-phenotype correlation and indicate therapeutical interventions, future studies with larger cohorts and objective sleep assessments are warranted.

DOWN SYNDROME REGRESSION DISORDER: COMPLICATIONS AFTER HYPOGLOSSAL NERVE STIMULATOR IMPLANTATION

Mitali S. Thanawala[1], Kevin Kaplan[1]
[1] Baylor College of Medicine

Introduction: Hypoglossal nerve stimulation (HNS) therapy is indicated in patients with Down syndrome (DS) with severe obstructive sleep apnea (OSA). HNS is well-tolerated with significant reduction in apnea-hypopnea index (AHI). This is a case of a patient with DS whose recovery after HNS implantation was complicated by Down syndrome regression disorder (DSRD).
Report of case: An 18-year-old female with DS, repaired complete atrioventricular septal defect and mitral valve cleft, asthma, polycystic ovarian syndrome, OSA, and obesity (BMI 44) was diagnosed with severe OSA as a 7-year-old with elevated obstructive AHI (oAHI of 20.11). After surgical interventions, including tonsillectomy, adenoidectomy, and turbinate reduction, her sleep apnea remained severe (oAHI 12.8). She did not tolerate continuous positive airway pressure (7 cm H2O). At 16 years of age, a repeat PSG showed persistent severe OSA (oAHI 14.82) and endoscopy demonstrated partial collapse of the lateral pharyngeal wall and tongue base. Three months before HNS implantation, she developed auditory hallucinations and nystagmus. An extensive evaluation was negative for infection, encephalopathy, autoimmune disorders, and drug intoxication. Without a formal diagnosis for her symptoms, she underwent HNS implantation. Post-implantation, further evaluation of her symptoms with magnetic resonance imaging (MRI) of the brain was delayed until the HNS could be activated. She was ultimately diagnosed with DSRD, a rare regression of functional skills with potential neurological deficits, hallucinations, and poor sleep in patients with DS. She was treated with intravenous steroid and immunoglobulin infusions, lorazepam, and aripiprazole and clinically improved. HNS was activated two months post-implantation. Initiation PSG with HNS showed optimal control with an amplitude of 0.6 voltage, electrode configuration A, pulse width 90 microseconds, rate of 33 hertz with residual AHI 0. Despite adherence with HNS, she continues to experience mild snoring, fatigue, and restless sleep.
Conclusion: This patient's DSRD symptoms complicated the understanding of clinical improvement post HNS implantation. Inability to obtain an MRI prior to activation of the HNS device may have delayed the diagnosis of her DSRD. This population of patients with DS treated with HNS warrants further screening for potential co-morbidities prior to surgical implantation and further understanding of complications post-implantation.

FALSE VOCAL CORD ENLARGEMENT IN TRANSGENDER PATIENT ON TESTOSTERONE THERAPY CONTRIBUTING TO OBSTRUCTIVE SLEEP APNEA

Katie L. Tribuls[1], Brian Soto[1], Karel Calero[2]
[1] University of South Florida, [2] University of South Florida Morsani College of Medicine

Introduction: Hormones have been shown to play an important part in obstructive sleep apnea (OSA). Female hormones are thought to be protective of obstructive sleep apnea with an increased prevalence of OSA in postmenopausal females. In transgender medicine, exogenous testosterone is the cornerstone of treatment with the goal of virilization to achieve physical attributes that match gender identity. Androgen excess in females leads to thickening of the vocal cords with hypertrophy and hyperplasia of the thyroarytenoid muscle, hyperplasia of the laryngeal mucosa epithelium, and edema of the connective tissue stroma and enlargement of the laryngeal cartilage.2 While these mechanisms can achieve the desired voice deepening, there is also concern that it may contribute to the development of OSA.
Report of case: Here we present the case of a 34 yo transgender female to male patient on testosterone therapy for the past 7 years who presents with CPAP intolerance. After struggling with CPAP for over a year, he was referred for PAP alternatives for his OSA and underwent drug induced sleep endoscopy (DISE) for evaluation for hypoglossal nerve stimulator. During the endoscopy he was found to have significant thickening of the false vocal cords (FVC) causing near complete obstruction of the airway, with improvement noted with jaw thrust. It was suspected that the patient's findings were related to testosterone therapy. The patient ultimately decided to continue the current dose of testosterone and opted for an oral appliance (OA) for management of his OSA.
Conclusion: Transgender medicine is an emerging field with an increased prevalence of gender affirming hormonal therapy and gender confirmation surgeries over the past decade. The findings of FVC thickening, likely related to testosterone use, has yet to be described in the literature and can give insight into the pathophysiology of OSA in patients on hormonal therapy. Special attention should be given to patients treated with testosterone who fail to improve with or report intolerance to PAP therapy as this may be linked to airway abnormalities such as FVC thickening reported here. DISE may help guide treatment decisions in these cases and patients may improve with alternative therapies such as OAs.

KLEINE-LEVIN SYNDROME: A TALE OF TWO SLEEP-WAKE STATES

Luke E. Buxton[1], Emory Steelman[2], Sunitha Nune[2], Ye Jin Jeon[2]
[1] Loma Linda University Medical Center, [2] Loma Linda University

Introduction: Kleine-Levin Syndrome (KLS) is a rare disease characterized by relapsing-remitting episodes of severe hypersomnolence in association with cognitive, psychiatric, and behavioral disturbances. Described below is a case of KLS associated with viral infection, menstrual cycles, and vaccination.
Report of case: A 17-year-old female presented to the pediatric sleep clinic for evaluation of recurrent episodic behavioral changes associated with prolonged sleep time. An initial episode of manipulative behavior associated with family stressors was concerning for underlying depression and she was prescribed escitalopram but continued to report 'dissociative' episodes. Approximately six months later, the patient developed a fever associated with acute changes in mentation and increased sleep duration of 18 hours per 24-hour period. The patient underwent evaluation in a pediatric ICU. Workup included MRI brain (negative), respiratory viral panel (positive for human metapneumovirus), urine drug screen (positive for cannabis), and a lumbar puncture with viral testing (normal protein, cell count, and microbiologic testing [note that CSF human metapneumovirus testing was not performed]). She was diagnosed with encephalopathy due to human metapneumovirus and was discharged home with persistent prolongation of sleep duration for the subsequent 8 days. Over the next 7 months, the patient experienced 3 more episodes of hyperphagia, hypersomnolence, and changes in behavior including self-gratifying behavior lasting for 7-12 days. Two of these episodes were associated with the onset of menstruation. The third episode occurred after influenza vaccination. Note that between episodes, the patient was noted by her mother to return to baseline mentation and a have a normalization of sleep duration within a given 24 hour period. Upon evaluation in the pediatric sleep clinic, the patient underwent polysomnography with mean sleep latency testing demonstrating absence of sleep disordered breathing and a mean sleep latency of 8 minutes 24 seconds with no observed sleep onset REM periods. Therapy with modafinil was trialed but she had recurrent episodes. The patient is currently on carbamazepine with an overall reduction in the frequency and duration of episodes.
Conclusion: Presented above is a rare case of KLS associated with various triggers including viral infection, menstrual cycle, and vaccination.

SLEEPY TEENS: A CASE SERIES OF DIAGNOSTIC DILEMMAS IN PATHOLOGICAL EXCESSIVE DAYTIME SLEEPINESS (EDS)

Katyayini Aribindi[1], Kiran Nandalike[2], Ambika G. Chidambaram[1]
[1] UC - Davis, [2] UCD Health

Introduction: Central disorders for hypersomnolence (CDH) consist of idiopathic hypersomnia (IH), narcolepsy type 1 and type 2. These are difficult to differentiate due to confounding social issues and mood disorders commonly encountered in pediatric clinical settings, which may contribute to the delay in diagnosis. These diagnostic dilemmas arise in patients who have significant sleepiness, but do not meet diagnostic criteria. Here, a case series of five patients with EDS, and their confounders will be presented.
Report of case: An eleven-year-old early teen with an Epworth Sleepiness Scale (ESS) of 17, who has undergone polysomnograms (PSG) and multiple sleep latency tests (MSLT) demonstrating 1-2 sleep onset rapid eye movement periods (SOREMP), and mean sleep-onset latency (MSL) of 8.7 minutes and 9 minutes. Genetic testing and cerebrospinal fluid orexin levels were normal. A twenty-year-old (ESS 13) with unrefreshing naps without cataplexy, underwent a PSG/MSLT demonstrating 3 SOREMPs and MSL of 3.3 minutes while on sertraline and trazodone, but 6.3 hours of sleep and AHI of 3.0/hr with normal genetic testing and orexin levels. An eighteen-year-old with hypersomnia (ESS 16) and snoring had no SOREMPs, but an MSL of 7.5 minutes and normal orexin levels with an AHI of 3.9/hr, while an eighteen-year-old with ESS of 20, cataplexy and hypnogogic hallucinations had no SOREMPs and an MSL of 14.3 minutes. Lastly, a 21-year-old with sleep paralysis had no SOREMPs and an MSL of 9.5 minutes on fluoxetine, with 1% REM sleep and 83.5% N3 sleep on the prior PSG. Sleep diaries had no significant findings. Each of these patients had confounding variables (Table 1). These patients all received trials of wake-promoting agents or stimulants with varying degrees of success.
Conclusion: These cases represent the challenges encountered in the children due to numerous confounders in EDS, and not meeting criteria for CDH. This is frustrating for both families and providers as they may or may not progress to narcolepsy or IH with time, hence, contributing to the problem of delays in diagnosis of CDH and treatment. Further studies and guidelines specific to children are needed to re-define CDH accounting for the variability in the presentation.

SEVERE UPPER AIRWAY OBSTRUCTION IN A PEDIATRIC PATIENT WITH PIERRE ROBIN SYNDROME: INCOMPLETE RESOLUTION AFTER SURGICAL MANAGEMENT

Mitali S. Thanawala[1], Sonal Malhotra[1]
[1] Baylor College of Medicine

Introduction: Pierre Robin syndrome (PRS) is characterized by micrognathia or retrognathia, glossoptosis, and cleft palate. Over 85% of patients have significant upper airway obstruction (UAO) with sleep-disordered breathing. Management of UAO in patients with PRS involves a multidisciplinary approach and often requires surgical management. The authors present a case of persistent obstructive sleep apnea (OSA) in a pediatric patient with PRS.
Report of case: Patient is a 7-year-old female with PRS with micrognathia, glossoptosis, and cleft palate, DiGeorge syndrome, and history of biliary embryonal rhabdomyosarcoma with complete resolution after chemotherapy. She was first diagnosed with severe OSA at one month of age with respiratory disturbance index of 176/hour. She underwent bilateral mandibular distraction at two months old. Repeat polysomnogram

(PSG) showed persistent severe OSA, although reduced in severity with obstructive apnea-hypopnea index (oAHI) of 54.7/hour. Titration PSG was completed with optimal control on bilevel positive airway pressure (BPAP) at 13/9 cm H2O. Repeat laryngoscopies showed improvement in glossoptosis and normal subglottis and trachea. However, given her persistent severe OSA and BPAP pressure intolerance, she underwent a second bilateral mandibular distraction at 3 years old. Repeat PSG showed persistent severe OSA with further reduction in oAHI to 13.41/hour. After multidisciplinary discussion, additional airway augmentation procedures were determined to not provide further benefit. Decision was made to proceed with cleft palate repair to facilitate improved speech and quality of life. She underwent palatoplasty at 4 years old and her initial post-operative PSG showed mild worsening of OSA with oAHI 21.12/hour. However, with continued healing and growth, repeat PSG at 6 years old shows improvement of OSA with oAHI 13/hour. Her OSA now remains well-controlled with optimal BPAP adherence. She continues to follow closely with speech therapy to improve articulation.

Conclusion: Mandibular distraction has become the mainstay of treatment for patients with PRS and severe UAO refractory to non-invasive treatment. Incomplete resolution of UAO after mandibular distraction is typically associated with infection, device failure, preoperative intubation, or laryngotracheomalacia, which this patient did not have. This case offers further understanding of the complexities of long-term management of patients with PRS and incomplete resolution of UAO after multiple surgical treatments.

FLOPPY EYELID SYNDROME: AN OVERLOOKED INDICATOR FOR DIAGNOSING OBSTRUCTIVE SLEEP APNEA

Robert Wu[1], Salma I. Patel[2]

[1] University of Arizona College of Medicine - Tucson, [2] The University of Arizona

Introduction: Obstructive sleep apnea (OSA) is characterized by recurrent episodes of disrupted breathing during sleep, caused by upper airway obstruction. It affects a substantial portion of the U.S. adult population, with millions estimated to have the condition, though most cases remain undiagnosed. Left untreated, OSA is associated with significant health risks, including obesity, hypertension, type 2 diabetes, cardiovascular disease, and stroke. While typical symptoms such as snoring, gasping, and witnessed apneic events occur during sleep, a less common but notable association exists with floppy eyelid syndrome (FES). FES, resulting from low-grade inflammation and elastin degradation in the eyelids, can serve as a visible indicator of OSA during wakefulness, especially for individuals without a bed partner to observe sleep-related symptoms.

Report of case: A 33-year-old male with morbid obesity and hypertension was referred to sleep medicine after his ophthalmologist observed floppy eyelids during an evaluation for a conjunctival growth. The patient reported mild excessive daytime sleepiness, as indicated by his Epworth Sleepiness Scale score, but did not recall symptoms like choking or gasping during sleep. However, his family reported snoring, gasping, and episodes of apnea. An overnight titration polysomnogram confirmed severe obstructive sleep apnea with an exceptionally high apnea-hypopnea index (AHI) and a significant obstructive component. Continuous positive airway pressure (CPAP) therapy at 13 cm H2O effectively reduced the respiratory disturbance index to 2.9 events per hour.

Conclusion: This case highlights the importance of floppy eyelids as a potential diagnostic clue for OSA, particularly in individuals who may not recognize or report common sleep-related symptoms. In this instance, the incidental finding of FES led to an OSA evaluation, resulting in diagnosis and treatment. Floppy eyelids provide a unique, observable indicator for clinicians and patients alike, serving as an accessible tool to aid in identifying OSA in the absence of self-reported or witnessed sleep symptoms.

COMPLEX IDIOPATHIC HYPERSOMNIA AND SEVERE OBSTRUCTIVE SLEEP APNEA CONTROLLED WITH HYPOGLOSSAL NERVE STIMULATOR

Christine Plichta[1], Cole Sedar[2], Syed Qasmi[2], Andre U. Aguillon[3]

[1] University of Toledo Medical Center, [2] University of Toledo, [3] The University of Toledo College of Medicine and Life Sciences

Introduction: Idiopathic hypersomnia requires an extensive work-up, only to be a diagnosis of exclusion. The clinical presentation can overlap with other pathologies, often requiring multiple diagnostic and laboratory investigations. This can result in a complex care plan.

Report of case: We present the case of a 43 year old male with severe obstructive sleep apnea with an apnea-hypopnea index (AHI) of 56.7 events per hour. Despite nasal turbinate reduction and septoplasty for deviated septum, he was intolerant to both CPAP and BPAP therapy. He underwent hypoglossal nerve stimulator insertion with a final AHI of 3.5 events per hour during his fine-tune polysomnography. Despite adequate therapy, Patient continued to have excessive daytime sleepiness. He was trialed on modafinil with no improvement despite increased doses. There was no significant symptomatic improvement on armodafinil with increased doses. A home sleep test was conducted with a resulting Respiratory Event Index (REI) of 7.7 events/hour. The patient underwent diagnostic polysomnography followed by multiple sleep latency test (MSLT) after holding armodafinil for 3 days. During the preceding night polysomnography, the patient had difficulty maintaining sleep due to the voltage of the hypoglossal nerve stimulator. This improved after a decrease in the voltage by two levels. MSLT resulted in mean sleep latency of 4.1 minutes and 0 SOREM periods, thereby ruling out narcolepsy without cataplexy. Patient was started on calcium, magnesium, potassium, and sodium oxybate with improved quality of life and decrease daytime sleepiness.

Conclusion: This case illustrates many complexities of sleep medicine and diagnosing multiple sleep problems with overlapping symptomatology. This can sometimes involve extensive diagnostic testing and trial medications, only to result in a diagnosis of exclusion. This case reveals the added complexity of conducting an MSLT on a patient with a hypoglossal nerve stimulator. While the goal of PAP therapy is an AHI of less than or equal to 5 events per hour, successful therapy with a hypoglossal nerve stimulator is an AHI < 15 events per hour or a 50% reduction in the diagnostic AHI. This can create a discordance

of what defines a negative or normal preceding night polysomnography when conducting an MSLT.

THE DIAGNOSTIC VALUE OF SLEEP ABNORMALITIES IN ANTI-IGLON5 ENCEPHALITIS: CLINICAL AND POLYSOMNOGRAPHIC INSIGHTS

Sonia Millan[1], María Camila R. Langer[2], Juan José Paba[3], Andrés-Felipe Patiño-Aldana[1]
[1] Universidad Nacional de Colombia, [2] Universidad Militar Nueva Granda, [3] Universidad el Bosque

Introduction: Autoimmune encephalitis (AE) is an underrecognized cause of sleep disturbances, presenting with motor and cognitive features that may raise suspicion. Identifying specific sleep-related abnormalities can provide critical insights for diagnosing AE.
Report of case: Patient 1: A 52-year-old women presented bilateral and symmetrical bradykinesia, rigidity and postural instability, and frequent falls. Her family reported frequent nightmares, dream-acting, yelling and hyper motor behavior during sleep. She was hospitalized for rapidly progressive dementia characterized by amnestic deficits, apraxia, impaired attention, and acalculia. Examination revealed a limitation in downward gaze. Brain MRI revealed diffuse cortical atrophy and CSF study showed albumin-cytological dissociation. Extensive evaluation ruled out nutritional deficits, neoplasms, infections and prions. Serum testing detected anti-IgLON5 antibodies via indirect immunofluorescence. She was treated with corticoids, intravenous immunoglobulin (IVIG) and cyclophosphamide, achieving clinical improvement. Follow-up polysomnography confirmed REM sleep behavior disorder with a non-atonic REM phase. Patient 2: A 52-year-old men with a history of snoring, diurnal somnolence and suspected obstructive sleep apnea syndrome underwent polysomnography study. His medical history included cervical dystonia, treated with botulinum toxin for a year. However, his symptoms were worsening with dysarthria and dysphagia. Moreover, the neurological assessment revealed bilateral bradykinesia and rigidity. The polysomnogram revealed stridor, OSA and a poorly integrated N2 phase. CSF showed isolated hyperproteinorrachia while MRI was unremarkable. Secondary causes of parkinsonism were excluded. A CSF autoimmune encephalitis panel had positive anti-IgLON5. The patient did not responded to high-dose corticosteroids and cyclophosphamide and it is currently waiting for monoclonal antibodies therapy insurance approval.
Conclusion: Anti-IgLON5 encephalitis is a rare autoimmune disorder with a subacute course, typically affecting individuals aged 40-60 years. Sleep disturbances including aberrant sleep architecture, parasomnia and insomnia are common. Bulbar symptoms such as dysphagia, dysarthria, stridor, and acute respiratory failure are frequent. The syndrome can mimic progressive supranuclear palsy due to vertical gaze limitations and atypical parkinsonian symptoms. Rapidly progressive dementia could precipitate hospital admission and complicate further the diagnosis. A suggestive clinical course among key findings in polysomnography could support diagnosis and proper early immunomodulating treatment.

CORRECTING SMILES AND AIRWAYS: ORTHODONTIC TREATMENT FOR PEDIATRIC OSA

Nida Qadir[1], Malti Bhamrah[1], Harjinder Singh[1], Rupa Koothirezhi[1], Cesar Liendo[1], Oleg Chernyshev[1]
[1] Louisiana State University Shreveport

Introduction: Pediatric OSA has been linked with cognitive impairments, behavioral effects leading to academic underperformance and significant cardiovascular and metabolic consequences. Craniofacial abnormalities are one of the contributing factors for an increased risk of OSA and a cause of relapse or incomplete resolution of OSA. Orthodontic treatments have emerged as one of the treatment options for patients with craniofacial abnormalities.
Report of case: A 17-year-old patient with a history of mild obstructive sleep apnea (OSA) diagnosed at age 10 presented with persistent sleep-disordered breathing (SDB). Symptoms began at age 8, including snoring and loud breathing. The patient underwent adenoidectomy at 6 years of age and tonsillectomy at 10 years of age, with persistent symptoms leading to referral to Sleep Medicine and ENT. Physical examination findings included Class II malocclusion, left posterior crossbite, high-arched palate, macroglossia, maxillary and mandibular hypoplasia with lip pursing, a right-sided deviated nasal septum with internal nasal valve collapse, and bilateral inferior turbinate hypertrophy. A CT sinus study revealed bilateral concha and a septal spur on the right. Despite offering surgical intervention with septorhinoplasty and turbinate reduction, the patient and mother opted against proceeding with surgery. A repeat split-night polysomnography study demonstrated progression to severe OSA, with an apnea-hypopnea index (AHI) of 10.7 and an oxygen nadir of 82%. CPAP titration identified an optimal pressure of 7 cm H2O, resulting in a residual AHI of 0. To address structural issues, the patient established care with an orthodontist and an oral maxillofacial surgeon. Orthodontic treatment with braces and RME was initiated, with an expected duration of approximately two years to optimize the craniofacial structure and improve airway patency. Meanwhile, the patient was bridged with auto CPAP (settings: 5-15 cm H2O), which was well-tolerated and demonstrated adequate compliance. Follow-up visits noted significant improvement in residual symptoms of SDB.
Conclusion: Rapid Maxillary Expansion (RME) can lead to optimal outcomes with early detection and timely intervention. RME increases maxillary width, influences the dimensions of nasal vault, and increases upper airway space, with improvements in PSG parameters observed after one year of treatment.

EFFICACY AND TOLERABILITY OF ULTRA-LOW DOSE MIRTAZAPINE IN ADULT CHRONIC INSOMNIA

Rony Berbara[1], Kamal Gandotra[1,2], Elizabeth Zink[2], Brigid Wilson[2], Meera Kumari[2], Kuldeep Vaghela[2], Amal Rubai[2], Trevor Shaver[2], Kingman Strohl[1]
[1] Case Western / University Hospitals, [2] Louis Stokes Cleveland VA Medical Center

Introduction: Mirtazapine is a commonly prescribed psychotropic for major depressive disorder, and can be used for its soporific as well as alerting properties. Mirtazapine's pharmacology is such that sedation is inversely related to dosage and may be clinically excessive in adults on 7.5mg and 15mg daily dose. Mirtazapine at low plasma concentrations (7.5mg and 15mg) predominately has antihistaminergic properties subsequently causing both an increased duration of sleep and increased sedation. At higher antidepressant doses (30mg and 45mg), the antihistamine activity is offset by increased noradrenergic and serotonergic transmission. Usage of mirtazapine even at 7.5mg and 15mg for insomnia may result in troublesome daytime drowsiness in 54% of patients; patients report feeling similar to being hungover. We speculated that an ultra-low dose (3.75mg) might improve insomnia without next day effects.
Report of case: In a retrospective review, 30 veterans were prescribed an ultra-low dose of mirtazapine due to lack of efficacy by traditional sleep aids (trazodone, doxepin). The Insomnia Severity Index (ISI) score was collected before and 1 to 3 months after initiating therapy. It is important to note that 7 patients did not complete the treatment. Two patients did not start the treatment, three stopped due to side effects, one stopped due to lack of efficacy, and one stopped for reasons unlisted. Of those who completed treatment, two subjects reported residual sedation.
Conclusion: Considering all patients, 50% of veterans showed a decrease in a meaningful ISI value (greater than 7 points). Ultra-low dose mirtazapine may produce an improvement in symptoms and ISI values for chronic insomnia with less possibility of residual sedation.

THIRD TIME'S THE CHARM: MANAGEMENT CHALLENGES IN STATUS CATAPLECTICUS IN A NARCOLEPTIC PATIENT FOLLOWING STROKE

Mohammad Shahbazi[1], Ashwini Bandi[2], Antara Mallampalli[1], Supriya Singh[1]
[1] Baylor College of Medicine, [2] McGovern Medical School at UTHealth Houston

Introduction: Cataplexy is a hallmark symptom of narcolepsy, occurring in 60-70% of patients with narcolepsy type 1 (NT1). In contrast, status cataplecticus is a rare manifestation of NT1 in which patients have extended or frequent episodes of cataplexy lasting longer than one hour. The literature on status cataplecticus is limited and true incidence are unknown. Triggers of status cataplecticus include strong emotions, sleep deprivation, situational stress, fatigue, and abrupt withdrawal of cataplexy-suppressing medications.
Report of case: The patient is a 52-year-old male with a long-standing diagnosis of NT1 who presented to the sleep clinic requesting medication refills. His narcolepsy symptoms were previously well-controlled on modafinil and venlafaxine. However, 2 months prior to this visit he suffered a pontine stroke causing residual left arm weakness. While in the clinic waiting room, he became unresponsive to questions, prompting activation of the rapid response team and a stroke alert. His vital signs were notably stable during this episode. He awoke spontaneously but became agitated with further stimulation and then had 2 successive episodes of cataplexy associated with sleep attacks. It was discovered that he was taking half of his prescribed doses of venlafaxine and modafinil due to low supply, and the correct diagnosis of status cataplecticus was recognized. Evaluation for other etiologies including brain imaging was unrevealing, and patient's mental status and exam returned to baseline without intervention. His previous doses of modafinil and venlafaxine were resumed with a tentative plan of adding sodium oxybate after the next follow-up visit (which could treat both his excessive daytime sleepiness and cataplexy but require additional caregiver supervision).
Conclusion: This case illustrates the importance of recognizing status cataplecticus, a rare manifestation of NT1 which presents as prolonged or repeated episodes of cataplexy and sleep attacks and can easily be mistaken for stroke or other more common etiologies of an acute change in level of responsiveness. Such misdiagnosis could lead to potentially inappropriate interventions. Our case highlights the importance of medication adherence in NT1, which can become more challenging due to comorbid conditions such as our patient's recent stroke requiring additional caregiver support to ensure proper medication management.

SLEEP AND EXERCISE AS EXACERBATORS OF HYPOXEMIA AND THEIR RESPONSES TO SUPPLEMENTAL OXYGEN AT HIGH ALTITUDE

Cristian Zhang[1], Alan Schwartz[2,3], William Checkley[4], Luu V. Pham[5]
[1] Jacobi Medical Center, [2] University of Pennsylvania Perelman School of Medicine, [3] Vanderbilt School of Medicine, [4] Johns Hopkins School of Medicine, [5] Division of Pulmonary and Critical Care, Johns Hopkins University School of Medicine

Introduction: Acute mountain sickness, a potentially life-threatening condition consisting of sleep disturbances, headache, cerebral edema and pulmonary edema, is a complication of travel to high altitude. These complications stem from hypobaric hypoxia. Sleep can further exacerbate hypoxemia, resulting in periodic breathing and nocturnal arousals. Exercise reduces pulmonary transit time, potentially worsening hypoxemia. In this report, we characterize the acute effects sleep and physical activity on oxygenation and their responses to low intensity pulse-dose supplemental oxygen in a traveler during the first night at high altitude.
Report of case: A healthy 44-year-old male ascended to Puno, Peru (3825 m. above sea-level). Prior to ascent, he received prophylaxis with acetazolamide 250 mg every 12 hours for 2 days. On the first night at high altitude, we conducted nocturnal polygraphy on ambient air for 2 hours, followed by pulse-dose supplemental oxygen at 420cc/breath and then ambient air again and found that oxyhemoglobin saturation (SPO2) decreased from approximately 89% at baseline to a mean of 82.8%. Apneas and hypopneas occurred at a rate of 14.9 per hour of recording. Pulse dose supplemental oxygen markedly improved SPO2 (mean 95%). On the second day, polygraphy was performed during moderately intense physical activity (5 minutes intervals of lunges, METs equivalent of 3.8) on room air and with 1260 cc/breath supplemental oxygen. Exercise resulted in reductions in SPO2 from a baseline of mean of 91% to a nadir of 81%. During latter stages of exercise, periodic breathing was observed. Supplemental oxygen reduced respiratory flow and eliminated periodic breathing but did not change oxygenation.
Conclusion: Sleep and exercise aggravate hypoxemia at high altitude. Low dose pulse dose of supplemental oxygen reversed nocturnal but not exercised induced hypoxemia. The findings suggest that conditions that elevate cardiac output worsen hypoxemia at altitude.

UNUSUAL PRESENTATION OF KLEINE-LEVIN SYNDROME

Valeria E. Munguia Jovel[1], Monica A. Giraldo[1], Amanullah Siddiqui[1], Alexandre Abreu[1], Kori B. Ascher[1], Hao Cheng[2], Douglas M. Wallace[3]

[1] University of Miami, Miller School of Medicine, [2] Miami VA Medical Center, [3] University of Miami

Introduction: Kleine-Levin Syndrome (KLS) is a rare neurological disorder characterized by recurrent episodes of hypersomnolence associated with cognitive dysfunction, altered perception, hyperphagia, hypersexuality and disinhibited behaviors. Between episodes there is typically a return to normal alertness and cognitive function. Patients with chronic hypersomnia presentations in KLS are less common.
Report of case: We describe a 23 year old male with Attention Deficit Hyperactivity Disorder (ADHD) and early-onset bipolar disorder (age 4). At age 16, he sought care after missing five months of school due to periods of severe somnolence sleeping 12-13 hours daily. He presented to the hospital on three occasions with episodes of hypersomnia, lethargy, bradycardia, and hypotension. Brain MRI, toxicology, a 24-hour Holter monitor, and an echocardiogram were unremarkable. Polysomnography (PSG) revealed mild obstructive sleep apnea (AHI: 8 events/hr), and the Multiple Sleep Latency Test (MSLT) showed a mean sleep latency of 5.8 min and 3 SOREMPs. He was unable to tolerate modafinil due to tremors, mood disturbance and, aggression. Eventually, he was diagnosed with KLS following a 3-day episode of hypersomnolence during which he was unarousable. Partial symptomatic improvement was achieved with clarithromycin and minocycline but residual hypersomnia was still debilitating. Due to inability to stay awake at school, he was enrolled in virtual high school. Despite this, he was unable to complete high school. He has become socially withdrawn and lost many of his friends. A year later, following the initiation of clarithromycin treatment, his wakefulness increased to 8 hours per day. However, symptoms worsened during the COVID-19 pandemic leading to an increased dosing with minimal effect. Despite treatment, he continued to experience episodes of hypersomnia lasting months at a time where he sleeps up to 18 hours daily. Severe weight loss (BMI: 17.0) has occurred due to limited wakeful hours and loss of appetite.
Conclusion: While still within the expected decade of symptom resolution in chronic KLS, he shows atypical features: persistence hypersomnolence in between episodes, significant weight loss causing failure to thrive, and social withdrawal leading to depression. Multidisciplinary management is crucial to address his complex clinical presentation of KLS and enhance his quality of life.

MANAGING MODERATE OBSTRUCTIVE SLEEP APNEA FOLLOWING EXPLANT OF HYPOGLOSSAL NERVE STIMULATOR DUE TO TRAUMA

Christine Plichta[1], Kathryn Williams[2]

[1] University of Toledo Medical Center, [2] Promedica Hospital

Introduction: Hypoglossal nerve stimulator implant remains an alternative therapy to patients who are intolerant to PAP therapy for obstructive sleep apnea. Complications can arise requiring removal of hypoglossal nerve stimulator implants. This can lead to difficulties treating PAP-intolerant patients with uncontrolled obstructive sleep apnea.
Report of case: We present a case of a 71 year old male with moderate to severe obstructive sleep apnea (apnea-hypopnea index (AHI) = 29.55 events/hour on diagnostic polysomnography) who was intolerant to PAP therapy. The patient successfully underwent hypoglossal nerve stimulator implantation with a residual AHI=2.5 events/hour. Twenty-two months following implantation, Patient was kicked in the chest by his 3 year old grandchild. He developed an erythematous violaceous nodule over the site of his implanted generator. The patient was evaluated by Wound Care and there was concern for underlying malignancy due to the patient having a prior history of skin cancer. A biopsy was recommended, but due to his thin body habitus (BMI=25.97 kg/m2) and lack of subcutaneous fat, the implant would be considered contaminated and therefore require removal. The patient underwent successful explant of hypoglossal nerve stimulator and biopsy of skin lesion. The final pathology was negative for malignancy with dense acute and chronic fibroinflammatory reaction and foreign body giant cell reaction with abscess formation. Given the patient's thin body habitus, there was concern re-implantation on the opposite side would be difficult due to thin body habitus and minimal subcutaneous fat. The patient was agreeable to dental consultation for oral appliance.
Conclusion: This case represents a unique situation of successful treatment of moderate to severe obstructive sleep apnea with hypoglossal nerve stimulator requiring explanation due to trauma. Given the patient's intolerance to PAP therapy, there is additional difficulty in treating his sleep apnea. Cases such as these create a unique treatment plan that is not often encountered. While an oral appliance may improve any residual respiratory events, it is unknown if this will result in successful treatment of moderate to severe obstructive sleep apnea.

SUPINE OR NOT? – HIDDEN SEVERITY OF OBSTRUCTIVE SLEEP APNEA DEPENDING ON POSITION DURING HOME SLEEP APNEA TEST

Bikash Khanal[1], Vishal K. Patel[1]

[1] Corewell Health William Beaumont University Hospital

Introduction: Severity of obstructive sleep apnea (OSA) varies significantly in some patients based on position. Here we present a case of positional OSA (POSA) which was masked in a home sleep apnea test (HSAT) due to lack of considerable time in supine position. This led to multiple tests along with second opinion with us prior to the correct diagnosis and management.
Report of case: A 74-year-old female presented to our sleep clinic for a second opinion on her OSA management. Initially, she was referred to outside sleep clinic by her cardiologist for suspected OSA, given snoring and new-onset Atrial Fibrillation. She underwent flow-based HSAT which revealed mild OSA with apnea hypopnea index (AHI) of 7.6/hour. She was given oral appliance with plan to repeat HSAT to determine efficacy. 6 months later, another flow-based HSAT with oral appliance revealed AHI of 17.8/hour. Given unexpected increase in AHI with oral appliance, outside sleep clinic performed another HSAT without oral appliance to confirm severity of OSA. Testing showed 90.5% supine sleep and AHI of 28/hour. After that test, patient sought second opinion with us. We reviewed

earlier studies thoroughly and explained that she has POSA. She had a delay of proper care as supine AHI was not reviewed in HSAT interpretation. Patient wanted to avoid using continuous positive airway pressure (CPAP) device, so we recommended a repeat HSAT with oral appliance and positional therapy (PT). Flow-based HSAT with combined oral appliance and positional therapy showed AHI of 1.6/hour. Recently, a classification system called Amsterdam positional OSA classification (APOC) is proposed for POSA. According to that, polysomnograms must have minimum 10% of total sleep time in their best and worst sleeping position. Our patient met criteria for APOC II which requires that AHI in their best sleeping position to be in a lower severity category compared to worst sleeping position.
Conclusion: Our case demonstrates the importance of reviewing sleeping position during sleep study interpretation as POSA may be masked by low supine sleep time. PT can be an effective first-line treatment in selective patients with POSA and supplemental treatment with oral appliance or CPAP in remaining patients with POSA.

REVISITING HYPOPNEA SCORING: THE SIGNIFICANCE OF RESPIRATORY AROUSALS

Aditi Desai[1], Vishal K. Patel[1]
[1] Corewell William Beaumont University Hospital

Introduction: The debate surrounding the criteria for hypopnea scoring—3% versus 4% oxygen desaturation—remains unresolved. In 2012, the AASM Scoring Manual recommended defining hypopnea based on a ≥3% oxygen desaturation and/or arousal, while also recognizing ≥4% desaturation as an acceptable alternative, subsequently adopted by CMS (Centers for Medicare & Medicaid Services). However, the 4% AHI (Apnea-Hypopnea Index) criterion excludes arousals, which are indicative of fragmented sleep and sympathetic activation. Respiratory events that trigger arousals are associated with severe sleep symptoms, including poor sleep quality, excessive daytime sleepiness, and increased risk for adverse health outcomes, such as hypertension, amyloidogenesis, and other conditions. Treatment with positive airway pressure (PAP) therapy has shown significant symptom improvement in such patients.
Report of case: Case 1: A 59-year-old female presented with snoring, daytime fatigue, insomnia, irritability, and mood disorder. Polysomnography (PSG) revealed a 3% AHI of 14.7, REM AHI of 41.2, and a 4% AHI of 1.3, with a respiratory arousal index (RAI) of 13.9. Case 2: A 53-year-old male with a recent stroke, loud snoring, witnessed apnea and unrefreshed sleep underwent PSG, which showed a 3% AHI of 21, REM AHI of 32.4, and a 4% AHI of 2.6, with an RAI of 14.8. Case 3: A 75-year-old female with snoring, chronic obstructive pulmonary disease, and pulmonary hypertension had a PSG revealing a 3% AHI of 21.4, 4% AHI of 1, and an RAI of 18.8. Case 4: A 48-year-old female with known obstructive sleep apnea (OSA) and end-stage renal disease on hemodialysis presented with morning headaches after discontinuing PAP therapy. PSG showed a 3% AHI of 12.6, REM AHI of 31.1, and a 4% AHI of 2.22, with an RAI of 11.7.
Conclusion: These cases highlight the significant disparity between the 3% and 4% AHI criteria, emphasizing the need to incorporate respiratory arousals into the 4% scoring metrics. The exclusive reliance of CMS on the 4% criterion results in inappropriate management, persistent symptoms, and a poor quality of life for patients. Adopting a standardized scoring system that captures the full spectrum of sleep-disordered breathing is crucial for ensuring optimal care and improved patient outcomes.

MANAGEMENT OF SLEEP DISORDERED BREATHING IN PRADER-WILLI SYNDROME

Harjinder Singh[1], Malti Bhamrah[1], Nida Qadir[1], Rupa Koothirezhi[1], Cesar Liendo[1], Oleg Chernyshev[1]
[1] Louisiana State University Shreveport

Introduction: Prader-Willi syndrome (PWS) is the most common syndromic form of obesity, and the majority of the cases arise sporadically. Patients with PWS are at a high risk of sleep-related disorders, such as obstructive sleep apnea (OSA), central sleep apnea (CSA), and nocturnal hypoventilation. Management of untreated sleep apnea is essential before starting growth hormone (GH) therapy for the treatment of PWS. We present a patient with PWS who was noted to have complicated sleep apnea during the preemptive workup, prompting the initiation of positive airway pressure (PAP) therapy.
Report of case: An 11-year-old male with PWS presented to the sleep medicine clinic for screening of sleep apnea before starting GH therapy. His past sleep medicine workup included a polysomnogram (PSG) at the age of 4 years, showing an apnea-hypopnea index (AHI) of 14.1/hour. He underwent tonsillectomy and adenoidectomy (T&A) after that study at the age of 4 and 7 years, and the repeat PSG showed residual OSA with AHI of 2.5/hour. The patient was not able to tolerate PAP therapy and was managed conservatively. On present evaluation, significant findings were excessive daytime sleepiness (EDS) with pediatric Epworth Sleepiness Score of 14/24, weight/age percentile of 62, and grade 2 facial malocclusion. Overnight PSG was performed, which showed an AHI of 8.0/hour (obstructive AHI 3.8/hour and central AHI of 4.2/hour, suggesting CSA), minimum oxygen saturation of 84%, average end-tidal carbon dioxide of 45.1 mm Hg, and time above 50 mm Hg of 40.2% of the total sleep time (suggesting nocturnal hypoventilation). A PAP titration study was done, which achieved adequate control with bilevel positive airway pressure (BPAP) of 12/8 cm H2O with a backup respiratory rate of 8 breaths per minute. The patient tolerated this therapy well during the titration study, and BPAP with the above settings was prescribed.
Conclusion: The management of sleep apnea in individuals with PWS remains challenging. Unlike in non-syndromic cases of pediatric sleep apnea, T&A is not as effective in these patients, who eventually require treatment with PAP therapy. Narcolepsy and cataplexy-like phenotypes are also common in this population, which also need to be adequately screened and treated.

A COMPLEX CASE OF OBESITY HYPOVENTILATION SYNDROME AND OBSTRUCTIVE SLEEP APNEA

ChiAyrsh Ford[1], Taylor Teague[1]
[1] The University of Texas Health Science Center at Tyler

Introduction: Partial or complete airway obstruction during sleep occurs with obstructive sleep apnea (OSA), while daytime underventilation related to obesity occurs in Obesity hypoventilation

Syndrome (OHS). CPAP therapy is recommended for OSA, while noninvasive ventilation is usually indicated for OHS. If either is left untreated, patients can develop hypertension, heart failure, pulmonary hypertension, respiratory failure, and poor sleep quality. We present a complex patient case with both entities.
Report of case: The patient is a 33-year-old male with class 3 obesity (BMI 75) and hypertension who initially presented to his cardiologist's office with dyspnea on exertion, orthopnea, and leg swelling. Transthoracic echocardiogram revealed right ventricular systolic function moderately to severely reduced, elevated right ventricular systolic pressure (40-50 mmHg), and preserved left ventricular ejection fraction (50-55%). He was diagnosed with decompensated diastolic heart failure and referred to sleep medicine. Further evaluation revealed excessive daytime sleepiness (Epworth Sleepiness Scale 15) and chronic hypoxemic, hypercapnic respiratory failure based on ABGs obtained during previous hospitalization for decompensated heart failure (7.35/57.5/74/32). Our patient underwent a split night polysomnogram. The diagnostic segment revealed severe OSA with an AHI of 86.8 events/hour with an oxygen nadir of 72% and 69 minutes spent < 85%.
Conclusion: During the therapeutic segment, optimal settings could not be identified. Our patient was titrated from CPAP 5 to 15 cm H20, then switched to bilevel PAP due to CPAP insufficiency. Bilevel PAP was titrated to 23/15 cm H20 with 2L of oxygen, but oxygen saturation remained below 88%. Due to persistent sleep-related hypoventilation, he was ultimately placed on a noninvasive home ventilator. CPAP and noninvasive ventilation have been shown to be an effective treatment for OHS with concomitant OSA. In refractory cases, noninvasive ventilation via a home ventilator should be considered until appropriate weight loss can be achieved.

DIAGNOSTIC AND THERAPEUTIC CHALLENGES IN OBSTRUCTIVE SLEEP APNEA WITH PROMINENT CENTRAL EVENTS: REVISITING THE 50% CRITERION

Karolina D. Perez[1], Marcy Ojeda[1], Misty Shah[2], Tingrui Wang[2], Salma I. Patel[2]
[1] University of Arizona COM Tucson, [2] University of Arizona

Introduction: Obstructive sleep apnea (OSA) is a prevalent sleep-related breathing disorder characterized by repeated upper airway collapse during sleep, leading to fragmented sleep, daytime fatigue, and increased cardiovascular risks. OSA is diagnosed with a respiratory disturbance index (RDI) ≥ 5/hour with symptoms or RDI ≥ 15/hour. Positive airway pressure (PAP) therapy is the primary treatment but can induce treatment-emergent central sleep apnea (TECSA), defined as central apneas accounting for >50% of respiratory events during PAP therapy. Primary central sleep apnea (CSA), distinct from TECSA, is diagnosed when central events comprise >50% of total apneas and hypopneas during diagnostic polysomnography. This case explores the diagnostic and therapeutic challenges when both obstructive and central events coexist.
Report of case: A 53-year-old male with prediabetes, obesity, atrial fibrillation, and a history of tobacco use presented with symptoms of loud snoring, gasping, witnessed apneas, and hypersomnolence. Home sleep apnea testing revealed severe OSA with an apnea-hypopnea index (AHI) of 70.2 events/hour, including 28.9 central apneas/hour. Despite the significant presence of central events, they accounted for < 50% of total events, leading to a diagnosis of severe OSA. During in-lab PAP titration, central events predominated with CPAP and bilevel PAP spontaneous (BPAP-S) therapy. Transitioning to bilevel PAP spontaneous/timed (BPAP-ST) therapy resolved both obstructive and central events. Final therapy was BPAP-ST 16/8 cmH2O with a backup rate of 10.
Conclusion: This case underscores the challenges in differentiating primary CSA from TECSA, particularly when central events are prominent but fall short of the 50% threshold. It raises questions about the applicability of current diagnostic criteria and whether a dual diagnosis of OSA and primary CSA might have been more appropriate. Nevertheless, following existing guidelines, the patient was diagnosed with OSA and TECSA. BPAP-ST therapy effectively addressed both obstructive and central components, highlighting its adaptability in managing complex sleep-disordered breathing cases. This case emphasizes the need for precise diagnostic criteria and individualized treatment to optimize patient outcomes.

SEVERE REM BEHAVIOR DISORDER IN A TRUCK DRIVER RESOLVED WITH OSA TREATMENT

Daniel Rongo[1], Likhita Shaik[1,2], Janey Dudley[1], Abha Patel[3]
[1] UT Southwestern Medical Center, [2] North Texas VA Medical Center, [3] Dallas VA Medical Center

Introduction: REM sleep behavior disorder (RBD) is characterized by dream enactment behaviors, which can be dangerous in occupational settings. Obstructive sleep apnea (OSA) has been associated with parasomnia presentations and can exacerbate sleep fragmentation and REM dysregulation. This case explores the interplay of RBD and OSA in a 50-year-old truck driver, emphasizing the life-altering outcomes of OSA treatment.
Report of case: A 54-year-old obese male (BMI: 39 kg/m²) with restless leg syndrome and OSA with a career as a long-distance truck driver presented with frequent episodes of acting out his dreams during sleep. His typical sleep routine involved bunking in the back of his truck at highway rest stops. Twice he woke up in his truck disoriented. He also found himself waking up eating, but he had no recollection of how he got the food. Polysomnography confirmed severe OSA with an apnea hypopnea index (AHI) of 84.9 events/hour. Symptoms met diagnostic criteria for RBD based on clinical history and PSG findings. Despite reluctance to start positive airway pressure (PAP) therapy, counseling directed towards the possibility of improving RBD-like behavior helped him gain the commitment for treatment. He was initiated on Auto-Bilevel PAP therapy at Max IPAP 20 Min EPAP 4 pressure settings resolved the patient's apneas. At a 3-month follow-up, the patient reported complete resolution of dream enactment behaviors with excellent BiPAP compliance.
Conclusion: REM Sleep Behavior Disorder (RBD) involves the loss of normal muscle atonia during REM sleep, resulting in behaviors ranging from yelling and kicking to highly complex actions. While some cases are idiopathic, various conditions can disrupt REM sleep regulation and contribute to its development. This case highlights the need for comprehensive sleep evaluations in parasomnia presentations, especially in high-risk occupations, to identify and address underlying conditions like OSA and potentially reduce the need for adjunctive pharmacologic therapies. Despite his severity of RBD, addressing underlying OSA as a primary therapy is a worthwhile approach. In this case, PAP therapy alone led to complete resolution of the patient's symptoms, highlighting its significance as a first-line treatment in certain clinical scenarios.
